

Chapter 2

Size, Sustainability, and Urban Climate Planning in a Multilevel Governance Framework

George C. Homsy

Abstract In the United States, the absence of federal leadership on climate change and a strong tradition of localism has created a system in which many greenhouse gas reduction efforts fall to the discretion of municipalities. This often leads to uncoordinated action across jurisdictional boundaries. Despite the widespread notion that cities can lead on climate policy from the bottom-up, I find, using a logistic regression analysis of data from 1837 municipalities, that local governments are more likely to enact climate change policies in an environment where higher levels of government have acted rather than in a decentralized one. Smaller municipalities, in particular, have increased odds of action when their states act. Using existing regional, state-based initiatives, I present options for a coordination and capacity building framework.

Keywords Local government · Climate change · Urban policymaking · Regionalism

2.1 Introduction

For much of its history, the United States has had trouble dealing with challenges of the commons or common-pool resources, especially pollution and natural resource protection. The rapid industrialization of the United States following the Second World War came with horrendous water and air pollution; rivers caught fire and deadly smog suffocated regions with pollution flowing easily across jurisdictional borders. In 1948, thick air pollution originating in Donora, Pennsylvania's zinc industry killed 13 people and sickened thousands in that city and downwind in the neighboring city of Webster (Snyder 1994). Municipalities pumped wastewater into the rivers from which downstream neighbors pulled their drinking water (Holloway et al. 2014). Local leaders were unwilling to shoulder cleanup costs or impose them

on industries that threatened to close factories and cut jobs (Andreen 2003). Starting in 1970, environmental protection over some issues in the United States was nationalized through the passage of more than a dozen new federal statutes (Andrews 2006). The top-down imposition of command and control regulation cleaned much of the worst air and water pollution in the United States (Fiorino 2006).

Today, climate change represents “the ultimate commons problem” (Stavins 2010) (see Chap. 6: Sarzynski). One approach to governing climate change involves the top-down imposition on local governments of rules by a central authority, such as a national government. This has made the U.S. a leader in environmental cleanup (Fiorino 2006). However, this approach does not work well in dealing with complex problems (Kettl 2002). Centralized, expert-driven solutions usually view all problems as if they are technical puzzles (Fiorino 2006) to be broken down like a machine and fixed piece-by-piece (Innes and Booher 2001). This approach is easy to administer, but does not reflect the complexity of the real world (Agranoff and McGuire 2003). Central mandates are traditionally command and control regulations, which provide little flexibility for adjusting to local conditions (Mazmanian and Kraft 1999). And, in the case of climate change, national-level climate policies in the United States are weak to non-existent. In 2015, President Barack Obama’s Clean Power Plan, which imposed federal regulations on the coal-fired power plants, also issued CO₂ emission goals for states. However, implementation has been delayed by lawsuits and the administration of President Donald Trump has begun to dismantle the plan.

The second approach to environmental protection focuses on local solutions without intervention from a central authority. A number of municipalities have undertaken greenhouse gas reduction efforts and the communities at this level of government have the potential to be important actors in the greenhouse gas reduction effort (Kousky and Schneider 2003; Gore and Robinson 2009). Developed as a theory of small-scale, common-pool resource management, this decentralized approach has been applied to climate issues (Ostrom 2010) and emphasizes local solutions to fit local problems (Nagendra and Ostrom 2012). It can ensure redundancy of potential solutions and increase accountability (Sovacool 2011). The mayor of one small city claimed that the most important climate change action would happen at the municipal level: “We will save the world one plan at a time, one initiative at a time, one strategy at a time... Make no mistake, we will save the world” (Homsy and Warner 2015). Despite such boasts and the extensive policy action in some big cities, adoption of municipality-based climate action plans and general sustainability policy actions remains low overall (Svara 2011; Homsy and Warner 2012). Further, a decentralized governance approach can result in negative externalities, spillovers, regional inequity, and capacity constraints (Howell Moroney 2008; Pastor et al. 2009; Feiock 2013).

An emerging literature argues for multilevel governance as the framework for environmental sustainability including climate change (Bulkeley 2010; Homsy and Warner 2013; Balme and Qi 2014). While cities may initiate environmental

protection, they must coordinate with each other, with regional and national governments, and with other non-state actors to be successful (Bulkeley and Betsill 2005). U.S. cities operate within complex governance systems and variations in local government outcomes may result from external factors, such as connections with non-governmental organizations and a central authority (Andersson and Ostrom 2008).

