Table of Contents

Foreword and Acknowledgements of the 4th Edition	1
1 Earth Observation Short-History	7
1.1 Sensor/Technology Development	11
1.1.1 Concepts in Optical Observations	12
1.1.2 Microwave Region, Active Observations (Radars)	28
1.1.3 Microwave Region, Passive Observations	39
1.1.4 Optical Region, Active Observations (Lidars)	42
1.1.5 Sounding of the Atmosphere	43
1.1.6 Sounding of the Ionosphere	49
1.1.7 Some Instrument/Observation Techniques	51
1.1.8 Cooling Techniques and HTS (High-Temperature Superconductivity) ..	61
1.2 Fundamental Science Limits in Space Flight and Earth Observation	64
1.3 Spacecraft Systems	67
1.3.1 Spacecraft Operations	76
1.3.2 Special S/C Maneuvers and Rescue Operations: Examples	86
1.3.3 Cooperative Distributed Systems, Satellite Formations	88
1.3.4 Bistatic Systems in Remote Sensing	92
1.3.5 On-orbit Propulsion	95
1.3.6 Space Environment Experiments	99
1.3.7 Tether Experiments	105
1.4 ISS (International Space Station) Built-up	106
1.5 Overview of Operational Meteorological Missions	108
1.5.1 LEO (Low Earth Orbit) Satellite Missions	108
1.5.2 GEO (Geosynchronous Orbit) Weather Satellites	113
1.6 Solar-Terrestrial Connection	116
1.6.1 Earth Radiation Budget and Solar Constant	117
1.6.2 Solar Wind Observation	121
1.7 Navigation	125
1.7.1 Tracking Techniques	125
1.7.2 Gradiometry , Accelerometry and Magnetometry	127
1.7.3 Satellite Laser Ranging	131
1.7.4 Attitude and Control Instruments	132
1.7.5 Altimetry	136
1.7.6 Orbits	140
1.7.7 On-Orbit Servicing	143
1.7.8 Satellite Radionavigation Systems	145
1.8 Services	156
1.9 Start of International Cooperation	160
Part A Atmosphere/Radiation/Aeronomy Missions	165
A.1 ACE (Atmosphere Climate Experiment)	165
A.2 ACRIMSAT (Active Cavity Radiometer Irradiance Monitor)	167
A.3 ADM (Atmospheric Dynamics Mission)	169
A.4 AE (Atmosphere Explorer)	173
A.4.1 AE-A (Aeronomy-A, Explorer 17)	174

A.4.2	AE-B (Aeronomy-B, Explorer 32)	174
A.4.3	AE-C (Atmosphere Explorer-C, Explorer 51)	176
A.4.4	AE-D (Atmosphere Explorer-D, Explorer 54)	181
A.4.5	AE-E (Atmosphere Explorer-E, Explorer 55)	182
A.5	AEM-2 (Applications Explorer Mission-2)	182
A.6	Aura Mission (EOS/Chem-1)	183
A.7	CLOUDS (Cloud and Radiation Monitoring Satellite)	183
A.8	CloudSat	191
A.9	COMPASS	195
A.10	Coriolis	196
A.11	CRRES (Combined Release and Radiation Effects Satellite)	200
A.12	Dynamics Explorers (DE-1 and DE-2)	202
A.12.1	DE-1 Instruments (High Altitude Mission)	203
A.12.2	DE-2 Instruments (Low Altitude Mission)	204
A.13	ERBS (Earth Radiation Budget Satellite)	205
A.14	ESSP-3 (Earth System Science Pathfinder-3)	207
A.15	FBM (French-Brazilian Microsatellite)	209
A.16	FORTE (Fast On-Orbit Recording of Transient Events)	212
A.17	GCOM (Global Change Observation Mission)	215
A.17.1	GCOM-A1	215
A.18	HCMM (Heat Capacity Mapping Mission)	219
A.19	Megha-Tropiques	220
A.20	ODIN	223
A.21	OrbView-1/Microlab-1	226
A.22	QuikSCAT (Quick Scatterometer Mission)	226
A.23	REX-II (Radiation Experiment Satellite II)	228
A.24	ROCSat-3/COSMIC (Constellation of Six Microsatellites)	229
A.25	SAN MARCO D/L	232
A.26	SCISAT-1/ACE (Science Satellite/Atmospheric Chemistry Experiment)	234
A.27	SORCE (Solar Radiation and Climate Experiment)	237
A.28	TIMED (Thermosphere, Ionosphere, Mesosphere Energetics and Dynamics)	242
A.29	TOMS Missions	245
A.29.1	TOMS-EP	246
A.29.2	TOMS/NSCAT on ADEOS	246
A.29.3	QuikTOMS (Quik Total Ozone Mapping Spectrometer)	247
A.30	Triana	249
A.31	TRMM (Tropical Rainfall Measuring Mission)	254
A.32	UARS (Upper Atmosphere Research Satellite)	258

Part B Commercial Imaging Satellites 263

B.1	Condor Series of NPO Machinostroyeniya	263
B.1.1	Condor-E (Condor Experimental)	264
B.2	Diamant, OHB Bremen	266
B.3	COSMO-SkyMed and Pléiades Programs	268
B.3.1	COSMO-SkyMed	270
B.3.2	Pléiades	274
B.4	EarthWatch (DigitalGlobe) Imaging Satellites	275
B.4.1	EarlyBird	275
B.4.2	QuickBird-1	277
B.4.3	QuickBird-2	280
B.5	EROS (Earth Remote Observation System), ImageSat International	281
B.5.1	EROS-A Spacecraft Series	282
B.5.2	EROS-B Spacecraft Series	283

B.6	IKONOS (Space Imaging Inc., Thornton, CO)	285
B.6.1	IKONOS-1	285
B.6.2	IKONOS-2	286
B.6.3	Kodak Model 1000 Camera System	287
B.7	Infoterra/TerraSAR (Astrium, ESA)	289
B.7.1	TerraSAR-X1 (X-band Satellite)	292
B.7.2	TerraSAR-L1 (L-band Satellite)	295
B.8	OrbView Satellite Series of ORBIMAGE	298
B.8.1	OrbView-1	298
B.8.2	OrbView-2 (renamed from SeaStar in 1997)	301
B.8.3	OrbView-3	304
B.8.4	OrbView-4	306
B.9	RapidEye Satellite Constellation	307

Part C Data Collection (Messaging) Systems 311

C.1	ARGOS (Data Collection System)	311
C.2	FAISAT (Final Analysis Inc. Satellite)	313
C.3	LLMS (Little LEO Messaging System)	314
C.4	Orbcomm Satellite System	316
C.5	SAFIR (Satellite For Information Relay)	319
C.5.1	SAFIR-1	319
C.5.2	SAFIR-2	321
C.6	SCD-1 (Satélite de Coleta de Dados)	322
C.6.1	SCD-2	324
C.7	TEMISAT (Telespazio MicroSatellite)	324
C.8	Store-and-Forward (S&F) Systems	328

Part D Earth Observation/Monitoring Missions 329

D.1	ADEOS (Advanced Earth Observing Satellite)	329
D.2	ADEOS-II (Advanced Earth Observing Satellite-II)	335
D.3	ALOS (Advanced Land Observing Satellite)	339
D.4	ALMAZ Program	343
D.4.1	COSMOS-1870 (also Kosmos-1870)	344
D.4.2	ALMAZ-1	344
D.5	BADR-B	346
D.6	Bhaskara	348
D.7	CBERS (China/Brazil - Earth Resources Satellite)	349
D.7.1	CBERS-1	349
D.7.2	CBERS-2	353
D.7.3	CBERS-3 & 4	353
D.8	CORONA	354
D.9	ENVISAT (Environmental Satellite)	355
D.10	EO-1 (Earth Observing-1)	375
D.11	EOS (Earth Observing System)	375
D.11.1	Terra Mission (EOS/AM-1)	377
D.11.2	Aqua Mission (EOS/PM-1)	386
D.11.3	Aura Mission (EOS/Chem-1)	390
D.12	ESE (Earth Science Enterprise)	396
D.13	ERS-1 (European Remote-Sensing Satellite)	399
D.14	ERS-2	406
D.15	HY-1 (Haiyang-1/Ocean-1)	409
D.16	ICESat (Ice, Cloud and land Elevation Satellite)	411
D.17	IRS (Indian Remote Sensing Satellites)	414

D.17.1	IRS-1A	415
D.17.2	IRS-1B	416
D.17.3	IRS-1E (P1)	417
D.17.4	IRS-P2	417
D.17.5	IRS-1C/1D	418
D.17.6	IRS-P3	420
D.17.7	IRS-P4 (OceanSat-1)	422
D.17.8	IRS-P5 (CartoSat-1)	426
D.17.9	IRS-P6 (ResourceSat-1)	427
D.18	JERS-1 (Japan Earth Resources Satellite)	427
D.19	KITSAT Program	430
D.19.1	KITSAT-2 (Korea Institute of Technology Satellite-2)	430
D.19.2	KITSAT-3 (Korea Institute of Technology Satellite-3)	431
D.19.3	K-4 (KAISTSAT-4)	434
D.20	KOMPSAT (Korea Multi-Purpose Satellite)	436
D.20.1	KOMPSAT-1	436
D.20.2	KOMPSAT-2	438
D.21	LANDSAT	440
D.21.1	Landsat-1 to -5	442
D.21.2	Landsat-6	445
D.21.3	Landsat-7	447
D.22	Lewis and Clark Missions	451
D.22.1	Lewis S/C	451
D.22.2	Clark S/C	455
D.23	MOS (Marine Observation Satellite)	458
D.24	MTI (Multispectral Thermal Imager)	460
D.25	NEMO (Navy EarthMap Observer)	463
D.26	OKEAN-O	467
D.26.1	Experimental Cosmos Program	468
D.26.2	OKEAN-O1 Operational Series	469
D.26.3	OKEAN-O Series	471
D.27	OrbView-2/SeaStar	476
D.28	PRIRODA	476
D.29	RADARSAT	487
D.29.1	RADARSAT-1	487
D.29.2	RADARSAT-2	489
D.30	RADCAL (Radar Calibration Satellite)	492
D.31	RESURS-F	492
D.32	RESURS-O	496
D.33	ROCSat (Republic of China Satellite)	498
D.33.1	ROCSat-1	499
D.33.2	ROCSat-2	501
D.34	SAC-C (Satélite de Aplicaciones Científicas-C)	504
D.35	SEASAT	508
D.36	SMOS (Soil Moisture and Ocean Salinity)	512
D.37	SPOT (Système Pour l'Observation de la Terre)	517
D.37.1	SPOT-3	519
D.37.2	SPOT-4	520
D.37.3	SPOT-5	525
D.38	SSR1 (Satelite de Sensoriamento Remoto)	528
D.39	VCL (Vegetation Canopy Lidar Mission)	529
D.40	UoSAT/SSTL Microsatellite Missions	532
D.40.1	UoSAT-1 (University of Surrey Satellite-1)	533

D.40.2	UoSAT-2	534
D.40.3	UoSAT-3 (HealthSat-1)	534
D.40.4	UoSAT-4	534
D.40.5	UoSAT-5	535
D.40.6	KITSAT-1 (Korea Institute of Technology Satellite)	535
D.40.7	S-80/T	536
D.40.8	HealthSat-2	536
D.40.9	PoSAT-1 (Portuguese Satellite)	537
D.40.10	KITSAT-2	538
D.40.11	CERISE	538
D.40.12	FASat-Alfa (Fuerza Aerea Satellite - Alfa)	539
D.40.13	FASat-Bravo (Fuerza Aerea Satellite - Bravo)	541
D.40.14	UoSAT-12	541
D.40.15	TMSat (Thai-Microsatellite)	545
D.40.16	SNAP (Surrey Nanosatellite Applications Program)	547
D.40.17	SNAP-1	547
D.40.18	Tsinghua-1	550
D.40.19	TiungSat	551
D.40.20	DMC (Disaster Monitoring Constellation)	553
D.40.21	TOPSAT	553

Part E Geodynamic/Earth-System Missions 555

E.1	CHAMP (Challenging Minisatellite Payload)	555
E.2	CryoSat	560
E.3	EGS (Experimental Geodetic Satellite, Ajisai)	565
E.4	ETALON	566
E.5	GEO-IK	566
E.6	GEOS (GEOstationary Satellite)	567
E.6.1	GEOS-1	567
E.6.2	GEOS-2	568
E.7	GEOS	568
E.7.1	GEOS-1 (Geodetic Earth Orbiting Satellite)	568
E.7.2	GEOS-2 (Geodetic Earth Orbiting Satellite)	570
E.7.3	GEOS-3 (Geodynamics Experimental Ocean Satellite)	571
E.8	GEOSAT (Geodetic/Geophysical Satellite)	572
E.9	GFO-1 (Geosat Follow-On Program)	574
E.10	GFZ-1 (GeoForschungsZentrum-1 Geodesy Satellite)	575
E.11	GOCE (Gravity field and steady-state Ocean Circulation Explorer)	576
E.12	GP-B (Gravity Probe B - Relativity Mission)	581
E.12.1	Mechanical Systems	584
E.12.2	Experiment Payload	584
E.13	GRACE (Gravity Recovery And Climate Experiment)	586
E.14	Jason-1 (Joint Altimetry Satellite Oceanography Network)	590
E.15	LAGEOS-I (Laser Geodynamics Satellite)	593
E.15.1	LAGEOS-II	594
E.16	MAGSAT	595
E.17	MIMOSA (Microaccelerometric Measurements of Satellite Accelerations)	596
E.18	Ørsted	598
E.19	Starlette	600
E.20	Stella	600
E.21	TOPEX/Poseidon	601
E.21.1	DORIS	603
E.22	WESTPAC (Western Pacific Satellite)	605

Part F Meteorology - GEO (Geosynchronous Earth Orbit) Missions 607

F.1	Elektro-M-1(Elektro-Modified-1)	607
F.2	Feng-Yun-2 (Geostationary Satellite Series)	609
F.2.1	FY-2A	609
F.2.2	FY-2B	611
F.3	GMS (Geostationary Meteorological Satellite)	612
F.3.1	GMS Data Collection System (DCS)	613
F.4	GOES (Geostationary Operational Environmental Satellite)	614
F.4.1	NOAA-GOES Data Collection System (DCS)	617
F.4.2	NOAA-GOES SEM Instruments	619
F.4.3	NOAA-GOES Second Generation	621
F.4.4	Next-Generation Imager for the NOAA GOES Series	627
F.4.5	Next-Generation Sounder for the NOAA GOES Series	628
F.4.6	LMS (Lightning Mapper Sensor)	628
F.5	GOMS (Geostationary Operational Meteorological Satellite)	630
F.5.1	Radio Complex for Data Collection, Transmission and Relay	632
F.6	INSAT	633
F.6.1	INSAT-1 Satellite Series	633
F.6.2	INSAT-2 Satellite Series	634
F.6.2.1	INSAT-2E	636
F.6.3	INSAT-3 Satellite Series	640
F.6.3.1	INSAT-3B	640
F.6.3.2	INSAT-3A	641
F.7	METEOSAT	641
F.7.1	Meteosat Data Collection System (DCS)	644
F.7.2	Meteosat DCP Retransmission System	645
F.7.3	MOSAIC	647
F.8	MSG (METEOSAT Second Generation)	647
F.8.1	MSG Ground Segment (Stations)	653
F.8.2	MSG Communication Services and Data Distribution	654
F.9	MTSAT (Multifunction Transport Satellite)	655
F.9.1	MTSAT-1R	656
F.9.1.1	Aeronautical Mission	657
F.9.1.2	Meteorological Mission	658
F.9.1.3	DCS (Data Collection System)	660

Part G Meteorology - LEO (Low Earth Orbit) Missions 661

G.1	DMSP (Defense Meteorological Satellite Program)	661
G.1.1	Description of Block 5D-2 and 5D-3 Sensors	663
G.1.2	Space Environment Sensors	669
G.1.3	Early Sensors of the DMSP Program	673
G.1.4	DMSP Data Availability - Visible and Infrared Imagery	675
G.2	EPS (EUMETSAT Polar System)	676
G.2.1	MetOp-1 Satellite	678
G.2.2	MetOp-1 Sensor Complement	681
G.3	Feng-Yun-1 (Polar Orbiting Satellite Series)	688
G.3.1	FY-1A, -1B	689
G.3.2	Feng-Yun-1C and -1D	691
G.3.3	Feng-Yun-3 (FY-3) Satellites	692
G.4	METEOR-1 Series	692
G.5	METEOR-2 Series	693
G.6	METEOR-Priroda Series	694
G.7	METEOR-3 Series	695

G.8	Meteor-3M Series	701
G.8.1	Meteor-3M-1	701
G.9	NPP (NPOESS Preparatory Project)	707
G.10	NPOESS (National Polar-orbiting Operational Environmental Satellite System) ...	711
G.10.1	NPOESS Transition Period Overview	711
G.10.2	The NPOESS Satellite	713
G.10.3	NPOESS Sensor Complement	713
G.11	TIROS Meteorological Satellite Series (with the POES Program)	720
G.11.1	TIROS-1 (TIROS-A)	720
G.11.2	TIROS-2 (TIROS-B)	721
G.11.3	TIROS-3 (TIROS-C)	722
G.11.4	TIROS-4 (TIROS-D)	723
G.11.5	TIROS-5 (TIROS-E)	723
G.11.6	TIROS-6 (TIROS-F)	724
G.11.7	TIROS-7 (TIROS-G)	724
G.11.8	TIROS-8 (TIROS-H)	725
G.11.9	TIROS-9 (TIROS-I)	725
G.11.10	TIROS-10	726
G.12	TOS/ESSA Satellite Series (2nd Generation)	726
G.12.1	ESSA-1 (TOS-1)	727
G.12.2	ESSA-2 (TOS-2)	727
G.12.3	ESSA-3 (TOS-3)	728
G.12.4	ESSA-4 (TOS-4)	728
G.12.5	ESSA-5 (TOS-5)	729
G.12.6	ESSA-6 (TOS-6)	729
G.12.7	ESSA-7 (TOS-7)	729
G.12.8	ESSA-8 (TOS-8)	729
G.12.9	ESSA-9 (TOS-9)	730
G.13	ITOS (Improved TIROS Operational System)	730
G.13.1	NOAA-1 (ITOS-A, also known as ITOS-1 and TIROS-M)	730
G.13.2	NOAA-2 (ITOS-D)	732
G.13.2.1	NOAA-3 (ITOS-F)	732
G.13.3	NOAA-4 (ITOS-G)	733
G.13.4	NOAA-5 (ITOS-H)	733
G.14	TIROS-N (4th Generation) Satellite Series	733
G.14.1	TIROS-N Satellite	734
G.14.1.1	NOAA-6 (NOAA-A)	735
G.14.2	NOAA-B	735
G.14.3	NOAA-7 (NOAA-C)	735
G.14.4	NOAA-8 (NOAA-E)	739
G.14.5	NOAA-9 (NOAA-F)	739
G.14.6	NOAA-10 (NOAA-G)	739
G.14.7	NOAA-11 (NOAA-H)	740
G.14.8	NOAA-12 (NOAA-D)	740
G.14.9	NOAA-13 (NOAA-I)	740
G.14.10	NOAA-14 (NOAA-J)	741
G.14.11	Sensor Descriptions of 4th Generation Series	741
G.14.12	SEM (Space Environment Monitor)	744
G.15	5th Generation Satellites of NOAA-POES Series	744
G.15.1	Sensors for the POES K, L, M, N, N' Series	747
G.15.2	SEM-2 (Space Environment Monitor-2)	752
G.15.3	IJPS (Initial Joint Polar System)	753
G.15.4	ARGOS on NOAA-POES Satellites	754

Part H Satellite Radionavigation Systems 757

H.1	Galileo	757
H.1.1	GalileoSat	758
H.1.2	System Integrity Concept	763
H.1.3	Signal Baseline	764
H.2	GNSS-1 Augmentation Systems	764
H.2.1	WAAS (Wide Area Augmentation System)	765
H.2.2	EGNOS (European Geostationary Navigation Overlay System)	766
H.2.3	MSAS (Multi-Transport Satellite Augmentation System)	768
H.3	GLONASS	769
H.4	GPS (NAVSTAR-GPS)	772
H.4.1	GPS Space Segment	772
H.4.1.1	Block I Satellites	772
H.4.1.2	Block II Satellites (NAVSTAR II-1 to II-8)	775
H.4.1.3	Block IIA Satellites (NAVSTAR IIA-10 to IIA-27)	776
H.4.1.4	Block IIR (Replacement Operational Satellites)	776
H.4.1.5	Block IIF Satellites	778
H.4.2	GPS Control Segment	780
H.4.3	GPS User Segment	780
H.4.3.1	Fundamental GPS Observables	781
H.4.3.2	Availability of GPS/GLONASS Systems	782
H.4.3.3	GPS Applications	783
H.4.3.4	Some GPS Orbit and Attitude Instruments	785
H.4.3.5	IGS (International GPS Service for Geodynamics)	787
H.4.3.6	CIGNET	788
H.4.4	DGPS (Differential GPS)	789
H.5	MTSAT (Multifunction Transport Satellite)	790
H.6	Transit - Navy Navigation Satellite System (NNSS)	790
H.7	Summary of Microwave Tracking Systems	794
H.7.1	DORIS Tracking System	794
H.7.2	PRARE Tracking System	794

Part I Satellite Emergency Services & Environmental Monitoring . 799

I.1	BIRD (Bi-Spectral Infrared Detection)	799
I.2	DEMETER (Detection of Electromagnetic Emissions transmitted from Earthquake Regions)	801
I.3	DMC (Disaster Monitoring Constellation)	801
I.4	Fuego/FOC (Fire Observation Constellation)	803
I.4.1	Fuego System Concept	804
I.4.2	FuegoSat	808
I.5	GMES (Global Monitoring for Environment and Security)	808
I.6	Search & Rescue (S&R) Satellite Systems	809
I.6.1	COSPAS-S&RSAT Constellation	809
I.6.1.1	Alert Signal Devices (User Segment)	810
I.6.1.2	Satellite Payloads (Space Segment)	811
I.6.1.3	COSPAS-S&RSAT Ground Segment	812
I.6.2	GEOS&R (Geostationary Search & Rescue)	813

Part J Shuttle - Selected Missions and Payloads 815

J.1	ASTRO-SPAS (Astronomy Platform - Shuttle Pallet Satellite)	815
J.1.1	ORFEUS-SPAS-1	815
J.1.2	CRISTA-SPAS-1	816
J.1.3	ORFEUS-SPAS-2	819

J.1.4	CRISTA-SPAS-2	820
J.2	ATLAS (Atmospheric Laboratory for Application and Science)	820
J.3	Bitsy-SX (Bitsy-Spacecraft in Future-X)	823
J.4	CIRRIS (Cryogenic Infrared Radiance Instrumentation for Shuttle)	824
J.5	EURECA (European Retrievable Carrier)	825
J.5.1	EURECA-1 Mission	825
J.6	IPS (Instrument Pointing System)	828
J.7	ISIR (Infrared Spectral Imaging Radiometer)	829
J.8	LDEF (Long Duration Exposure Facility)	830
J.9	LFC (LARGE FORMAT CAMERA)	833
J.10	LITE (Lidar In-Space Technology Experiment)	834
J.11	MAPS (Measurement of Air Pollution from Satellites)	835
J.12	MOMS-01 (Modular Optoelectronic Multispectral Scanner)	836
J.13	MOMS-02 (Modular Optoelectronic Multispectral Scanner)	837
J.14	SAC (Satélite de Aplicaciones Científicas)	839
J.15	SAC -A (Satélite de Aplicaciones Científicas-A)	839
J.16	SHIMMER (Spatial Heterodyne Imager for Mesospheric Radicals)	840
J.17	SLA (Shuttle Laser Altimeter)	842
J.17.1	SLA-1	842
J.17.2	SLA-2	843
J.18	SPARTAN (Shuttle Pointed Autonomous Research Tool for Astronomy)	843
J.18.1	SPARTAN-1	844
J.18.2	SPARTAN-Halley	844
J.18.3	SPARTAN-201	844
J.18.4	SPARTAN-204	845
J.18.5	SPARTAN-206	845
J.18.6	SPARTAN-207	847
J.18.7	SPARTAN-250 Carrier System	847
J.18.8	SPARTAN-251	847
J.18.9	SPARTAN-401	847
J.19	SIR-A (Shuttle Imaging Radar)	848
J.20	SIR-B	849
J.21	SIR-C/X-SAR	849
J.22	Spacelab-1	853
J.23	Spacelab-3	854
J.24	Shuttle EO Imaging Cameras	854
J.24.1	Shuttle Film Camera Systems	855
J.24.2	IMAX Space Cameras	856
J.24.3	IMAX-3D Space Cameras	856
J.24.4	ICBC (IMAX Cargo Bay Camera)	856
J.25	SRTM (Shuttle Radar Topography Mission)	858
J.26	SSBUV (Shuttle Solar Backscatter Ultraviolet Spectrometer)	861

Part K Space Science/Solar-Terrestrial Missions 863

K.1	ACE (Advanced Composition Explorer)	863
K.2	ACTIVE (AKTIVNY-IK)	865
K.2.1	Subsatellite Magion-2 (C2-AK)	867
K.3	ALEXIS (Array of Low-Energy X-Ray Imaging Sensors)	869
K.4	AMPTE (Active Magnetosphere Tracer Explorers)	871
K.4.1	IRM Instrumentation (Sensors)	874
K.4.2	UKS Instrumentation (Sensors)	875
K.4.3	CCE Instrumentation (Sensors)	875
K.5	APEX (Active Plasma Experiment)	875

K.5.1	APEX Subsatellite (Magion-3) Scientific Payload	877
K.6	ASTRID	878
K.6.1	ASTRID-1	878
K.6.2	ASTRID-2	880
K.7	CLuster (Four S/C Mission in Concert with SOHO)	881
K.7.1	Cluster-I	881
K.7.2	Cluster-II	886
K.8	CORONAS-I	888
K.8.1	CORONAS-F	892
K.8.2	PHOTON	893
K.9	Equator-S	896
K.10	EXOS (Exospheric Observations)	898
K.10.1	EXOS-A (Kyokko)	898
K.10.2	EXOS-B (Jikiken)	899
K.10.3	EXOS-C (Ohzora = Sky)	900
K.10.4	EXOS-D (Akebono)	901
K.11	FREJA	905
K.12	Genesis (Solar-Wind Sample Return Mission)	909
K.13	GEOTAIL	913
K.14	HESSI (High Energy Solar Spectroscopic Imager)	916
K.15	IMAGE (Imager for Magnetopause-to-Aurora Global Exploration)	918
K.16	IMP-8 (International Monitoring Platform)	923
K.17	INTERBALL	926
K.17.1	“Auroral Probe” Sensors	927
K.17.2	“Tail Probe” Sensors	928
K.18	ISEE (International Sun-Earth Explorer)	931
K.18.1	ISEE-1 and -2 Mission	931
K.18.2	ISEE-3 Mission	933
K.19	POLAR	936
K.19.1	SAC-B (Satélite de Aplicaciones Científicas-B)	941
K.20	SME (Solar Mesosphere Explorer)	942
K.21	SMEX (Small Explorer Program)	944
K.21.1	SAMPEX (Solar Anomalous and Magnetospheric Particle Explorer)	945
K.21.2	FAST (Fast Auroral Snapshot Explorer)	947
K.21.3	TRACE (Transition Region and Coronal Explorer)	949
K.22	SMM (Solar Maximum Mission)	952
K.23	SOHO (Solar and Heliospheric Observatory)	955
K.24	SOLAR-A (Yohkoh)	960
K.25	Solar-B	961
K.26	STEREO (Solar-Terrestrial Relations Observatory)	963
K.27	TWINS (Two Wide-angle Imaging Neutral-atom Spectrometers)	971
K.28	Ulysses	973
K.29	Viking	978
K.30	WIND	980

Part L Space Stations 983

L.1	ISS (International Space Station)	983
L.2	ISS Utilization - Selected Payloads and Instruments	984
L.2.1	ACCESS (Advanced Cosmic-Ray Composition Experiment for Space Station)	985
L.2.2	ACES (Atomic Clock Ensemble in Space)	986
L.2.3	AMS (Alpha Magnetic Spectrometer)	986
L.2.4	ARISS (Amateur Radio on the International Space Station)	986

L.2.5	CRESPO (Coral Reef Ecosystem Spectro-Photometric Observatory)	986
L.2.6	EUTEF (European Technology Exposure Facility)	987
L.2.7	FOCUS (Fire Detection and Analysis Sensor System)	987
L.2.8	GTS (Global Transmission Services)	988
L.2.9	LCDE (Laser Communications Demonstration Equipment)	989
L.2.10	PARCS (Primary Atomic Reference Clock in Space)	990
L.2.11	PET (Photovoltaic Engineering Testbed)	990
L.2.12	RACE (Rubidium Atomic Clock Experiment)	991
L.2.13	SAGE-III (Stratospheric Aerosol and Gas Experiment III)	991
L.2.14	SEDA-AP (Space Environment Data Acquisition equipment-Attached Payload)	991
L.2.15	SMILES (Superconducting Submillimeter-wave Limb-Emission Sounder) .	992
L.2.16	Solar-A (Solar Monitoring Observatory)	994
L.2.16.1	SOVIM (Solar Variability and Irradiance Monitor)	994
L.2.16.2	SOLSPEC (Solar Spectral Irradiance Measurements)	996
L.2.16.3	SOL-ACES (Solar Auto-Calibrating EUV/UV Spectrophotometers)	996
L.2.17	SUMO (Superconducting Microwave Oscillator)	996
L.2.18	WORF (Window Observational Research Facility)	996
L.3	MIR-1 Orbital Station	997
L.4	Salyut Space Station	1001
L.5	SKYLAB Space Station	1002

Part M Technology Missions 1005

M.1	ARGOS (Advanced Research and Global Observation Satellite)	1005
M.2	ARTEMIS (Advanced Relay and Technology Mission Satellite)	1013
M.3	Bitsy-SX (Bitsy-Spacecraft in Future-X)	1017
M.4	DODGE (Department of Defense Gravity Experiment)	1018
M.5	DS1 (Deep Space 1)	1019
M.5.1	Advanced technology payload complement	1021
M.5.2	Major events and status of extended mission in 2000	1024
M.6	EO-1 (Earth Observing-1)	1025
M.6.1	Sensor Complement	1026
M.6.2	Demonstration of seven new technologies on EO-1	1030
M.7	EO-3 (Earth Observing-3, GIFTS-IOMI Mission)	1032
M.8	ETS (Engineering Test Satellite)	1035
M.8.1	ETS-VII (Engineering Test Satellite VII)	1036
M.8.2	ETS-VIII (Engineering Test Satellite VIII)	1039
M.9	FedSat-1 (Federation Satellite One)	1042
M.10	MDS (Mission Demonstration Satellite)	1045
M.10.1	MDS-1	1045
M.11	MightySat	1047
M.11.1	MightySat I	1047
M.11.2	MightySat II.1 (Sindri)	1049
M.12	MINISAT	1053
M.12.1	MINISAT-01	1053
M.13	MITA (Minisatellite Italiano di Tecnologia Avanzata)	1055
M.14	MSX (Midcourse Space Experiment)	1057
M.15	Myriade (CNES Microsatellite Program)	1064
M.15.1	DEMETER	1065
M.15.2	Microscope	1066
M.15.3	PARASOL	1068
M.15.4	Picard	1069

M.16	NEMO (Navy EarthMap Observer)	1071
M.17	Nimbus	1075
M.17.1	Nimbus-1	1076
M.17.2	Nimbus-2	1077
M.17.3	Nimbus-3	1078
M.17.4	Nimbus-4	1080
M.17.5	Nimbus-5	1082
M.17.6	Nimbus-6	1084
M.17.7	Nimbus-7	1086
M.18	OICETS (Optical Inter-orbit Communications Engineering Test Satellite)	1090
M.19	PICOSat (STP)	1093
M.20	PROBA (Project for On-Board Autonomy)	1095
M.21	RADCAL (Radar Calibration Satellite)	1102
M.22	SJ (Shi Jian Program)	1102
M.22.1	SJ-5 (Shi Jian - 5)	1103
M.23	SMART-1 (Small Mission for Advanced Research in Technology)	1105
M.24	SPORT (Small Payload Orbit Transfer)	1110
M.25	STRV (Space Technology Research Vehicle)	1111
M.25.1	STRV-1a and -1b	1111
M.25.1.1	STRV-1a Sensor/Experiment Complement	1112
M.25.1.2	STRV-1b Sensor/Experiment Complement	1114
M.25.2	STRV-1c and -1d	1116
M.25.2.1	STRV-1c Sensor/Experiment Complement	1116
M.25.2.2	STRV-1d Sensor/Experiment Complement	1119
M.26	TEAMSAT	1120
M.27	Tether Missions/Experiments	1123
M.27.1	ASTOR (Advanced Safety Tether Operation and Reliability)	1125
M.27.2	BOLAS (Bistatic Observations with Low Altitude Satellites)	1125
M.27.3	METS (MIR Electrodynamic Tether System)	1126
M.27.4	OEDIPUS	1126
M.27.5	PMG (Plasma Motor Generator)	1126
M.27.6	ProSEDS (Propulsive Small Expendable Deployer System)	1127
M.27.7	SEDS (Small Expendable Deployer System)	1127
M.27.8	STEP-AIRSEDS	1128
M.27.9	STEPS (Station Tethered Express Payload System)	1128
M.27.10	TiPS (Tether Physics and Survivability)	1129
M.27.11	TSE (Tether System Experiment)	1130
M.27.12	TSS (Tethered Satellite System)	1131
M.28	TOPSAT	1132
M.29	TSX-5 (Tri-Service Experiments Mission 5)	1134
M.29.1	STRV-2 (Space Technology Research Vehicle-2)	1135
M.29.2	CEASE (Compact Environmental Anomaly Sensor Experiment)	1137

Part N University/Student-Developed Satellites & Payloads 1139

N.1	ASUSat-1 (Arizona State University Satellite 1)	1140
N.2	BREM-SAT 1	1141
N.3	CHIPSat (CHIPS Satellite)	1143
N.4	CX-I (Citizen Explorer-I)	1146
N.4.1	On-board Sensor Complement	1147
N.4.2	Ground Instruments	1148
N.4.3	Technology Demonstrations	1148
N.4.4	Data Distribution Scheme and User Involvement	1149
N.5	FS-1 (FalconSat-1)	1149