In this chapter, I use a survey of U.S. municipalities to test the hypothesis that jurisdictions will be more likely to adopt climate change policies in a multilevel governance environment that is encouraging of such action as opposed to a decentralized framework in which local governments must act on their own. In addition, I examine the role that a municipality's population size plays with the second hypothesis that smaller places will benefit more from a multilevel environment than bigger cities. The federated nature of the 50 American states provides a good laboratory for testing the importance of multilevel action versus a more polycentric one since each state has different regulations, policies, and incentives governing the policy options available to municipalities. Although no governance level (states, region, or federal) mandates local climate change mitigation by municipalities, some states have climate change plans and supportive policy and programmatic frameworks that may enhance emissions reduction efforts; others do not. In addition, groups of states are organized into regional initiatives specifically seeking reductions in greenhouse gas emissions; these organizations present another level of governance with which municipalities might interact.

I find municipalities take cues within a complex multilevel environment from a variety of internal and external drivers. Unlike much literature that argues decentralized municipal action on the environment is most effective, the data here show that municipalities in states supportive of climate change action are more likely to act, even without legal requirements to do so. The research also identifies internal factors that push climate mitigation. The combination of top-down and bottom-up factors indicate the advantage of multilevel governance in climate change mitigation.

The chapter also fills a hole in the literature regarding climate change actions across localities of different sizes. Sustainability and climate change research focuses on big cities, which are consistently described as leaders. However, most Americans live in small, often suburban municipalities. These smaller places have different relationships with state governments, different access to technical and fiscal capacity, and different political environments. I find that state influence and internal politics do act differently in communities of different population size and metropolitan status. Both sets of findings can reframe our understanding of local policy-making as it relates to regional and global commons issues. These understandings have important implications for research as well as policy. In the concluding section, I offer another, possibly more cohesive, policy approach that could bring comprehensive multilevel governance to local action in the United States.

2.2 American Cities and Climate Action

In the United States, the federal government has paid little attention to the climate policies of local governments. National climate change policy focuses on industrial sectors, especially the reduction of emissions from coal-fired power plants and the increase in motor vehicle fuel efficiency (Crane and Landis 2010). In 2009, the federal government announced the Partnership for Sustainable Communities, a multi-agency effort to craft a national vision for local sustainability, which included greenhouse gas emissions reduction. Although the Partnership supported scores of community and regional projects, particularly to improve coordination between land use and transportation planning, the program suffered funding losses and failed to develop the measures and tools necessary to establish concrete standards (Birch and Lynch 2012). The 2015 Clean Power Plan set goals for state emissions reductions, but 2 years later the plan was still held up in courts and in the spring of 2017, the administration of President Donald Trump began to withdraw from the plan's regulations and international commitments (Davenport and Rubin 2017).

Given the failures at the national and international levels, some have targeted municipalities as the appropriate scale for government action on climate change for four reasons. First, in an increasingly urbanized world, cities emit a significant portion of the greenhouse gases (Bulkeley 2010). Second, American municipalities can choose to construct energy efficient government buildings or retro-fit older ones; they can install more efficient street and traffic lights; and some experiment with alternative energy generation (Svara et al. 2011). Such strategies not only save power, but also model policies to the private sector. Third, local governments can impact (through incentives, regulations, or other policies) non-public activities within their borders by, for example, imposing green building requirements on private projects (Salkin 2009). Municipalities, through their land use regulations, can also require denser, more efficient developments or provide transportation alternatives to the private automobile (Jepson 2004). Others, through their municipal electric utilities, have the ability to induce energy sustainability in both the public and private sectors (Homsy 2016). Fourth, cities will be first responders to potential climate-caused disasters (FEMA 2008).

Most research on climate change action in US cities examines large, urban centers or cities that are pioneers (e.g., Berry and Portney 2013; Bulkeley and Betsill 2003; Kousky and Schneider 2003; Tang et al. 2010). However, in the United States, just over half of the population lives in smaller municipalities (fewer than 25,000 people). Only a quarter of Americans live in the fewer than 300 cities with more than 100,000 residents. Auto-centric American suburbs are the least carbon efficient (Glaeser and Kahn 2010) and rural commuting comprises a large and growing portion of total miles driven (Renkow and Hoover 2000).