N.6	NanoSat	1150
N.7	JAWSAT (Joint Airforce Academy / Weber State University Satellite)	1151
N.8	NavGold	1153
N.9	Munin	1155
N.10	NUSAT (Northern Utah Satellite)	1157
N.11	OPAL (Orbiting Picosat Automatic Launcher)	1158
	N.11.1 Sensor/payload complement	1159
	N.11.2 StenSat	1160
	N.11.3 PICOSAT1.0	1161
	N.11.4 Artemis	1162
N.12	PANSAT (Petite Amateur Navy SATellite)	1163
N.13	SAPPHIRE (Stanford AudioPhonic Photographic IR Experiment)	1164
N.14	SEDSAT-1 (Students for the Exploration & Development of Space)	1166
N.15	Sputnik-II	1167
N.16	STARSHINE (Student-Tracked Atmospheric Research Satellite for Heuristic International Networking Equipment)	1168
	N.16.1 STARSHINE-1	1168
	N.16.2 STARSHINE-2	1169
	N.16.3 STARSHINE-3	1169
N.17	STEDI (Student Explorer Demonstration Initiative)	1170
	N.17.1 SNOE (Student Nitric Oxide Explorer)	1170
	N.17.2 TERRIERS	1173
	N.17.3 CATSAT (Cooperative Astrophysical and Technology Satellite)	1175
N.18	SUNSAT (Stellenbosch University Satellite)	1177
N.19	SURFSAT (Summer Undergraduate Research Fellowship Satellite)	1180
N.20	TechSat/Gurwin-II	1181
N.21	TUBSAT (Technical University of Berlin Satellite)	1184
	N.21.1 TUBSAT-A	1184
	N.21.2 TUBSAT-B	1185
	N.21.3 TUBSAT-N (Technical University of Berlin Satellite-Nano)	1185
	N.21.4 DLR-TUBSAT	1186
	N.21.5 Maroc-TUBSAT	1188
N.22	UniSat (University Satellite)	1190
N.23	WeberSat	1191

Part O Reference Data and Definitions 1193

O.1	Definitions, Concepts, Summaries	1196
	O.1.1 Remote Sensing across the Electromagnetic Spectrum	1196
	O.1.2 Types and Classes of Remote Sensors and Sensing Data	1197
O.2	Some Aspects of Radiometric Instrument Calibration	1201
	O.2.1 GNSS Radio Occultation Sounding	1203
	O.2.2 Correction/Calibration Methods for Sensor Data	1205
	O.2.3 Electron-scanned Imaging Devices	1206
O.3	Scanners	1206
	O.3.1 Line Scanners	1207
	O.3.2 Electromechanical Line Scanner	1208
	O.3.3 Optoelectronic Scanners	1209
	O.3.4 Observation Schemes	1210
	O.3.4.1 Line (or linear) Detector Array	1211
	O.3.4.2 Area Arrays	1212
	O.3.5 Staring Array Systems	1212
	O.3.6 Time Delay Integration (TDI)	1213
O.4	Sensor Detector Systems	1215

O.4.1	Definitions	1215
O.4.2	Charge-Transfer Devices	1223
O.4.2.1	Charge-Coupled Device (CCD)	1224
O.4.2.2	Charge-Injection Device (CID)	1227
O.4.2.3	CMOS/APS Detectors	1228
O.4.3	Infrared Detection	1229
O.4.3.1	Detector Arrays and Focal Plane Assemblies (FPAs)	1230
O.4.4	Radiation Detection Limits	1231
O.4.5	Acousto-Optic Devices	1233
O.4.6	Resolution (for Visible and Infrared Imagery)	1235
O.4.7	SQUID Sensors in Magnetometry	1237
O.5	Cryocooling Techniques	1237
O.5.1	Stirling Cycle Cooler	1238
O.5.2	Pulse Tube Cooler	1238
O.5.3	Hybrid Cryogenic System: CSE (Cryo System Experiment)	1238
O.5.4	Optical Cooling	1239
O.6	Imaging Spectrometers	1240
O.7	Passive Radiometry (MW/MMW)	1241
O.7.1	Radiometer Instruments	1243
O.7.2	Aperture Synthesis in Radiometry	1247
O.8	Active Radiometry	1247
O.8.1	Types of Radar Sensors	1248
O.8.2	SAR Terminology and Definitions	1250
O.8.3	SAR Imaging Modes	1252
O.8.4	Looks, Speckles and Radiometric Resolution of SAR Images	1252
O.8.5	Lidars (Laser-Based Remote Sensing)	1253
O.8.5.1	Backscatter Lidar	1253
O.8.5.2	Differential Absorption Lidar (DIAL)	1254
O.8.5.3	Raman Lidar	1254
O.8.5.4	Doppler Wind Lidar (DWL)	1254
O.8.5.5	Ranging and Altimeter Lidar	1255
O.8.5.6	Lidar Principle	1255
O.9	Fourier Transform Spectrometer (FTS)	1258
O.10	Interferometry	1259
O.10.1	Radar Interferometry	1261
O.10.2	VLBI (Very Long Baseline Interferometry)	1263
O.11	Spatial Heterodyne Spectroscopy (SHS)	1263
O.12	Orbital Concepts and Terminology in Remote Sensing	1265
O.12.1	Sun-synchronous Orbit	1267
O.12.2	Geosynchronous Orbit	1268
O.12.3	Repeat Coverage or Temporal Resolution	1270
O.12.4	LEO (Low Earth Orbit)	1271
O.12.5	MEO (Medium Earth Orbit)	1272
O.12.6	HEO (Highly-Elliptical Earth Orbit)	1272
O.12.7	EEO (Elliptical Earth Orbit)	1272
O.12.8	The Interferometric Cartwheel Orbit	1272
O.12.9	Some Orbit Selection Requirements	1275
O.12.10	Walker Constellation	1275
O.12.11	Libration Points/Lagrange Points	1276
O.13	Observational Scales in Modeling	1278
O.14	On-Orbit Electric Propulsion	1280
O.14.1	Basic Thruster Concepts	1281
O.14.1.1	Specific Impulse (Isp)	1281

O.14.1.2	Electrothermal thrusters	1281
O.14.1.3	Electrostatic thrusters	1282
O.14.1.4	Electromagnetic thrusters	1283
O.14.2	Some Developed Thruster Systems	1284
O.15	Summary of World Data Centers (WDCs)	1290
O.16	Committee on Earth Observation Satellites - CEOS	1293
O.17	Space Shuttle Mission Chronology	1296
O.18	Solar Wind and the Magnetosphere - An Introduction	1300
O.19	Frequency Designations	1303

Appendix A Glossary 1313

Appendix B Acronyms and Abbreviations 1393

Appendix C Index of Sensors 1477

The sections P and Q are only part of the CD-ROM that comes along with the book. All information up to and including Appendix C are part of the 4th edition (a single volume) as well as part of the CD-ROM.

Part P Survey of Airborne Sensors 1511

P.1	AAHIS (Advanced Airborne Hyperspectral Imaging Spectrometer)	1513
P.2	AAMAS (Aircraft-borne Automatic Mass Spectrometer)	1514
P.2.1	TQMS (Triple Quadrupole Mass Spectrometer)	1515
P.3	ADS40 (Airborne Digital Sensor 40)	1516
P.4	Aerosol Experiment	1518
P.5	AeS-1 (Aerosensing-1)	1518
P.6	AES (Airborne Emission Spectrometer)	1520
P.7	AHSTRA (Airborne Heterodyne Spectrometer THz Astronomy)	1520
P.8	AIMR (Airborne Imaging Microwave Radiometer)	1521
P.9	AIMS-1000 (Airborne Imaging Mapping and Surveillance System)	1522
P.10	AirCam	1522
P.11	AIRDAS (Airborne Disaster Assessment System)	1523
P.12	AirMISR (Airborne Multi-angle Imaging SpectroRadiometer)	1524
P.13	AIRSAR (Airborne SAR)	1525
P.13.1	TOPSAR (Interferometric Radar Topographic Mapping Instrument)	1527
P.14	AIS (Airborne Imaging Spectrometer)	1529
P.15	AISA (Airborne Imaging Spectrometer for different Applications)	1529
P.16	ALAS (Airborne Laser Altimeter System)	1531
P.17	ALF (Airborne Laser Fluorosensor)	1532
P.18	ALIAS (Aircraft Laser Infrared Absorption Spectrometer)	1534
P.18.1	ALIAS-I on ER-2 Aircraft	1534
P.18.2	ALIAS-II on Perseus Aircraft	1534
P.19	ALPS (Airborne Laser Polarization Sensor)	1535
P.20	ALTM (Airborne Laser Terrain Mapping)	1536
P.21	AMMR (Airborne Multichannel Microwave Radiometer)	1537
P.22	AMMS (Airborne Microwave Moisture Sounder)	1537
P.23	AMPR (Advanced Microwave Precipitation Radiometer)	1537
P.24	AMPS (Airborne Multisensor Pod System)	1538
P.24.1	Sony DXC-750 3-CCD Video Camera	1539

P.24.2	Wild RC30 Large Format Camera	1539
P.24.3	AGEMA Thermal Imager	1540
P.24.4	Sandia SAR	1540
P.24.5	COHU 5560 Low Light Camera	1541
P.24.6	CASI (Compact Airborne Spectrographic Imager)	1541
P.24.7	AMS (Airborne Multispectral Scanner)	1541
P.24.8	EGS (Echelle Grating Spectrometer)	1541
P.24.9	AC-ITMS (Air Concentrator-Ion Trap Mass Spectrometer)	1542
P.24.10	TTS (Target Tracking System)	1542
P.24.11	AKS (Aerial Krypton Sampler)	1542
P.24.12	R-TARAC (Real-Time Airborne Radionuclide Analyzer and Collector) ...	1543
P.25	AMSOS (Airborne Millimeter & Submillimeter-wave Observing System)	1543
P.26	AMSS MK-II (Airborne Multi-Spectral Scanner)	1544
P.27	AOL (Airborne Oceanographic Lidar)	1544
P.28	APDOR-95 (Airborne Polarimetric Doppler Radar)	1545
P.29	APE (Airborne Polar Experiment)	1546
P.29.1	SAFIRE-A (Spectroscopy of the Atmosphere w. FIR Emission - Airborne)	1547
P.29.2	ARIAS (Airborne Remote-Sensing & In-Situ Aerosol Measuring System) .	1548
P.29.3	GASCOD (Gas Absorption Spectrometer Correlating Optical Differences)	1549
P.29.4	ABLE (Airborne Lidar Experiment)	1550
P.29.5	MAL (Micro-Joule Airborne Lidar)	1551
P.29.6	ECOC (Electrochemical Ozone Cell)	1552
P.29.7	FLASH (Fluorescent Airborne Stratospheric Hygrometer)	1552
P.29.8	ACH (Aircraft Condensation Hygrometer)	1553
P.29.9	ACAP (Airborne Counter of Aerosol Particles)	1553
P.29.10	FOZAN (Fast Ozone Analyzer)	1554
P.29.11	COPAS (Condensation Particle Detection System)	1555
P.30	APEX (Airborne PRISM Experiment)	1555
P.31	APMIR (Airborne Polarimetric Microwave Imaging Radiometer)	1557
P.32	ARES (Airborne Remote Earth Sensing)	1559
P.33	ARGUS (Two-Channel Atmospheric Tracer Instrument)	1561
P.34	ARL (Airborne Raman Lidar)	1563
P.35	ARMAR (Airborne Rain Mapping Radar)	1564
P.36	ASAS (Advanced Solid-State Array Spectroradiometer)	1565
P.37	ATHOS (Airborne Tropospheric Hydrogen Oxide Sensor)	1566
P.38	ATLAS (Airborne Tunable Laser Absorption Spectrometer)	1567
P.39	ATLAS (Airborne Terrestrial Applications Scanner)	1568
P.40	Atmospheric Measurements on Commercial Airline Flights	1570
P.40.1	MOZAIC (Measurement of Ozone by Airbus In-Service Aircraft)	1570
P.40.2	ACORN	1571
P.40.3	CARIBIC	1572
P.40.4	ASE (Automatic Air-Sampling Equipment)	1574
P.41	ATSS (Airborne Terrain Survey System)	1576
P.41.1	ScaLARS-2 (Scanning Laser Altitude and Reflectance Sensor)	1577
P.42	AVIRIS (Airborne Visible/Infrared Imaging Spectrometer)	1578
P.43	AWI Sensors	1581

This documentation, in particular all previous editions, were made possible with the resources and support of the German Remote Sensing Data Center (DFD). My special thanks go to DLR/DFD for the opportunity to complete the 4th edition.

This book is again dedicated to my wife Mechtild
and to our daughters Monika, Ursula and Mechtild.

My family provided unequivocal support in my long-term book-writing efforts.
It is the reason why this edition could be completed.

Foreword and Acknowledgements of the 4th Edition

An effort has been made to update the material presented in previous editions. In addition, a considerable amount of new information is provided. The 4th edition contains a number of changes in scope and layout.

- After the 3rd edition in 1996, I realized that some sort of “Earth observation history” was needed to put a lot of space-age facts into proper context for a better overview and understanding of the subject matter. I started by searching my documentation base for a number of themes and by reviewing the published literature with a more conscious view for the historic perspective. This resulted in a long-term and virtually daily update process of my history kernel. The initial emphasis was in collecting as many meaningful items of “technology introduction” as possible. Over the years, many computer printouts were given to colleagues from various space agencies and institutions with the intent of a review. Fortunately, I received some valuable comments and suggestions from experts in various fields. The compilation of the history represents indeed a major amount of time and effort on my part; I do hope it serves as a valuable introduction and reference to the readership and to all interested in the wide field of Earth observation.

I am quite aware of the fact that my “history” is incomplete and a bit lopsided in favor of the western space-faring nations. In particular, it does not reflect properly the accomplishments of the Soviet/Russian space program in the field of Earth observation. This is definitely not intended. The unavailability (and/or non-existence) of documentation on the Russian space program with regard to sensor developments is the prime reason for this deficit. My requests for history reviews, for critical comments and for background information on particular topics were only of very limited success. The language barrier, the secrecy of the past political system, the heritage of a military-dominated space program, and the working habits of the Russian research community are at the root of the problem. The nature of any reliable history depends, however, on access to multiple information sources for checks and cross checks for verification.

- Most emphases are given to the documentation of spaceborne missions and sensors, a field that grew considerably during the past five years. As a consequence, my effort to cover airborne instruments and campaigns had to be reduced considerably. With regard to the latter, updates were only made when readily available (I didn’t search consciously for documentation of new airborne instruments because there was simply no time left to do so).

- A thematic re-ordering of the spaceborne missions was done (Part A to N). The different themes or categories were selected according to my own judgment. Obviously, most missions fit into several categories due to the functional/observational variety of the sensor complement. [A case in point is the Envisat mission of ESA with its sensor complement. It features ASAR as a SAR imaging instrument; the optical imaging instruments are: AAT-SAR and MERIS; the radar altimetry mission is covered with RA-2, MWR, DORIS and LRR; in addition there are atmospheric instruments with GOMOS, MIPAS and SCIAMACHY] Of course, many other arrangements are conceivable. I took the freedom of placing each mission into the category of my choice because of the lack of suggestions from anywhere else (I did ask for advice). - The new arrangement may lead to a bit more searching in the table of contents. Still, I feel the thematic ordering scheme is rather positive for the layout.

- My agreement with the publisher calls for a single volume limited to about 1500 pages plus a CD-ROM, the intent is to keep the documentation affordable. Hence, the book contains the spaceborne missions and sensors, the “history” and a few appendices. The CD-ROM, however, contains all information, including Part P: “Survey of Airborne Sensors” and Part Q: “Survey of Campaigns.” The CD-ROM is intended as a search tool; it is not to be used as a copy tool.

- The spacecraft/instrument illustrations in the previous editions were mostly presented as line drawings. This standard could not be kept in the 4th edition because of lack of manpower. Hence, in the review cycle of my draft, I usually requested a spacecraft illustration from the information provider and converted this into my Interleaf (Quicksilver version) documentation system.
- The 4th edition contains also many internet references. I am aware of the fact that the behavior of many of these “addresses” is rather volatile and elusive. I inserted them to indicate the source of information.
- During the past years, spacecraft and instrument design and development has become part of the curriculum at many universities throughout the world, where a fresh look is being taken at many of the problems facing the future of spaceflight. SSTL (Surrey Satellite Technology Ltd) of Surrey, UK, since 1985 a commercial company whose principal shareholder is the University of Surrey, started out early with classroom teaching and getting “engaged” by solving practical problems. SSTL was the first to take a new look at affordable space flight by introducing its microsatellite program along with a wealth of new ideas for ways of doing things. Another example is SunSpace and Information Systems (Pty) Ltd. of the University of Stellenbosch, South Africa, which set up shop in 2000, following a successful launch of SUNSAT in Feb. 1999. - These university activities are certainly a new stimulant for technology introduction and demonstration in many fields. As a consequence, I integrated a number of these small missions into Part N of the book to reflect to some extent the activities in this field. Unfortunately, most of my partially documented missions (which didn’t make it into the 4th edition due to a lack of communication or of interest by my university contacts) are part of this section. The US UNP (University Nanosatellite Program) of 10 nanosatellites, an initiative sponsored by the US Department of Defense, NASA, and industry and developed by a number of US universities, is such a case in point.

By its very nature, the book can only be an “approximation of Earth observation reality” - a fair try at short descriptions of past and current missions and some perspective of the future (a best-effort approach); it is also a product of many compromises, omissions and interpretations. There are still dozens of partially documented projects (mostly in an early project phase) that didn’t make it into the book, a sign of continuous progress and development. Reality is much more bizarre, diverse and complex than can be portrayed in this technical volume. Still, I do hope that the general field of “Earth observation” has been given a boost with the completion of this edition.

Electronic mail (e-mail) was the dominant means of communication between myself and over 500 contacts worldwide to get most of the project information transferred (faxes and letters were the mainstay in the previous editions). In addition, I monitored the published literature and many internet websites for information on new space projects.

All editions of my book were written without a mandate or an endorsement from anyone. I could only count on the cooperative attitude of many individuals (hundreds) in numerous organizations, willing to share information and to provide reviews of my draft descriptions. On many occasions my requests were simply met with indifference or disregard, in spite of reminders. Of course, this has to be seen in relation to the global scope of the book, the working environment of the individual contacted, the pressure exerted by the project he or she was working on, the language barriers of the non-English-speaking world, and/or to local attitudes and experiences. Some institutions are simply not accustomed to open policies, to public outreach, to e-mail communications, or to any documentation standards. The best results were achieved with those contacts who were acquainted with previous editions of my book. They realized in particular the value of such a survey and they were eager to help and to get their project also into the new edition.

There is some coverage of US military service missions (navigation, weather) and technology missions as far as information could be found or was made available through contacts.

This time around, I experienced in particular good cooperation from NRL (Naval Research Laboratory) in Washington, DC. It was more difficult to get information on such missions as MightySat, ARGOS, TSX5 and PICOSat. As a US citizen, I spent a day at SMC (Space and Missile Systems Center) and at JPO (Joint Program Office of GPS) in El Segundo, CA, trying to get a contact on several programs, but in the end there was no chance to meet anyone. A similar fate occurred to me at Kirtland AFB in Albuquerque, NM. In my experience, everything seems to be classified on European military missions in the field of Earth observation. I simply resigned after a few tries.

In my requests for information (not only to military establishments, but also to commercial entities and to some space agencies as well), I was often considered a potential security risk. However, my policy was always to respect the wishes of the information provider. I don't want to publish anything "considered secret," thereby compromising these sources. The security aspect of projects was one of the reasons why I was always asking for reviews. But I also insisted on certain standards of description and completion to present a text in context. I do admit that I didn't succeed in all cases.

The writing of the 4th edition turned out to be a major problem with regard to support. All previous editions were sponsored by DLR/DFD. But with the submission of the 3rd edition in early 1996, DFD management insisted on external support for continuation of the work. As a consequence, I applied for support at nearly all space agencies of the world, at German and European institutions, at the UN. All applications were met with negative replies or simply with silence. I was treated by all space agencies with benign neglect. My experience: All potential sponsors are very interested in a global view of Earth observation, but should it come to sponsoring, then they are only interested in the proper presentation of their own projects.

On the other hand, I received lots of encouragement and invigoration from the reader community. Many inquired about the 4th edition. In early 1999, I took the "early retirement option" from DLR (effective as of Feb. 2000), to be able to dedicate my work to the 4th edition. In this new arrangement, DFD generously provided an office, access to e-mail and internet services and a postal address for my mail, all other expenses (like a computer, licenses, data backup services, information trips to the US and Russia, needed documentation, etc.) were my own, including my time. DFD management gave notice in June 2001 requesting my office room back without any alternate accommodation possibility. As a consequence, I moved out on July 11, 2001.

In spite of all handicaps, I found my work exciting and fascinating being exposed to hundreds of projects and to an ever evolving field of technologies and applications in the wide field of Earth observation. It gave me a new interdisciplinary education in many aspects, since I had to understand the principles involved prior to explaining them to the reader. In particular, I wasn't afraid of asking the experts in the field. I am grateful for all comments and advice received to improve the quality of the book.

Looking back on a dozen years of Earth observation coverage, the book has become my way of life; it provided me with a sense of accomplishment and of self-assurance in spite of enormous work loads. But the 4th edition is definitely going to be my last. I can visualize an engagement on a rather reduced scale in the future, but I cannot afford to continue with book-writing at the required pace of personal time and monetary investment. My experience: growing a few vegetables in the garden is more profitable than book-writing. In particular, I want to be able to share more time with my family.

May the book be a rich source of information and a solid reference for all readers.

Acknowledgements:

I would like to thank the legion of individuals throughout the world who provided information or contributed their talents in other ways for the completion of this book. I have en-

deavored to list all of them below, in no particular order (but grouped to institutional affiliations), and want to thank every one of them, with apologies to anybody I may have accidentally forgotten. Naturally, there are considerable differences in the level of support provided. Again, I was very fortunate to enjoy the backing of some key contacts in several agencies, who opened doors that led to further contacts and/or contributed substantially with advice or reviews. Many of my contacts became my friends; only a few select treated me in a rather demeaning way (simply by disregarding all of my questions or pushing their particular interests of presentation), wielding their power and letting me feel my position as humble requester.

History reviews or contributions: In particular, I am very grateful for the cooperation and contributions of the following individuals: William Bandeen of GSFC, Greenbelt, MD (Bill retired from GSFC in 1990 and provided actually two complete reviews of the history within a period of two years); Michael D. King and Leslie M. Cusick of GSFC; Friedrich E. Jochim and Boris S. Zhukov of DLR; Peter Schwintzer of GFZ, Potsdam; David L. Glackin of the Aerospace Corporation, El Segundo, CA; R. Keith Raney of JHU/APL, Laurel, MD; Lee J. Rickard and Michael Zedd of NRL, Washington, D.C.; Arnold Schoonwinkel of Stellenbosch University, Stellenbosch, South Africa; Dominique D. Crommelynck of IRMB, Brussels, Belgium; and Walter Flury of ESA/ESOC, Darmstadt, Germany. Ursula Weisgerber of Springer-Verlag, Berlin, was very helpful in the production of the CD-ROM.

At this point I would like to thank Ron Baalke of JPL. I consulted frequently his “Space Calendar Website” (<http://www.jpl.nasa.gov/calendar/>) for update information in particular on mission launches, meetings, etc. My thanks go also to Jonathan McDowell of Harvard University. I used his website “Jonathan’s Space Report” for reference material.

I am dedicating this book also to the memory of Friedrich L. Porsch, a young colleague at DLR/DFD who died in an accident on Feb. 21, 1997 at the age of 39. Friedrich provided a lot of superb line drawings to all editions of this book, I owe him many thanks for his long-term cooperation. His last drawing was that of the AVHRR instrument.

Oberpfaffenhofen, August 2001

Herbert J. Kramer

1 Earth Observation Short-History

Prior to the space age (conventionally dated from 1957), humankind had never been able to take in the whole of a hemisphere in a single glance. In fact it had never had a global view of the world in which it lived. It was not until the first spacecraft went into orbit that our horizons expanded and we saw our planet as never before. During more than four decades of spaceflight, planet Earth has been rediscovered through the systematic collection and analysis of vast amounts of information. At the turn of the century/millennium, satellite-provided services in many fields of application (environmental monitoring, navigation, weather forecasting, communication, etc) are taken for granted. We've come to depend on the satellites in a way that would have been unimaginable a few decades ago.

Before the space age, remote sensing, although not named as such, was done exclusively with photographic cameras. The so-called aerial photo emerged in the 1850's, a mere dozen years after the invention of photography, with pictures taken from a tethered balloon - the French photographer, Gaspard Félix Tournachon (1820-1910), alias Nadar, obtained the first aerial photographs over Paris (Oct. 23, 1858) from an altitude of about 80 m. Thereafter, tethered balloons were used a few times during the US Civil War (1861-1865) by General George McClellan, to study enemy positions using aerial photographs. At the beginning of the twentieth century, the aeroplane proved its advantage as a civil and military observation platform. Aerial photography was extensively employed during both World Wars for military reconnaissance. In 1947, a few captured V-2 rockets were used by the US military to photograph the clouds from 110-165 km altitudes. [In the same year (Oct. 18, 1947), the Soviet Union launched its first LRBR (Long Range Ballistic Rocket) based on the German rocket A4 (V-2)]. The photographs demonstrated the immense potential of observing weather.¹⁾ After the wars and prior to 1960, the development of aerial color and color infrared film gave civilian remote sensing a distinct boost. The color infrared photography allowed some interpretation means for a rough classification of some vegetation types. High-speed cameras, combined with wide-angle lenses, provided greater opportunities to image Earth's surfaces.

Earth observation covers a wide field of remote sensing as well as of other sensing methods (in-situ), it encompasses the Earth itself (in particular its outer surface) and also the Earth's environment, including the study of interactions with the outside. Space-age Earth observation (although not named as such initially) started with the launch of Russia's first Sputnik satellite on Oct. 4, 1957 on the R-7 launch vehicle from Baikonur (satellite mass = 83.6 kg, diameter = 58 cm, perigee = 228 km, apogee = 947 km, inclination = 65.1°, period = 96 min, RF frequencies: 20.005 MHz and 40.002 MHz). The chief designer and general manager of the Sputnik project was Sergei Pavlovich Korolev. Sputnik-1 made measurements that permitted a first estimation of the density of the upper atmosphere. In the following period each new spacecraft launch produced new discoveries. The first successful US satellite was Explorer-1 (launch Jan. 31, 1958 with a S/C mass of 5 kg; orbit of 384 km x 1859 km, inclination of 32.2°) of the US Army, built by the Army Ballistic Missile Agency and by JPL. Explorer-1 (instruments included a cosmic ray and micrometeorite package, a micrometeorite impact microphone, micrometeorite erosion gages, and internal and external temperature gages) provided preliminary information on the environment and conditions in space outside Earth's atmosphere. It resulted in the discovery of the Van Allen radiation belts. Explorer-1 reentered the Earth's atmosphere on March 31, 1970.

The first spaceborne sensors flown were the film cameras, looking toward Earth and providing a "bird's eye view" from space. Initial efforts concentrated on the most obvious phenomenon to study, namely the weather. However, the major goals of the early US and Russian space programs were set to explore outer space, and not to look at Earth. Strangely enough,

1) "The conception, growth accomplishments and future of meteorological satellites," NASA Conference Publication 2257, 1980

Earth was somehow considered to be sufficiently known. It is interesting to note that planning for a deliberate and systematic approach to Earth observation, i.e. the survey and research of the Earth's surface (and many other items), did not start before the mid 1960s. The reason for the new interest in Earth was stimulated mainly by the study of some 1100 photographs (film imagery), taken of Earth during the Gemini missions and subsequently being used in preparation for the Apollo program (the objective was the study of possible lunar landing sites as seen from space). In any case, in trying to analyze and to interpret the Earth imagery at hand, it began to dawn upon some people (familiar with the basic physics of the electromagnetic spectrum) that these photographs might contain a wealth of information - worthy of systematic analysis. Quantitative interpretation schemes had to be developed to interpret the data! ²⁾

The planning for the first civil spaceborne Earth-surface imaging project was initiated at a press conference on Sept. 20, 1966 in Washington, DC. ^{3) 4)} At this conference, Stewart Udall, the Secretary of the Department of the Interior (DOI), and William Pecora, Director of USGS (United States Geological Survey), announced plans for a program called Earth Resources Observation Satellites (EROS). Fortunately, President Johnson, the US Congress, and the US public supported this idea, there were strong objections voiced by DoD and the State Department. ⁵⁾ This was indeed a new direction in the US space program at a time, when young NASA's foremost task was to get a man on the moon (a national goal), in the middle of the Cold War and a hot war (Vietnam). NASA was given the task to plan and build the newly designated ERTS (Earth Resources Technology Satellite) spacecraft (launch of ERTS-1 on July 23, 1972) that was later renamed to Landsat-1. ⁶⁾

New types of instruments were developed and flown, many of them capable of detecting and measuring radiation (such as radiometers) in the visible to microwave region of the spectrum. The creativity of the new space age generated an evolution in sensor technology resulting in a multitude of sensor types and many other innovations. The concepts of these new instruments were based on such diverse fields as optics, solid-state electronics, pattern recognition, signal processing, computer technology, and communications. At the start of the 21st century it can safely be stated that the space age was instrumental of initiating and fostering new and vastly improved measurement technologies, accompanied by the greatest instrument-development spree in the history of science.

A most important space-age achievement (along with parallel developments in the wide field of electronics) is the ability, to observe the Earth and its environment as well as the universe in **the entire breadth of the electromagnetic spectrum**. This in turn opened a new era in experimentation and discovery in virtually all fields of the Earth and space sciences. For instance, synoptic observations over wide regions of the Earth and the capability to communicate, process and interpret vast amounts of information, practically in real-time, has revolutionized the way we do things and in which scientists study the atmosphere, oceans, land, vegetation, glaciers, sea ice, and other environmental aspects of the Earth's surface and their interactions. Earth observation has become the prime source of input for the considerable advances in the geosciences and many related disciplines. As a conse-

3) <http://academic.emporia.edu/aberjame/remote/landsat/landsat.htm> (Author: J. S. Aber)

4) Ironically, objections of the State Department and DoD against the distribution of civil high-resolution Earth imagery (in the optical and microwave regions) and the proliferation of space technology have been around ever since and continue to be a major issue in US space policy. Special rules (including shutter control) may be imposed in particular conflict situations to restrict US-based commercial remote-sensing firms from unauthorized distribution of their imagery. Special rules apply also to the export of space technology by US companies. However, with space-imaging technology readily available outside the USA, the US-internal control functions became more or less ineffective as of 2000.

5) The policies on US remote sensing technologies and their restrictions evolved from two primary sources: a) the secret capabilities first developed for the NRO (National Reconnaissance Office), and b) civil systems like the Landsat series instruments MSS and TM. Originally, commercial considerations were not a factor in either of these areas.

6) P. L. Hays, R. F. Houchin, "Commercial Spysats and Shutter Control: The Military Implications of the US Policy," Proceedings of AIAA Space 2000 Conference and Exposition, Long Beach, CA, Sept. 19-21, 2000

quence, Earth itself assumed a new clarity and gave us a better awareness of its dynamic nature. In the Sun-Earth system, space exploration provided for the first time a perception and understanding of the electromagnetic state of the interplanetary space between the Sun and the Earth.

Beside the research benefits, Earth observation has also evolved to become a technology driver and a mature service provider for a large spectrum of useful applications, ranging from weather forecasting over monitoring and managing of Earth resources (crop surveys, mineral surveys) to navigation-aid systems and monitoring of international treaty compliance. Also, more emphasis is being placed on such fundamental issues as the global environment and its changes (global interconnectivity of weather phenomena, preservation of the bio-environment, etc.). The goal is to develop predictive environmental, climate, natural disaster, and natural resource models to help ensure sustainable development and improve the quality of life on Earth. - At the turn of the century/millennium, the new concept of “**formation flying**” [a combination of Earth observation, navigation (on-board propulsion), inter-satellite communication, on-board autonomy, and on-board processing functions] has the potential of revolutionizing the way the space community conducts Earth observation missions. The space community is just beginning to understand the potential and perspectives of satellite formation flying. New distributed observation concepts of spaceborne **bistatic systems** are in the planning stage that may eventually permit more affordable spacecraft constellations for interferometric imagery. The utilization of solar energy from LEO or MEO space power stations and conversion of the electricity into microwave energy for transmission to Earth are other concepts being explored and investigated today (lasers are also under consideration for beaming the energy from space). Space solar power - a dream today - has a good chance of becoming a reality in the decades ahead. - In a long-term perspective, the past forty–five years of space flight at the start of the 21st century can be regarded as the “early or adolescence period” in the field of Earth observation. All indications on enabling technology developments lead to the conclusion, that the best is yet to come, leading to a better understanding of the total Earth system.

“Earth functions as a system - a large, complex, and dynamic one, but a system nonetheless. It is affected in measurable ways by external forces such as the sun and its variability, and by the internal forces that are shaped by variations in the atmosphere, oceans, continents, life, and the complex web of interactions among them.

We are the first generation with the ability to observe global-scale changes from the perspective of space and the scientific knowledge to link them with their causes and consequences. This ability to record and understand global change will be among the greatest gifts that we can offer our children and their children after them, for it will put in their hands the power to make informed decisions about the environmental challenges of the future.

The quest for a true predictive capability for Earth system changes requires a flexible and progressive space system architecture. That’s why we need to design and establish a smart, autonomous, and flexible constellation of Earth-observing satellites that can be reconfigured based on the contemporary science and specific issues at hand.” ⁷⁾

United Nations statistics in the 1990s reveal that less than half of the Earth’s exposed land has been mapped at scales suitable for economic development measures. The need is particularly great for Africa. The answer lies in satellite image maps, which are accurate and can be quickly compiled and systematically updated. Satellite image maps have become the mapmaker’s benchmark for small and medium scale mapping. Moreover, Earth observation satellites have become the precious allies of a new type of agriculture managed from the sky, especially in developing countries where agricultural management is still at an early stage. With a single glance they report on crop areas, identify soil types and inventory water

7) Daniel S. Goldin, “NASA in the 21st Century,” Millennial Challenges Colloquium series, Oct. 10, 2000, the address was presented at JHU/APL, Laurel, MD

resources. All of which can be used to plan future agricultural development. Likewise, as the season changes, they monitor crop changes and enable early detection of diseases. Today, Earth observation satellites are becoming an extremely valuable monitoring and decision-making tool for disasters and environmental hazards (assessment of the extent of destruction, etc.).

The term “Digital Earth” was coined by US Vice President Al Gore, presented in a speech at the California Science Center in Los Angeles, on Jan. 31, 1998. His vision of the proposed concept model of “Digital Earth” refers to a multi-resolution, 3-D representation of Earth, into which geo-referenced data can be embedded. A “Digital Earth” could, for instance, provide a mechanism for users to navigate and search for geospatial information, etc. - Obviously, such an objective is so vast, that no one organization in government, industry or academia could undertake such a project. A vast standards infrastructure is needed to make it happen! The benefits of such a seamless system are apparent to the entire Earth Observation community. - Eventually, the data from “Digital Earth” may also contribute to a new genre of virtual reality applications.

During the 1990s, industry is gearing up as a commercial total system (space and ground segment owner and operator) service provider. The global research community is still a very large user of remotely sensed data, but an increasing amount of Earth observation data (information) permeates also into applications for everyday use. This development into a wider base is indeed a good perspective for a maturing service and utility environment.

At the turn of the 21st century, first attempts are being made by space agencies to design and demonstrate optical instruments to permit “remote sensing applications” from GEO (Geostationary Orbit). Earth observation missions (with spatial resolutions in the range of 1-4 km in the optical region of the spectrum) from GEO are rather challenging due to their enormous distance from the Earth’s surface (about 36,000 km, or 45 times further away than from normal LEO altitudes of 800 km). Still, Earth observation missions from GEO are very attractive, offering the advantage of a continuous viewing capability, which so far has only been employed by GEO weather satellites (with much larger resolutions). NASA plans to fly GIFTS (Geosynchronous Imaging Fourier Transform Spectrometer) in 2004.

The intent of this chapter on “Earth Observation Short History” is to put some events, pertaining to the wide field of Earth observation, into proper context - the past has to be known and understood in order to plan for the future. The emphasis is on sensor technologies, system concepts, observation techniques, operational aspects, and navigation. Of interest is also the introduction/provision of general services and the start of international cooperation. The select nature of this EO-history overview precludes any claim for completeness. The scope of Earth observation is so immense, I simply do hope that some of the most important achievements are properly covered or even mentioned. It should also be pointed out that there is plenty of room left, as well as considerable needs, for creativity and innovation to continue to change things for the better.⁸⁾ - At the beginning of the 21st century, a better understanding is emerging of the relationship between technology development and the ability to do science.

In parallel to this chapter on “Earth Observation Short History,” the interested reader should also refer to Part O of the document for more detailed descriptions and background on particular topics.

Of all satellite launches on a worldwide scale, 70-75% are commercial communication satellites, the rest are military and civil satellites for such services as surveillance, technology development, Earth observation and navigation. Hence, telecommunication is by far the

8) The fields of signal processing, data processing, interpretation and use (applications) are topics outside the scope of this text. The interested reader is given a good survey reference: Celebrating a half Century of Signal Processing, “The Past, Present and Future of Image and Multidimensional Signal Processing,” IEEE Signal Processing Magazine, March 1998, pp. 21-58

most widespread application of space technology.⁹⁾ The field of Earth observation is in second place when compared by the number of spacecraft launches. Next to telecommunications, remote sensing may be the most significant commercial application in the space industry – one which, like satellite telecommunications, has the potential to fundamentally change the way certain industries operate.

1.1 Sensor/Technology Development

In the early years of Earth observation (in particular satellite meteorology) attention was focused on those phenomena which could be observed relatively directly in the visible and infrared bands of the spectrum. First images were obtained by photographic systems¹⁰⁾ such as automated still or movie cameras, followed eventually by vidicon electronic imaging systems [a framing system of TV heritage - the image from the photoconductive surface (detector) is raster scanned by an electron beam; example: RBV (Return Beam Vidicon), AVCS], and later by optomechanical scanner systems [examples: M-7 an airborne multispectral mapper of ERIM (first flown in 1971) and MSS on Landsat-1, launch July 23, 1972]. The TV cameras of the TIROS-1 satellite (launch April 1, 1960) provided daily low-resolution black and white pictures in the visible spectrum (panchromatic) of cloud cover and the Earth's surface where clear. A time sequence of these synoptic coarse-resolution images permitted a visual interpretation by the meteorological community of large weather patterns which moved slowly across a continent (inferring atmospheric motions) - a first application of the emerging field of Earth observation. The TV cameras of the very next TIROS satellites experimented already with the infrared spectrum. The resulting images permitted a first look at the Earth's heat distribution. In addition to the TV cameras, TIROS-2 and its successors experimented with the infrared spectrum by adding, variously, medium-angle, omni-directional and scanning radiometers. - The first years in Earth observation were dominated by such overall requirements for **repetitive coverage** (frequent observations) and the need of an **operational capability**, in particular for meteorological satellites. But it was also recognized that to create the new remote sensing technology, and to begin its utilization, would require an interdisciplinary effort by all parties involved. The challenges were monumental for research and technology development on all fronts, to create an infrastructure and to come up eventually with operational services.

The success of initial large-scale weather sensing started a planning and development period for better sensor systems, in particular with improved spatial and spectral resolutions, capable of land-surface imaging. Spectral resolution meant parallel sensing and detection in several bands of the visible and near-infrared spectrum. This technique was referred to as multispectral sensing, enhancing considerably the value (interpretability) of imagery. The MSS (Multispectral Scanner System) instrument of the Landsat series (for land surface imaging) is such an early multispectral instrument (1972), with the visible and near-infrared spectrum almost evenly divided into four bands (band specification for MSS was simply adopted from airborne photographic experience of films).¹¹⁾

Starting with Landsat-4 in 1982, a more sophisticated multispectral imaging sensor with the name of Thematic Mapper (TM) began its operation. It featured seven spectral bands and a ground resolution of 30 m in the VNIR bands. The TM band-selection process was on the basis of a comprehensive study and analysis of spectral reflection features for a variety of vegetation types. - The rather successful Landsat instruments eventually spawned other

9) Background Paper No 5: "Space Communications and Applications," UNISPACE-III Conference in Vienna, Austria, July 19-30, 1999, p. 112, A/CONF.184/BP/13 with the title: Space Benefits for Humanity in the Twenty-First Century, ISBN: 92-1-100818-2

10) Note: A photographic system is also referred to as a framing system. It means that all of the data in an image are acquired simultaneously.

11) In the Soviet Union, a parallel development to MSS (on Landsat) took place with the development of the MSS Fragment instrument at IKI (Space Research Institute), an 8-channel imager with a spectral range of 0.4-2.4 μm , flown on Meteor-Priroda-5 (launch June 18, 1980). Fragment operated successfully onboard the spacecraft for four years.

spaceborne Earth-surface imaging systems. Some of them are: The MOMS sensor missions on Shuttle (MOMS-01 in 1983), the SPOT satellite series sensors HRV (High Resolution Visible) of CNES (SPOT-1 launch in 1986), the Resurs-O1 series of Russia with MSU-E and MSU-SK (launch of Resurs-O1-1 in 1985), the IRS series of ISRO (launch of IRS-1A in 1988), JERS-1 of NASDA with OPS (launch of JERS-1 in 1992), ADEOS of NASDA with AVNIR (launch Aug. 17, 1996). See Table 1. At the beginning of the 21st century, the data from the Landsat S/C series constitute the longest record of the Earth's continental surfaces as seen from space. It is a record unmatched in quality, detail, coverage, and value.

Most of the instruments placed into orbit for the study of the Earth's atmosphere and surface have been of the type **passive sensors**, imagers and sounders operating in the visible, infrared and microwave spectral regions. Technology developments over the past four decades have allowed the capabilities of the current generation of passive sensors to advance far beyond those of the first instrument on Sputnik-1 and also the TV cameras on TIROS-1. - The first spaceborne **active sensors** were radar systems on Skylab (the instrument was named S-193, a combination of passive microwave radiometer with an active scatterometer, and radar altimeter) operated between May 1973 and Feb. 1974. The next radar altimeter was flown on GEOS-3 (launch April 9, 1975, E.7.3) of NASA (see Table 47).

Many items of technology introduction (the emphasis is on civil Earth observation programs, military programs are considered only when enough published information is available) are presented below.^{12) 13) 14)} The scope of description must be limited to abstract level detail due to the vast number of topics in the general field of Earth observation. The reader is invited to consult also the survey references of the published literature as well as the bracketed references in the text, referring to descriptions in other chapters of the book.

1.1.1 Concepts in Optical Observations

The principal detection methods used in optical observations are photographic (e.g., film), photoemissive (photomultipliers), and photoconductive (semiconductor).

- The first low-resolution space photograph of the Earth was taken and transmitted by the US satellite Explorer-6, a spin-stabilized S/C with a mass of 64 kg (launch Aug. 7, 1959 on a Thor vehicle from Cape Canaveral into a highly eccentric orbit, perigee = 237 km, apogee = 41,900 km, inclination = 47°, period = 765 minutes) in August of 1959. The camera system flown was a TV optical scanner, consisting of an optical unit containing a concave spherical mirror and phototransistor, a video amplifier, timing and logic circuits, and telemetry. The scanner's optical axis was directed 45° away from the S/C spin axis, which was parallel to the orbital plane. The vehicle's spin furnished the line scanning, and the spacecraft's forward motion along its trajectory provided the frame scanning. The first "television" photo, received in Hawaii, took nearly forty minutes to transmit.
- On June 7, 1967 the first color image of the Earth from space was taken by the Molniya-1 spacecraft of the USSR. In the US, the first color picture of the Earth from a near-synchronous orbit was taken on July 25, 1967 by the Dual Vidicon Camera system of the DODGE satellite (M.4).
- Spaceborne photographic film imagery for reconnaissance and mapping. The early US military program, endorsed by President Dwight D. Eisenhower in Feb. 1958, employed traditional camera technology for information gathering (to support SALT treaty verification). The US Discoverer-14 satellite [also known as the CORONA mission 9009 of NRO (DoD), launch Aug. 18, 1960 with a Thor vehicle from VAFB, CA] opened a new era in

spaceborne reconnaissance by successfully returning the film product in a reentry vehicle (capsule) and subsequent mid-air recovery on Aug. 19, 1960. A total of 95 successful CORONA missions took place over a period of 12 years, ending on May 25, 1972 with mission 1117 (D.8). The high-resolution Earth-surface imagery (5-12 m) of the programs CORONA, ARGON (12 missions between Feb. 17, 1961 and Aug. 21, 1964), and LANYARD (single mission in 1963) predated the imagery of the civil program Landsat. Declassification (i.e. availability to the civil community) of the imagery of the three programs was announced by the US government on Feb. 24, 1995 (Executive Order 12951, declassifying reconnaissance satellite images from the Corona program and two related subprograms - Argon and Lanyard). This, in turn, extends the baseline for systematic Earth surface coverage backwards by more than a decade. - Note: The US military reconnaissance program gave up the concept of high-resolution film imagery and film capsule recovery in the mid-seventies in favor of optoelectronic imaging (more practical for routine operations, but lower resolution than film) with the launch of the KH-11 (Keyhole designation) spacecraft series. The KH-11-1 satellite was launched Dec. 19, 1976. ^{15) 16) 17)}

- The former Soviet Union launched its first photoreconnaissance satellite, Zenit, on April 26, 1962 (built by NPO Energia). - A film camera of some sophistication on this spacecraft is MKF-6 (Multi-Kanal-Fotografie-6) or “multispectral film camera-6”, developed at VEB Carl Zeiss, Jena, German Democratic Republic. The camera employed a battery of six lenses (two rows of 3 lenses in parallel), looking into the same footprint, each for a different spectral band and furnished with a special filter, in the spectral range of 0.45 - 0.90 μm . Thus, color imagery with a high degree of geometric and radiometric accuracy and resolution was obtained in six spectral bands by using different films for each band. Un-perforated 70 mm films of 120 m length were used (shutter speeds of 7-56 ms, image format of 55 mm x 81 mm). MKF-6 was initially flown on aircraft (Antonov-30). The so-called “data processing” consisted of an opto-analog image analysis using MSP-4 (Multispectral Projector-4). This instrument assisted in the human visual inspection process by generating a color-coded synthesis, using multiple negative imagery of a multispectral set (analysis by superposition). A first spaceborne demonstration of MKF-6 took place on Soyuz-22 (launch Sept. 1976) within the framework of a Kosmos experiment called “Raduga” and within the Intercosmos program. During the 8-day flight of Soyuz-22, Soviet Kosmonauts took over 2,500 Earth images with the hand-held MKF-6 camera. Thereafter, MKF-6 was also utilized on the Salyut-6 and -7 space stations. ¹⁸⁾

- TV camera observations. Among the very early imaging sensors in space were shutter-style TV cameras, used to collect meteorological data. These so-called RBV (Return-Beam Vidicon) TV cameras employed a frame-sensor technique, where an electron beam scans the image on a photosensitive surface (raster scan of a complete image). In this concept, the image is exposed by a shutter device and stored on a photosensitive surface within each camera. This surface is then scanned in raster form by an internal electron beam to produce a video signal (the image is focused onto a photoconductor which causes the intensity of the electron beam, discharged from the electron gun, to vary with the intensity of the light). The values of the video signal are converted into digital information. Such RBV cameras were flown in several early satellite series such as: TIROS (TIROS-1 launch April 1, 1960), ESSA (launch of ESSA-1 on Feb. 3, 1966), Landsat-1 to -3 (LS-1 launch July 23, 1972), DMSP (Block IV series started in 1965), and Meteor (Meteor-1-1 launch March 23, 1969). - The pictures obtained in this fashion were relayed to the ground and required substantial signal processing, including oscilloscopes, to recover a satellite image.

- Solid-state (digital) imaging - a key technology in optical remote sensing capability which started a new era in quantitative information collection. The technique (introduced in the early 1960s) uses silicon-based photodetectors onto which radiation (photons) can be focused and an electronic readout scheme (scanner) for image capture. The new method, later referred to as an optomechanical system (later optoelectronics system with CCD technology), converts incident photons directly into electrical current, offering many advantages [true space-point (pixel based) information, high dynamic range, low power dissipation, low voltage operation, no geometric distortions, sampled signal output, rapid response, etc.] over the electron beam scanning vacuum tube technology, such as the vidicons, traditionally used in the RBV TV cameras. The new solid-state-oriented imaging technology provides considerable flexibility; in particular, it is suitable for digital processing, offering a variety of readout schemes [imaging arrays (1-D, 2-D) such as self-scanned photodiodes, CIDs, CCDs], and permitting the use of many detector element types.^{19) 20)}

The new solid-state radiation detection concept employs scanner systems (see chapter O.3) permitting the acquisition of imagery within and outside the VNIR spectral region of photographic films, offering also a strategy of separating the received radiation into a number of spectral bands. This key technology provides the only practical means for obtaining high-accuracy radiometric information. The early scanners form an image successively on a cell-by-cell basis by the process of scanning. The first scanners employed were optomechanical whiskbroom systems where imaging occurs on a cell-by cell basis in the cross-track direction; these were followed by more efficient parallel line-scanned pushbroom (CCD) systems.

The newly available scanner technology (whiskbroom/pushbroom)²¹⁾ offered a means of making imagery quantitatively available to computer processing methods; it stimulated in turn the development of new sensor systems with greatly enhanced performance and observation capabilities, it permitted also a better modular design concept of imaging sensors. An imager based on solid-state technology consists of a suitable lens system (the optics subsystem), a scanner subsystem with the detector positioned at the focal plane, and operating electronics.^{22) 23)}

- Solid-state multispectral imaging in the 1960s. It signifies a great step forward in image interpretation capability, namely from visual or machine-sensed photointerpretation (analysis based on image characteristics) to quantitative interpretation of several bands of imagery (analysis based on spectral characteristics). The new quantitative approach relies on image processing methods of the evolving computer industry of the time.

The pioneering airborne instrument of spatially-registered multispectral scanners is M-5, developed by the Willow Run Laboratories of the University of Michigan. The M-5 whiskbroom scanner is based on solid-state technology, and developed around an optomechanical scanning system called the S-5 (built by HRB Singer for the US Army). The S-5 had two optical channels (not registered) and recorded its data on film. From 1963 to 1965, two of these instruments were flown in tandem, each in a DeHavilland

21) Conventional photographic films with high resolution imagery were not amenable for direct processing and transmission methods in remote sensing. Film material was not suitable for quantitative radiation measurements, only a small spectral range (VNIR, SWIR) could be covered with film.

22) Note: Realizing the value of multispectral data, there were a number of implementations in the early 1960s to obtain multispectral data (i.e. photographs) by special cameras. Spectral separation was accomplished by using photographic filters with multi-objective camera systems, each for a separate spectral range. This left the photo-interpreter with a dozen or so photos of the same scene, each at a different spectral band. The human eye finds it difficult to keep track of tonal variations over 16 or more levels of gray for even a modest number of different scene objects. - The discrimination problem was eventually solved with the availability of data from multispectral scanners and the development of proper algorithms for computer interpretation of imagery.

23) D. Landgrebe, "The Evolution of Landsat Data Analysis," PE&RS, July 1997, pp. 859-867

Beaver aircraft, to obtain four unregistered bands (selectable from UV through LWIR). From June 1963 through June 1964, around-the-clock (every 4 to 6 hours) imagery was collected once a month over a local fifty mile flight path, selected for natural and cultural diversity. These data were manually analyzed to form the initial basis for an understanding of day-night-seasonal spectral imaging phenomena. The M-5 instrument provided support of the developing ERTS (Landsat) program, in particular for the design of MSS (Multispectral Scanner). The M-7 multispectral scanner was a direct successor of M-5, it became operational in 1971, was upgraded several times, and provided a long-term source of remotely-sensed multispectral imagery (P.82.2).²⁴⁾ ²⁵⁾ A much later descendent of optomechanical whiskbroom technology was AVIRIS (Airborne Visible/Infrared Imaging Spectrometer) of NASA/JPL (P.42). This first airborne hyperspectral imager was introduced in 1987 and became operational in 1989, the first sensor to contiguously cover the 0.4-2.5 μm region with narrow spectral bands. At the start of the 21st century, its data is still very much in demand. - The short dwell-time problem of these cross-track whiskbroom scanners was solved by introducing a parallel coverage arrangement of detector arrays in the along-track direction. In this way, the wide along-track coverage permitted sufficient integration time for all parallel cells in each cross-track scan sweep.

Note: In some instances, preference is given to a whiskbroom imager design (the older imaging technology) because the optics for pushbroom operation must always cover FOV (the total field of view - meaning the full swath width) while the optics for whiskbroom operation deal with IFOV (instantaneous field of view) which is much smaller than FOV. Hence, there are less distortions at the swath edge for whiskbroom systems.

Spaceborne scanners. In 1968, SBRC (Santa Barbara Research Center) of Hughes Aircraft Company proposed to NASA to place a new type of imaging device on the planned ERTS spacecraft, namely a “scanner system.” At the time, scanners were viewed with great skepticism by most scientists for two reasons. First, the scanner employed a moving part, an oscillating mirror, which was considered unreliable. Second, the scanner was not a full-frame imaging device; it created images from strips. Cartographers were suspicious of the scanner’s geometric integrity.

The scanner did have one important advantage, namely its multispectral capability. Agricultural research had demonstrated the value of multispectral imagery. For example, the 0.63 to 0.68 μm band measures chlorophyll absorption; the 0.79 to 0.9 μm band indicates water content in leaves; and the 1.55 to 1.75 μm band displays soil moisture. SBRC initially designed a six-band scanner for the satellite. However, NASA’s small satellite could not house the large scanner, so a more modest four-band MSS (Multispectral Scanner) was built for ERTS-1. The spectral bands were chosen to simulate false-color infrared photography.²⁶⁾ NASA put RBV cameras as well as the new scanner system (MSS) on-board the ERTS-1 satellite (in 1975 renamed to Landsat-1) to compare imagery from both types of systems. Within hours after launch of ERTS-1 (launch July 23, 1972), the first MSS images created a sensation with their amazing clarity and synoptic views of the landscape. Spatially, both systems (RBV and MSS) provided a resolution of about 80 m. Spectrally, each of the three-camera RBV system was designed to cover a band: the blue-green, yellow-red, and red/NIR. MSS provided a similar band set along with a fourth band to extend coverage into the infrared region. The imagery of MSS was in digital form. The scan mirror assembly of MSS was the key to providing wide-field and ‘high-resolution’ coverage. The new technique of scanning had the promise of more things to come. Thus, on the spaceborne side, MSS (with a

24) Information provided by B. Horvath of ERIM, who operated the M-5 imager and analyzed the data.

25) Note: In 1973 the Willow Run Laboratories team separated from the University of Michigan and became ERIM (Environmental Research Institute of Michigan). In 2000, ERIM became part of Veridian ERIM International

cross-track whiskbroom scanner) ushered in an era of previously unimaginable synoptic knowledge of the Earth.

- The TM sensor on LS-4 (launch July 16, 1982) is a much improved successor in spatial and spectral resolutions to MSS. A good portion of land-surface observation history is intimately connected with this pioneering sensor (TM) and program (Landsat). All TM instruments (including ETM+ of Landsat-7) employed the optomechanical whiskbroom technology. Other spaceborne optomechanical (whiskbroom or flying spot) instruments of note are: AVHRR (on the NOAA/POES series, all three generations of instruments, since 1978 starting with TIROS-N, see Table 34), OLS (flown on DMSP series, first introduced in 1976 - OLS uses a flying spot design), ASTER and MODIS (Terra, launch Dec. 18, 1999), and OSMI (Ocean Scanning Multispectral Imager, flown on KOMPSAT-1, launch Dec. 20, 1999). Note: Instrument designs like AVHRR and MODIS are of the optomechanical type because the extended focal planes, coupled with relatively short focal lengths, lead to unworkable field angles and geometric distortion problems (pushbroom designs are not well suited to moderate-resolution wide-field systems).

Launch Date	Satellite Platform (Agency or Company)	Earth Imaging Sensors of respective Payload	Comment (ops = operations)
Jul. 23, 1972	Landsat-1 (NASA)	MSS, RBV	MSS whiskbroom imaging End of service Jan. 6, 1978

tion in optical imaging capabilities (resulting in the birth of digital photography), providing in addition a wide forum for multi-disciplinary applications. Early industry CCD manufacturers were: TI (Texas Instruments), RCA (Radio Corporation of America), Fairchild Semiconductor, GEC (General Electric Co., UK), and Thomson-CSF (France, since 1978). At the start of the 21st century, the CCD technology is still having profound effects in the fields of optical imaging, particle tracking, x-ray detection, as well as analog storage devices. The application spectrum ranges from security monitoring to high-definition television, from endoscopy to desktop videoconferencing, from Earth observation to astronomy and to cosmology.

A CCD is a photosensitive solid-state silicon-based detector implemented with large-scale integration technology based on MOS (Metal Oxide Semiconductor) capacitors that collect and transfer photon-generated charge.^{30) 31)} A MOS capacitor is a three-layer sandwich formed by positioning a metal electrode, insulated by a layer of silicon dioxide, onto a silicon substrate (buried channel). Typically, the device is built on a p-type substrate. An n-type region (about 1 μm in thickness) is formed on the surface. The gate electrode consists of a thin silicon dioxide layer either on a metal surface or on a heavily doped polycrystalline silicon layer.

In remote sensing, the CCD pushbroom concept permits simultaneous measurements of an entire scan line (detector line array) for each spectral band (and serial shift-register read-out), thereby improving the dwell time (or sampling time) over whiskbroom systems. (Note: very short dwell times, in the order of a few microseconds, limit the number of photons that can be detected without using very large optics). Advantages of the digital CCD technology lie in the real-time processing capabilities of the data, the high accuracy potential, the good radiometric characteristics, and the availability of relatively inexpensive system components. - The first astronomical CCD ground observation (of Jupiter, Saturn and Uranus) was done in early 1976 at the Mount Bigelow observatory of the University of Tucson, AZ (CCD detector array built by Texas Instruments).³²⁾ - The first experimental airborne opto-electronic instrument, featuring a pushbroom CCD detector line array, was EOS (Electro-Optical Scanner) of DLR (former DFVLR), designed and developed by Astrium GmbH (formerly MBB) of Munich in 1977, and flown on a DLR aircraft (DO-28) in early 1978 (chapter P.79). MEIS (P.127) of CCRS followed in 1978, and TIMS of Daedalus in 1981. ISRO built a single-band CCD camera in the late 1970s and had it flight-tested on an aircraft in 1980.

Spaceborne CCD detector technology was introduced with the **MSU-E** (Multispectral Scanning Unit-Electronic) flown on the Meteor-Priroda-5 (launch June 18, 1980) spacecraft of the former Soviet Union.³³⁾ MSU-E was built at ISDE (Russian Institute of Space Device Engineering) in Moscow; it featured a CCD line array of 1024 pixels, three parallel line arrays, each of 1024 elements, provided pushbroom imagery in three spectral bands (visible and near-infrared range); the spatial resolution was 28 m on a swath of 28 km. The CCD line arrays were designed and manufactured in the "Pulsar" plant, Moscow. The results obtained with MSU-E confirmed the potential of CCD technology for use in high-resolution multispectral monitoring. The MSU-E pushbroom instrument was also introduced on the Soviet Resurs series starting with Resurs-O1-1 (launch Oct. 3, 1985).³⁴⁾ Further early CCD instruments were: MOMS-01 of DLR (built by Astrium GmbH, and flown on Shuttle flights STS-7 in June 1983 and STS-41B in Feb. 1984), the HRV sensors on the SPOT series

of CNES (launch of SPOT-1 on Feb. 22, 1986), and LISS on the IRS series of ISRO (launch of IRS-1A on March 17, 1988). - The first spaceborne CCD area array detectors were introduced in the TVS (TV System) instrument, a wide-angle TV camera (TVS, an IKI instrument, was developed in cooperation with France and Hungary) of the Soviet Vega interplanetary missions to Venus and later to Halley's Comet in 1984 (launched Dec. 15 and Dec. 21, 1984, respectively). On June 9 and 13 1985, each Vega S/C deployed a Venus capsule. In March 1986, each Vega S/C encountered Halley's Comet. TVS provided color images of Halley's coma and core [about 500 images from Vega-1 and about 700 images from Vega-2, each at closest approach (8000-9000 km) to Halley's Comet].

In the meantime CCDs have evolved to a sophisticated level of performance (high radiometric and spatial resolution). Starting with the 1990s CCDs have become the technology of choice for most imaging applications in remote sensing. The microelectronics industry provides CCD technology (area arrays) on a chip level. A high-resolution VNIR camera can be built around a CCD chip by combining it with a suitable lens system, a cooling method, and operating electronics. CCDs take the place of vacuum tube-based imagers and film in conventional cameras. They provide a wide field of applications in science as well as in the consumer market. An astronomical imaging system with the name of STIS (Space Telescope Imaging Spectrograph) on Shuttle flight STS-82 (launch Feb. 11, 1997) was installed aboard the orbiting Hubble Space Telescope; the key element of STIS is a very sensitive CCD array (developed by SITe) enabling faint radiation measurements of distant stars. Also in 1997 Philips Co. with several partners was testing a CCD area array of 9216 by 7168 detectors (pixels) on a chip. The pixel size is 12 μm x 12 μm , the chip size is 111 mm x 86 mm. - Some drawbacks of the CCD technology are: CCD's provide good image quality, but they are expensive, power hungry, and rather bulky with the required accessory chips.

- An alternate approach to the proven CCD-imaging concepts may be provided by the emerging CMOS/APS (Complementary Metal-Oxide Semiconductor/Active Pixel Sensor) technology, a second generation solid-state sensor technology (CSMT of JPL is the inventor of APS technology and a major developer in this field) which utilizes active transistors in each pixel to buffer the detected photon signal. The APS method basically provides a current as a function of the irradiance for each pixel. Normally, the output is proportional to the irradiance falling onto the APS detector (there are also APS versions providing a logarithmic output of the irradiance). The CMOS/APS technology employs an amplifier at each pixel site, thereby eliminating the bus capacitance and resistance problems of CIDs. It was not until sub-micron photolithography became available that APS imagers became useful. CMOS/APS imagers sense radiation (light) in the same way as CCDs. Both technologies convert incident photons into electronic charge (electrons) by the same photo-conversion process. The charge packets are not transferred, they are instead detected by the charge-sensing amplifiers, which are made from CMOS transistors. - The microprocessor (CMOS) compatibility of CMOS/APS concepts (widely available techniques) results in reduced fabrication costs over similar CCD devices. Other performance advantages of the CMOS/APS technology are: TTL-compatible operation (0-5V), only a single power supply is needed, electronic shuttering, readout windowing, variable integration time, on-pixel amplification, noise reduction, random access readout, a single CMOS/APS chip can integrate image capture, A/D conversion and digital processing. The CMOS detectors provide considerably higher radiation hardness over CCD detectors. However, current drawbacks of CMOS technology are seen in the small pixel sensitivity (low quantum efficiency and non-uniformity), the relatively high noise levels of relatively small pixel arrays, and in reduced calibration capabilities of the array. The CMOS/APS imager in silicon technology offers a spectral response in the UV/VNIR spectral regions. The CMOS/APS micro-technology implies low-power micro-instruments (imagers and other devices) for near-future microsatellites. Other fields of CMOS/APS technology applications may include: optical communications, multimedia machine vision, and biomedical imaging. Note: APS (Active Pixel Sensor) is also being referred to as APA (Active Pixel Array), both terms have the same meaning.

- The first spaceborne demonstration of a camera with CMOS/APS technology was probably VTS (Visual Telemetry System), built by DSS/OIP (Delft Sensor Systems/Optron-ic Instruments & Products), and IMEC, Belgium, and flown on TEAMSAT (M.26), an ESA low-cost satellite demonstrator mission, launched on Oct. 30, 1997 from Kourou (2nd quali-fication flight of an Ariane-5 vehicle). VTS, with a 512 x 512 pixel array for each of the three camera modules, performed visual post-launch monitoring of deployment structures. The TMSat (Thai-Phutt) microsatellite of Thailand, built by SSTL of Surrey, UK (launch July 10, 1998), carries a CMOS Video Camera with APS technology.- APS (Active Pixel Sensor) technology is also part of MICAS (Miniature Integrated Camera Spectrometer) flown on DS1 (Deep Space 1, launch Oct. 24, 1998, M.5) of NASA/JPL. The 3CSat (Three Corner Satellite) constellation of UNP (University Nanosatellite Program), consisting of three cooperating S/C (planned launch in 2001) – built by CU (University of Colorado) at Boul-der, ASU (Arizona State University), and NMSU (New Mexico State University) and spon-sored by DoD, NASA and US industry – utilizes CMOS/APA (Active Pixel Array) imaging technology in a distributed observation concept.

- APPS (Active Pixel Position Sensor). At the start of the 21st century, APPS represents an advanced type of APS detector with the added capability of very accurate position sens-ing/determination in conjunction with online processing (so-called “smart vision chips” provide the processing). The APPS detector concept provides a signal proportional to a mo-ment equation of the irradiance falling onto the detector. The APPS detector itself com-putes the desired moment equations with appropriate circuitry. The APPS technology was developed at AFRL (Natalie Clark, with DARPA, AFSOR and NASA funding) in com-bination with adaptive optics methods to improve star tracking methods by higher accuracy centroiding. With CCD and APS methods, it is rather difficult to centroid on a star with a pixel accuracy of better than 1/10. The APPS method, on the other hand, provides centroid-ing in the order of 1/100 of a pixel accuracy. Further features of the APPS technology are:

- Detection of very low-light conditions
- APPS does not require the star light to be spread over an array of pixels; this enables much higher SNR, bandwidth and accuracy
- APPS enables a wide dynamic range permitting simultaneous imaging of faint and bright target objects (stars) in a single image frame
- APPS supports high-accuracy attitude sensing

The APPS scheme can of course also be used in support of conventional imaging applica-tions. However, in this operations mode the detector signals are added rather than differ-enced.

- Detector technology extension. The measurement of electromagnetic radiation in the various spectral ranges, in particular in the infrared region, is at the heart of the problem.³⁵⁾ Significant advances in Earth observation capability have come from the development of on-chip detector circuitry (see chapter O.4).

- The “digital camera,” a commercial product of the photo industry (e.g., Kodak, Sony, Agfa, Canon, Fuji, Konica, Minolta, Nikon), is a natural application derivative of the CCD and CMOS/APS detector technologies, pioneered by the remote sensing and the electron-ics industry. The digital camera became a consumer product in the latter part of the 1990s when the detector densities (multi-megapixel detectors - approaching high-resolution qual-ity) and storage capacities for image capture were sufficient and in addition economical for an evolving consumer market.

Since CCD detectors are inherently monochromatic, special filters are needed to separate the RGB radiation reflected by an object. A number of techniques are in use to capture col-or: a) RGB filter wheel (three exposures), b) tri-linear sensor (use of three linear sensors), c) multi-chip detectors, etc.

³⁵⁾ A good reference is: W. D. Rogatto, “The Infrared and Optical Systems Handbook, Vol. 3 Electro-Optical Com-ponents,” Copublished by ERIM and SPIE, 1993, chapter 4.5.2

- **Spatial resolution.** The requirement of high spatial resolution (and with it the ability to discriminate between small objects), in particular to land surface imagery, has been around since the early days of remote sensing. In parallel, there are virtually always the needs for wide-swath coverage and high temporal resolution (i.e., frequent repeat coverage capability). High spatial resolution implies of course high data rates which conflicts in turn wide-area coverage. An overview of major land-surface imaging missions³⁶⁾ (Figure 1, Table 2) demonstrates the trends and practical compromises taken with the best available technology of the time.