The majority of municipalities do nothing about climate change. A 2010 national survey of American cities (Svara 2011) found that only 12% of responding municipalities have created a baseline of emissions or set reduction targets of some sort; 22% of respondents sought to reduce energy use in transportation fleets and

outdoor light fixtures; only 5% offered energy audits to private businesses. Smaller communities lag larger ones in the adoption of general sustainability policies (Homsy and Warner 2012). The reasons why local governments, especially smaller ones, choose to act on climate change remains a significant gap in academic and practitioner understandings.

2.3 Local Governance of the Global Commons

As more municipalities initiate efforts to mitigate climate change, there is a debate over whether local governments can act on their own or not. Although no states mandate local government action on climate change, the states do have differing levels of commitment to the environmental challenge which can be conducive or not for policy action. In addition, numerous states have joined multistate initiatives that focus on climate change mitigation. In this section, we discuss the theoretical foundations for two conflicting frameworks of local action on commons issues: decentralization and multilevel governance.

2.3.1 *Decentralized Governance*

Decentralized governance is a public choice model in which the competition for residents and businesses drives the provision of public goods. It arose as metropolitan-level polycentrism in the 1960s, when Ostrom, Tiebout, and Warren (1961) demonstrated that some public services, such as policing and education, seemed to be best provided at the local level. They maintained that intermunicipal competition and local government's close connection to constituents result in cost-effective outcomes, local innovations, and a diversity of options. The actors in a decentralized system better understand local needs and thus better provide for local public goods than a higher authority (McGinnis 1999).

Elinor Ostrom (2009) hypothesized that this polycentric manner of public goods provision at the local level offers a model for the governance of the global commons. She contended that a variety of public and private actors (including municipalities, utilities, households, firms, nations, etc.) will be driven by competition and local advantages to create independent solutions to greenhouse gas reductions. Such a competitive approach to resource allocation envisions municipalities using strategies best suited to the local environment, citizenry, and other particulars of circumstance. Diffuse local action unburdens the dysfunctional international climate negotiation agenda by having priorities taken up by lower levels of government (Rayner 2010).

Benefits of local independent action include: more experimentation and innovation, local tailoring of action to fit circumstances, political testing of policies, and local experience in enforcement (see Chap. 16: Ninomiya and Burch). However,

municipally driven initiatives also have the potential to cause an economically ineffective patchwork of regulations, duplicative enforcement efforts, cross-boundary mismatches between pollution sources and effects, shuffling of high-carbon activities to weaker regulatory areas, and confusion over responsibility between levels of government (Lutsey and Sperling 2008). Local stakeholders acting on their own can grow frustrated with the lack of coordination and express the desire for a holistic approach to greenhouse gas mitigation (Greenwood 2012).

Some empirical analysis seems to indicate that municipalities can act on their own with regards to local climate action (Pitt 2010; Krause 2011a, b). For example, communities are more likely to act when climate change mitigation is linked to a policy already on the local government agenda (Betsill 2001). Such an approach reframes global problems as more local concerns (Metz and Below 2009) and ones on which local governments have the authority to act (see Chap. 12: Brown). These local co-benefits emerge in various forms, such as: reduction in energy costs (Kousky and Schneider 2003; Svara et al. 2011), increased public health (Bloomberg and Aggarwala 2008), or sustainable economic development and local job production (Jochem and Madlener 2003).

2.3.2 *Multilevel Governance*

The multilevel governance framework emerged as a way to analyze and organize the new European Union's relationship to its member states (Bulkeley and Betsill 2003). This approach engages multiple tiers of government in a communicative process that requires the co-production of knowledge and policy up and down levels of authority (Corburn 2009; Homsy and Warner 2013). It requires a respect for local knowledge in the creation of place-specific policies. At the same time, it recognizes the role of a central authority, which has technical expertise as well as the ability to coordinate local governments and induce compliance through incentives or regulations (Homsy et al. 2016). Hooghe and Marks (2003) describe two types of governments within a multilevel framework: one is geographically bound while the other focuses on managing common-pool resources across jurisdictions.