Figure 1: Spaceborne surface imaging resolution trends in the civil & military fields

Mission/Launch Date	Sensor	Spatial Resolution (best band)	Swath width	Data Rate
Landsat-1 / Jul. 23, 1972	MSS	80 m	185 km	15 Mbit/s
Landsat-4 / Jul. 16, 1982	TM	30 m	185 km	85 Mbit/s
Resurs-O1-1 / Nov. 3, 1985	2 MSU-E	45 m x 33 m	80 km (total)	
SPOT-1 / Feb. 22, 1986	2 HRV	10 m	117 km (total)	50 Mbit/s
IRS-1A / Mar. 17, 1988	2 LISS-II,	36 m	2 x 74 km	2 x 10.4 Mbit/s
Resurs-F / (series)	KFA-1000	6-8 m	70 km	Film
IRS-1C / Dec. 28, 1995	PAN	6 m	70 km	125 Mbit/s
ADEOS / Aug. 17, 1996	AVNIR	8 m	80 km	60 Mbit/s
Landsat-7 / Apr. 15, 1999	ETM+	13 m x 15 m	185 km	150 Mbit/s
EO-1 / Nov. 21, 2000	ALI	10 m	185 km	300 Mbit/s
Ikonos-2 / Sept. 24, 1999	OSA	1 m PAN 4 m MS	11-13 km	320 Mbit/s
QuickBird-1 / Nov, 20, 2000 (launch failure)	BGIS 2000	1 m PAN 4 m MS	27 km	320 Mbit/s
NEMO / 2003	COIS, PIC	30 m, 5 m	30 km	150 Mbit/s

Table 2: Spatial resolutions of major land-surface imagers

36) J. Pike, <http://www.fas.org/eye/imint.htm>

- A notable exception of the trend away from photographic film in spaceborne imaging technology was and is the RESURS-F satellite series of State Center Priroda, Moscow, Russia. The Resurs-F1 series (58 satellites in the time frame 1979-1993, Resurs-F2 series since 1995, see chapter D.31) on-board sensors are film cameras whose data (namely the films) are recaptured after the end of each mission. The film camera systems are returned to the ground in small spherical descent capsules which are reused an average of three times. The films are processed after each mission (average mission life is in the order of 14 to 30 days in orbits of 240 - 275 km). Note: At the turn of the millennium, film still holds the edge in resolution over CCD technology. However, digital technology can usually deliver images faster while allowing greater flexibility in storage, manipulation and distribution. The real-time aspect of digital imagery is of considerable importance for many applications.
- The directional pointing capability of a sensor (on command) in the cross-track direction was introduced in the SPOT series in 1986. The new pointing technique introduced the term “FOR (Field of Regard)”, designating the angular coverage capability beyond (and including) the swath - it allowed the imaging of events of interest that happened to be outside the regular (nadir-centered) swath width.
- Hyperspectral imaging [an optical sensing technique breaking up the incoming radiation into numerous contiguous spectral bands (normally 20 - 200 narrow bands or more)], enabled primarily through improved filtering and CCD detector technologies, was introduced with such pioneering airborne instruments as AIS (1982, 128 spectral bands) and AVIRIS (1989, 224 spectral bands), both of JPL. - The first spaceborne hyperspectral imagers launched were: a) **UVISI** on MSX of DoD (launch Apr. 24, 1996; b) HSI and LEISA, both on the Lewis spacecraft (launch Aug. 23, 1997; however, Lewis never became operational and reentered the Earth’s atmosphere on Sept. 28, 1997); c) FTHSI on MightySat II.1 of AFRL (Air Force Research Laboratory) with a launch July 19, 2000 (FTHSI demonstrates the advantage of Fourier systems over dispersive hyperspectral imagers, in that it can record the full spectra without any time delay and can decouple the spatial and spectral signatures). The Hyperion and LAC (LEISA Atmospheric Corrector) instruments on EO-1 (NASA/GSFC), of HSI and LEISA heritage, respectively, were launched Nov. 21, 2000. COIS (Coastal Ocean Imaging Spectrometer) of the NRL NEMO satellite has a planned launch date in 2003. Note: The hyperspectral imagers are also known by the term of “imaging spectrometers.” 37) 38)

Typical examples of hyperspectral filter techniques include dispersive gratings, prisms, multi-order etalons, interference filters, Michelson interferometers, and acousto-optic tunable filters (AOTF). The other key feature is detector array technology which allows multiple spatial and/or spectral samples through 1-D or 2-D arrays.

The passive remote sensing technique of hyperspectral imaging offers an unparalleled spectral interpretation capability of the data (quantitative monitoring) for many applications, including land, water and atmospheric parameters (detection/discrimination of spectral fingerprints from objects that cannot be derived from coarser multispectral imagers). Land applications include vegetation studies (species identification, plant stress, leaf water content), soil science (erosion), geology (mineral identification and mapping, detection of underground/camouflaged structures), and hydrology (liquid/solid water differentiation, snow/grain size). Water applications include monitoring of water quality, bathymetry, etc. Atmospheric applications include the measurement of water vapor, ozone, aerosols, and cloud characteristics. - A disadvantage of the technique is the generation, communication, processing, interpretation and storage of immense data volumes.

The spectra retrieved with an imaging spectrometer show absorption features that are matter specific and depend on quantum mechanical interactions as well as molecular structure

and scattering properties of the observed material. Observing reflected solar illumination with such detailed spectral resolution enables direct identification of virtually all diagnostic absorption features in minerals and soils, the examination of physical and biological components in marine and inland waters, and the study of biochemical processes in vegetation.

Table 3: Summary of some early hyperspectral airborne imaging spectrometers

- A spaceborne spectroradiometer (multi-channel scanning radiometer) by the name of CZCS (Coastal Zone Color Scanner), launched on Nimbus-7 (Oct. 24. 1978) provided first images of **ocean color** (chlorophyll and gelbstoff concentrations) distribution. The parameter measurements were optimized for use over water. The data of this first-generation ocean color instrument contributed greatly to our understanding of the marine environment and its biological, biochemical, and physical processes. Monitoring of marine phytoplankton is of great importance because it accounts for nearly half of the world's total primary productivity. Biomass turnover rates for plankton ecosystems are 100 times faster than those for terrestrial systems, leading to a close relationship between upper-ocean ecology and physical forcing.

The value of ocean-color data lies in the long-term monitoring of the marine environment, thereby providing a better understanding of the role of oceans in the global carbon cycle (climate research, etc.). The prime observables of ocean-color instruments are basically the chlorophyll and gelbstoff concentrations in the surface layer of the ocean. The concentration of chlorophyll is used to estimate the abundance of phytoplankton in ocean waters, and hence the abundance of ocean biota.

Table 5: Performance parameters of ocean color sensors (multispectral radiometers)

- Size/mass/power/cost reduction of imaging instruments. Miniaturization and the introduction of new technologies is the name of the game, in particular in the late 1990s and the early 21st century. The JHU/APL sensor MSI (Multispectral Imager) with a 537 x 244 CCD detector array, a spectral range of 0.4 to 1.1 μm , and a FOV of 2.9° x 2.25° (pixel resolution of 95 x 161 mrad), was flown on NEAR (Near Earth Asteroid Rendezvous/Shoemaker) of NASA (launch Feb. 17, 1996). A newer MSI design of JHU/APL with a lightweight

reflective telescope, high-density solid-state memory and miniaturized on-chip-board electronics has a mass of 0.5 kg and a power of 1 W.³⁹⁾

Mission	Instrument	Instrument Mass, Power	Comment
Landsat-5 (launch Mar. 1, 1984), NASA	TM	285 kg, 385 W	Optomechanical instrument
IRS-1C (launch Dec. 28, 1995), ISRO	LISS-III	171 kg, 78 W	Optoelectronic instrument
NEAR/Shoemaker (launch Feb. 17, 1996), NASA	MSI	7.7 kg, 6.9 W	Optoelectronic instrument
DS1 (launch Oct. 24, 1998), NASA	MICAS	12 kg,	CMOS/APS technology
Landsat-7 (launch Apr. 15, '99), NASA	ETM+	425 kg, 590 W	Optomechanical instrument
IKONOS-2 (launch Sept. 24, '99), SI	OSA	171 kg, 350 W	Optoelectronic instrument
Terra (launch Dec. 18, 1999), NASA	ASTER	421 kg, 463 W	Optomechanical instrument
QuickBird-1 (launch Nov. 20, 2000), Earthwatch	BGIS 2000	380 kg, 430 W	Optoelectronic instrument (launch failure)
EO-1 (launch Nov. 21, 2000), NASA	ALI	106 kg, 100 W	Optoelectronic instrument
Diamant-1 (launch 2003), OHB-System	MSRS	70 kg, 120 W	Optoelectronic instrument
RapidEye (launch 2003 & 4) RapidEye	REIS	62 kg, 73 W	Optoelectronic instrument
PROBA (launch 2001), ESA	CHRIS	15 kg, 10 W	Optoelectronic instrument
SMART-1 (launch 2003) ESA	AMIE	0.45 kg, 0.5 W	Optoelectronic instrument
NPOESS (launch 2008)	VIIRS	160 kg, 134 W	Optomechanical instrument

Table 6: Mass/power reduction trends in typical spaceborne imaging instruments

- Phased array optical technology.⁴⁰⁾ Optical phased arrays (or laser radars) are passive arrays, consisting of phase shifters (based on liquid-crystal technology). Optical phased arrays are the direct functional analogs of the microwave phased array. However, due to the orders-of-magnitude difference in wavelengths between the microwave and optical worlds, a different implementation approach is used for optical arrays. The current (late 1990s) generation of optical devices are 1-D, space-fed, passive, phase-only, apertures. An already formed beam is fed to the array of phase shifters, which then affects steering of the beam. The imposed phase profile steers, focuses, fans out, or corrects phase aberrations on the beam. High efficiency large-angle steering with phased arrays requires phase shifter spacing on the order of a wavelength or less; hence, addressing issues make 1-D optical arrays more practical than 2-D arrays. - Laser radars may be used for such applications as target detection and wind profiling.
- Spaceborne stereoscopic along-track imaging of the Earth's surface was introduced by MOMS-02, a three-line camera system on Shuttle flight STS-55 in April/May 1993, followed by a MOMS-02 reflight on MIR/Priroda (launch of Priroda April 23, 1996).⁴¹⁾ The OPS sensor of JERS-1 (launch Feb. 11, 1992) offers stereoscopic along-track imaging. The parallel HRV sensors of the SPOT series provide some stereo capability with their individual side-viewing feature (up to 27° cross-track pointing capability). The EarlyBird S/C (launch Dec. 24, 1997) of Earthwatch with the EBP sensor (along-track slewing capability) offered a stereo capability; however, the satellite could not be made operational by the ground system. - Stereo imagery is particularly suitable for topographic mapping applications (photogrammetry). Further instruments with stereoscopic imaging capability are operational (or planned) in the following missions:
 - Ikonos-2 S/C of Space Imaging (launch Sept. 24, 1999) with the OSA sensor (along-track slewing capability of up to $\pm 30^\circ$)

39) Binh Q. Le, P. D. Schwartz, Sharon X. Ling, et al., "A Low-Cost Miniaturized Scientific Imager Design with Chip-on-Board Technology for Space Applications," Johns Hopkins APL Technical Digest, Vol. 20, No 2, 1999, pp. 170-179

40) P. F. McManamon, et al., "Optical Phased Array Technology," Proceedings of the IEEE, Vol. 84, No.2, Feb. 1996, pp. 268-298

41) Note: The three-line observation concept results in forward, nadir and aft views of the CCD pushbroom array. The imagery from each scan line is assembled into strips. Relief displacement in the line perspective geometry of the strip approach differs from conventional nadir perspective geometry. Every object appears on all three strips. In contrast, on film imagery only about 60% of the area of any one photograph is in a triple overlap.

- Terra (formerly EOS/AM-1) of NASA with the NASDA instrument ASTER (along-track two-line system in VNIR), and with the NASA/JPL instrument MISR (along-track nine line camera system), launch Dec. 18, 1999
- BIRD (Bi-Spectral Infrared Detection) of DLR (planned launch in 2001) with the WAOSS-B (Wide-Angle Optoelectronic Stereo Scanner, BIRD version) instrument. A modified version of WAOSS flown on the Russian Mars-96 mission (launch on Nov, 17, 1996 from Baikonur; however, the S/C failed to obtain a Mars orbit). The along-track stereo imaging system of WAOSS-B is based on 3 CCD-lines (single optics and focal plate), operating in pushbroom mode, and taking images simultaneously in the forward-, nadir- and backward-pointing direction of the orbital ground track.
- IRS-P5 (CartoSat-1, launch in 2002) of ISRO flies a two-camera assembly. PAN-F (Panchromatic Forward-pointing Camera) is tilted at 26° forward from nadir while PAN-A (Panchromatic Aft-pointing Camera) is tilted 10° aft. A spatial resolution of 2.5 m is provided on a swath of 30 km.
- SPOT-5 of CNES with HRS (High Resolution Stereoscopic instrument, an along-track two-line camera system), projected launch in 2002. A pixel size of 5 m (along-track) by 10 m (cross-track) is provided on a swath of 120 km.
- ALOS S/C of NASDA with PRISM (Panchromatic Remote-sensing Instrument for Stereo Mapping), an along-track three-line camera system, projected launch in 2003. A spatial resolution of 2.5 m is provided on a stereo swath width of 35 km. The nadir pointing camera has a swath of 70 km.
- On the airborne side, DLR developed HRSC (High-Resolution Stereo Camera) which features three-line stereo imaging. The instrument is flown since Feb. 1997. A completely automatic photogrammetric and cartographic processing procedure including digital image matching, digital terrain model (DTM) and ortho-image generation, mosaicking and merging of multispectral data has been developed at DLR (P.101)
- Another airborne example of a three-line stereo pushbroom camera is DPA (Digital Photogrammetric Assembly) of DASA/MBB Ottobrunn (P.71). DPA has been operational since the end of 1992 and is a parallel development to MOMS-02.
- **Acousto-Optic Tunable Filters (AOTF)** in acousto-optic imaging systems (O.4.5). An acousto-optic cell is a transparent birefringent crystal excited by a radio frequency transducer. Propagating acoustic waves inside the crystal create regular spatial variations of the refractive index. Under phase-matching conditions, light of a particular linear polarization and wavelength, incident on the crystal at a very specific angle, is diffracted by the moving grating produced by the acoustic wave. ^{42) 43) 44) 45)}

In the 1990s AOTF devices are based on solid-state technology, they are RF-tunable and random access devices, offering the important capability of spectral agility. When combined with a 2-D CCD array, the complete spectral, spatial, and polarimetric characterization of a scene can be measured with an imaging system that has no moving parts. An AOTF device, can switch from one spectral range to another in the time that it takes an acoustic wave to traverse the crystal, (typically in the μ s range). By making the AOTF part of an imaging system [i.e. an AOS (Acousto-Optic Spectrometer)], and projecting the diffracted light onto a 2-D array, it is possible to form an image extracted from the particular spectral component of the incident radiation. CCD arrays have been utilized for this purpose. - Because the crystal is birefringent, the polarization of the light incident on the device affects the angle to which the light is diffracted. Diffraction changes the polarization of the incident

45) D. A. Glenar et al., "Acousto-optic imaging spectropolarimetry for remote sensing," Applied Optics, Vol. 33, No. 31, Nov. 1, 1994, pp. 7412-7424

radiation so that some of the initially ordinary polarization emerges from the device with extraordinary polarization, and some of the initially extraordinary polarization emerges from the device with ordinary polarization. **The result of this sensitivity to polarization is that an AOTF imager can be used to discern polarization information about a scene in addition to spectral information.** Because the two polarizations of incident light are diffracted differently, it is possible to use two CCD arrays in order to capture separately the image generated by each polarization. The birefringent material of TeO₂ (Tellurium dioxide) is frequently used due to its high acousto-optic figure of merit, and good transmission in the UV, visible and infrared (range of application 0.25-4.5 μm). Some airborne precursor instruments with AOS (Acousto-Optic Spectrometer) technology, leading toward AOTF capabilities are: POLAS (Polarization-sensitive Acousto-optic Spectrometer) of Russia introduced in 1989, AHSTRA (Airborne Heterodyne Spectrometer THz Astronomy) of the Max-Planck-Institute for Radio Astronomy, Bonn; AMSOS (Airborne Millimeter & Submillimeter-wave Observing System) since winter 1997/98, Univ. of Bern, Switzerland; SUMAS/ASUR (Submillimeter Atmospheric Sounder/Airborne Submillimeter SIS Radiometer), Institute of Environmental Physics at the University of Bremen, Germany; THOMAS (THz OH Measurement Airborne Sounder), DLR (Institute of Optoelectronics, Oberpfaffenhofen, Germany).

In the field of spaceborne Earth observation, the Russian instrument Trasser with AOTF technology was first flown on OKEAN-O1-N2 (or Cosmos 1869) with a launch on July 16, 1987. The instrument was operational until 1990. Another Trasser-O instrument was flown on OKEAN-O-1 (launch July 16, 1999, end of mission fall 2000). All Trasser instruments were designed and built by STCUI (Scientific Technological Center of Unique Instruments), Moscow. The Swedish SMR (Submillimeterwave Radiometer) instrument on ODIN (launch Feb. 20, 2001) features an AOS detector provided by France. The Japanese instrument SMILES (Superconducting Submillimeter-wave Limb-Emission Sounder) employs two acousto-optical spectrometers (AOS) with the objective to observe submillimeter-wave radiation (monitoring of trace gas distribution in the atmosphere). SMILES is an ISS payload planned to be launched in 2005 (L.2.15).

In spaceborne science, the NASA SMEX mission SWAS (Submillimeter Wave Astronomy Satellite) with a launch on Dec. 5, 1998 carries the instrument AOS (Acousto Optical Spectrometer), provided by the University of Cologne, Germany, to investigate the composition of dense interstellar clouds.⁴⁶⁾ AOS on SWAS is used as a backend in combination with a heterodyne receiver to analyze the intermediate frequency signal. Inside AOS, the RF signals are converted to acoustic waves within a crystal causing pressure waves to travel through the crystal. When illuminated by laser light, the alternating patterns of compression and expansion within the crystal act like the finely spaced lines of a grating causing the laser light to be dispersed along one dimension with intensity variations along this direction that are proportional to the intensities within the input 1.4 to 2.8 GHz band.

1.1.2 Microwave Region, Active Observations (Radars)

- Active microwave instruments (providing their own illumination) of the type SLAR (Side-Looking Airborne Radar), RAR (Real Aperture Radar), and SAR (Synthetic Aperture Radar) were developed and flown. Originally discovered in the 1950s, SAR uses high-range resolution waveforms and synthetic aperture techniques to produce images of objects. Rather than depending on a large physical (real) aperture, a SAR forms a large virtual aperture in the processor when operating on an ensemble of received signals. In this way, an antenna only about 10 m in length on the S/C leads to image resolutions comparable to those of very large real antennas (several km in length). First radar systems for range measurements (tracking of aircraft, ships, etc.) were developed during World War II. The first Earth-orbiting civilian spaceborne imaging radar instrument (SAR) was flown on

46) <http://www.ph1.uni-koeln.de/spec.html>

SEASAT (NASA/JPL, L-band SAR, launch June 27, 1978). A side-looking spaceborne RAR instrument with the name of RLSBO was first flown on the Cosmos-1500 satellite (launch Sept. 28, 1983), later also on the Okean series of the former Soviet Union (launch of Okean-O1-1, July 5, 1988).

The standard or conventional architecture of a spaceborne SAR instrument features a SAR antenna (analogous to a telescope of an optical instrument), mounted in a side-looking configuration (O.8.2 and Glossary) and tilted at a look angle, usually between 15-60°, into the swath. As the platform moves in its orbit, a continuous strip of swath width is mapped in the along-track direction of the satellite.

SAR instruments provide high-resolution imagery (typically 10-30 m spatial resolution) of selected polarization and frequency in the microwave region (typical wavelengths from a few cm to about 1m). SAR observation is transparent to cloud coverage and rain, and does not need any sun illumination.

Some background on early SAR developments: 47) 48) 49)

The earliest statement that Doppler frequency analysis could be used to obtain fine cross-range resolution is attributed to Carl Wiley of the Goodyear Aircraft Corporation in June 1951. Wiley observed that a one-to-one correspondence exists between the along-track coordinate of a reflecting object (being linearly traversed by a radar beam) and the instantaneous Doppler shift of the signal reflected to the radar by that object. In 1953, the Doppler-frequency technique was studied by the US Army in the Project Wolverine at the University of Michigan, resulting in an Army project to further develop the range-Doppler radar principle. Part of the program was to develop a practical data processor which could accept wideband signals and carry out the required Doppler-frequency analysis at each resolvable range interval. A group at the Willow Run Laboratories at the University of Michigan (ERIM since 1973) was assigned the problem of developing an optical computer for the purpose. - In the summer of 1957, the Willow Run researchers constructed an X-band radar and built an optical computer. The first fully focused SAR map was produced in August 1957. Soon afterwards, the Willow Run group, in cooperation with Texas Instruments, constructed the first demonstration system, AN/UPD-1, on Army request. Five radar systems were built and various demonstration flights on aircraft were conducted in early 1961.

On the civilian side, a three-wavelength SAR instrument was developed and flown by NASA on the Apollo-17 lunar mission (launch Dec. 7, 1972, moon landing on Dec. 11, return to Earth on Dec. 19, 1972). The objectives of ALSE (Apollo Lunar Sounder Experiment) were to detect subsurface geologic structures (“sounding”), to generate a continuous lunar profile, and to image the moon at radar wavelengths. 50) 51) The ALSE instrument, aboard the Apollo-17 CSM (Command and Service Module), operated at the wavelengths of 60 m, 20 m, and 2 m (corresponding to 5, 15, and 150 MHz). The instrument consisted of two distinct coherent radar subsystems, one operating at two frequencies in the HF-band and the second at a single VHF frequency. The combined HF/VHF radar had a mass of 49 kg and required 103 W of power. The radar data were recorded on 70 mm photographic film (optical recorder - CRT film type) in a conventional SAR format, and returned to Earth for processing. The HF-1 system (5 MHz) was capable of the deepest exploration. The HF-2 system (15 MHz) was operated simultaneously with the HF-1 system to provide partial overlap in the depth of exploration, trading off for improved resolution. The VHF system (150 MHz) was designed for shallow sounding and for surface imaging. All three frequen-

Table 7: Chronological survey of spaceborne imaging radars (SAR instruments)

The first high-quality images (from a ground-based instrument) of near-Earth space objects were obtained in the early 1970s with ALCOR (ARPA, Lincoln Laboratory, C-band, Observables Radar). The data of ALCOR were processed by Lincoln Laboratory of MIT (MIT/LL/) and Syracuse Research Corporation. Successful results were made possible by the range resolution of 50 cm, by the coherent recording, and by sufficient sensitivity to image low-altitude satellites. In the late 1970s, LRIR (Long-Range Imaging Radar), an X-band instrument, was an ALCOR successor system, built at MIT/LL. The objective: imaging of satellites at geosynchronous range. In particular, significant image processing developments were achieved with LRIR such as ECP (Extended Coherent Processing).

NASA/JPL ⁵²⁾ started its coherent radar test program in 1968, resulting in the development of an airborne L-band SAR instrument, flown on the CV-990 aircraft of NASA/ARC since 1971. The objective was to observe ocean surface patterns and to study the relationships between the image and the surface effects by using synthetic aperture techniques. The L-band SAR (1.215 GHz, bandwidth of 10 MHz) featured a phased array antenna with HH and HV polarization. This airborne instrument was a predecessor to the L-band SAR on Seasat. -

Table 8: Overview of some early airborne SAR systems

- Tilting capability of a SAR antenna. The SIR-B Shuttle mission (launch: Oct. 5, 1984) provided for the first time the ability to mechanically tilt the antenna over a range (15° - 55°) so that radar imagery from multiple angles of incidence could be obtained.

- First on-board recording of high-rate SAR data. The USSR missions Kosmos-1870 (launch July 25, 1987) and Almaz-1 (Launch March 31, 1991) were the first to record and dump SAR data during station passes, followed by JERS-1 (launch Feb. 11, 1992). JERS-1 is regarded the first long-term mission which provided an on-board SAR-recording capability for its user community on a regular basis. This enabled extended observations beyond the limits of available ground stations. JERS-1 is also the first S/C carrying two types of imaging instruments, namely a microwave imager (SAR) and an optical imager (OPS).⁵³⁾
- Until 1978, SAR images were formed using analog techniques, incorporating optical lenses and photographic film. In 1978, the first reconstruction of a SAR image was formed on a digital computer. This SAR processor was developed by MDA (MacDonald Dettwiler) of Richmond, BC, Canada, for the purpose to manage SEASAT SAR data. Early digital SAR processors required all the processing power available of a system; they were installed on mainframe computers or on large dedicated hardware. - On the other hand, today's SAR images (since the late 1990s) can be formed on relatively inexpensive equipment like a workstation or a PC.
- ScanSAR. Refers to a radar imaging technique permitting extended observation coverage (e.g. wider swath). In ScanSAR mode, the scene size in range is extended by scanning the antenna in elevation and alternating illumination of several subswaths. Like in stripmap SAR, the scene extension in azimuth is principally only determined by the length of the observation period. The ScanSAR mode requires rapid electronic steering of the elevation beam pattern of the antenna (phased array antenna). The principle of ScanSAR is to share radar operational time between two or more separate subswaths in such a way, as to obtain full image coverage of each. However, scanning in elevation implies that the synthetic aperture length is reduced to the burst length (the burst length or burst duration is defined as the time interval for each target illumination in a ScanSAR cross-track sequence). A consequence of the shorter burst length (as compared to stripmap SAR) is that each target has a different Doppler history (depending on its azimuth position) resulting in a reduced ScanSAR azimuth resolution. The basic differences between ScanSAR and stripmap SAR processing are:^{54) 55)}
 - The azimuth consists of several bursts, each of them corresponding to a fraction of the full synthetic aperture
 - The azimuth resolution is limited by the burst duration and is no longer determined by the synthetic aperture length
 - The Doppler history of each target within a burst has a different frequency offset depending on its azimuth location
 - The azimuth multilook technique is constrained more by the scanning strategy than by the processing strategy
 - The radiometric correction due to the azimuth antenna pattern is much more critical than in stripmap SAR since each target is illuminated by different parts of the azimuth antenna diagram
 - For SAR data processing, an additional mosaic operation is needed in azimuth and range directions to join the azimuth bursts and the range subswaths, respectively.

The ScanSAR technique was initially developed by JPL and first flown on two Shuttle missions with the SIR-C/X-SAR payload in 1994, SRL-1 (STS-59, April 9 - 20, 1994) and SRL-2 (STS-68, Sept. 30 - Oct. 11, 1994). Further implementations of ScanSAR are on RADARSAT-1 (Canada, launch Nov. 4, 1995), SRTM/C-RADAR (NASA/JPL, launch Feb. 11-22,

53) Note: The two Shuttle imaging radars, SIR-A and SIR-B, had recorders, but data was collected only for select sites due to the short mission duration of one week each.

55) A. Moreira, J. Mittermayer, R. Scheiber, "Extended Chirp Scaling Algorithm for Air- and Spaceborne SAR Data Processing in Stripmap and ScanSAR Imaging Modes," IEEE Transactions on Geoscience and Remote Sensing, Vol. 34, No. 5, Sept. 1996, pp. 1123-1136

2000), Envisat/ASAR (ESA, launch 2001), and ALOS/PALSAR (Japan, launch in 2003). - Until RADARSAT-1, the maximum swath width of any previously orbiting SAR instrument had been 100 km, a parameter tightly constrained by the need to: a) “fill the aperture” and b) receive all the returned energy between transmitter pulses. RADARSAT-1 achieved with ScanSAR swaths up to 510 km with 100 m resolution, from an 800 km orbit, through the use of multiple electronically steered antenna beams and carefully synchronized transmitter pulse timing. ^{56) 57) 58) 59)}

The advantage of wider ScanSAR observation coverage is crucial in obtaining global repeat SAR imagery in several days, eventually on a daily basis (enhanced sampling capability) irrespective of cloudcover or sunlight conditions. [The narrow-swath high-resolution (<10 m) SAR imagery yields exciting periodic snapshot views of the 2-D ocean surface to study a number of applications (interactions with the atmosphere, long waves, and current)]. The wide-swath ScanSAR capability of RADARSAT (up to 510 km), Envisat (up to 400 km) and ALOS (up to 350 km) permit for the first time the study of larger-scale phenomena (mesoscale wind fields and circulation features, atmospheric boundary-layer processes, study of storm dynamics, etc.), thus providing a better monitoring capability that may eventually lead to operational SAR missions. The potential of SAR imagery wind-field monitoring alone is much higher than is possible with spaceborne scatterometers. A future operational SAR mission service can of course also provide several other services for land surface monitoring besides ocean surface monitoring, such as monitoring of natural hazards in a wide variety of applications: flooding, earthquakes, wildfires, severe weather events, etc. ^{60) 61)}

- In SpotSAR mode (see O.8.3 for definition of SAR imaging modes), the antenna is steered in the azimuth direction. During the formation of the synthetic aperture, the antenna is constantly looking into the scene center direction. The available synthetic aperture is in this case much longer than in stripmap mode and is denoted by spotlight aperture. The long spotlight aperture provides azimuth signals with a large Doppler bandwidth and therefore provides a high geometric resolution in azimuth.

- Phased array microwave technology (SAR antennas). ⁶²⁾ The observation requirements of wide swaths for global coverage led eventually to the introduction of a new scanning concept referred to as ‘phased array technology,’ making use of electronic beam steering in the elevation domain (the use of electronic scanning allows flexibility in beam pointing and beam shape control for swath coverage). Naturally, the technology requires a lot of computer power to handle such complex radar functions as: beam switching, signal detection, frequency management, ranging, etc. The technique was first tested on active sensors (SARs) in the microwave region of the spectrum and later on laser radars. The SAR sensor of Seasat (launch June 27, 1978) pioneered this rapid-pointing method for spaceborne instruments. Other instruments with phased array technology followed or are being planned, such as: L-/C-band antenna of the SIR-C/X-SAR missions (Shuttle, SRL-1 April 1994, SRL-2 Sept. 1994), SAR on RADARSAT-1 (launch Nov. 4, 1995), PR on TRMM (launch Nov. 27, 1997), C-RADAR on SRTM (launch Feb. 11-22, 2000), ASAR on Envisat (launch 2001), and PALSAR on ALOS (launch 2003). The following instruments are operational on

62) Note: JHU/APL was instrumental in developing the phased array radar technology for the US Navy whose construction began in 1959. A first prototype was installed on a Navy ship in 1961. See: A. Kossiakoff, “APL - Expanding the Limits,” Johns Hopkins APL Technical Digest, Vol. 13, No. 1, 1992, pp. 8-27

the airborne side: FOLPEN (SRI International), PHARUS (TNO), CRL-SAR (CRL), and Sandia SAR (SNL). In the 1990s the phased array has become a key component in the design of advanced antenna systems, taking advantage of the considerable advances in microelectronics, transmitter/receiver architectures, miniaturized device (module) integration methods, and signal processing techniques.

- **Digital chirp generator.** The radar chirp concept of pulse frequency modulation was developed at the Bell Telephone Laboratories (at Whippany and Murray Hill, NJ) by J. R. Klauder et al. in the 1950s and first reported in the literature in 1960 (declassification of work supported by the US military).⁶³⁾⁶⁴⁾ Early experimental work on radar signal design used the chirp, a linearly frequency-modulated (FM) pulse with a frequency range set by the required angular resolution, and with a pulse duration set for the required range resolution performance. By transmitting a modulated pulse, it was possible to obtain range resolutions that were smaller than the transmitted pulse length by very large factors. The reported technique employed the so-called “pulse compression technique” (covering a frequency range many times the inherent bandwidth of the envelope), permitting radars to transmit a pulse with about 100 times the energy of a short pulse with equivalent resolution and peak power.

Modern spaceborne SAR instruments are equipped with a digital chirp generator that allows to generate pulses with a programmable slope and bandwidth.⁶⁵⁾ The resulting flexibility in terms of pulse duration and frequency-tuning capability allows the operation of the SAR system in different modes like a high-resolution mode and a wide swath, low resolution mode. Also, within one mode of operation it is useful to adjust the chirp bandwidth according to the incidence angle in order to maintain a more constant ground-range resolution and a more homogeneous signal-to-noise ratio over the access region. This method is used for example in the ASAR instrument of Envisat for the global monitoring and the wide swath mode with its 5 different swaths. The chirp waveform (linear FM) is also used for better on-board processing of the radar signals including compression schemes.

- **SAR interferometry (O.10.1).** Two interferometric observation concepts are in use: ‘single-pass’ and ‘two-pass’ (or multi-pass) interferometry. The interferometric phase, i.e. the phase difference between two images acquired with slightly different sensor positions, contains geometric information allowing the derivation of the 3-D position of the scattering element. SAR interferometry techniques promise to produce global topography maps in a similar fashion as stereo photogrammetry.

- **Simultaneous observation of the same footprint by two antennas in parallel (single-pass interferometry)** separated at a distance (baseline). Two separate images are received of the same ground track by two spatially-separated antenna systems (the interferometric baseline) to produce phase differences from slightly different viewing angles. DCS (Data Collection System of ERIM) is probably the first single-pass airborne INSAR instrument with first flights in 1987. TOPSAR (JPL) started its observations in 1991. On the spaceborne side, the SRTM (Shuttle Radar Topography Mission, J.25) of NASA represents the first fixed baseline single-pass spaceborne IFSAR (Interferometric SAR) system with simultaneous dual-polarization wide-swath scanning SAR and dual-frequency (C-band and X-band) coverage. The launch of the 11-day STS-99 Shuttle mission is planned for Jan. 2000. The SRTM digital topographic map production objective (referred to as C-RADAR) calls for a spatial pixel (30 m x 30 m) posting with a 16 m absolute vertical linear accuracy and 20 m absolute horizontal radial accuracy at 90%.

- **Two-pass measurements of a single-antenna SAR platform.** This refers to a superposition technique of imagery (in data processing) of fairly close repeat tracks. The ERS-1/-2

63) J. R. Klauder, A. C. Price, S. Darlington, W. J. Albersheim, “The Theory and Design of Chirp Radars,” The Bell System Technical Journal, Vol. 39, No 4, July 1960, pp. 745-808

64) The term “chirp” was coined at the Bell Telephone Laboratories in the 1950s to designate a new and more effective radar signal generation method.

65) M. Suess, C. Schaefer, R. Zahn, “Discussion of the Introduction of On-board SAR Data Processing in Spaceborne Instruments,” Proceedings of IEEE/IGARSS 2000, Honolulu, HI, July 24-28, 2000

tandem mission (start in Aug. 1995, end in May 1996) was flown with a one day delay of a coinciding ground track of the second S/C, providing good interferometric results. The SRL-1/2 missions in 1994 (April 9-20 for SRL-1, Sept. 30 - Oct. 11 for SRL-2) employed two-pass (and repeat pass) interferometry for topographic mapping (detection of topographic surface change in SRL-1 and SRL-2). The C-band SAR instruments of the ERS-1/2 and RADARSAT-1 (launch Nov 4, 1995) missions demonstrated the ability to detect cm-scale surface strain over large contiguous areas. The L-band SAR of JERS-1 (launch Feb. 11, 1992) demonstrated also two-pass SAR-interferometry for change detection.

- Scatterometers are normally active microwave instruments (radars that measure the target reflectivity or backscatter over a wide range of incidence angles; values are reported in terms of the normalized radar cross section) offering a capability of wind speed and direction determination.⁶⁶⁾ Newer instruments under development, like Windsat on Coriolis and CMIS (Conical-scanning Microwave Imager/Sounder) on NPOESS, can also be passive microwave radiometers, capable and sensitive enough of measuring, among other parameters, also ocean surface wind speed and direction. The ocean surface wind vector is a key parameter in understanding the weather due to its dominant role in the energy exchange at the air-sea interface. Winds over the ocean modulate air-sea exchanges in heat, moisture, and gases regulating much of the global weather. - Scatterometry has its origin in early radar used in World War II. Early radar measurements over oceans were corrupted by sea clutter (noise). It was not known at the time that clutter was the radar response to the winds over the oceans. The radar response was first related to wind in the late 1960s - by realizing that the sea surface roughened by the wind modifies the surface backscatter (reflected signal or echo) properties.

Mission	Launch Date	Spatial Resolution (km)	Swath Width (km)	Frequency GHz (Band)	Polarization	Data Rate (kb/s)	Altitude, Inclination (km/ [°])	Sensor, Remarks

Table 10: Overview of some airborne radar scatterometers

Wind vector retrievals by today's operational scatterometers (like AMI and SeaWinds) are based on indirect measurements, where the wind vector is inferred through a relationship between the backscattered power, the small-scale ocean surface roughness, and the local wind vector at the ocean surface. This relationship is empirical, based primarily on matches between sensor measurements, buoy wind measurements and analysis from numerical weather prediction models. ⁶⁷⁾

The first spaceborne scatterometers were S-193 on Skylab (launch 1973) and SASS on Seasat (launch June 28, 1978), followed by MRSE on Spacelab-1 and the AMI-SCAT (wind scatterometer mode) instrument on ERS-1 (launch July 17, 1991). See Tables 9 and 10. ⁶⁸⁾ The newer (since 1999) spaceborne wind vector measurement instruments can be put into three classes: ⁶⁹⁾

- Broad-swath, dual-pencil beam active Ku-band scatterometers (e.g. SeaWinds)
- Dual swath, 3-look active C-band scatterometers (e.g., ASCAT)
- Dual- and single-look passive polarimetric radiometers (e.g., Windsat, CMIS)

Sensor Name	Sensor Provider	Introduction	Microwave Band
E-SLAR	DFVLR (DLR), Germany	1976	X-band

HUTSLAR	HUT, Finland	1988	X-band
SLAR	TNO/NLR, The Netherlands		X-band

Table 11: Some SLAR instruments

With the launch of ADEOS-II, there is the first opportunity since Seasat to obtain collocated active microwave radar with SeaWinds-II and passive microwave radiometer data of AMSR (Advanced Microwave Scanning Radiometer), from the same platform.

Traditional **fan-beam** scatterometer designs such as SASS, AMI-SCAT, and NSCAT require significant power and mass and have antenna systems which are difficult to accommodate aboard any spacecraft. ⁷⁰⁾ ⁷¹⁾ The fan-beam systems employ multiple fixed antennas to cast broad fan-shaped beams on the Earth's surface at multiple azimuth angles needed to measure wind. These designs have degraded wind performance limitations in particular in the near-nadir region of the measurement swath. The reason: the backscatter measurements in the region ± 200 km to either side of the nadir track are at small incidence angles and are insensitive to wind direction, thus, creating a large "nadir gap" in their coverage. - Newer scatterometer designs employ the **conical-beam scanning technique** (with dual-

⁶⁷⁾ P. S. Chang, L. N. Connor, J. R. Carswell, R. S. Dunbar, "Operational Scatterometry: High Wind Speed Retrievals," Proceedings of IEEE/IGARSS Conference, Honolulu, HI, July 24-28, 2000

⁶⁸⁾ Note: Wind retrievals are also available from SSM/I, flown since 1987 on the DMSP series. However, the design of SSM/I, a microwave radiometer, only permits the retrieval of the speed component of the wind vector.

⁷¹⁾ W-Y. Tsai, S. V. Nghiem, J. N. Huddelston, et al., "Polarimetric Scatterometry: A Promising Technique for Improving Ocean Surface Wind Measurements," IEEE Transactions on Geoscience and Remote Sensing, Vol. 38, No 4, July 2000, pp. 1903-1921

beams). SeaWinds (of NASA/JPL on QuikSCAT, launch June, 19, 1999) introduced a scanning pencil-beam scatterometer with a dual-beam conical scan, provided by a 1 m diameter reflector (rotating dish) antenna.⁷²⁾ Although the pencil-beam approach adopted by SeaWinds significantly lessens the nadir gap problem by making measurements at suitably high incidence angles, the problem is not completely eliminated. Measurements in the extreme inner and outer swath still suffer some degradation because the relative azimuth angles of backscatter measurements are too close together (approaching 0° for the outer swath), or are too far apart (approaching 180° for the inner swath) to determine the wind speed direction accurately. - A performance improvement is also introduced with the ASCAT instrument of ESA on MetOp-1, it employs a solid-state design and the use of a double-beam scanning technique. Scatterometer antenna and radar electronic concepts remain key technology issues in the design of efficient and low-cost instruments.

Beyond the original mission of spaceborne scatterometers to provide measurements of wind velocity over the ocean, a large number of applications of the radar data have emerged in such areas as: a) land applications, b) polar snow and ice, c) oceans and NWP (Numerical Weather Prediction), and d) polarimetric scatterometry.

The capabilities of future polarimetric scatterometers are of particular interest. They will be able to simultaneously measure the conventional co-polarized backscatter as well as the polarimetric correlation of the co- and cross-polarized radar returns from the ocean surface. The technique promises potential performance gains by improving in particular the ambiguity resolution.

- Microwave rain measurement instruments. First radiometer data evaluations with regard to rainfall started around 1975 using ESMR data of Nimbus-5 (launch Dec. 11, 1972) and later SMMR data of Seasat (launch June 27, 1978). The SSM/I radiometer on the DMSP series is flown since 1987, rainfall is determined for sea surface regions. The airborne radiometer AMR (NASDA, since 1995) is to confirm AMSR on ADEOS-II (planned launch in 2002). Active microwave instruments: CRL Radar/Radiometer (CRL Tokyo, since 1981), ARMAR (NASA/JPL, since 1992) is an airborne rain radar in support of the spaceborne PR (Precipitation Radar) instrument on TRMM (launch Nov. 27, 1997). The TRMM mission represents the first concerted effort (NASA/NASDA) to tackle the complex nature of rainfall with a complement of passive and active sensors.⁷³⁾
- The GPM (Global Precipitation Mission), a follow-up mission to TRMM with a reference constellation of eight microsatellites and advanced rain-measuring instruments, is in the proposal state as of 2000/1 (NASA/NASDA, ESA also considers to join the project) with a planned launch date in 2007. The GPM close-neighborhood constellation employs a completely new observation technology, namely the so-called interferometric cartwheel concept (first proposed by CNES), where a single spacecraft is equipped with an active radar and a passive radiometer, while the rest of the constellation is outfitted with just a radiometer (receiver). All observation instruments of the constellation look into the same footprint. Thus, all passive instruments in the constellation are also able to collect the echo information from the single active radar. The multi-location (or nodal) spacecraft data collected in this fashion provides automatically interferometric imagery after ground processing. Parasitic observation systems, like Cartwheel (Europe) and GPM, are under intensive study.
- Microwave medium-penetrating instruments, in particular with regard to soil and foliage penetration (see also: 'microwave signal penetration' in Glossary), were first introduced with airborne instruments (Table 12). Microwave observations of active and passive sensors in L-band, P-band, UHF, VHF and UWB are of interest. The microwave

permittivity of water is an order of magnitude higher than that of any natural dry material. Radar penetration and resolution tend to be reduced by the EM attenuation, with a range that goes from a few meters in conductive media, to 50 m at most for low-conductivity (below 1 ms/m) materials such as sand, gravel, rock and fresh water. High-power pulses are essential in order to increase the ratio between signal and clutter (or noise). For this reason, instead of using a pulse radar, one may use swept-FM or step-frequency transmitters. The frequency synthesizer technique seems to overcome some of the limitations of pulse radars which makes them interesting for future developments.⁷⁴⁾

System	Description
GPR (Ground Penetrating Radar) SRI, P.94.1	First airborne tests/studies (ice penetration) were conducted in 1974, GPR first flown in 1993
FOLPEN, SRI, since 1990, P.94	FOLPEN-I and-II are VHF impulse SAR systems with foliage penetration capability
CARABAS, FOA, Sweden, P.49	Penetration of vegetation/foliage and to some extent of the ground surface, since 1992
TOPSAR, JPL (upgrade 1994), P.13.1	Calculation of the differential penetration characteristics of the dual-frequency radar waves for different Earth terrain types
P3/SAR, ERIM/Navy (upgrade 1994), P.82.3	Support of foliage and ground penetration experiments/applications
LARSEN, CCRS, since 1985, P.111	A lidar for the measurement of shallow water depths
LFS, University of Oldenburg, P.116	Lidar for the analysis of the upper sea surface layers, since '93
SHOALS, USACE, 1994, P.184	A lidar for the measurement of shallow water depths
SASAR, U. of Cape Town, since 1996, P.181	The VHF-band of SASAR offers a surface/foliage penetrating capability
PBMR, GSFC/WFF, since 1983, P.160	L-band radiometer for the measurement of soil moisture, etc.
RADIUS, NPO Vega, since 1986, P.171	Microwave radiometer for the measurement of soil moisture, etc.
ESTAR, MIRSL/GSFC, 1988, P.87	L-band radiometer for the measurement of soil moisture and ocean salinity
AIMR, AES, Canada, since 1989, P.8	Microwave radiometer for the measurement of soil moisture and snow depth
PORTOS, CNES, since 1992, P.167	Microwave radiometer for the measurement of soil moisture
MIRAS, ESA, since 1996, P.132	L-band radiometer for the measurement of soil moisture and ocean salinity

Table 12: Overview of medium-penetrating airborne microwave instruments

Spaceborne L-band SAR instruments were flown on SIR-A (NASA/JPL, Shuttle, Nov. 12, 1981), SIR-B (Shuttle, Oct. 5, 1984), and SIR-C/X-SAR (Shuttle, SRL-1 April 1994, SRL-2 Sept. 1994), and on JERS (NASDA/MITI, launch Feb. 11, 1992).

In the late 1990s, the applications of medium-penetrating radars (a non-destructive monitoring technique), are becoming rather divers. The technique is employed in civil engineering for void detection, prediction of concrete deterioration from variations of its permittivity by the presence of moisture and chloride, pavement profiling for programmed road and bridge deck maintenance, reinforcing bar location, subgrade deterioration in railroad and airport runways. Object detection and classification by extent and permittivity contrast with the overburden, it is crucial in environmental engineering. Furthermore, the technique is useful for mapping hazardous wastes and buried contaminant containers, imaging and monitoring subsurface contaminants (e.g., gasoline and other hydrocarbon fuels). Stratigraphic and bedrock mapping are essential in geotectonic, archaeologic, and hydrogeologic applications, in site characterization, in mining planning (e.g., borehole profiling), in tunnel excavations, ice thickness profiling, permafrost mapping, etc.⁷⁵⁾

1.1.3 Microwave Region, Passive Observations

- Radiometric imaging. The NOAA-2 S/C (launch Oct. 15, 1972) was the first operational weather satellite to rely solely upon radiometric imaging to obtain cloudcover data.
- Radiometers. The spectral range of remotely-sensed data was considerably enlarged by the use of radiometers in the microwave region [the overall microwave region is considered for wavelengths from about 1 mm (300 GHz) to 1 m (300 MHz); remote sensing is being conducted in the MMW (millimeter-wave) region (i.e., 1-10 mm or 300 GHz to 30 GHz); the frequency range from 1-20 GHz is mostly used for surface radiometry due to atmospheric attenuation]. Passive microwave (MW and MMW) Earth observation radiometry introduced such applications as temperature sounding for meteorological purposes, sea-ice mapping for navigation in polar regions, measurements of ocean surface temperature and ocean surface wind speeds. Eventually the applications of radiometers included also observations of land surface features and the measurement of atmospheric constituents (trace gases).- Two generic types of radiometers have evolved, profiling instruments (or sounders, also referred to as broadband radiometers), and surface imaging instruments (multichannel radiometers). In general, atmospheric window frequencies are used to study surface (ocean, ice, land) phenomena.
- Spaceborne microwave observations started September 23, 1968 with the launch of Cosmos 243 satellite (in sun-synchronous LEO) which carried a non-scanning, nadir-viewing 4-channel radiometer [wavelengths: 8.5 cm (3.5 GHz), 3.4 cm (8.8 GHz), 1.35 cm (22.2 GHz), and 0.8 cm (37.5 GHz)] with the objective to estimate atmospheric water vapor, liquid water, ice cover, and sea temperature. The same radiometer was also flown on Cosmos 384 with a launch in 1970. Nimbus-5 (launch Dec. 11, 1972) carried a radiometer with the name of NEMS (Nimbus-E Microwave Spectrometer). This represented the first step in the application of the microwave spectrum to global sensing of the atmospheric temperature structure. Another radiometer on Nimbus-5 was ESMR (Electrically Scanning Microwave Radiometer). The Skylab (launch of Skylab-1 May 14, 1973) series flew two radiometers, S-193 and S-194. The NEMS instrument on Nimbus-5 was followed by SCAMS (Scanning Microwave Spectrometer), flown on Nimbus-6 (launch June 12, 1975), which led to the first MSU (Microwave Sounding Unit), flown on TIROS-N (launch Oct. 13, 1978). The SMMR sensor was flown on SEASAT (launch June 27, 1978) and on Nimbus-7 (launch Oct. 24, 1978). See also chapter O.7 and Table 546.^{76) 77)}
- Passive spaceborne radiometers have been primarily frequency-tuned to vertically sound and map specific constituents (gases and dust in atmospheres, and bulk properties on planetary surfaces). The first systems implemented were sounders (profiling systems). These were followed by the new type of surface imaging radiometers with the availability of focal plane antennas and better processing capabilities. The 1980s and 1990s mark a shift away from Dicke-switched superheterodyne radiometers to total-power systems, facilitating radiometer configuration simplification and sensitivity improvements. In the 1990s, superheterodyne receivers with mixers directly coupled to feedhorns and feeding low-noise IF amplifiers continue to dominate MMW radiometry. The mixers in superheterodyne radiometers remain the critical element for sensitivity. Mixers with whiskerless diodes yield significant improvements in reliability relative to mixers with whisker-contacted diodes.
- Future radiometer instruments are expected to include more receiver channels in a wider spectral range (MW, MMW, and sub-MMW). Improvements are likely to come from solid-state technologies based on MMIC (Microwave Monolithic Integrated Circuit) receiver chip development, providing direct amplification and detection in combination with

77) A. E. Basharinow, et al., "Some Results of Microwave Sounding of the Atmosphere and Ocean from the Satellite Cosmos 243," in COSPAR Space Research XI, Proceedings of Open Meetings of Working Groups of the Thirteenth Plenary Meeting of COSPAR, Leningrad May 20-29, 1970, Akademie-Verlag, Berlin, 1971, pp. 593-600

FPA (Focal Plane Array) imaging. In addition, the aperture synthesis method seems to be a promising development, providing a capability of 2-D radiometer imagery generation. Note: the MMIC technology is replacing the older MIC (Microwave Integrated Circuit) and TWTA (Traveling Wave Tube Amplifier) technology in RF electronics.

- Submillimeter-wave radiometers [300 GHz (1 mm) < frequency range > 3000 GHz (0.1 mm)].⁷⁸⁾ At the end of the 1990s, new generations of microwave limb sounders (profilers) and imaging radiometers (or spectroradiometers) are emerging with advances in microwave detector technology, extending their measuring capability into the sub-mm wavelength region. The technology for these high-frequency ranges requires radiometers with superconducting heterodyne receivers or with FTS-based systems (the FTS technique provides a means to measure atmospheric radiance).⁷⁹⁾ The cooling to superconducting temperatures of the detection system represents always a major investment in instrument design. The problem of past LTS (Low-Temperature Superconductivity) cooling seems to be gradually replaced by HTS (High-Temperature Superconductivity) cooling systems. - The interest in the short wavelengths is due to the fact that many molecules of importance in photochemistry exhibit emission lines in these wavelengths (e.g. HCl, OH). Submillimeter remote sensing has in addition advantages that complement visible and infrared techniques. Since the wavelength of submillimeter radiation is comparable to the size of ice particles in cirrus clouds, observed brightness temperature changes from cirrus are correlated to ice mass.⁸⁰⁾ Some early airborne instruments in this class are: MIR (Millimeter-wave Imaging Radiometer) of NASA/GSFC flown on ER-2 which was upgraded in 1994 with three 325 GHz channels. THOMAS (THz OH Measurement Airborne Sounder, since 1994) of DLR, and ASUR (Airborne Submillimeter SIS Radiometer, since 1994) a cooperative sensor of SRON (Groningen, Netherlands) and the Institute of Environmental Physics at the University of Bremen. The NASA-sponsored FIRSC (Far Infrared Sensor for Cirrus) FTS instrument is flown on a T-39 (Sabreliner) aircraft since April 1998.^{81) 82)}

The first spaceborne sub-mm instruments for the measurement of trace gases are: SMR (Submillimeterwave Radiometer) flown on the Swedish S/C ODIN (launch Feb. 20, 2001). There are sub-mm channels and one lower frequency channel on SMR. SMILES (Superconducting Submillimeter-wave Limb Emission Sounder) of NASDA/CRL is planned to fly on ISS/JEM in 2005. ESA/ESTEC has the following limb-sounding sensors (in the sub-mm region) under development: MASTER (Millimeter-wave Acquisition for Stratosphere Troposphere Exchange Research), SOPRANO (Sub-millimeter Observation of Processes in the Absorption Noteworthy for Ozone) and PIRAMHYD (Passive InfraRed Atmospheric Measurements of HYDroxyl). NASA is developing MLS (Microwave Limb Sounder), with three channels in the mm-range and two double sideband sub-mm channels, to fly on Aura (EOS-CHEM) in 2003. The new MLS instrument (frequencies of >600GHz) is a further development of MLS flown on UARS [Note: MLS on UARS has observed atmospheric thermal emissions from chlorine monoxide (ClO), ozone (O₃), water vapor (H₂O), sulfur dioxide (SO₂), and molecular oxygen (O₂), at frequencies of 63, 183 and 205 GHz].

- **Synthetic aperture radiometry.** Aperture synthesis is a relatively new technique for microwave remote sensing of the environment. The technique (pioneered in radio astronomy)

78) G. W. Schwaab, "Heterodyne spectrometers," *Infrared Physics & Technology*, Vol. 40, 1999, pp. 207-218

79) Note: The heterodyning technology is particularly suitable for the detection of very weak infrared and microwave radiation sources; heterodyning instruments (microwave limb sounders) play a crucial role for the monitoring performance of the Earth's atmosphere (chemical composition of the atmosphere, monitoring/deduction of the fine structure of the spectra) as well as in the study of astronomical objects. The heterodyning technique is applicable in the spectral range from about 10 μ m (TIR) to the microwave region of about 10 mm wavelength.

82) J. Mees, S. Crewell, et al., "ASUR - An Airborne SIS Receiver for Atmospheric Measurements of Trace Gases at 625 to 760 GHz," *IEEE Transactions on Microwave Theory and Techniques*, Vol. 43, No 11, Nov. 1995, pp. 2543-2548

generates high spatial resolution images by dividing the collection area of a telescope (or antenna) into smaller apertures spread out in a pattern covering several baselines. In microwave radiometry the concept employs an interferometric technique, in which the product from antenna pairs is sampled as a function of pair spacing. Substantial reductions in the antenna aperture needed for a given spatial resolution can be achieved with this technique. However, the advantages gained from aperture synthesis comes at the expense of reduced sensitivity resulting from the corresponding reduction in physical aperture. Detection sensitivity is an especially critical issue for measurements in LEO orbits (with orbital speeds of about 7 km/s) because of very limited instrument integration time availability per scene. - ESTAR [of NASA/GSFC and MIRS (Univ. of MA, Amherst), P.87, first flown in 1988], a hybrid real-and-synthetic aperture combination, was the first radiometer built to test the concept of aperture synthesis. The experiences with the airborne ESTAR and MIRAS (ESA, P.132) instruments have demonstrated in particular the potential of aperture synthesis for remote sensing of **soil moisture** (Table 12).⁸³⁾ While ESTAR is based on a 1-D (across-track) interferometer approach, MIRAS employed the 2-D synthetic aperture alternative. The new technology may eventually lead to a new generation of spaceborne passive microwave sensors by helping to overcome limitations set by antenna aperture size. The advantage of aperture synthesis is that it can achieve spatial resolutions equivalent to a total power radiometer with a large effective collecting area using relatively small antennas. The reduction in sensitivity that this entails can be restored because the synthetic aperture system does not need to scan and collect energy from many independent antenna pairs simultaneously.

Soil moisture. In this context, soil moisture is a fundamental parameter of the terrestrial environment. Its spatial distribution and temporal variation are crucial ingredients of hydrologic, ecologic, and climatic models, on regional and global scales. Spaceborne soil-moisture sensing may already get a start with two active instruments, namely ASAR (Advanced SAR) on Envisat (launch Oct. 2001), and with PALSAR (Phased Array L-band Synthetic Aperture Radar) on ALOS (launch in 2003). Each of these SAR instruments is dual-polarized, permitting the retrieval of soil moisture for bare soil surfaces and for surfaces with short vegetation cover.

A first spaceborne demonstration project, employing synthetic aperture radiometry (i.e. passive microwave sensing) with a sparsely filled 2-D antenna design, is **SMOS** (Soil Moisture and Ocean Salinity) of ESA (an approved science-driven demonstration mission in the ESA Explorer program). A launch of SMOS with a microwave imaging radiometer (the interferometric design employs aperture synthesis) is planned for 2005 (D.36). In this concept, the required spatial resolution of <50 km for global brightness temperature retrieval (3 day revisit) in the microwave range (L-band), demands in turn a large number of aperture synthesis radiometers elements - each having an independent receiver. The swath width of the radiometer is 934 km at an orbital altitude of 755 km, sufficient for a 3-day equatorial revisit time. The quest for still higher resolutions (in the order of 10 km x 10 km) of future missions will certainly increase the number of receivers in their designs.⁸⁴⁾ - On the applications side such data is very much needed for the implementation of hydrologic models of large basins.

- Microwave sounding from GEO satellites. So far, infrared/microwave sounder instrument combinations, [like the TOVS instrument series with HIRS, SSU and MSU flown since TIROS-N (launch 1978), and the HIRS/AMSU combination first flown on NOAA-15 (launch May 13, 1998)], have only been flown on weather satellites in polar orbits. These combined observations have the advantage to provide more nearly all-weather soundings (recovery of vertical distribution of temperature and humidity soundings). Such S/C ob-

servations have had a significant impact on weather forecasting accuracy, especially in region where in-situ observations are sparse. Infrared sounders alone do not have adequate cloud-penetration ability to satisfy most forecast requirements, while microwave sounders alone do not satisfy observations in the infrared region. - On the geostationary (GEO) side, NASA was planning the GEO/SAMS (Geostationary Synthetic Aperture Microwave Sounder) instrument to be flown on the EO-3 mission (Earth Observing-3, launch in 2003) in geostationary orbit. The GEO/SAMS concept employs the synthetic aperture radiometer technique (a sparsely populated antenna array is substituted for a filled array). However, in 2000 the GEO/SAMS proposal was not accepted. ^{85) 86)}

1.1.4 Optical Region, Active Observations (Lidars)

- Laser radars (active instruments), or lidars, combine the principles of submillimeter-wave radar and optics. The introduction of lidar (Light Detection and Ranging) technology, generally used in the spectral range of 0.3 μm to about 10 μm or the equivalent frequency range of 1000 - 30 THz, provided a new capability to study fine-scale phenomena of the atmosphere (with respect to structure, dynamics, models and climatology) as well as of the Earth's surface (texture, terrain profiling, shallow water depth sounding, etc.). Some lidar measuring techniques employed are: incoherent backscatter, DIAL (Differential Absorption Lidar), coherent Doppler (wind), laser altimetry, etc. (see O.8.5). Airborne lidars are flown since about 1977 [AOL (1977), CALS 1979), ALEX (1979), ALPHA-1 (1979), etc.], most instruments were developed during the latter 1980s and the 1990s. MACAWS of NASA/MSFC (since 1995) is the first airborne 'coherent atmospheric wind lidar' measuring 2-D, 3-D or vertical wind fields. - On the spaceborne side, the first lidars were introduced in 1994 for atmospheric applications (detection of stratospheric and tropospheric aerosols; measurement of the planetary boundary layer, cloud top heights, atmospheric temperature and density); these were followed by lidar altimeters, mainly used for ocean surface or terrestrial surface monitoring.

- Atmospheric lidars: LITE (Lidar In-Space Technology Experiment) of NASA/LaRC, a triple wavelength lidar, was test-flown on Shuttle (STS-64) in Sept. 1994. Balkan-1 of Atmospheric Optics, Tomsk (Russia), flown on the MIR/Spektr module (launch May 20, 1995). ALISSA, a CNES-developed lidar flown on MIR/Priroda (launch April 23, 1996). In Europe, the instruments ATLID (Atmospheric Lidar) of ERM (Earth Radiation Mission) and ALADIN (Atmospheric Laser and Doppler Instrument) of ADM (Atmospheric Dynamics Mission) are part of ESA's spaceborne lidar program. ALADIN will probably be the first spaceborne instrument in a sustained mission using the incoherent DWL (Doppler Wind Lidar) technique of direct detection of wind profiles on an optical detector (with no LO). In this measurement scheme the backscattered optical signal field is analyzed and dispersed in an interferometric filter (or in diffraction grating) prior to detection. A combined Mie and Rayleigh backscattering fringe-imaging receiver is employed to analyze aerosol and cloud backscatter.

Instrument name	LITE	Balkan-1	ALISSA	ALADIN	ATLID
Platform/Mission	Shuttle STS-64	MIR/Spektr	MIR/Priroda	ADM (ESA)	ERM (ESA)
Orbit altitude (km)	260	350-400	350-400	400	400
Laser type	Nd:YAG	Nd:YAG	Nd:YAG	Nd:YAG	Nd:YAG
Wavelength (nm)	1064,532,355	532	532	355	1064
PRF (Hz)	10	0.18	50	100	100
Telescope diameter	100 cm	27 cm	40 cm	110 cm	60 cm

Instrument power	2000 W	250 W	3000 W	304 W	520 W

Table 13: System performance parameters of spaceborne atmospheric lidars

- Altimeter lidars: ⁸⁷⁾⁸⁸⁾⁸⁹⁾ SLA-1 (Shuttle Laser Altimeter), was flown on STS-72 (Jan. 11-20, 1996), SLA-2 was flown on STS-85 (Aug. 7-19, 1997) to acquire altimetric samples of land topography (see J.17). GLAS (Geoscience Laser Altimeter System) is being built by NASA/GSFC (to be flown on the ICESat mission in 2001, see D.16) to determine the mass balance of the polar ice sheets and their contributions to global sea level change. The MBLA (Multi-Beam Laser Altimeter) lidar instrument is flown on the VCL (Vegetation Canopy Lidar Mission), a NASA/GSFC mission with a launch in mid 2002. The objective of the SLA and VCL instruments (D.39) is to provide lidar altimetry for Earth surface monitoring (in particular land surface processes and interactions). - Advantages of the laser technology include small footprint size, individual pulse processing of surface elevations, and dense ground sample spacing.

The early EOS (Earth Observing System) program of NASA considered the development of LAWS (Lidar Atmospheric Wind Sounder), a coherent Doppler wind lidar with a carbon dioxide laser. However, the project was cancelled in 1994 due to severe budget cuts in the EOS program.

1.1.5 Sounding of the Atmosphere

- Sounding (see also: Limb/occultation sounding in Glossary). Airborne and spaceborne Earth observation adapted fairly early the ancient technique of sounding ('to find bottom' - originally used for the measurement of shallow water depths) into the development of suitable sensors (sounders) to measure conditions of the medium 'atmosphere.' Sounders provide profiles of state parameters (a series of measurements of temperature, pressure, moisture, etc.) in a particular plane of observation (nadir or limb configuration) at various heights. The early sounder measurements were obtained from filter radiometers with a spectral resolving power ($\lambda/\Delta\lambda$) typically in the order of 100. At the start of the 21st century the spectral resolving power of typical radiometers is more in the range of 1000.

Later applications included also the sounding of aerosols, trace gas constituents ("absorptive" or "extinctive" occultation monitoring), and of wind components with a variety of instruments, employing such techniques as FTS (Fourier Transform Spectrometry) and Doppler. The technique of sounding has also been extended far beyond the Earth's atmosphere to measure plasma densities of the solar wind. Active airborne sounders (namely lidars) are also used to fathom the depths of shallow waters (FLASH since 1989, SHOALS since 1994), to detect sea surface pollution, and to measure surface emissions. Naturally, the entire spectrum may be used for sounding measurements, but the microwave region is the traditional and dominant arena for sounders.

The presence of clouds in the field of view of sounders has a detrimental effect on the quality of a retrieval. The absorption properties of cloud droplets and ice particles at infrared sounding wavelengths are so strong that even thin clouds contaminate the measurement of radiances. As a result, a number of post-processing techniques have been developed to minimize the effects of clouds on soundings. These usually require some way of identifying cloudy scenes to arrive at an equivalent clear-sky radiance quantity. Methods accounting for the effects of clouds on the data are generally based on higher-resolution visible and infrared imaging data that are required to supplement the sounding channels.

89) Courtesy of A. Ginati of OHB-System, Bremen

- The first airborne devices used were self-registering instruments (referred to as sondes) on balloons to record meteorological data. The MTS (Microwave Temperature Sounder of GSFC) instrument was first flown on aircraft in 1976. - A large number of daily atmospheric profiles from spaceborne sounders [SSH on the DMSP series, launch of F-1 Sept. 11, 1976; TOVS (TIROS Operational Vertical Sounder), on TIROS-N consisting of HIRS/2, SSU and MSU, launch Oct. 13, 1978; SBUV/TOMS on Nimbus-7, launch Oct. 24, 1978], ILAS and IMG on ADEOS (launch Aug. 17, 1996) and ILAS-II on ADEOS-II (launch in 2002) began to find their way into global forecasting models.

Today's sounders like AMSU (Advanced Microwave Sounding Unit), first flown on NOAA-15 (launch May 13, 1998), provide atmospheric temperature profiles with a sensitivity of about 1 K and a vertical resolution of about 2 km in the troposphere. SSMIS (Special Sensor Microwave Imager Sounder) of the DMSP series, first flown on F16 (launch 2001), features a similar performance as AMSU. Current generation sounder performance (AMSU, SSMIS) still falls short of the requirements for NWP (Numerical Weather Prediction). Some examples of next-generation sounders are: AIRS (Atmospheric Infrared Sounder) on Aqua (launch 2001), ATMS (Advanced Technology Microwave Sounder) and CrIS (Cross-track Infrared Sounder) on NPP (launch in 2005). Their data is planned to be used in NWP models.

- **Aerosol monitoring** plays an important role in global climate change. Spaceborne monitoring of aerosols started with SAM of NASA/LaRC [SAM (Stratospheric Aerosol Measurement) was flown on ASTP (Apollo-Soyuz Test Project), July 15-24, 1975, to perform the first successful solar occultation measurement of stratospheric aerosol], SAM II (launch Oct. 24, 1978 on Nimbus-7, see M.17.7), SAGE I, SAGE II). Both SAM and SAM-II were single spectral instruments measuring the aerosol extinction near the 1000 nm wavelength region. Multiple spectral measurements began with SAGE-I, with a launch on the AEM-2 (Application Explorer Mission-2) satellite, Feb. 18, 1979 (see A.5). SAGE-II is an advanced version of SAGE-I with 7 channels at 385, 448, 453, 525, 600, 940, and at 1020 nm. SAGE-II was flown on ERBS with a launch on Oct. 5, 1984 (see A.13). The measurements of SAM-II, SAGE-I and SAGE-II have provided long-term observations of aerosol and ozone for over 20 years.

Table 14: Some aerosol-monitoring instruments of spaceborne missions

SAGE-III is an Earth limb-scanning grating spectrometer (part of NASA's EOS mission) scheduled to fly on Meteor-3M-1 (Russia) with a launch in 2001. An important objective of SAGE-III is to characterize tropospheric and stratospheric aerosols and upper tropospheric and stratospheric clouds, and investigate their effects on the Earth's environment, including radiative, microphysical, and chemical interactions. SAGE-III is also scheduled to fly on ISS in 2004. - Note: There is an inherent coverage weakness in the solar occultation technique by offering only two measurement opportunities per orbit. It has been estimated that six spaceborne SAGE-III instruments on various orbits would be needed to achieve a weekly coverage of the Earth.

- **Spatial Heterodyne Spectroscopy (SHS)**, see O.11 and J.16. SHS provides the first practical approach to extend interference spectroscopy into the FUV (Far Ultraviolet, 1200-2000 Å) spectral range. The technique appears to be offering high-resolution spaceborne spectroscopy applications in astronomy (detection of faint interstellar emission lines, study of the dynamics of hot interstellar gases) as well as in Earth observation. Examples in this field include the measurement of vertical density profiles of the hydroxyl (OH) radical in the middle atmosphere (30-100 km), study of the distribution of aerosols in the mesosphere, and to investigate the role of OH in the photochemistry of water vapor and ozone in the presence of aerosols in the mesosphere. NRL (Naval Research Laboratory) in Washington, DC has been cooperating with UWM (University of Wisconsin-Madison) for the last years to develop an instrument. A first implementation of the SHS concept is realized in SHIMMER (Spatial Heterodyne Imager for Mesospheric Radicals). The instrument is planned of be flown on Shuttle in 2002.

- **Refractive occultation monitoring**, also referred to as **radio occultation monitoring** (Earth-observation applications of navigation systems and use of GPS receivers as science instruments).^{90) 91) 92) 93)} In 1995 retrieval of atmospheric limb soundings (moisture and temperature distributions) was demonstrated by GPS receiver sounding techniques referred to as "refractive occultation monitoring." The technique makes use of occulting navigation signals of the GPS constellation they pass through the atmosphere and are intercepted by a GPS receiver on a LEO S/C. The highly accurate measurements obtained with these special-function GPS receivers permit the derivation of vertical profiles of the temperature, pressure and humidity in the atmosphere, as well as profiles of electron content in the ionosphere.

90) Note: The radio occultation technique was initially invented in the early 1960s by NASA/JPL in its planetary exploration programs to Venus, Mars (Mariner-IV flyby in 1964) and later to the outer planets (the first relevant proposal came from Stanford University in 1962). Applying this technique to the Earth's atmosphere and using the GPS constellation as a source and a GPS receiver in LEO was first suggested in the late 1980s in two papers: a) A. S. Gurvich, T. G. Krasilnikova, "Navigation Satellites for Radio Sounding of the Earth's Atmosphere," *Issled. Zemli Kosmosa*, Vol. 6, 1986 (in English: *Soviet Journal of Remote Sensing*, 6, 1990), and b) T. P. Yunck et al. "The role of GPS in precise Earth observation, Proceedings of the IEEE Position, Location, and Navigation Symposium, Orlando, FLA, 1988.

91) T. P. Yunck, C. H. Liu, R. Ware, "A History of GPS Sounding," Special issue of TAO (Terrestrial, Atmospheric and Oceanic Science, Vol. 11, No 1, March 2000, pp. 1-20

92) W. G. Melbourne, et al., "The Application of Spaceborne GPS to Atmospheric Limb Sounding and Global Change Monitoring, JPL Pub. 94-18, Pasadena, CA, 147 pp., 1994

93) W. Bertiger, Y. Bar-Sever, S. Desai, et al., "Precise Orbit Determination for the Shuttle Radar Topography Mission using a New Generation of GPS Receiver," ION GPS-2000, Sept. 19-22, 2000, Salt Lake City, UT, pp.1646-1654

The GPS/MET instrument of UCAR/JPL on OrbView-1/Microlab-1 (launch April 3, 1995, B.8.1) introduced this alternate sounding technique to Earth observation, starting a new era of atmospheric profiling technology. GPS/MET temperature retrieval accuracies of better than 1K have been demonstrated in the altitude range of 10-30 km during the proof-of-concept phase of the mission with vertical resolutions of better than 1 km. This all-weather sounding technique promises to greatly contribute to global atmospheric monitoring, offering an abundance of data for operational meteorology and climatology.⁹⁴⁾ The TRSR (TurboRogue Space Receiver) instruments of GFO (Geosat Follow-On, launch Feb. 10, 1998), SUNSAT and Ørsted (both were launched Feb. 23, 1999) missions are a further development of the GPS/MET instrument on OrbView-1/Microlab-1. The TRSR instruments of NASA/JPL were manufactured by Allen Osborne Associates Inc. of Westlake Village, CA.