Unlike in Europe, the United States federal government rarely participates with local governments on climate issues, leading to uncoordinated efforts, differing goals, and inconsistent time horizons (Selin and VanDeveer 2009). In 2010, 35 states either had completed or were in the process of developing climate action plans (Center for Climate and Energy Solutions 2011). No states have mandated local government action. The closest is a 2008 California law that requires urban regions to meet greenhouse gas reduction goals by coordinating land use and transportation policy (Barbour and Deakin 2012). While an increasing number of states and regions continue to enact policies on climate change (Rabe 2009), most efforts focus on industry sectors, not local governments (Selin and VanDeveer 2009).

A multilevel framework is not completely foreign to American governance structures and has led to some environmental successes. The federal government in the United States has experimented with cooperative federalism, in which local and state governments participate in the implementation of federal standards (Fischman 2005). The U.S. Environmental Protection Agency engaged in a more co-productive relationship in an effort to clean the polluted Rouge River Watershed. By threatening to impose expensive top-down regulations, the federal government successfully built a coalition of local governments and private actors to cut water pollution, reduce the danger of toxic chemicals, and improve the habitat in the almost 1,200 square kilometer watershed (Homsy et al. 2016).

While there have been some implicit (e.g., auto fuel efficiency standards) and explicit (e.g., 2015 Clean Power Plan) federal policies that have reduced greenhouse gas emissions, subnational governments remain the major drivers of action in the United States (Karapın 2016). The national government is absent due to the inability of most officials and citizens to see climate change impacts; the polarized state of the U.S. party system and the general ideology of limited government intervention; the lack of national authority over many issues; and the lack of strong international institutions (Hale 2010).

Some state governments in the United States have formed state-to-state horizontal networks focused on environmental issues with varying degrees of success. Water quality in the Great Lakes was dramatically improved through the creation in the 1950s of the Great Lakes Commission, which advised on and advocated for clean water for clean water, and the Council of the Great Lakes Governors, which provided a forum for information flows among state leaders (Rabe 1999). In 2001, the Conference of New England Governors and Eastern Canadian Premiers created a climate action plan with aggressive greenhouse gas emissions targets while the Western Governors Association established clean energy goals aimed at new technology development (Rabe 2009). Such networks could lead to greater emissions reductions than single state efforts due to greater geography and population encompassed, potential for uniformity of regulation, ability to capitalize on shared resources and economies, and development of a shared regional vision (Engel 2005). However, these networks remain state-to-state affairs with plans encompassing only the state level of operations and rarely engaging or organizing local governments.

2.4 Research Method

This chapter seeks to empirically investigate the debate around the ability of local governments to act on climate change on their own versus the need for higher level government support. My first hypothesis is that municipalities are more likely to adopt climate change policies if they are within supportive states and regions. I also examine a second hypothesis that smaller municipalities will benefit more from such support than bigger cities.

This project takes advantage of a comprehensive survey of sustainability policy-making by U.S. municipalities. The 2010 Sustainability Survey, conducted by International City/County Management Association,¹ asked county and municipal leaders about their adoption of policies and programs in areas such as climate change, water quality protection and provision, building construction, and land use. Surveys were mailed to a sample of municipalities with populations of more than 2500 people and fewer than 1,000,000 people. Within these parameters, managers of 7257 local governments received surveys and 1874 responded (25.8% response rate). Complete demographic, fiscal, and governance data was gathered for 1837 municipalities, which represents the final number of local governments in the sample.

2.4.1 *Dependent Variable*

The dependent variable measures whether or not a community is a *climate change actor*. The variable is based on six climate change actions that a municipality might undertake. For each community, this dichotomous variable had a value of one (1) if officials indicated on the survey that their jurisdiction created any one or more of the following:

- A baseline of greenhouse gas emissions produced by the local government;
- A baseline of greenhouse gas emissions produced by the community;
- Greenhouse gas reduction targets for local government operations;
- Greenhouse gas reduction targets for businesses;
- Greenhouse gas reduction targets for multi-family residences; or
- Greenhouse gas reduction targets for single-family residences.

Establishing a baseline of emissions for either the local government or the community is a major undertaking for a municipality and indicates a commitment to climate change action. Adoption of the various targets can be symbolic, but also indicates an official intention by local leaders to address greenhouse gas emissions. Table 2.1 shows the distribution of municipalities considered climate change action communities by population size. The adoption of policies is more prevalent among larger municipalities.