Mission	Instrument	Comment
OrbView-1/Microlab (launch Apr. 3, 1995)	GPS/MET	NASA
GFO (launch Feb. 10, 1998)	TRSR (JPL)	US Navy
SUNSAT (launch Feb. 23, 1999)	TRSR	University of Stellenbosch, South Africa
Ørsted (launch Feb. 23, 1999)	TRSR	Danish geomagnetic mission
SRTM (Feb. 11-22, 2000) Shuttle mission	BlackJack (JPL)	NASA, DLR, ASI
CHAMP (launch Jul. 15, 2000)	BlackJack	GFZ, DLR
TiungSat (launch Sept. 26, 2000), D.40.19	Experimental GPS	ATSB (Malaysia) S/C built by SSTL. Refractive sounding of the ionosphere
SAC-C (launch Nov. 21, 2000)	BlackJack/ GOLPE	CONAE, NASA
GRACE (launch Nov. 2001)	BlackJack	US-German mission
ICESat (launch 2001)	BlackJack	NASA
PICOSat (launch Aug. 2001) of USAF/SSP	IOX (SMC)	Ionospheric Sounding Experiment measures electron profiles (TEC) with GPS IOX is of TRSR heritage
FedSat (launch 2002), TEC (Total Electron Content)	BlackJack (AstroNav)	Australian mission (CRCSS), single antenna configuration, TEC monitoring
ROCSat-3/COSMIC (launch 2005) Constellation of six microsatellites	BlackJack	Taiwanese-US mission
ACE (Atmosphere Climate Experiment) Cluster of six microsatellites, (launch 2005)	GRAS (Saab Ericsson Space)	ESA mission
MetOp-1 (launch 2005)	GRAS	EUMETSAT/ESA mission
GCOM-A1 (launch 2006)	GRAS	NASDA/Japanese mission
NPOESS (launch 2008)	GPSOS (Saab Ericsson Space)	NOAA/NASA/DoD mission
WATS (Water vapor in Atmospheric Troposphere and Stratosphere), launch 2008	GRAS	ESA mission (constellation of 8 microsatellites)

Table 15: Overview of missions with refractive occultation measurements

The following missions use the BlackJack configuration (built by SpectrumAstro of Gilbert, AZ, for JPL - AstroNav is the SpectrumAstro product name for BlackJack) a new generation of GPS flight receiver and a TRSR successor: SRTM (Feb. 11-22, 2000), CHAMP (launch July 15, 2000), SAC-C (launch Nov. 21, 2000), GRACE (launch 2001), Jason-1 (launch 2001), ICESat (launch 2001), , and VCL (2003). As an integrated service system (offering the functions of tracking mode, occultation mode, and altimetry mode support), the full BlackJack configuration is using a multiple antenna design. - Other missions using refractive radio occultation techniques are: a) MetOp-1 (launch 2005) with GRAS (GNSS Receiver for Atmospheric Sounding), and b) ROCSat-3/COSMIC (Constellation Observing System for Meteorology, Ionosphere and Climate), a collaborative US/Taiwanese six-microsatellite constellation, planned for launch in 2005. ROCSat-3/COSMIC (A.24) will demonstrate - for the first time - the usefulness of microsatellite constellations in obtaining global atmospheric “snapshots” in near-real time. The system has the potential to furnish

valuable data for weather prediction, global climate-change analysis and research, and ionospheric research and prediction.^{95) 96)}

Background: The deployment of GNSS (Global Navigation Satellite Systems) constellations such as GPS and GLONASS with their network of navigation signals made radio occultation techniques possible in the Earth's atmosphere for applications of weather and climate studies. Prior to GPS, there was a general lack of radio sources suited to meet the performance requirements of refractive radio occultation.

The basic functions of the radio occultation technique include: a) reception of signals that have crossed the atmosphere at varying altitudes by means of two antenna arrays; b) acquisition of such signals, also during the rise (ascending) of occultation events, when a signal first appears after crossing dense tropospheric layers causing large dynamics in amplitude and phase; c) signal tracking to provide precise amplitude and phase measurements; d) on-board processing to support occultation-event predictions, also to aid the tracking.⁹⁷⁾

Table 16: Major spaceborne instruments for the global measurement of ozone

- **Monitoring of ozone** (global coverage). Detection of short-term and long-term (seasonal) changes in ozone with measurements of total column amounts and stratospheric and tropospheric profiles of ozone. See also Table 430 for a survey of Shuttle flights with the SSBUV payload.

Atmospheric ozone has several environmental implications, it can be classified according to atmospheric layers (or altitude). Long-term trend measurements are of great importance.

- Stratosphere. About 90% of the atmospheric ozone is contained in the stratosphere. Ozone plays a critical role in absorbing UV radiation and preventing it from reaching Earth's surface. The so-called "ozone hole" is a consequence of stratospheric ozone depletion over the poles of the Earth.
- Troposphere. In the upper and middle troposphere, ozone is a major greenhouse gas, causing inhomogeneous radiative forcing.
- Troposphere. Ozone is an oxidizing power in the lower and middle troposphere.
- Surface air. Ozone is a pollutant, toxic to humans and to vegetation.

- Airborne cloud investigations (properties, interactions, phases, droplets, microphysics, etc.) with radiometers, lidars, radars, hyperspectral imagers, etc. have been performed since the mid 1970s (with most observations in the 1990s) on various scales with a number of instruments, such as: ARES (NASA/JSC), AWR (NOAA), AMMS, CALS and CAR (NASA/GSFC), CVI (MISU), Deimos and MARSS (UKMO), ALEX, OLEX, H₂O-DIAL and Microlidar (DLR), MPR (SNL), CDL (LLNL), ELDORA/ASTRAIA (NCAR/CRPE), LASAL (GSFC), LEANDRE (CNRS/CNES), MCR and MIR (GSFC), MTP (JPL), NAILS (NCAR), OVID (MPIfM Hamburg), RAMS (NASA/NOAA), MAKREL-2 and M2M (Tomsk), APDOR-95 (MIRSL).

- The first project to use in-service aircraft for trace-constituent data collection took place in 1968 with carbon monoxide (CO) measurements made from Lufthansa B-707 aircraft. A vertical CO gradient was observed in the tropopause, this resulted in an estimation of the size of the stratospheric CO sink.⁹⁸⁾ (The same group of researchers employed a manned laboratory inside a container on 10 German cargo service flights between 1981 and 1987 to measure CO).

- The meridional distribution^{99) 100)} of tropospheric ozone concentrations was studied by MP Ae (Max-Planck-Institut für Aeronomie, Katlenburg-Lindau, Germany) on 37 commercial flights between Northern Europe (Frankfurt) and South Africa (Cape Town) during the period 1970-1974.

- GASP (Global Atmospheric Sampling Program) was introduced by NASA in 1975 to measure trace gases on commercial airliners.¹⁰¹⁾ Four B-747 (two Pan American, one United, and one Qantas) aircraft were equipped with instruments to routinely measure ozone, carbon monoxide, water vapor, aerosols, temperature, and horizontal winds. GASP was over the period 1975-1979 with over 6900 flights.
- The Japanese ASE (Automatic Air-Sampling Equipment)¹⁰²⁾ program with instrumentation on a Boeing 747 aircraft between Japan and Australia was introduced in 1993. It lasted until 1996.
- Also in 1993, the EU started its MOZAIC (Measurement of Ozone by Airbus In-Service Aircraft) program. During MOZAIC-I (1993- Sept. 1996), fully automated devices, developed by CNRS (France) and Forschungszentrum Jülich (Germany), were flown on five Airbus aircraft in normal airline service (Air France, Qantas, Lufthansa, Sabena). MOZAIC-II started in Oct. 1996 with the aim to continue the ozone and water vapor measurements, several new instruments were added to measure CO and NO_y. Between Sept. 1994 and Dec. 1997, 7500 flights (54,00 flight hours) were made in the MOZAIC program over the continents (Europe, North America, Asia, South America, and Africa) and the Atlantic Ocean. A MOZAIC-III program is currently being carried out in the Fifth Framework Program of the EU.^{103) 104)}
- NOXAR (Nitrogen Oxides and ozone measurements along Air Routes)¹⁰⁵⁾ was conducted aboard 540 flights of Swissair B-747 aircraft in the period from May 1995 to May 1996. The instruments recorded data at a temporal resolution of 3s.
- Another German program, CARIBIC (Civil Aircraft for Remote-Sensing and In-Situ-Measurements in Troposphere and Lower Stratosphere Based on the Instrumentation Container Concept), started in 1996.

1.1.6 Sounding of the Ionosphere

Ground-based echo sounding of the ionosphere has been conducted since about the 1920s to obtain information about the upper atmosphere and the effects of solar emissions. Spaceborne soundings of the ionosphere started very probably with the launch of Alouette-1 in 1962.

- **Topside sounding.** The term refers to RF (Radio Frequency) sounders looking from a LEO spacecraft into the nadir direction for ionospheric electron density observations. Other ionospheric parameters such as TEC (Total Electron Content), critical frequency (f_oF_2) and F2-layer peak height, plasma temperature, and ion composition may be derived from the topside ionograms (Note: the ionospheric F-layer is extending from about 160 km to about 1000 km with a peak electron concentration around 250-300 km altitude). The ionosphere below the peak electron concentration is referred to as bottomside ionosphere, while the outer part of the ionosphere, extending to about 2000 km (Note: at altitudes below 2000 km in altitude the plasma is simply part of the “ionosphere”), is referred to as the topside ionosphere. A sounder, installed onboard a LEO satellite (800-1000 km) and practically immersed in the medium it is measuring, is able to see only the uppermost portion of the

ionosphere down to about the peak electron height, i.e., the topside ionosphere; hence, such a sounder is referred to as a “**topside sounder**.” 106) 107) 108)

The Canadian spacecraft Alouette-1 (launch Sept. 29, 1962 from VAFB) can be regarded as the first satellite (with a circular orbit of 1000 km altitude and an inclination of 80.5°) carrying a topside sounder to investigate the ionosphere (Canada/USA cooperative venture). The primary purpose of the Alouette-1 mission was to investigate the geographic, seasonal, and diurnal properties of the topside ionosphere up to 1000 km in altitude. The Alouette-1 swept-frequency sounder revealed that an equatorial anomaly extends high into the topside ionosphere; it also demonstrated its usefulness in observing HF electron resonances. The Alouette-1 ionospheric sounder had the following parameters: Frequency range of 1-12 MHz, transmitter power of 100 W, pulse width of 100 μ s, pulse repetition frequency of 62 Hz, and a frequency sweep rate of 1 MHz/s. In a supporting experiment, an untuned VLF receiver operated in the range of 400 Hz to 10 kHz. The VLF receiver permitted the measurement of relative ion abundances in conjunction with the sounder. A worldwide network of 22 ground receiving stations collected the sounding data of Alouette-1 and -2. 109) 110)

Alouette-2 followed in 1965, also with a topside sounder. 111) Other spacecraft in the early era of spaceflight of countries or agencies with various techniques of topside sounding implementations were: Explorer-20 of NASA (launch Aug. 25, 1964), the basic sounder instrumentation comprised a two-frequency transceiver coupled to an electrically short dipole antenna (three transceivers were used for sounding at six fixed frequencies between 1.5-7.22 MHz); Explorer-22 of NASA (launch Oct. 10, 1964); ISIS-I (International Satellite for Ionospheric Studies-I) of NASA with a launch in 1969 (the ISIS program was actually an extension of the Alouette program); Cosmos-381 (launch in 1970) of the Soviet Union; ISIS-2 of NASA (launch April 1, 1971); ISS-A (Ionospheric Sounding Satellite-A) of NASA with a launch in 1976; ISS-B of NASA (launch Feb. 16, 1978); EXOS-B (Exospheric Satellite-B or Jikiken) of NASDA (launch Sept. 16, 1978); ISEE-1/-2 of NASA/ESA (launch Oct. 22, 1977); Intercosmos-19 of the Soviet Union (launch Feb. 27, 1979); EXOS-C (Ohzora, launch Fe. 14, 1984) of NASDA; Cosmos-1809 (launch Dec. 1986) of the Soviet Union; Coronas-I of Russia (launch March 2, 1994 from Plesetsk), and the orbital MIR Space Station (the topside sounder was installed on the Priroda module in 1998).

Topside sounding from a satellite reveals the response of the ionosphere to disturbances such as a geomagnetic storm. The pulses emitted by the sounder on consecutive frequencies are reflected on different heights depending on electron density height distribution. The time delay dependence of emitted pulses on the frequency is called the height-frequency characteristic of the ionosphere, referred to as the ionogram. With the help of a special algorithm, which takes into account the propagation characteristics of electromagnetic waves in magnetized plasma, the measurements are transformed into density height distributions from the satellite altitude down to the maximum F2-layer density distribution, which is usu-

109) Note: Swept-frequency sounding is a technique in which a measurement is made of the frequency shift, phase shift, or time delay between the transmitted signal and its echo. Because of the Earth’s magnetic field, the ionosphere is birefringent with the result that a transmitted electromagnetic wave normally splits into two characteristic waves which travel independently at different velocities and different polarizations. These are called the ordinary (O) and the extraordinary (X) waves and are typically elliptically polarized. As the sounding frequency is increased, the electron number density required to reflect the transmitted signal increases until reflection occurs at a region or height of maximum ionization. Above the critical frequency corresponding to the electron number density at the peak of the F2-layer, reflection can no longer take place and the ionosphere becomes transparent to the sounding signal.

110) C. A. Franklin, M. A. Maclean, “The Design of Swept-Frequency Topside Sounders,” Proceedings of the IEEE, Vol. 57, No 6, June 1969, pp. 897-929

ally located at altitudes of 250 to 350 km.¹¹²⁾ In equatorial regions, especially in geomagnetically disturbed conditions, the F2-layer peak height may extend to altitudes of 500 km and even more.

Direct observations of ionospheric features are crucial for various applications in the fields of communications, navigation, early warning, radar, etc. - In spite of the numerous early missions, topside global sounding of the ionosphere has not become an operational service at the turn of the 21 century, rather it can still be put into the experimental category of missions.

- Possible future applications of topside ionospheric monitoring may involve the capability to diagnose the effect of anomalous atmospheric electric fields that penetrate into the ionosphere. The data analysis from the topside sounder on the Intercosmos-19 (1979) spacecraft showed strong variations in the vertical structure of the ionosphere over regions of impending earthquakes.¹¹³⁾ The ionosphere rises over a seismic active region forming a dome of density depletion. One of the main sources of atmosphere-ionosphere modification over the regions of preparing earthquakes is the emanation of various gases (radon, hydrogen and helium) from the ground as well as sub-micron aerosols. These may lead to the changes in the electrodynamic properties of the atmosphere-ionosphere that can be observed by the topside sounder.

- The COMPASS microsatellite (launch in fall of 2001) of IZMIRAN is a new topside sounding mission dedicated to the study of the structure of the geodynamic processes (in particular above deep tectonic faults and earthquake regions). The sensor complement of the mission employs ionospheric tomography (monitoring of electromagnetic fields of various intensities and frequencies as well as heat distributions). The combined measurements are processed and analyzed in search of possible earthquake indicators.

- Hyperspectral imaging of the global ionosphere is provided by the HIRAAS (High-Resolution Airglow/Aurora Spectroscopy) instrument package of NRL flown on the ARGOS satellite of DoD (launch Feb. 23, 1999, M.1). The imagery of the ionosphere obtained is "hyperspectral" at wavelengths from 50 to 310 nm. The HIRAAS, GIMI (Global Imaging Monitor of the Ionosphere) and EUVIP (Extreme Ultraviolet Imaging Photometer) instruments on the ARGOS S/C provide a powerful remote sensing exploration of the global ionosphere. This unusual combination of hyperspectral imagers and imagers provides a unique database of global structure and variability of ionospheric structure.

1.1.7 Some Instrument/Observation Techniques

- TDI (Time Delay Integration) is a concept of increasing the effective dwell time of CCD detector arrays in the pushbroom imaging mode. In scanned infrared imaging systems, TDI is one of the most important functions performed by CCDs. It was developed along with the early CCD technology at several places in the US industry and at NRL (DoD) in the later 1970s as well as at RSRE (Royal Signal and Radar Establishment, Malvern, UK) in 1982. RSRE introduced TDI into an infrared detector system by the name of SPRITE (Signal Processing In The Element). The TDI technique refers to a cumulative exposure concept of each ground image line by a CCD detector array (or any equivalent array). In TDI operation, signals generated by a moving scene-segment in successive detectors are sequentially delayed and added to the CCD. The main objective is to improve the SNR (signal-to-noise ratio) value which is one of the most important issues for high resolution imaging. [Since the total detector noise is given by the root mean summation while the total sig-

113) S. A. Pulinets, "Strong Earthquake Prediction Possibility with the help of Topside Sounding from Satellites," *Advances in Space Research*, Vol. 21, No. 3, 1998, pp. 455-458

nal is given by a simple sum, an increase in SNR equal to the square root of the number of detector rows is obtained].^{114) 115) 116)}

Spaceborne instruments with TDI implementations are: The SeaWiFS instrument of SeaStar (the renamed OrbView-2 mission, launched Aug. 1, 1997), the ISIR sensor of NASA/GSFC flown on Shuttle flight STS-85 (Aug. 7-19, 1997), the OSA instrument of the Ikonos-2 satellite (launch Sept. 24, 1999), BGIS 2000 of QuickBird-1 (launch Nov. 20, 2000 - launch failure), PIC-2 of the EROS-B satellite program of ImageSat International, Cayman Islands - with a planned launch EROS-B1 in 2002/3), and MSRS (Multi-Spectral high Resolution System) of the Diamant satellite of OHB-System, Bremen (launch 2003) - are examples of more recent TDI implementations in 2-D CCD line-array technology in the visible range of the spectrum. Note: For extrinsic detector arrays (such as silicon detectors in the visible range) there are two possible observation approaches: TDI or "staring array." (see also O.3.6)

- Introduction of polarimetric measurements in the optical and microwave (radar) regions of the spectrum (retrieval of scattering matrix).

- Polarimetric SAR (microwave): In addition to measuring the amplitude of the radar return from a target, a polarimetric radar measures the relative phase difference between the four linear polarizations. This allows calculation of the target scattering matrix that can be used to optimize the polarization combination of radar for various applications.¹¹⁷⁾

First airborne radar (SAR) polarimeters started to be flown in the time frame 1988 to 1990 with such instruments as C/X-SAR (CCRS), ARMAR (NASA/JPL), DO-SAR (Dornier), HUTSCAT (HUT), MMW-SAR (MIT/LL), NUSCAT (NASA/JPL), P-3/SAR (ERIM), IMARC (NPO Vega), and RAMSES (ONERA). First spaceborne polarimetric data were obtained from the L/C-band SAR (NASA/JPL) of the SIR-C/X-SAR Shuttle missions (SRL-1 in April 1994, SRL-2 in Sept/Oct. 1994). See also Table 8.

- Polarimetric radiometry: Refers to microwave and optical observations and interpretation of polarized microwave/optical emission from natural surfaces. The technique represents an extension of the measurement of vertically and horizontally polarized microwave/optical brightness temperatures by considering, in addition, the third and fourth Stokes parameters. Collectively, the four Stokes parameters provide a complete characterization of Gaussian-random electromagnetic field. - On the airborne side, there is PSR (Polarimetric Scanning Radiometer), a multi-channel conical-scanning instrument of NOAA/ETL and Georgia Tech, flown since 1997, providing fully polarimetric imagery in the microwave and optical regions. POLDER on ADEOS (launch Aug. 17, 1996) is an example of a passive spaceborne polarimetric imaging radiometer in the optical region.

- Introduction of FTS (Fourier Transform Spectrometer) technology in sensor development, usually in combination with an interferometer (Michelson, Sagnac, Fabry-Perot, etc.) for the measurement of the composition of the atmosphere (trace gases, air pollution monitoring, monitoring of accidental releases of toxic gases at industrial plants, etc.). See Tables 17 and 18 as well as chapter O.9. The first spaceborne FTS instrument [sometimes also referred to as FTIR (Fourier Transform Infrared) spectrometer, due to the fact that most observation occurs in the IR region] flown was IRIS on Nimbus-3 (launch April 14, 1969) and on Nimbus-4 (launch April 8, 1970), followed by SI-1 (also referred to as SI-GDR) and SI-2 aboard the USSR satellites Meteor 25 (also referred to as Meteor-Priroda-2, launch May

15, 1976) and Meteor 28 (also referred to as Meteor-Priroda-3, launch June 29, 1976).¹¹⁸⁾ ATMOS of NASA/JPL was an FTS sensor flown on the Shuttle (STS-17) in 1985. Mark-IV of JPL collected first ground-based spectra in April 1985, in 1987 the sensor was flown on a balloon and in aircraft campaigns. The interested reader should also consult the following reference.¹¹⁹⁾

The first FTS instrument to be flown in GEO is GIFTS (Geosynchronous Imaging Fourier Transform Spectrometer) on EO-3 (Earth Observing-3), a NASA technology demonstration mission with a planned launch in 2004. The GIFTS measurement concept combines a number of advanced technologies, including LFPA (Large-area format Focal Plane detector Array) and a compact, light-weight Fourier Transform Spectrometer (FTS). The GIFTS design offers high sounding resolutions, about 4 km (IR) vertical and 1-2 km (VIS) in the horizontal direction, for temperature and water vapor profiles. Dynamic observations of temperature, water vapor, and wind enable a better understanding of climate physics, hydrology and the water cycle, the transport of chemical species, and weather processes.

Table 18: Survey of spaceborne Fourier Transform Spectrometer (FTS) instruments

- **TDLAS (Tunable Diode Laser Absorption Spectrometer).** TDLAS is an alternate technique of measuring atmospheric trace gases. The in-situ measurement technique makes use of the existence of rotational-vibrational molecule transitions in the mid IR spectrum and monitors a single absorption line. The airborne instrument FAST (Frequency-modulated Absorption Spectroscopy by TDLAS) of MPIC (Max-Planck-Institut für Chemie) of Mainz, Germany, flown since 1992, is an example of the TDLAS technique.
- **Wedge Imaging Spectrometer (WIS) technology.** WIS is a spectral separation technique in which the spectral separation filters are mated to the detector array to achieve two-dimensional sampling of the combined spatial/spectral information passed by the filter. The technique obviates the need for a complex aft-optics assembly; it was developed by Hughes SBRC and sponsored by ARPA (introduced in 1992, see chapter P.207). The technology (hyperspectral imaging in the VNIR and SWIR regions) was initially flown on airborne sensors (WIS). It is also employed for the spaceborne sensor AC (Atmospheric Corrector) of the EO-1 mission (launch Nov. 21, 2000).
- **On-board sensor calibration.** The goal of any calibration procedure is to determine a functional relationship between the target source flux and the sensor output signal. Instrument calibration provides a means for consistent long-term data set interpretation by reducing the assumptions to be made. - The very early spaceborne instruments (cameras) didn't provide a calibration capability. But the need for on-board calibration became evident from the very start of regular observations. Today's sensor calibration involves usually comparing the detector of a particular spectral range against a known reference. For the VNIR region, a calibration source may be internal lamps or the sun (external source). In the infrared region, a suitable calibration reference may be an internal black body or an external source like deep (cold) space that may be viewed periodically. A calibration 'period' may be a scan sequence, each orbital eclipse period, the pass over a dedicated ground calibration site, or it may be a month or more, depending on need or opportunity. Some sensors employ several calibration techniques (for instance: GOME on ERS-2 retrieves ozone distributions by exploiting the traditional backscatter calibration approach, as well as by differential optical absorption spectroscopy). The ETM+ sensor on Landsat-7 uses three independent on-board calibration systems [the two new systems are: FAC (Full Aperture Calibrator),

and PAC (Partial Aperture Calibrator)], representing a significant step forward in absolute radiometric calibration accuracy.

- Another (rather costly) method of data calibration occasionally employed is that of airborne underflights of spaceborne missions. Many spaceborne sensors (in particular since the 1980s) have their airborne predecessors, which makes underflight calibrations a natural extension for independent parameter checks. Very important observations of a mission (proving a concept, etc.) are usually verified with parallel campaigns to compare spaceborne, airborne and ground-based observations. An example of such a scenario are the SRL-1/2 (Space Radar Laboratory) missions in 1994 (see SRL Campaigns). ESA's ERS-1 mission is another example of extensive underflight campaigns. A very special instrument among the airborne underflight sensors is NASIC (P.148), operated by NASA/GSFC since 1988 (built in 1980), capable of providing independent calibration data for several long-term satellite sensors, such as: AVHRR (on several NOAA satellites), TM (Landsat), VAS (GOES satellites), and CZCS (Nimbus-7).

- Adaptive optics.^{120) 121) 122)} A technology referring to the physical modification of components of an optical system for the purpose of compensating for the distortion of electromagnetic radiation (refractive index variations) as it passes through the turbulent atmosphere and the optical system. Although the problem of aberration was long recognized in the field of optics (in particular in astronomy), two initial solutions were proposed by H. Babcock (1953, USA) and by V. Linnik (1957, USSR). They independently published papers with the conjecture that the aberrations caused by atmospheric turbulence could be corrected in real-time by (what became later known as) an "adaptive optical system." Essential elements of an adaptive optical system are a high-speed wavefront sensor (sensing the turbulence-induced aberrations), a thin flexible mirror whose surface can be electronically controlled to correct for aberrations, and a computer controller that converts the wavefront measurements into deformable mirror commands. The mirror is physically deformed in real-time by a large number of piezoelectric actuators. The device that measures the distortions in the incoming wavefront of light is called a "wavefront sensor" (analysis of wavefront, estimation of the shape of the original wavefront, derivation of the correction signals for the deformable mirror). High update rates are an essential ingredient for distortion removal.

Examples of early installations with adaptive optics technology in the field of astronomy: In 1997, a 3.5 m telescope by the name of ALFA (Adaptive optics with a Laser For Astronomy system), a cooperative project of MPIA Heidelberg and MPE Garching, was installed at the Calar Alto Observatory in Almería (Southern Spain). In 1997/8, some demonstrations of the adaptive optics technique were conducted with MMT (Multiple Mirror Telescope) at the University of Arizona in the field of astronomy.¹²³⁾ A 10 m telescope of the Keck Observatory in Arizona started operations in fall of 1999, using an adaptive optics system.

The technology of adaptive optics is also being considered for Earth observation instruments (looking from space toward Earth). The RedEye (Regional Environmental Dynamics Active-aperture Infrared Imager) instrument proposed for NASA's EO-3 mission (Earth Observing-3, launch in 2003) in geostationary orbit demonstrates a deformable mirror design to correct for residual wavefront errors in a large segmented aperture optical system. However, as of spring 2000 the RedEye proposal was not accepted by NASA management.

Not all adaptive optics implementations are used to correct for atmospheric turbulence. The technique is also being used to compensate in general for optical aberrations in the de-

sign of very small and light-weight optical systems to improve the optical characteristics (including focal length, aberrations, removal of misalignments, improvement of wider FOV, etc.) of a system subjected to space environment variations. Not all adaptive optics implementations use piezoelectric actuators in combination with computers for mirror control. Newer adaptive optics instrument designs employ so-called MOEM (Micro Optoelectronic-Mechanical) devices (tiny chips), able to physically react to a non-normal situation, for micro-mirror control (i.e., actuation) at high update rates (about 1 kHz). A star tracker with these capabilities is being developed at AFRL and planned to be flown on the TechSat-21 mission of DoD (the star tracker has a pointing accuracy of better than 0.20 arcsec).¹²⁴⁾

- MEMS (Micro-Electro-Mechanical System) - also known as “microsystems” in Europe or “micromachines” in Japan. MEMS technology first emerged in the late 1960s and early 1970s. MEMS devices, tiny machines virtually invisible to the naked eye (they range in size from a few μm to mm), fashioned largely from silicon with techniques adapted from the microchip industry, are able to **“touch” the physical world and act upon it**. There is a trend toward complete microsystems - merging sensing, actuating, computing and communications. Microtechnology represents essentially a synergetic combination between thin film technology, semiconductor technology, silicon micromechanics, ultra precision engineering, LIGA technique, laser lithography, and several technologies for packaging and assembly. The new microsystems offer enhanced levels of perception, control, and performance (nanoscale design, low power quantum electronics, high bandwidth photonics, etc.). The evolving list of MEMS features includes: provision of inputs and outputs for information systems, permitting multiple and mixed technology integration (CMOS/MEMS integration, integrated trench technology, etc.); in particular, there is the ability **to sense and measure changes of physical parameters on the micro-scale (atomic) level**, orders of magnitude better, than traditional techniques. At the end of the 1990s, the technology of miniaturization experiences a tremendous growth. It is destined to become a natural pick for a divers number of applications in all fields, in particular for the design of new instruments in the space industry. The potential of MEMS as an enabling technology has a definite impact on new designs, similar to the impact of integrated circuits for the electronics industry during the 1960s and 1970s. Some examples of space applications are:^{125) 126) 127) 128)}

- MEMS technology is being applied to a variety of optical applications, ranging from adaptive mirrors to integrated optical benches, grating spectrometers, optical scanners, fluid pumps, etc.
- MEMS technology is making possible the development of many different types of thermal sensors for spaceborne instruments and operational hardware. At the start of the 21st century, these are becoming available with high performances and in the case of arrays (linear or matrix) make possible a new class of imaging and spectrographic instruments.
- Integrated microaccelerometers and gyros
- Uncooled infrared detectors
- MEMS technology is used to form miniature antennas for millimeter-wave applications
- MEMS technology is applied for distributed sensors and actuators (closed-loop control is a viable option)
- MEMS is being used for electromechanical signal processing

128) M. Lacher, W. Ehrfeld, “Microproducts for Space Applications,” Proceedings of the 2nd International Conference on MicroNanotechnology for Space Applications, Apr. 11-15, 1999, Pasadena, CA, Vol. 1, pp. 4-25

- In the early 1980s, the Institute of Microstructure Technology of KfK (Kernforschungszentrum Karlsruhe (Nuclear Research Center, Karlsruhe, Germany) initiated/developed a micromachining technology by the name of LIGA [Lithographie, Galvanoformung und Abformung (lithography, electroplating and moulding)]. LIGA is widely used throughout industry and the research community for advanced MEMS applications. LIGA is a three-stage process which can be used for the manufacture of high aspect ratio, 3-D microstructures in a wide variety of materials (e.g. metals, polymers, ceramics and glasses). By using the penetrating power of x-rays from a synchrotron, LIGA allows the fabrication of structures which have vertical dimensions from hundreds of microns to millimeters and horizontal dimensions which can be as small as microns. SUMMiT (Sandia Ultra-planar Multi-level MEMS Technology) is another fabrication process developed by SNL (Sandia National Laboratories).
- MEMS technology is applied to micropropulsion systems.¹²⁹⁾
- In 1993 the term **nanosatellite** was first coined and defined by Siegfried W. Janson, Henry Helvajian, and Ernest Y. Robinson of the Center for Microtechnology at The Aerospace Corporation, El Segundo, CA.¹³⁰⁾ In this paper, the proposed nanosatellite architecture employs MEMS and ASIMs (Application Specific Integrated Microinstruments). The integration of MEMS with microelectronics for data processing, memory, signal conditioning, power conditioning and communications results in stand-alone ASIMs (chip-to-chip wireless integration).¹³¹⁾ ASIMs with silicon or other semiconductor substrate can be applied to S/C systems, i.e. tiny instruments, for such functions as guidance, navigation and control, attitude sensing, attitude control, thermal control primary propulsion, power and communication. In this concept, the nanosatellite denotes a S/C built almost entirely of ASIMs. The silicon satellites are spacecraft that utilize single-crystal silicon wafers for electronic substrates, mechanical structure, thermal control system, and radiation shield.
- Optical (laser) free-space communications. Laser links have the potential to offer much higher transmission rates (up to 10 Gbit/s) for LEO-to-ground communications than conventional TT&C radio frequency (RF-based) links which are limited to rates of about 250 Mbit/s.¹³²⁾ The optical information bandwidth of a signal is only a fraction of the RF carrier frequency, typically 0.1 that of RF systems. Extremely high ‘antenna’ gains with relatively modest apertures are obtained in optical communication systems, resulting in very low carrier power (for instance 60 mW in SILEX data transmissions of 50 Mbit/s over a distance of 42,000 km). The optical spectrum for TT&C applications may range in bandwidth from about 532 nm (563 THz) to about 1550 nm (194 THz), providing for many GHz of information transfer on optical carriers. Another advantage of laser links is that by their very nature, there can be no interference between optical and radio transmissions. The technical challenge of the technology demonstration involves in particular alignment and stabilizing issues, it requires pointing errors of $<10 \mu\text{rad}$ (or $<0.0005^\circ$). This pointing accuracy is several orders of magnitude lower (better) than open-loop pointing of a typical platform. Also, platform jitter caused by the operation of other payload instruments, must be mitigated. Other constraints to be considered deal with eye-safety issues and with weather and atmospheric effects. The optical signals can be greatly attenuated by the weather and the atmosphere. - Numerous applications of optical communication links are envisioned, such as:

129) J. Mueller, I. Chakraborty, et al., “MEMS-Micropropulsion Activities at JPL,” Proceedings of the 2nd International Conference on MicroNanotechnology for Space Applications, Apr. 11-15, 1999, Pasadena, CA, Vol. 1, pp. 175-200

130) Siegfried W. Janson, Henry Helvajian, Ernest Y. Robinson, “The Concept of “Nanosatellite” for Revolutionary Low Cost Space Systems,” Proceedings of the 44th Congress of the International Astronautics Federation, Oct. 16-22, 1993, Graz, Austria, IAF-93-U.5.573

131) S. W. Janson, “Silicon Satellites for 21 st Century Missions,” Proceedings of the 2nd International Conference on MicroNanotechnology for Space Applications, Apr. 11-15, 1999, Pasadena, CA, Vol. 1, pp. 535-544

132) Note: In Feb. 1996, researchers at Fujitsu Laboratories Ltd (Japan) achieved for the first time data rates of 1.1 Tbit/s using WDM (Wavelength Division Multiplexing) technology in an optical transmission experiment over a distance of 150 km (with 50 km amplifier spacing). In the experiment, 55 optical channels in the 1.55 μm range (0.6 nm spacing) were used, each at 20 Gbit/s, for a total data rate of 1.1 Tbit/s.

Space-to-ground, interorbit (LEO-GEO), intersatellite (LEO-LEO or GEO-GEO), or deep space to ground. Some demonstrations are:

- **LCE** (Laser Communication Equipment)¹³³⁾ ¹³⁴⁾, a CRL (Japan) payload flown on ETS-6 (Experimental Test Satellite-6) of NASDA and NTT. Launch of ETS-6 on Aug. 28, 1994. Note: ETS-6 attained a highly elliptical orbit (instead of a planned GEO) due to a failure in the launch vehicle propulsion system. In spite of this misfortune, some LCE experiments were conducted with ground stations in Japan and at JPL.
- **SILEX** (Semiconductor Intersatellite Link Experiment), an ESA experiment built by MMS. SILEX consists of two optical terminals, a LEO and a GEO terminal, namely **PASTEL** (PASSager SPOT de Télécommunication Laser), a LEO terminal on-board SPOT-4 (launch March 22, 1998) on the anti-Earth side of the SPOT platform, and **OP-ALE** (Optical Payload for Intersatellite Link Experiment) a GEO terminal mounted on ESA's geostationary satellite ARTEMIS. ARTEMIS was launched on July 12, 2001. The ARTEMIS downlink to the ground segment at CNES Toulouse uses a conventional radio transmission (Ka-band). See also SILEX under D.37.2.
- **LUCE** (Laser Utilizing Communications Equipment), a Japanese payload (built by NEC) flown on OICETS (Optical Interorbit Communications and Engineering Test Satellite) of NASDA (planned launch in early 2002). OICETS in LEO conducts inter-orbit communications experiments with ARTEMIS of ESA in GEO.
- **Lasercom** (Laser Communication Experiment), an experiment on the AFRL mission TSX-5 and its payload STRV-2 (launch on June 6, 2000), see M.29.

With constantly increasing communication rates, optical systems are also being considered for small satellites. - Apart from governmental/institutional research in the area, a significant driver for the development of advanced TT&C systems is the prospect of commercial LEO communication systems, such as the Teledesic/Celestri constellations which include laser communication crosslinks as part of their baseline design.¹³⁵⁾

- **QWIP** (Quantum-Well Infrared Photodetector). QWIP represents a new infrared photoconductive detection technology (using 2-D focal plane arrays), holding great promise for a variety of infrared imaging applications in the spectral region of 6-25 μm which includes TIR (Thermal Infrared). The technology employs large-bandgap compound semiconductor materials such as GaAs (Gallium Arsenide) and AlGaAs (Aluminum Gallium Arsenide) with different aluminum compositions. The potential advantages of QWIPs (GaAs and AlGaAs) include the use of standard manufacturing methods based on GaAs growth and processing techniques. However, the QWIP technology requires low-temperature cooling for good spectral performance. Note: Infrared detection may also be implemented on QWIP structures operated in photovoltaic mode (as opposed to photoconductive mode). - QWIP structures are intrinsically very fast photodetectors since the re-capture time of optically excited carriers is very short, in the order of a few picoseconds (ps). Besides thermal imaging applications, QWIP structures are also interesting for heterodyne applications, where the high electrical bandwidth results in an improved spectral range of a heterodyne spectrometer. - The first experimental demonstration of 2-D QWIP imaging arrays took place in 1985. First imaging instruments of the QWIP technology are:¹³⁶⁾ ¹³⁷⁾

- The first demonstration model of a QWIP FPA camera with a 128 x 128 pixel array was developed by B. F. Levine and his colleagues at AT&T Bell Laboratories, Murray Hill, NJ, in 1991.

137) B. F. Levine, "Quantum-well infrared photodetectors," Journal of Applied Physics, Vol. 74, No. 8, Oct. 15, 1993, pp. R1 - R81, part of the series: Applied Physics Reviews; it includes an extensive review of the QWIP literature.

- In 1996, JPL/CSMT of NASA and Amber (of Raytheon) demonstrated the QWIP technology with the development of a hand-held infrared camera (256 x 256 pixel FPA of QWIPs to detect radiation at 8.5 μm).¹³⁸⁾
- In 1997, FhG/IAF (Fraunhofer Gesellschaft / Institut für Angewandte Festkörperphysik) of Freiburg in partnership with AIM (AEG Infrarot Module) of Heilbronn, Germany, demonstrated also a QWIP-based camera system (256 x 256 pixel FPA with a peak wavelength of 8.1 μm , the FPA is cooled to 65 K.^{139) 140) 141)} - Note: Objects at room temperature glow brightest in the wavelength range of 8-10 μm). The camera exhibits extremely low noise levels corresponding to NEDT (Noise Equivalent Differential Temperature) of 9.5 mK over the entire array. The research was supported by the German Ministry of Defence. The same camera, with the name of AIM-640Q, is also commercially available.
- A spaceborne QWIP camera, funded by BMDO and built by JPL, is flown on the STRV-1d (launch Nov. 16, 2000) satellite of DERA (UK), to demonstrate the radiation detection performance within the 11-17 μm spectral region (M.25.2.2).
- DOAS (Differential Optical Absorption Spectroscopy).^{142) 143) 144) 145) 146) 147)} A measurement technique of atmospheric spectra, first developed by Dieter Perner at KfA Jülich (now Forschungszentrum Jülich, Germany) in the early 1970s for the analysis of spectral windows. The distinguishing feature of DOAS (as compared to other spectrometers measuring atmospheric constituents) is that it aims to measure differential rather than absolute spectra. This means that broadband absorption or scattering effects arising from aerosols or gases can be separated (in ground analysis) from differential features which are characteristic of the trace gases absorbing in a given window. The distinguishing feature of a DOAS instrument is that it records simultaneously the entire spectrum of a selected spectral window. The DOAS technique was first applied to long-path tropospheric investigations by D. Perner, U. Platt and co-workers. This resulted in an experimental ground-based DOAS-UV and VIS spectrograph installation at KfA Jülich in 1978, Germany (measurement of atmospheric CH_2O , O_3 , and NO_2). Further ground-based DOAS instruments were built. Two airborne instruments, DOAS-VIS, developed by the Institute of Environmental Physics at the University of Heidelberg, and DOAS-UV of MPI for Chemistry (MPICH), Mainz, are flown since Jan. 1991 on a C160 Transall aircraft. A DOAS-type experiment by the name of "Mapping Atmospheric Pollution" was first proposed to ESA in March 1985 by J. P. Burrows, D. Perner, and P. J. Crutzen to fly on the EURECA free-flyer platform (EURECA was launched on STS-46 on July 31, 1992 and retrieved with STS-57 on July 1, 1993).
- First spaceborne DOAS instruments are GOME (Global Ozone Monitoring Experiment)

flown on ERS-2 (launch April 21, 1995) and SCIAMACHY (Scanning Imaging Absorption Spectrometer for Atmospheric Cartography) to be flown on Envisat of ESA (planned launch in Oct. 2001). Since the launch of ERS-2, there are also several ground-based DOAS stations in Europe providing ground truth measurements for GOME and SCIAMACHY. 148)

- ALOS of NASDA (launch 2003, D.3) is the first satellite in Earth observation capable to obtain optical and SAR imagery of the same area (70 km swath) at the same time.
- Supermode acquisition of imagery. The term “supermode” refers to an acquisition process, introduced by CNES for the HRG (High Resolution Geometric) instrument of SPOT-5 (planned launch in 2002), through which an image, sampled at 2.5 m, may be obtained from two 5 m resolution panchromatic images acquired simultaneously, keeping within the same borders as the two 5 m resolution images. See chapter D.37.3.

The new sampling concept of imagery, technically referred to as **quincunx sampling pattern** (an arrangement of five things with one at each corner and one in the middle of an area), employs a linear dual-array CCD detector in the focal plane, offset by one half pixel in one direction and 3.5 pixels in the other to avoid overlapping.¹⁴⁹⁾ This configuration is sufficient to improve the sampling grid without doubling each array’s acquisition rate. The new sampling concept is based on Shannon’s theory of information which states that “the sampling frequency must be equal to or greater than twice the maximum signal frequency” to obtain clean images. A specific image processing software, developed by CNES, is used to reconstruct the final image after three processing steps: interleaving, interpolation and restoration.

- Lightning detection instruments (event-based monitoring). In the early 1980s, the NOSL (Night-time and daytime Optical Survey of Lightning) instrument of NASA/MSFC was flown in the Space Shuttle program on flights STS-2 (Nov. 12-14, 1981), STS-4 (Jun. 27-July 4, 1982) and STS-6 (Apr. 4-9, 1983). This was followed by MLE (Mesoscale Lightning Experiment) on Shuttle flights in the late 1980s (STS-26, Sept. 29- Oct. 3, 1988; STS-30, May 4-8, 1989; STS-34, Oct. 18-23, 1989; STS-32, Jan. 9-20, 1990). The OLS (Operational Linescan System) of the DMSP weather satellite series of DoD is also able to detect lightning activity (data sets exist starting from 1973).¹⁵⁰⁾ An airborne sensor with a capability for lightning detection is LIP (NASA/MSFC, an upgraded instrument as of 1990). A further spaceborne sensor with a capability for lightning detection/distribution is Blackbeard (an RF experiment), flown on ALEXIS of LANL and SNL (launch of ALEXIS April 25, 1993). The OTD (Optical Transient Detector) of NASA/MSFC is being flown on OrbView-1/Microlab-1 (launch April 3, 1995, B.8.1). This was followed by simultaneous observations of optical and RF emissions of lightning activity with the instruments: OLS (Optical Lightning Subsystem) and the RF-System, both flown on the FORTE spacecraft (LANL/SNL, launch Aug. 29, 1997, A.16). The LIS (Lightning Imaging Sensor, NASA/MSFC) is flown on TRMM (launch Nov. 27, 1997, A.31). A further instrument, LMS (Lightning Mapper Sensor) of NASA/MSFC is planned to be flown on the GOES spacecraft series starting with an experimental flight on GOES-O in 2004 (F.4.6).¹⁵¹⁾ The LMS on GOES represents the first lightning instrument to monitor lightning from GEO, permitting the study of the electrosphere over dimensions ranging from the Earth’s radius down to individual thunderstorms. The student-built Emerald microsatellite of Stanford and Santa Clara University (launch in late 2001) as part of UNP (University Nanosatellite Program) flies LDE (Lightning Detection Experiment), a VLF instrument. The objective is to detect electromagnetic radiation and lightning. The ROCSat-2 mission of NSPO (Taiwan, planned launch in 2003) flies the

instrument ISUAL (Imager of Sprite Upper Atmospheric Lightning) with the objective to observe the natural upward lightning discharge phenomenon toward the ionosphere on top of the troposphere.

1.1.8 Cooling Techniques and HTS (High-Temperature Superconductivity)

- Cryocoolers (active cryogenic devices). Depending on the temperatures required, two different cooling technologies are commonly used to actively cool focal planes. These are:

- 1) TEC (Thermoelectric Coolers). The TEC scheme is capable of cooling focal planes to 180 K starting from an ambient temperature of 300 K. TEC instruments are small, lightweight, and, being solid-state, have no vibration. TECs have the main disadvantage of having an efficiency that drops off rapidly with decreasing temperature and tending towards zero around 180 K. - Examples of thermoelectric cooler implementations are: RBV (Return Beam Vidicon Camera) flown on early Landsat spacecraft; GERB (Geostationary Earth Radiation Budget) flown on MSG (Meteosat Second Generation) satellites of EUMETSAT (launch of MSG-1 in 2002);
- 2) Mechanical coolers, such as Stirling cycle engines and pulse tube coolers. They can produce temperatures below 20 K and are more efficient than TECs. However, mechanical coolers are much larger than TECs and can produce vibrations that must be canceled or isolated.

A Stirling cycle engine can operate at very low temperatures [about 5 K to 80 K range, they are usually closed cycle cooler (CCC) based cryostats]. Mechanical cryocoolers compress and expand a gas, usually helium, through heat exchangers, which lowers the temperature. A typical application is the provision of a cold environment for infrared sensor detector systems. - Early cryocoolers in space were rather heavy devices (due to the dewar construction) with relative limited cooling capacities (about 0.5 W) and life times of less than one year. The basic types of cryocoolers in use are: a) the Stirling cycle cooler, b) the Joule-Thomson cryocooler, and c) hybrid designs (of Stirling and Joule-Thomson technologies). The Stirling designs of the 1990s seem to be all of “Oxford cryocooler” heritage, flown on several US and European programs (O.5).

- The Oxford cryocooler ¹⁵²⁾, designed and built by Oxford Instruments Plc., UK, was first flown on the NASA UARS satellite (launch Sept. 12, 1991) to provide cooling for the ISAMS (Improved Stratospheric and Mesospheric Sounder) instrument, a limb-sounding radiometer of Oxford University. Its design cooling power was 0.8 W at 80 K. Its mass about 4.3kg. Two coolers were installed for vibrational balance. Another Oxford cryocooler was part of the NRL HTSSE-II instrument flown on ARGOS (launch Feb. 23, 1999).
- SHOOT (Superfluid Helium On-Orbit Transfer), a NASA/GSFC cooling demonstration experiment, was part of the space shuttle STS-57 mission in June, 1993. ¹⁵³⁾ The experiment objectives included: transfer of superfluid between two dewars in a low gravity environment at different flow rates; operation of two different liquid acquisition devices within the dewars; liquid/vapor phase separation for normal liquid helium as well as superfluid at varying venting rates; accurate mass gauging and flow metering; and autonomous control of the transfer process by an expert system aboard a computer on the Shuttle.
- The CSE (Cryo System Experiment) cooler of Hughes, first flown on STS-63 (Feb. 3-11, 1995), provides 1.2 W of cooling at 65 K, it is the first US-built long life (1.5 years of continuous operation) Stirling cooler to operate in space.
- Pulse tube cooler. A mechanical refrigerator capable of achieving cryogenic temperatures of <20 K in the 0.5-3.5 W cooling capacity range. The principal benefits of a pulse tube

¹⁵²⁾ Oxford cryocooler information provided by Manny Tward of TRW, Redondo Beach, CA

¹⁵³⁾ J. G. Tuttle, M. J. DiPirro, P. J. Shirron, “Liquid/gas phase separators for the Superfluid Helium On-Orbit Transfer (SHOOT) project,” *Advances in Cryogenic Engineering*, 39, 1994, p. 121

cooler are greater reliability and lower cost compared to the Stirling cooler and an order of magnitude lower mass, lower cost, and longer life than the current state-of-the-art coolers. A pulse tube cooler is also more efficient than a TEC-type instrument, however, as a mechanical cooler, it is much larger than a TEC. In addition, mechanical coolers can produce vibrations that must be canceled or isolated.

The NASA Lewis satellite (launch Aug. 23, 1997 - however, the S/C was lost and reentered the atmosphere Sept. 28, 1997) was the first S/C in civil Earth observation featuring pulse tube cryocooler technology (built by TRW) in its HSI (Hyper-Spectral Imager) for low-noise SWIR cooling. Already in 1994, TRW delivered its first pulse tube instrument, built under contract to the Air Force's Phillips Laboratory. Other instruments planned with pulse tube cooling technology are AIRS (Atmospheric Infrared Sounder) of NASA's Aqua satellite (launch in 2001) and TES (Tropospheric Emission Spectrometer) on the Aura mission (launch in 2003).

- Optical cooling by fluorescence is an alternate and new concept in refrigeration that represents possible applications in small cryocooler technology, in particular for infrared devices and spectrometers (O.5.4). The method uses anti-Stokes fluorescence to remove heat from a glass or crystal that is pumped with laser light. A first demonstration instrument by the name of LASSOR (Los Alamos Solid-State Optical Refrigerator) was developed at LANL (Los Alamos National Laboratory).¹⁵⁴⁾ In Oct. 2000, NASA/LaRC awarded to BATC (Ball Aerospace & Technologies Corporation) a contract to develop an optical cryocooler (infrared focal plane demonstrator).¹⁵⁶⁾ Optical cryocooling is a feasible method for cooling focal planes and has a distinct niche in extended solid-state cooling to those temperatures that cannot be achieved efficiently (or at all) by TEC methods. Optical cryocoolers have a clear advantage over mechanical coolers in vibration, ruggedness, EMI (Electromagnetic Interference) and magnetic field, and cooler mass. Nevertheless, they are at a disadvantage to mechanical coolers based on efficiency. Optical cryocoolers have an advantage over TECs in minimum operating temperature, magnetic field, and ruggedness. They are at a disadvantage to TECs in cooler mass, however.

Active cryogenic refrigerators offer an alternative to passive radiators. Active coolers offer greater capacity and provide additional freedom in packaging and locating the sensor on the spacecraft, since there are no preferred orientations or constraints on view factors. These benefits are provided at the expense of fairly high power consumption, added mass, and diminished reliability. Indeed, there is a crossover point in size/mass efficiency: Passive coolers tend to be the better choice for modest heat loads (<1 W) at temperatures above approximately 80 K; active coolers are more attractive for higher heat loads (>2 W) at temperatures of 65 K or colder.

- On spacecraft, focal planes are sometimes cooled with passive radiators, the performance of which is highly dependent on mission parameters and spacecraft configuration. Passive radiative coolers are well developed and provide exceptional reliability for detector arrays. The size of these coolers is, however, governed by the first-order physics of Planck's radiation law. The required minimum area for the radiative surface is governed by the relationship $W = A\epsilon sT^4$, where W is the radiated power, A is the area of the radiator, ϵ is the effective emissivity of the radiator's surface, s is the Stefan-Boltzmann constant, and T is absolute temperature. This relationship can be expressed as $A = W/(\epsilon sT^4)$. Thus, the area of the radiator needed to achieve a given cryogenic temperature depends directly upon the amount of cooling power required and upon the inverse fourth power of temperature. This is a highly nonlinear relationship; for example, it takes four times as much radiator area to reach 60 K as to reach 85 K. Consequently, application of this comparatively straightforward

ward technology is limited to relatively modest levels of cooling power at temperatures of about 65 K or warmer. This is more than adequate for sensors such as MODIS, but passive cooling would be a challenge for a high-resolution pushbroom longwave infrared imager, for example.¹⁵⁷⁾

- Use of uncooled detector arrays in the spectral region of TIR (Thermal Infrared) for surface imaging. The technology employs silicon micromachined microbolometer focal plane arrays. The NASA/GSFC instrument ISIR (Infrared Spectral Imaging Radiometer) demonstrated the potential of the concept on Shuttle flight STS-85 (Aug. 7-19, 1997, see J.7). Note:¹⁵⁸⁾ The first micromachined MBAs (Microbolometer Array) were probably developed in the USA in the late 1980's and early 1990's under DARPA's HIDAD (High Density Array Development) program and built by the Honeywell Sensor and System Development Center. This early MBA had about 80,000 pixels (336 x 240) with an average room-temperature sensitivity ($NE\Delta T$) of less than 50 mK, measured at a 30 Hz frame rate, with f/1.0 optics and a broadband (8-14 μm) filter.

- HTS (High-Temperature Superconductivity), see also "superconductivity" in the Glossary. The characteristics/performance of superconductive electronic devices have exceptionally low loss, high speed, high dynamic range, and low noise. Superconducting materials (in hybrid components, hybrid digital circuits, semiconductors, sensors) are promising to reduce loss by several orders of magnitude at RF frequencies, increasing the sensitivity and precision of signal discrimination in advanced electronic systems. A new detector type, based on SQUID (Superconducting Quantum Interference Device) technology, offers promising results in such applications as absolute magnetic field measurements.

- The first program to demonstrate the operation and survivability of simple HTS electronic components in space was initiated by NRL (Naval Research Laboratory) in 1988 within the framework of HTSSE-I (High Temperature Superconducting Space Experiment I).¹⁵⁹⁾
- The DoD ARGOS satellite (launch Feb. 23, 1999), operated by SMC, carries HTSSE-II (High Temperature Superconducting Space Experiment II) of NRL to demonstrate the performance of superconducting (semiconductors and RF) components at cryogenic temperatures of 70-80 K (see M.1). Reductions in power by several orders of magnitude as well as signal speed increases of an order of magnitude are expected with this technology. HTSSE-I of NRL, with relatively simple HTS devices, the majority being passive components made from a single HTS film, were to be placed in orbit to investigate the durability of HTS in space. However, the DoD satellite with HTSSE-I aboard experienced a launch failure in 1993. Despite the unfortunate loss of on-orbit data from HTSSE-I, the program did conclusively demonstrate that viable and robust HTS microwave devices could be fabricated, packaged and space-qualified. - Note: The HTSSE project started at NRL in December 1988 as a long-term joint venture with other labs/industry [which in turn started CSE (Consortium on Superconducting Electronics) in 1989].
- Another HTS demonstration, namely SUPLEX (Superconductivity Experiment), based on thin-film technology is flown on TechSat/Gurwin-II (launch July 10, 1998), a satellite built by the Haifa-based Technion Israel Institute of Technology. N.20
- A magnetometer based on SQUID (Superconducting Quantum Interference Device) technology is flown on Gravity Probe-B (planned launch for 2002).
- SMILES (Superconducting Submillimeter-wave Limb Emission Sounder) of NASDA/CRL is planned to fly on ISS/JEM in 2005. The superconductive technique enables 3-D global observation of trace gases in the stratosphere in the frequency band of 640 GHz. A heterodyne receiver detects very low level signals in the submillimeter-wave band ra-

diated from trace gases using a sensitive SIS (Superconductor-Insulator-Superconductor) mixer method to perform high-resolution spectral analysis.

- A European consortium by the name of HIFI (Heterodyne Instrument for FIRST), led by SRON (Groningen, The Netherlands), is designing HET (Heterodyne Instrument) to be flown on ESA's FIRST (Far InfraRed and Submillimeter Telescope) satellite (launch 2005-7). HET takes very high-resolution spectra of astronomical objects in thousands of frequencies simultaneously. HET features a large telescope (> 3 m diameter), a large dewar for liquid Helium, and SIS mixers covering the frequency range of 500-1200 GHz continuously, and possibly a Hot Electron Bolometer (HEB) mixer operating at about 1.8 THz.
- SRON is also developing the ESA instrument PIRAMHYD (Passive InfraRed Atmospheric Measurements of HYDroxyl) which features an HTS transition edge bolometer to measure the signal from a spectrally isolated emission line of the OH molecule in the far infrared spectrum of wavelength 84.420 μm .

1.2 Fundamental Science Limits in Space Flight and Earth Observation

All system design is subject to the fundamental limits imposed by the laws of physics, especially those formulated by Kepler, Newton, Maxwell, Airy, Nyquist and Planck.¹⁶⁰⁾

1) Kepler's laws of planetary motion (his first two laws were announced in 1609, the third law in 1619), after Johannes Kepler (1571-1630) a German astronomer, who discovered that the Earth and planets travel about the sun in elliptical orbits.¹⁶¹⁾ Kepler's laws, based on extraordinarily accurate observations of the 16th century Danish astronomer Tycho Brahe, describe the motion of a body subject to gravitational forces - and thus describe a satellite in orbit about Earth, the sun or the moon. Kepler's deduction of the three fundamental planetary laws (which he solved geometrically) were key elements that later enabled Isaac Newton to formulate his theory of gravitational force.

- Kepler's 1st law: A planet orbits the sun in an ellipse with the sun at one focus
- Kepler's 2nd law: A ray directed from the sun to a planet sweeps out equal areas in equal times
- Kepler's 3rd law: The square of the period of a planet's orbit is proportional to the cube of that planet's semimajor axis; the constant of proportionality is the same for all planets.

For a satellite in Earth orbit, the time required to complete one revolution is determined primarily by its mean radial distance. LEO spacecraft with typical altitudes of 700-800 km require about 100 minutes for one orbit. Many Earth observation missions require global coverage (see also chapters 1.7.6 and O.12.1). The laws of orbital mechanics, in combination with the daily Earth rotation, demand a space-time trade-off: a shorter revisit interval implies less dense spatial coverage. Under such constraints, it may not be possible with only one spacecraft to achieve the simultaneity required for fine spatial coverage and short revisit intervals. In this case, a constellation may be the only solution.

2) Newton's laws of motion (first published in the Principia in 1687), named after Isaac Newton (1642-1727), English physicist and mathematician. Newton's laws of motion (two of them were already discovered experimentally by Galileo) describe the response of a body to its own inertia and to forces applied from internal or external sources - relative to an inertial reference frame. Both sorts of forces impact all spacecraft. Examples of internally applied forces are:

¹⁶⁰⁾ Excerpts are reprinted with permission from "Assessment of Mission Size Trade-offs for NASA's Earth and Space Science Missions," pp. 6-12, National Academy Press, 2000, Copyright (2000) by the National Academy of Sciences. Courtesy of the National Academy Press, Washington, D. C.

¹⁶¹⁾ Kepler is considered a founder of modern astronomy, he formulated the famous three laws of planetary motion. They comprise a quantitative formulation of Copernicus's theory that the planets revolve around the sun.

- S/C pointing by the attitude control subsystem. Observation requirements might call for a particular orientation of the S/C along its orbital path.
- In addition to S/C pointing, there may be a requirement for subsystem pointing. This is for instance the case when the solar panels are rotated to keep them facing into the sun for maximum power generation.

In general, instruments that must provide very fine angular resolution require in turn that their host S/C satisfy very stringent angular stability requirements. The unwanted reactive movements generated by these subsystems are in turn offset by reaction wheels or torque rods. - Examples of externally generated forces are:

- All S/C must be launched from Earth. Newton's laws and the characteristics of the available propulsion system impose strict limits on the payload mass that can be lofted into Earth orbit or beyond. These limits are expressed in Newton's second law of motion.
- The solar radiation pressure (a surface force) changes the S/C orbit over long periods of time, depending on S/C mass. The drag in LEO orbits is also a surface force. Both, radiation pressure and drag, represent non-gravitational orbit perturbations.
- Orbital maneuvers. A S/C propulsion subsystem might change the orbital altitude.

3) Maxwell equations (publication of Treatise on Electricity and Magnetism in 1873), named after James Clerk Maxwell (1831-1879) a Scottish physicist. Maxwell's equations describe the behavior of the electromagnetic waves as they propagate in space. Portions of the electromagnetic spectrum are used by all space missions. Observation instruments as well as the communication subsystems for the transfer of data through space must be designed within the constraints of the Maxwell equations. The first and most obvious constraint is that radio waves travel at the speed of light (c , the speed of light in vacuum, is 299,792,458 m/s). Even at this speed, light travel time imposes substantial delays on all communication between Earth and satellites. This is already quite noticeable for two-way GEO communications, it is in particular apparent for deep-space probes. A further consequence of the Maxwell equations is that all radiation gets weaker in proportion to the square of the distance between the radiation source and the observer.¹⁶²⁾ Hence, very distant radiation sources become very faint and therefore require much larger viewing apertures. The system design takes the signal weakening into account through the link budget of the communication system (with corresponding antenna designs and sizes). - The same physical principles as discussed above apply of course also to a satellite's electrical power generating capability.

4) Airy diffraction (ca. 1835), named after George Biddell Airy (1801-1892), an English astronomer. The problem: Observed imagery can never be perfect in the geometrical sense. It is either degraded by geometrical aberrations, which are a function of the lens parameters, and/or by diffraction, which is a physical optics effect. The diffraction degradation is due to the wave nature of light.

The Airy diffraction limit enforces a lower limit on the resolution (or beam width) of any device that radiates or receives electromagnetic energy. The principle applies of course also to all S/C imaging instruments (the resolution of an imaging system depends on the size of the collecting aperture). The diffraction limit requires that the optical aperture diameter must be directly proportional to the satellite's distance from the observed surface. - As an illustration, the optics system on a S/C at GEO altitude (of about 36,000 km) must have an aperture 45 times larger than a similar instrument on a spacecraft at typical LEO altitudes (of about 800 km) to obtain the same surface resolution. In addition, the GEO sensor's internal optical path length also has to grow in proportion to the aperture diameter if similar performance to the LEO instrument is to be obtained. As a consequence, instruments at GEO tend to be larger than their LEO counterparts.

¹⁶²⁾ Note: The "signal weakening" effect is due to the widening cross-sectional area of the light ray as it propagates through space - resulting of course in ever fewer photons per unit area of cross-section, hence, of measurable energy.

Figure 2: Diffraction limit as a function of aperture diameter, GSD and altitude

The diffraction limit on aperture size has deeper implications as well. For any device that sends or receives energy, the size of the aperture must be proportional to the wavelength it uses. The so-called optical spectrum extends from $0.01 \mu\text{m}$ to $1000 \mu\text{m}$ (or 1 mm), i.e., from the UV to the FIR region inclusively. The microwave region (radar) of the electromagnetic spectrum is generally considered from 1 mm to 1m wavelengths. In general, there are at least three orders of magnitude in wavelength between the optical and microwave instruments. Hence, for radar systems the diffraction limit implies apertures in the order of a thousand times larger than their optical counterparts. To meet a given level of performance, an instrument's minimum aperture size is dictated by wavelength and observable distance, it cannot be reduced by technology. Thus, even when a major SAR design goal is smallness, the SAR antenna size cannot be reduced to fit that objective. Any mission that relies on SAR to conduct science observations will continue to require a medium-sized or large S/C platform. - Future distributed (complex and expensive) apertures in special circumstances may to some extent circumvent this limit.

Enhanced performance can be obtained under favorable conditions. For example, a thinned array (also referred to as a sparse array or a sparse aperture) may substitute for a filled array if the viewing objective is relatively sparse. The angular resolution of such a thinned array, however, is governed by the Airy diffraction limit, and by the radiometric sensitivity of the array (proportional to the areas summed of all contributing sub-apertures). Some examples are:

- ESTAR (Electronically Steered Thinned Array Radiometer) a passive airborne instrument developed by NASA/GSFC and the Microwave Remote Sensing Laboratory of the University of Massachusetts at Amherst (P.87). The key feature of a thinned array is that all the required baselines are obtained with fewer antennas than there are spacings.
- The high angular resolution of radio telescopes (in astronomy) is achieved by using the principles of interferometry to synthesize a very large effective aperture from a number of small elements. In a simple two-element radio interferometer, the signals from an unresolved, or "point" source alternately arrive in phase and out of phase as the Earth rotates and causes a change in the difference in path from the radio source to the two elements of the interferometer.

- Each SAR instrument is by definition an aperture synthesis device. The resolution is limited by the synthetic aperture length, and so is the effective received power. Of course, a SAR instrument's antenna is "real."

5) Nyquist frequency (1929), named after Harry Nyquist, a US physicist of Swedish descent and a pioneer in the field of communication theory (1889 -1976). - The Nyquist frequency dictates the minimum number of samples per second, required to transport a given amount of data over a communication channel of certain bandwidth (analog-to-digital conversion begins with sampling, or measuring the amplitude of the analog waveform at equally spaced discrete instants of time). The sample frequency is also determined by how often a point on the surface must be sampled to resolve the variations in the physical processes over time. In general, more information implies more detail but also more data. If those data have to be transferred rapidly, then the data rate must increase in proportion. The Nyquist sampling theorem in its simplest form states that a signal can be uniquely represented by periodic discrete samples whose period is no larger than 1/2 of the signal's inverse bandwidth.

6) Planck's radiation law, named after Max Planck (1858-1947), a German physicist who originated quantum theory. In 1900, Planck formulated an equation to explain the spectral energy distribution of thermal radiation from a perfect absorber (blackbody) and showed that the formulation required a discontinuous process of emission or absorption involving discrete quantities of energy. Planck's radiation law relates the energy of radiation to its frequency ($E=h \times \nu$). The energy E of each quantum, or of each photon, equals Planck's constant h multiplied by its radiation frequency ν .

Within the electromagnetic spectrum the spectral radiance (i.e. energy per unit time, area, solid angle, and wavelength) varies considerably and with it the ability to detect (measure) radiation. In general, photons are considerably more energetic at shorter wavelengths than at longer wavelengths.

All instrument observation techniques based on radiation measurements (there are indeed many instruments in this category) are constrained to Planck's radiation law. Chapter O.4.4 provides some information as to the radiation detection limits in the various spectral ranges. To illustrate the spectral energy distribution, let us consider three imaging instruments on the same spacecraft, all looking into the same footprint, with each instrument observing incoming radiation in a different spectral range, namely:

- The VIS range (0.4 - 0.7 μm) with photon energy levels of 3.1 - 1.8 eV
- The FIR range (10 - 1000 μm) with photon energy levels of 124 - 1 meV
- The MW range (1 mm - 1 m) with photon energy levels of 1 meV - 1 μeV

The photon energy levels for each spectral range decrease practically by three orders of magnitude from VIS to FIR and again from FIR to MW. This vast photonic energy range of 10^6 puts in particular great demands on the detector technology in the microwave range to measure such minute energy levels and to discriminate between signal differences.

1.3 Spacecraft Systems

- Spacecraft design. Early satellites featured custom designs (in shape, size, etc.) to suit the requirements of a particular mission. It meant continued change for the S/C builders to incorporate general support functions over and over again along with specific mission instruments. The availability of a standard S/C bus (for a particular observation capability) was practically unknown until the end of the 1970s. The Magsat mission (launch Oct. 1979), a dual-spin satellite, demonstrated to NASA in particular the usefulness of a general-purpose bus for science applications. The bus could support a variety of bolt-on experiments. The concept has been used extensively ever since. - Integration of flight hardware and sub-systems has become an important aspect of modular design. Introduction of such items/concepts as: GaAs solar cells, light-weight composite materials, multi-purpose platforms.

Satellite design lives have improved considerably they are now approaching seven to ten years (depending on applications), mini- and microsatellites. In the 1990s, onboard processing is becoming a service.

Spacecraft design (for Earth observation) has experienced interesting trends. Early space-age satellites were small due to the limitations of launch capabilities. The current classes of microsatellites (10 - 100 kg) and minisatellites (100 - 500 kg) are a fitting description for these early space-age satellites (only with regard to mass). As the space age progressed into the 1970s and 1980s, the capabilities of launch vehicles increased constantly. Hence, satellites became much larger and much more complex. In parallel, electronics became much more dense, many subsystems could be combined into a single instrument on a satellite. The new complexity, along with its demands for reliability and quality assurance, had to be managed, generating bureaucracy and large organizations. As a consequence, overall creativity suffered considerably while costs increased rapidly. It meant a reduction in launches with longer in-between periods. Large projects like ISS, EOS, and Envisat encountered planning (and re-planning) phases alone that came close to a decade. For the experimenter, it meant a reduction in flight opportunities for observations as well as a reduction in technology advances.