¹The survey was conducted in collaboration with researchers at Arizona State University's Center for Urban Innovation and ASU's Global Institute of Sustainability. A descriptive summary of the results can be found in Svava (2011).

Table 2.1 Distribution of climate change actor communities by population size

Population size	Percent climate change actors	Number of <i>climate change actors</i>	Total number of communities in sample
2500 to 9999	8.1	69	848
10,000 to 24,999	15.2	77	504
25,000 to 99,999	34.7	135	389
100,000 to 499,999	49.5	45	91
500,000 to 999,999	60.0	3	5
Total	17.9	329	1837

2.4.2 Independent Variables

The independent variables and the sources of the data are described in Table 2.2 and are grouped into following subject areas.

Multilevel variables. Two dichotomous variables examine the potential link between a multilevel governance framework and local government climate action. The first measures whether a municipality's state has a climate action plan, which was true for 327 municipalities in the sample. The second indicates whether the state is a member of a regional climate change initiative. In 2010, there were four regional initiatives (Western Climate Initiative, Regional Greenhouse Gas Initiative, Midwest Greenhouse Gas Reduction Accord, and the Transportation and Climate Initiative) that covered 14 states. The data includes 526 municipalities that were in states within one of the regional initiatives.

The following variables examine the internal drivers of climate action within communities.

Local politics variables. The first variable in this category indicates whether or not a community has a council-manager form of government, which research shows enact more innovative policies (Nelson and Svara 2012) including around issues of sustainability (Svara 2011). Second, I measure political attitudes, which can impact local sustainability policy in general and climate change in particular (Krause 2011a; Slavin 2011; Barbour and Deakin 2012). I employ an index of New Political Culture, which uses demographic information to predict local adoption of progressive policies. My index is based upon one developed by Saha (2009) and is built from the standardized values of the percentages in a jurisdiction of non-family households; unmarried households; people working in professional, scientific, technical, or educational jobs; residents between ages 18 and 44 years; women in workforce; and those who hold a bachelor's degree or higher.

Table 2.2 Summary statistics for variables

Variables	Municipalities (<i>n</i> = 1837)			
	Mean (or percent 'yes' for 1/0 variables)	St. Dev.	Minimum	Maximum

Dominant economic players. Environmental protection is often seen as in conflict with economic development (Campbell 1996). However, three studies focusing on climate change show no correlation between the presence of manufacturing and climate policy action or general environmental sustainability (Krause 2011a; Sharp et al. 2011; Homsy and Warner 2015), though other studies indicate that local manufacturing decreases the chances that a community would act (Bulkeley and Betsill 2003; Gustavsson et al. 2009; Krause 2011b). Three variables test this conflict in the current study. The first is the 1999 to 2009 change in the number of jobs within the municipality's county, which represents general economic development. The other two variables are the percentage of people employed in agriculture/extractive operations and in manufacturing.

Local capacity variables. Local capacity examines the ability of a municipality to carry out policies, including climate change planning. Local government revenue per capita measures the ability of a community to raise funds through taxes and fees and thus fund policy-making and programming. Educational attainment (percentage of the population with a bachelor's degree or more) is a measure of the potential for community members to provide volunteer expertise. Finally, per capita income has been shown to correlate with general sustainability policies (Lubell et al. 2009) and climate change action in particular (Zahran et al. 2008; Sharp et al. 2011).

2.5 Analysis of Results

The research hypotheses were tested using a series of six logistic models. Since the local governments are clustered within states, I used a hierarchical approach to control for the influence of states beyond the state climate variable tested. The first three models include just the presence of a state climate action plan across communities differentiated by population size: municipalities with populations of more than 25,000 people ($n = 485$); smaller communities between 2500 and 25,000 in size ($n = 1352$); and the entire sample ($n = 1837$). Models four, five, and six include the state's participation in a regional initiative as an additional factor, again across the different-sized local governments. If municipalities operate in a purely polycentric manner, then the influence of the state and regional initiative will be insignificant. If top-down factors push climate change action, then internal drivers will be small or insignificant. The results of the logistic regression models are presented as odds ratios in Table 2.3.

The results support the main hypothesis that multiple factors—internal and external—positively correlate with the increased odds that a municipality undertakes climate change planning. The first external factor, the presence of a state climate plan, increases the odds of local action from 1.867 times to more than 2.431 times in five of the six models—even though no state plan directly requires action by municipalities. The exception is model five, focused on bigger cities, in which the presence of a state plan is insignificant, but the other external variable, regional

Table 2.3 Results of multilevel logistic regression

Model	State climate plan			State climate plan and regional initiative		
	1	2	3	4	5	6

initiative, correlated to increased odds of local climate change planning by 3.546 times.² At the same time, internal drivers are also significant and sizable.

The significance of multilevel drivers contradicts the results of some previous research, which finds that municipalities act independently on this issue and that states play no role in local climate action (Pitt 2010; Krause 2011a, b). Two factors might account for this divergence in findings. First, the dataset in the current study is larger and broader. In her two studies, Krause only examines places with populations greater than 25,000 and 50,000 respectively. The second factor is the difference in the construction of the dependent variables. In one study, Krause (2011a) uses the U.S. Mayors Climate Protection Agreement as a dependent variable, which requires neither the resource investment of a greenhouse gas inventory process nor the political capital needed to adopt emissions reductions targets.

The second Krause study (2011b) and Pitt (2010) employ as the dependent variable an additive index of policies which could reduce greenhouse gas emissions. However, many of the included policies (e.g., tree ordinances, recycling, bike lanes, public transit incentives, and encouragement of mixed-use/pedestrian-oriented development) need not have been undertaken with the intention of reducing emissions. Do a community's efforts to encourage public transit, for example, derive from a desire to fight climate change or reduce congestion or provide transportation to low-income residents? To a practitioner, these differences are not important because the multiple facets broaden the pool of policy supporters. However, researchers seeking to study climate change need to make such distinctions; otherwise we are simply testing smart growth or general sustainability (see Chap. 4: Boswell and Mason). The dependent variable in the current study is targeted to a community's actions (emissions baselines) and intentions (adopted goals and targets) and represents specific climate change policy commitments. It offers a clear measure of policy intention and such precision is important if we are to understand what drives climate change policy at the local level.

The secondary hypothesis, that smaller municipalities would benefit more in a multilevel environment than larger cities, is also largely supported. The impact of a state climate plan is greater among small municipalities (models three and six) than larger ones (models two and five, where it is insignificant). Participation in a regional climate change initiative produces no benefit to smaller places while it increases the odds of climate change planning in larger places. In bigger cities, fiscal and technical capacity pose less of a challenge; this frees them up to more fully engage in the discourse and positive environment created by a state that has taken the extra step of joining a regional initiative. Smaller places, however, may remain tied to their states on which they rely for fiscal and technical capacity as well as political cover. This is an important difference between larger and smaller municipalities. Population change and density are not significant in any model.

²The models were also run without the presence of the multilevel variables and the results for the internal factors changed little in the six models.

One of the internal variables, percentage of manufacturing employment, also indicates an important difference between larger places, where it is not significant, and smaller places, where it has a negative correlation to the odds of climate change planning. In smaller communities, the power of such dominant economic players could work against greenhouse gas reduction by local governments; in these small places, factory management and large numbers of employees would hold the most sway. Manufacturing interests have less power in bigger cities with more diverse voter and tax bases. The other two economic variables, employment change between 1999 and 2009 and level of agricultural employment, are not significant.

Two variables test form of government and political progressiveness—important internal factors. The form of government variable (presence of a council manager) is not significant, which is opposite of what was expected given the innovative nature of managers. Despite the rhetoric, climate change planning is still a pioneering action (Tang et al. 2010), perhaps still so new that the typical advantages of city manager forms of government do not apply. Political progressiveness, another internal driver and tested in the form of the Progressive Political Culture Index, was significant across all six models.

Educational attainment, a measure of local capacity to act, is most important in smaller places. Larger places may have staff and resources to drive climate mitigation policies, but in smaller places, capacity may have to come from the populace. Local government revenue per capita, which describes a local government's ability to act on its own, was significant across all six models.

2.6 Creating a Multilevel Governance Framework for Climate Action

My analysis of a broad municipal dataset indicates that a multilevel governance framework facilitates more climate change planning by local governments than a decentralized approach. Without some leadership by state governments, larger cities will pioneer local climate change action, but the vast majority of cities will do nothing independently. Unlike in Europe where some national governments and the European Union took up the cause of climate change (in word if not in deed), the U. S. lacks an overarching climate framework for municipalities. The question for practitioners and policy makers is identifying the programs that will provide supportive environments at the state or regional level. Municipalities across metropolitan regions have coordinated to achieve affordable housing, economic development, open space conservation, and watershed protection goals (Wheeler 2002) though there is little cooperation around issues of climate change.

Here I want to introduce a potential approach to fostering the kind of governance environment that could induce more local government action. This new kind of regionalism builds on a supra-state structure already existing in the regional climate change initiatives around the U.S., such as the Regional Greenhouse Gas Initiative

or the Western Climate Initiative. These state-to-state projects have little direct interaction with municipalities, but, as our findings demonstrate, they do create a supportive environment for climate mitigation in larger cities. As organizations of states, they have the authority to require or incentivize greenhouse gas reductions in all municipalities in the multistate region.

The strength of these multistate regions over single state or metropolitan regional governance is their broader geographic scope, which can more effectively eliminate free-rider problems and reduce leakage that pushes polluting industry to states or municipalities with less stringent regulations. States and municipalities may simply be too small geographically and economically to be effective. In the proposed multilevel structure, central knowledge could be gathered and targeted to specific regional initiatives. Innovative policies developed by local governments could be more relevant to other members of the region. For example, municipalities in the northeast could band together around reducing their natural gas emissions, while those in coal-producing states can develop shared outcomes for their challenges.

The recognized ineffectiveness of voluntary networks (Kern and Bulkeley 2009) might stem from their national or international scope; they are a coalition of communities with interests that are simply too different. Multistate regions might be more effective at incentivizing or requiring action because the states (and their municipalities) within these new geographically based regional networks will more likely share economic goals and political constituencies. For example, the cap and trade program run by Regional Greenhouse Gas Initiative (RGGI) in the northeastern United States, which also provides technical capacity to states, realized a net positive economic impact of \$1.6 billion (Hibbard et al. 2011). Such successes make membership and action enticing, especially when states share geography, weather, negative impacts of a changing climate, and economic situation. In the case of RGGI, for example, none of the current nine-member state governments produce coal within their borders. If RGGI tried to add coal-producing Pennsylvania to the mix, it is likely the network would become unstable and policy innovations would prove to be less common to all members. In some ways, the new boundaries would create regions about the size of European nations, each with a common heritage, similar climate, and comparable economic situation.

2.7 Conclusion

Much has been written describing the contents and effectiveness of climate change planning by local governments. Less well investigated is the motivation for local action on such a global commons problem. My analysis of 1837 municipalities indicates that both internal and external factors drive climate change action in those places that do act. Since most communities simply have not adopted climate policies on their own as expected by proponents of decentralized theories of urban policy-making, policy-makers need to create a supportive multilevel environment

that recognizes the importance of top-down goal setting and sanctioning power with bottom-up knowledge and buy-in (Homsy and Warner 2013).

Despite the hype, municipal level climate action planning remains disappointingly low. The new US administration of President Trump has called climate change a hoax and, therefore, will likely provide no new—and probably dismantle existing—federal efforts (Davenport 2017). Planners and other policy-makers must realize that the hope for a locally driven, bottom-up approach to climate change will remain limited to pioneering municipalities, even under the best of circumstances. In the absence of federal oversight, state and municipal leaders might build on existing regional networks that group “like” states together and create a multilevel structure within which, this analysis indicates, local action is more likely to thrive.

Author Biography

George C. Homsy is an assistant professor in the Department of Public Administration at Binghamton University (Binghamton, New York, USA), and researches the factors that shape sustainability policies at the municipal level, especially in small- to medium-sized cities and towns. Homsy also explores the nexus of heritage and sustainability at the neighborhood level as well as the ways that cities plan programs and the built environment to foster lively and healthy communities for citizens of all ages. Homsy frequently links his research to practice through collaborations with professional organizations, such as the International City/County Management Association and the American Planning Association. Previously, Homsy was a planning consultant helping small- and medium-sized municipalities in the northeastern United States create environmentally and economically sustainable communities.

Climate Change in Cities

Innovations in Multi-Level Governance