Organization	S/C Bus	Mission
NASA	MMS (Multimission Modular Spacecraft) SMEX (Small Explorer Program) S/C bus SMEX-Lite	SMM, launch Feb. 14, 1980 SAMPEX, launch Jul. 3, 1992 Triana, planned launch in 2004
ESA	PPF (Polar Platform) bus, based on an enlarged version of the SPOT Mk2 bus AMM (Advanced Microsatellite Mission) platform	Envisat, launch 2001 Metop-1, launch 2005
CNES	Spot Mk1; Mk2; and Mk3 bus; Proteus (Alcatel Space), mass of 100-500 kg	SPOT-1 to 3, ERS-1/2; SPOT-4; SPOT-5; Jason-1
SSTL (UK)	MicroBus since UoSAT-3 and -4 (launch Jan. 22, 1990); MiniBus since UoSAT-12	UoSAT-1, launch Oct. 6, 1981 UoSAT-12 launch, Apr. 21, 1999
Spectrum Astro	SA-series platforms	MSTI-1 to -3, (1992 to 1996) DS1 (launch Oct. 24, 1998)
OSC	MicroStar platform (payloads up to 68 kg), mission life between 3-5 years	OrbView-1 (Microlab), Apr. 3, 1995 QuikTOMS, planned launch in 2001
Astrium GmbH Germany	1) FLEXBUS (minisatellite bus); S/C mass of 100-1000 kg, power of 150-1000 W average 2) MiniFlex bus, S/C mass of 80-250 kg	CHAMP, launch July 15, 2000 GRACE, planned launch in 2001
ASI	1) PRIMA (Reconfigurable Italian Platform for Multiple Applications) of Alenia Aerospazio. Support of payload masses up to 1000 kg 2) MITA (Minisatellite for Advanced Technology) of Carlo Gavazzi Space.	RADARSAT-2, planned launch in 2003 MITA S/C launch Jul. 15, 2000
Stanford University	SQUIRT (Satellite Quick Research Testbed)	ORION, planned launch in 2001
Astrium Ltd., UK	Snapdragon (a deployable bus)	TerraSAR-L1 (launch in 2006)
CNES	Myriade microsatellite bus for missions of <120 kg	DEMETER (launch in 2003), PARASOL and Microscope (launch in 2004), Picard (launch 2006)

Table 19: Introduction of some S/C bus designs

A rethinking of the situation started with the re-invention of microsatellites in the early 1980s. SSTL [Surrey Satellite Technology Ltd (University of Surrey, UK)] was such a pioneer of microsatellite design, including a modular and flexible platform (MicroBus), instruments, looking for new concepts in functionality, services, and cost reductions. Miniaturization techniques of solid-state electronics, sensors, optics, actuators (i.e. miniature mechanisms), etc., are important enabling factors in microsatellite design. Short development times from project approval to S/C launch were the result. This new approach seems to gain momentum, everywhere. There is also a realization that small-project financing can easier

find support in tight budgets, this applies to government sponsorship of research projects as well as to the commercial sector. Calculated risks are being taken again. Many organizations are ‘re-organizing’ to improve the conditions for innovation and creativity. The future seems to have room for microsatellites as well as for larger-class satellites, depending on applications.¹⁶³⁾

The early microsatellites of the 1980s were simple S/C, they were for instance built without a propulsion system, due to the cost and complexity of such a system. Attitude control was typically performed using magnetic torquers and gravity stabilization, at a later time reaction or momentum wheels were introduced. Also, propulsion for attitude control using tiny thrusters could be implemented using cold pressurized gas. However, for orbit changes, such a cold gas system remained simply too inefficient. - Small satellite projects have also small budgets. Thus, by their very nature, they depend on launch opportunities as secondary payloads which are offered by larger satellites. As a consequence, a microsatellite project has only the choice of taking the same orbit of the main satellite payload. - In the late 1990s the miniaturization technology is considered viable for integration of electric propulsion systems onto small satellites - to obtain orbit maneuverability. Examples: STRV-1a (launch June 17, 1994) a microsatellite of DERA (S/C mass of 52 kg), made flight tests of the xenon gas flow control system, developed for the UK-10 IPS (Ion Propulsion System), with associated solenoid valves, orifices, and valve actuating electronics (M.25.1.1). Deep Space 1 (launch Oct. 24, 1998) a minisatellite of NASA/JPL with a mass of 490 kg, carried IPS (Ion Propulsion System) to demonstrate deep space propulsion. UoSAT-12, a minisatellite of SSTL (launch April 12, 1999, S/C mass of 325 kg) carries an electric propulsion system, a 100 W resistojet, which uses nitrous oxide as its working fluid.

Launch Date	Nanosatellite	Comment
Nov. 3, 1997	Sputnik-II, built by French students from the l'Aeroclub of France and staff from the Russian Aeronautical Federation	A S/C of only 3 kg deployed from the MIR space station (with VHF-FM beacon transmitter)
July 7, 1998	TUBSAT-N and -N1 of TU Berlin, Germany	A dual underwater/space launch of data collection satellites
Jan. 27, 2000	ASUSat-1 (Arizona State University)	S/C mass of 5.9 kg (launch on JAWSAT)
June 28, 2000	SNAP-1 of SSTL (UK) and an academic team of Surrey University	S/C mass of 6.5 kg. SNAP-1 was deployed from the Nadezhda mother ship
Nov. 21, 2000	Munin of IRF Sweden (S/C mass of 6 kg)	Space science and space weather activity,
Launch Date	Picosatellite	Comment
Jan. 27, 2000	All picosats were ejected from OPAL of Stanford University (as mother ship) StenSat, of amateur enthusiasts Artemis, of Santa Clara University PICOSAT1.0, a tethered 2 S/C system from the Aerospace Corporation	No ground communication with StenSat No ground communication with Artemis Communication established with ground and in cross-link
July 19, 2000	PICOSAT1.1, a tethered system from the Aerospace Corporation was launched and flown on MightySat II.1 (as mother ship)	Each PICOSAT has a mass of 0.275 kg. The system will be ejected from MightySat II.1 one year after launch.

Table 20: Chronology of early nanosatellite and picosatellite launches

At the start of the 21st century, the spectrum of microsatellite services is by all means as impressive as that of their bigger brother satellites, but at considerably reduced costs.¹⁶⁴⁾ Overall, microsatellites experienced an impressive evolution from flying gadgets to real and advanced service providers. In fact, microsatellites make it possible to open up new fields of services previously considered too expensive (in particular technological missions are in this category). As a consequence, the space agencies as well as the military establishments

164) A. L. Lew, B. Q. Le, P. D. Schwartz, et al., "Microsatellites: An Enabling Technology for Government and Commercial Aerospace Applications," JHU/APL Technical Digest, Vol. 22, No 2, 2001, pp. 124-134

of the world are re-evaluating their programs, in favor of smaller systems, to offer a solution for ever tighter budgets.

- S/C instrument mounting. A cartwheel mounting configuration was realized in TIROS-9 (launch Jan. 22, 1965). For the first time, the two TV-WA cameras were mounted into the sidewalls of the S/C cylinder, 180° opposite to each other. This cartwheel concept allowed each camera to observe the same ground target during each cycle of rotation. Prior to this time, instruments were generally mounted axially into spin-stabilized S/C.

- Spacecraft stabilization. Early S/C employed spin-stabilization techniques for S/C attitude control (i.e. S/C orientation in space), the simplest method of S/C stabilization (enough S/C spin provided gyroscopic stiffness, hence the S/C axis remained fixed in inertial space). However, such a spinning spacecraft introduced some limitations to Earth observations by the sensor complement. Note: The world's first weather satellite, TIROS-1 (launch April 1, 1960) and the follow-up TIROS and ESSA series S/C (up to ESSA-9, launch Feb. 26, 1969) were all spin-stabilized.

- A dual-spin configuration [Advanced Vela ¹⁶⁵) satellite series of USAF (launch of Vela-7 on April 28, 1967; six S/C, Vela-7 to -12 were launched from 1967 to 1970) and SAS-1 (launch Dec. 12, 1970)] followed the single-spin concept, where a portion of the platform rotated, while the payload portion was despun to allow instrument Earth observation (or to ensure proper antenna communications toward Earth). The first EO missions with dual-spin Earth-pointing were METEOSAT-1 of ESA (launch Nov. 23, 1977) and MAGSAT of APL/NASA/USGS with a launch on Oct. 30, 1979.

- The gravity-gradient boom technique, particularly suitable for microsatellites, was first introduced by the LEO Transit navigation satellite series of the US Navy (starting with the launch of Transit-5A-3 on June 16, 1963), followed by other missions: the GGSE (Gravity Gradient Stabilization Experiment) satellite series of DoD started on Jan. 11, 1964 with GGSE-1, GGSE-4 and -5 were launched May 31, 1967 along with Timation-1 (NRL, launch May 31, 1967); ATS-2 (NASA, launch April 6, 1967). GGTS-1 (Gravity Gradient Test Satellite-1 with a mass of 47 kg) of the USAF was launched June 16, 1966 from Cape Canaveral. The UoSAT microsatellite series of SSTL, UK (launch of UoSAT-1 on Oct. 6, 1981) is using the gravity-gradient concept (in LEO) extensively. The DODGE S/C (launch July 1, 1967, see M.4) was the first to study a number of advanced biaxial and triaxial gravity-gradient stabilization techniques at near-synchronous altitudes.

- This was followed by three-axis stabilization (offering better size and space options, in particular with the mounting of deployable solar panels). The Nimbus-1 satellite (launch Aug. 28, 1964) was the first three-axis stabilized spacecraft (followed by the Nimbus series). The Improved TIROS Operational Satellite,ITOS-1 (launch Dec. 11, 1970, the NOAA-1 satellite that followed it (launch Dec. 11, 1970), and all follow-up satellites of the series) featured also three-axis stabilization. The three-axis control concept is still the most applied stabilization method in space flight.

- The first passive magnetic field stabilization system of a satellite was introduced at JHU/APL on the US Navy's Transit-1A (launch Sept. 17, 1959), Transit-1B (Apr. 13, 1960, see H.6) and DME-A (Direct Measurement Explorer - A) with a launch on Nov. 29, 1965. The principle of operation: If three mutually orthogonal electromagnets are placed in a S/C, a magnetic dipole \mathbf{M} can be created in any direction. The satellite can determine the Earth's magnetic field \mathbf{H} by means of a vector magnetometer. By activating the electromagnets appropriately in response to the magnetometer measurements, a torque $\mathbf{T} = \mathbf{M} \times \mathbf{H}$ in any direction can be obtained. This torque can be used for S/C attitude control (including spin/despin). Essentially, the satellite acts like the rotor of an electric motor, with the

¹⁶⁵) Note: The Vela (meaning "watchman" in Spanish) S/C series of DoD was designed to monitor worldwide compliance with the 1963 nuclear test ban treaty. Vela-1 was launched Oct. 17, 1963, Vela-6 was launched July 20, 1965.

Earth’s magnetic field being the stator. The method has been used many times since (see also Table 42). Examples:

- a) The ESRO satellites ESRO-1/Aurora (launch Oct. 3, 1968) and ESRO-1/Boreas (launch Oct. 1, 1969) as well as the German Azur-1 (launch Nov. 11, 1969).
- b) The Magion-1, -2, and -3 subsatellites of the Czech Republic (launch of Magion-1 on Oct. 24, 1978) all employed the technique of magnetic field stabilization (the Magion-4 and -5 S/C were spin-stabilized). The Magion S/C were part of the USSR mission ACTIVE (K.2);
- c) The AMSAT OSCAR microsatellite series [OSCAR 5 (launch Jan. 23, 1970), 16, 17, 18, 19, 26, and 30, for example] employ magnetic field stabilization with its SAPPHIRE ACS (Attitude Control Subsystem);
- d) the Munin nanosatellite of IRF (Sweden, launch Nov. 21, 2000).

In the late 1990s, an evolving micro-technology is permitting the design of single-board spacecraft, referred to as nanosatellites (1 kg < mass < 10 kg) and picosatellites (mass < 1 kg). In such single-board designs, there is no physical separation between platform and payload. Naturally, the capabilities and performance of these tiny pioneering monsters are still very limited and “inferior” to those of their bigger brothers, the micro- and minisatellites (because they have less pointing accuracy, less power, less communication capability, etc. - than the larger micro- and minisatellites). However, the main advantages of nano- and picosatellites are their very low cost and the speed of designing/building a satellite practically from off-the-shelf components; these are indeed strong arguments, even for a limited set of objectives that can be achieved. In particular, such applications as technology demonstrations are favored within the class of nano- and picosatellites (an example is the introduction of such concepts as spacecraft constellations (networks or clusters) for distributed Earth observations or for communication purposes in LEO orbits).¹⁶⁶⁾ The satellite classification of the Glossary (table 562), is simply repeated here for better reference to the reader.

Satellite Class		Mass
Large satellite (observatory, etc.)		> 1000 kg
Medium size satellite		500 - 1000 kg
Minisatellite	Small Satellite Class (or LightSats)	100 - 500 kg
Microsatellite		10 - 100 kg
Nanosatellite		1 - 10 kg
Picosatellite		< 1 kg

Table 21: Satellite classification by mass criterion

- Most existing lightsats, in particular nanosatellites, feature one of two types of primary bus structures: 1) a load-bearing shell structure, or 2) a stack of component trays with stiffeners.¹⁶⁷⁾ The designs use either a sandwich construction, stiffened plates, or thin-walled trays (also referred to as cast design). The materials chosen are either fiber-reinforced composites or aluminum as primary structures. Sandwich structures are usually composed of two face sheets bonded to a core. The most common core type material is aluminum honeycomb, constructed of bonded strips of aluminum foil which are expanded to create hexagonal cells. Both metals and fiber-reinforced composites can be used in honeycomb panels. At the beginning of the 21st century, the sandwich design approach seems to be the most efficient S/C structure design technique, offering compact and modular choices with minimal mass. On the other hand, the cast structure design approach seems to be particularly suitable for mass production of nanosatellites that are needed for larger constellations. The cast design is based on different modules attached to the main structure. Some advantages of the cast or tray structure are: modular design, flexibility, each assembly can be handled independently, minimum assembly time, less number of parts.

167) B. Shigur, D. Shannon, “The Design and Feasibility Study of Nanosatellite Structures for Current and Future FSI Micro-missions,” 14th AIAA/USU Conference on Small Satellites, Logan, UT, Aug. 21-24, 2000, SSC00-VII-5

- Spacecraft busses (as listed in Table 19) come in all shapes and sizes. A very special bus in this listing is **Snapdragon**, a deployable bus of Astrium Ltd., Portsmouth, UK, developed under ESA contract. The design of Snapdragon resulted from the requirement to fly rather large structures, like a SAR antenna, and to accommodate this payload structure elegantly into the available space of a launch vehicle fairing (the smaller the launch vehicle, the lower the launch cost). In Snapdragon, the accommodation problem was approached from the payload's point of view. It resulted in a series of "diametric" SAR accommodations, meaning that the SAR antenna is stowed (two hinged halves) across the diameter of the launcher fairing. The basic snapdragon configuration features two similar structural assemblies to either side of the diameter of the launcher payload fairing. A single central deployment mechanism is placed at the foldline between the two halves of the spacecraft, with the rotation axis in the separation plane of the launcher-satellite interface. A series of HRMs (Hold-down and Release Mechanism) up each side of the S/C ensures structural integrity during launch. Thus, the Snapdragon concept represents essentially a re-packaging of existing hardware into a new structure. A typical Snapdragon deployment sequence is illustrated in chapter B.7.2, it demonstrates also vividly the apt name giving of Snapdragon. Several design variations make the Snapdragon concept very attractive for a number of potential applications with a range of options (not only for large structures) in Earth observation as well as in communication payloads. For instance, the Snapdragon concept is capable to support other missions than SAR. It can carry a large optical telescope simultaneously with radar, multi-frequency radars; and when fitted with fixed arrays and a control-moment gyro it can be very agile having a deployed S/C stiffness > 10 Hz. Snapdragon configurations may also be used for large communication antennas as well as antenna farms. A hinge removal provides the option of flying two similar spacecraft. ¹⁶⁸⁾

- Spacecraft on-board recorders. There was a need for on-board data recording from the very beginning of the space age. TIROS-1 with a launch on April 1, 1960, had already a tape recorder. The first satellite electronic memory in space (384 bits of magnetic core register - required to store its own orbit ephemeris) was flown on Transit-3B (Feb. 21, 1961). Science data storage into solid-state memory followed much later this trend. Some S/C with the provision of solid-state memory are: SAMPEX (NASA, launch July 3, 1992), ALEXIS (LANL, launch Apr. 25, 1993), TEMISAT (Telespazio, launch Aug. 31, 1993), PoSAT-1 (SSTL, launch Sept. 26, 1993), FASat (SSTL, launch, Aug. 31, 1995).

An on-board storage capacity of 1 Gbit was first realized with FAST (NASA, launch Aug. 21, 1996), followed by ACE (NASA, launch Aug. 25, 1997) with 2 Gbit, and Equator-S (MPE, launch Dec. 2, 1997) with 1.5 Gbit. EarlyBird (Earthwatch, launch Dec. 24, 1997) had a storage capacity of 16 Gbit. STEX of DoD/NRO (launch Oct. 3, 1998) has a 51 Gbit recorder and uses 64 Mbit DRAM technology. ARGOS of DoD (launch Feb. 23, 1999) provides a storage volume of 64 Gbit as well as Ikonos-2 (Space Imaging, launch Sept. 24, 1999). The Landsat-7 storage capacity (NASA, launch April 15, 1999) is 378 Gbit. The EO-1 (Earth Observing-1 of NASA, launch Nov. 21, 2000) demonstrates with WARP (Wideband Advanced Recorder Processor) a number of high density electronic board advanced packaging techniques. WARP utilizes advanced integrated circuit packaging (3-D stacked memory devices) and "chip-on-board" bonding techniques to obtain very high density memory storage per board (24 Gbit/memory card). It also includes a Mongoose V processor which can perform on-orbit data collection, compression and processing of land image scenes. WARP consists of a high-rate (up to 840Mbit/s capability), high-density (48 Gbit storage), low weight (< 25 kg) solid-state recorder/processor with X-band modulation capability. ALOS of NASDA (launch 2003) provides a storage capacity of 768 Gbit for its high-resolution optical and SAR imagery.

- Solar arrays (S/C power generation). Over the years, the main effort has been to increase the conversion efficiency of silicon-based semiconductor technology; another im-

¹⁶⁸⁾ D. M. Simpson, "The Snapdragon Family," Proceedings of the European Conference on Spacecraft Structure, Materials & Mechanical Testing, ESA/ESTEC, Noordwijk, The Netherlands, Nov. 29 - Dec. 1, 2000, pp.337-344

portant aspect is to extend their life times, the end-of-life (EOL) power generation capability per unit mass (W/kg). Conventional solar arrays of the late 1990s provide power/mass ratios of <40 W/kg. In the 1980s, silicon cells offered EOL efficiencies ranging from 13-16%, while the costlier GaAs cells delivered efficiencies of 16-19%. In the 1990s the silicon cell efficiency improved to 17-18%, the GaAs cells (and GaAs/Ge) to that of 19-21%.¹⁶⁹⁾ - In 1997, AEC-Able Engineering Co., of Goleta, CA (in cooperation with Entech Inc. and Spectrolab, the program was sponsored by BMDO and NASA/LeRC), developed and introduced a new variant of solar cells, referred to as SCARLET (Solar Concentrator Array with Refractive Linear Element Technology). The method employs curved, glass-composite optics to concentrate the solar energy on a strip of photovoltaic cells (use of cylindrical silicone Fresnel lenses to concentrate sunlight onto GaInP₂/GaAs/Ge cells). Efficiencies of 22% are obtained. Some inherent benefits of concentrator arrays are: a) high array efficiency, b) protection from space radiation effects, and c) minimized plasma interactions. A disadvantage of this technique is that the solar panels have to be pointed and stabilized (e. g., articulated toward the sun) for maximum output.¹⁷⁰⁾ SCARLET-II is flown on Deep Space 1 (launch Oct. 24, 1998), it uses dual-junction solar cells. DS1 is the first S/C to rely exclusively on refractive concentrator arrays, it is among the first to use only multi-bandgap cells. The first dual-junction cells were introduced in 1997 (Spectrolab of Hughes Electronics Corporation and HSC, who built PAS-5) with an efficiency of about 21%. Spectrolab produced also triple-junction solar cells in 1998 to be flown in 1999 (efficiency of 27%). - At the turn of the 20th century the state of the art in solar array technology provides specific power levels of 50-80 W/kg and packing efficiencies of about 8 kgW/m³. with the highest demonstrated power of 15 kW. These systems represent a power generation cost of approximately \$1000-2000/W.

System/Technology	Comment
Thin GaAs/Ge solar cells	Mass saving, flown on many S/C such as UoSat series (since UoSat-5, launch: July 17, 1991)
Multijunction solar cells	MightySat-I (launch of STS-88, Dec. 4, 98) uses InP (Indium Phosphide) dual-junction solar cells; STEX (launch Oct. 3, 1998) uses dual-junction solar cells PAS-5 (launch July 30, 1997) is the first commercial S/C to use dual-junction GaAs solar cells
Concentrators for solar cells	DS1 (launch Oct. 24, 1998) employs refractive concentrator arrays (SCARLET-II) in combination with cylindrical lenses and dual-junction GaInP ₂ /GaAs/Ge solar cells
Lightweight solar arrays	Cells on flexible Kapton substrate and inflatable Torus solar array. LFSA (Lightweight Flexible Solar Array) is a technology demonstration on EO-1 (launch Nov. 21, 2000)
Micromachined blue-red reflective cover glasses	Increase of solar cell efficiency

Table 22: Emerging solar cell technologies at the start of the 21st century

An alternative approach is seen in thin-film solar cell technology which offers large reductions in power cost and in weight over traditional cells. However, due to their relatively low efficiency the needed thin-film arrays turn out to be quite large. At the start of the 21st century the US military (AFRL) is developing a new PowerSail (PS) program to meet the power requirements of future missions (Space Based Radar, Space Based Lidar, etc.). The goal of the PS initiative is to develop a scalable solar power generation array technology with performance levels of up to 100 kW; the specific power increases with the new technology are estimated to be 3-5 times higher than conventional systems, there is also a reduction in packing volume and cost. The PS concept replaces the thin polyimide blanket with an

169) M. Williamson, "Advancing Satellite Technology," Space & Communications, March-April 1998, pp. 3-7

170) Note: Solar concentrators reflect radiation so as to expose the cells to more radiation, together with multi-junction devices that capture a larger slice of the spectrum (UV, VNIR, and IR). Efficiencies of about 30% and more are expected to be achieved in the early years of the next decade.

FTFPV (Flexible Thin-Film Photovoltaic) solar cell blanket. An FTFPV blanket consists of a thin-layer deposition of amorphous or polycrystalline semiconductors onto a lightweight polymer or steel substrate. This configuration permits the FTFPV structure to be pointed (directed into the sun) and to be used in a similar fashion as the Kapton sail. Four key technologies are targeted to support this program: large deployable/inflatable structures, FTFPV blankets, advanced GNC (Guidance Navigation and Control), and electric propulsion. The PS flight demonstration is based on a 50 kg system package and is expected to be flown in the time frame of 2007. ¹⁷¹⁾

- Electrical power subsystem (EPS). ^{172) 173)} An EPS of a spacecraft normally consists of the following elements: a solar array for power generation, a power conditioning electronics unit providing a regulated or unregulated bus voltage, and a battery for energy provision to all required satellite functions during eclipse phases of the orbit. The EPS mass is generally dominated by the solar array and battery mass portions (the electronics unit represents the smallest portion of the mass). Nickel Cadmium (NiCd) batteries have been the battery standard for a long time. Higher efficiency Nickel Hydrogen (NiH₂) are being used since the 1980s (NiH₂ batteries have the advantage of a high number of charge-discharge cycles). The Lithium-Ion (LI) battery still holds greater promises in efficiency at the turn of the 21st century.

Battery type	Time frame	Energy/unit mass
NiCd (Nickel Cadmium)	Up to the early 1980s and later	20-30 Wh/kg
NiH ₂ (Nickel Hydrogen)	In the early 1980s	36-40 Wh/kg
NiH ₂ (Nickel Hydrogen)	At the end of the 1990s	45-50 Wh/kg
NiMH (Nickel Metal Hydride)	First use probably on Falcon Gold of USAF Academy and UCCS (launch Oct. 24, 1997), SEDSAT-1 (launch Oct. 24, 1998), UniSat (launch Sept 26, 2000)	50-60 Wh/kg
LI (Lithium Ion)	Introduction at turn of the 21st century	60-120 Wh/kg
Polymer battery	Introduction on PICOSat (planned launch Aug. 2001)	20-90 Wh/kg

Table 23: Overview of S/C battery evolution

JHU/APL offers an innovative architecture in EPS design for small spacecraft systems (micro and nanosatellites). The patented system is called IPS (Integrated Power Source). IPS includes highly integrated electronics technologies as well as the integration of functions (normally implemented in separate elements) which combines energy storage (a matrix of LI battery cells), solar array electronics (dual-junction solar cells), and processor-based charge control electronics into a single structural element. The final IPS product is a multi-purpose panel that may even be used as a S/C side panel. ¹⁷⁴⁾

- Satellite structure vibration/jitter damping. The operation of cryocoolers, needed for the cooling of detectors in the infrared region (to lower the thermal noise threshold), as well as attitude actuators (momentum wheels, power thrusters, etc.) introduce unwanted micro-vibrations into the satellite structure which in turn degrade the quality of instrument measurements. - Examples of experiments involving vibration damping are: The STRV-1b satellite of DERA (launch June 17, 1994, see M.25.1.2) is flying CVSE (Cryocooler Vibration Suppression Experiment), provided by BMDO and JPL, to demonstrate a new vibration suppression design by employing piezo materials. The NASA/JPL CSE (Cryo System Experiment) demonstrated vibration suppression on Shuttle flight STS-63 (Feb. 3-11, 1995) in the launch phase and on-orbit by using the Hughes-built ISSC (Improved Standard Space-

craft Cryocooler) Stirling cooler and an experimental diode oxygen heat pipe.¹⁷⁵⁾ The TSX-5 mission of AFRL (launch June 6, 2000) flies VISS (Vibration, Isolation, Suppression and Steering System), a self-contained precision vibration control device designed to provide an ultra-quiet environment for sensitive optical sensors, laser transmitters, and other detection and measurement devices (M.29). The NASDA spacecraft OICETS (Optical Inter-orbit Communications Engineering Test Satellite) with a launch in early 2002 is carrying MVE (Micro-Vibration Measurement Equipment) to sense the vibration environment of the spacecraft.

- The first university/student developed microsatellite was NUSAT-1 (Northern Utah Satellite), built as a senior class project at Weber State University, Ogden, Utah. NUSAT was deployed from a modified GAS (Get Away Specials) canister on Shuttle flight STS-51B (Spacelab-3 mission, April 29 - May 6, 1985). The 54 kg microsatellite orbited for 20 months (reentry in Dec. 1986). NUSAT-1 was designed to study high-altitude radar field patterns for FAA (Federal Aviation Agency). - During the 1990s, satellite and payload development projects have become the program of choice for challenging (multi-year) training courses in quite a few engineering departments at universities throughout the world (see Part N).
- Reusable space platforms. Flown on Shuttle flights as free-flyer structures for experiments/payloads with special requirements, and offering a number of service functions for operational autonomy. SPAS-1 (Shuttle Pallet Satellite) on STS-7 initiated the free-flyer scenario.

Platform	Mission	Comments
SPAS-1 (Shuttle Pallet Satellite)	STS-7, June 18-24, 1983 STS-41B, Feb. 3-11, 1984	MOMS-01 imaging instrument of DLR (MOMS-01 and SPAS-1 built by MBB, Munich)
LDEF (Long Duration Exposure Facility)	STS-41-C, Apr. 7, 1984	NASA/LaRC free-flying S/C. Retrieval of LDEF on STS-32, Jan. 12, 1990
SPARTAN-1 (Shuttle Pointed Autonomous Research Tool for Astronomy)	STS-51G, Jun. 17-24, 1985	NASA free-flyer platform
SPARTAN-Halley	STS-51-L, Jan. 28, 1986	Challenger accident
SPAS-II	STS-39, Ap. 28 - May 6, '91	DoD payload
EURECA-1 (European Retrievable Carrier)	STS-46, Jul. 31, 1992	ESA platform. Retrieval during STS-57 mission, June 21-July 1, 1993
SPARTAN-201-1	STS-56, Apr. 8-17, 1993	Solar physics mission
ORFEUS-SPAS-1	STS-51, Sept. 12-22, 1993	ORFEUS-1 is a DARA/NASA science mission
SPARTAN-201-2	STS-64, Sept. 9-20, 1994	Solar physics mission coordinated with Ulysses south polar pass
CRISTA-SPAS-1	STS-66, Nov. 3-14, 1994	Joint flight of CRISTA-1 and ATLAS-3 mission
SPARTAN-204	STS-63, Feb. 3-11, 1995	
SPARTAN-201-3	STS-69, Sept. 7-18, 1995	Solar physics mission coordinated with Ulysses north polar pass
SPARTAN-206	STS-72, Jan. 11-20, 1996	Also retrieval of SFU (Space Flyer Unit)
SPARTAN-207	STS-77, May 19-29, 1996	Inflatable Antenna Experiment (IAE)
ORFEUS-SPAS-2	STS-80, Nov. 19, Dec. 7, 96	ORFEUS-2 is a DARA/NASA science mission
CRISTA-SPAS-2	STS-85, Aug. 7-19, 1997	Reflight of CRISTA-1 mission
SPARTAN-201-4	STS-87, Nov. 19-Dec. 7, 97	Solar physics mission coordinated with SOHO
SPARTAN-201--5	STS-95, Oct. 29 Nov., 98	Solar physics mission coordinated with SOHO

Table 24: Chronology of retrievable free-flyer structures on Shuttle missions

- Inflatable antenna structures.¹⁷⁶⁾ Inflatable structures have the advantages of low mass, low stored volume, and of low cost. They also have the potential to deploy much more reliably than the conventional mechanical systems used for deploying rigid structures. In-

¹⁷⁵⁾ <http://www-techtrans.jpl.nasa.gov/success/stories/cse.html>

¹⁷⁶⁾ C. E. Willey, R. S. Bokulic, W. E. Skullney, R. C. Schulze, "Ka-band Hybrid Inflatable Dish Antenna," JHU/APL Technical Digest, Vol. 22, No 2, 2001, pp. 110-111

inflatable antennas can be used in various frequency ranges (in particular VHF, UHF, MW) for such diverse applications as measuring soil moisture and ocean salinity or communications and power generation for satellites. First examples:

- The airborne SAR instrument CARABAS (Coherent All Radio Band Sensing) of FOA (National Defense Research Establishment, Linköping, Sweden), first flown in 1992, used two inflatable and flexible canvas sleeves which were trailed behind the aircraft in flight and employed as its VHF antenna system (P.49).
- On the spaceborne side, IAE (Inflatable Antenna Experiment) was flown on SPARTAN-207 (STS-77, May 19 - 29, 1996) to demonstrate the performance of a 14 m diameter inflatable deployable antenna reflector structure in orbit.
- The US AFRL at Kirtland AFB, NM, launched an inflatable sphere, named OCSE (Optical Calibration Sphere Experiment), on the JAWSAT mission (launch Jan. 27, 2000 on a Minotaur launcher into LEO) of Weber State University, Ogden, UT. The objective is to refine and support spacecraft SLR tracking from the ground.
- STR (Spring-Tape-Reinforced) booms.¹⁷⁷⁾ Besides antennas, inflatable structures may also be employed for other components of space structures such as: solar arrays, sunshades, solar concentrators, and telescope reflectors. The STR technology, invented at JPL, represents another enabling element of inflatable structures, including self-rigidizable booms made of stretched aluminum laminates. A typical boom consists of a tube, formed of aluminum laminate sheet, and seamed by a Kapton tape and two end caps. A number of distinct advantages of the STR booms have been identified and demonstrated during the development process. These include: simplicity of the design, self-rigidizable in space, high-load carrying capability, high packing efficiency, and low inflation deployment pressure.

1.3.1 Spacecraft Operations

- **Satellite on-board autonomy** (in the context of unattended operations). The provision of enhanced functional autonomy demonstrations has been a goal of a number of technology missions by various agencies/institutions and satellite integrators. The intent is always to reduce operating costs, in particular to free resources of routine operations for long-term follow-up missions, with minimum ground involvement. The nature of “autonomy provision” turns out to be rather complex (in the end it requires nothing less but fault-tolerant systems on all levels). One aspect of autonomy is the automatic performance of routine operations over a limited period of time, requiring on-board monitoring, analysis and self-correcting measures for each functional aspect on the instrument level, prior to updates from ground control. The other aspect of autonomy is the provision of realistic backup scenarios to handle failure situations. - It has long been realized by all parties involved that so-called “cheapsats” are not really cheapsats, if overall costs (all operations + S/C costs + launch) cannot be reduced. And operations happen to be an important and persistent long-term item in the overall bill. The requirement for an autonomous on-board navigation function seems to be on the agenda of many missions (see also autonomy under Navigation in chapter 1.7.8). The reason: on-board knowledge of satellite position in ground coordinates is needed for many operational functions such as: activation (start/stop) of Earth observation instruments, data transmission, satellite attitude control. Examples of partial autonomy demonstrations are:

- Redundancy design. Satellite reliability is an important consideration for continued provision of operational services. In Transit-3-A (launch in 1960), a US Navy navigation satellite, JHU/APL integrated for the first time a passively redundant battery system that could automatically switch to a backup battery. - Further redundant designs followed for such subsystems as RF and telecommand.
- Enhancements on the various generations of GPS satellites. The block I S/C series (with launches from Feb. 1978 to Oct. 1985) was able to sustain unattended operations

¹⁷⁷⁾ M. Lou, H. Fang, L. M. Hsia, “Development of Space Inflatable/Rigidizable STR Aluminum Laminate Booms,” Proceedings of the AIAA Space Conference and Exhibition, Long Beach, CA, Sept. 19-21, 2000

for up to 3.5 days between navigation message uploads from the ground. The latest block IIR S/C series features autonomous satellite operations for a period of up to six months without ground control corrections (first launch of a block IIR S/C on July 23, 1997).

- The PoSAT-1 microsatellite mission of SSTL (launch, Sept. 26, 1993) reached a certain degree of operational autonomy through its on-board orbit determination capability (first orbital elements).
- For NASA's Clark satellite (launch in 1998), a GPS receiver with the name of GADFLY was used to demonstrate autonomous orbit determination and to use GADFLY also for coarse attitude knowledge. Note: At the end of Feb. 1998, NASA cancelled the Clark mission due to severe cost overruns and launch delays.
- The DS1 (Deep Space 1) technology mission of NASA/JPL (launch Oct. 24, 1998) introduced the concept of an autonomous **"Remote Agent,"** a technology demonstration package which includes an onboard mission manager with a mission plan expressed in terms of high-level goals. A planning and scheduling engine uses the goals, along with a comprehensive knowledge of the S/C status, and constraints on S/C operations - to generate a set of time-based or event-based activities. The autonomous Remote Agent concept was successfully tested on May 17, 1999 when the primary S/C command was given over to Remote Agent for three days of S/C operations. In this period, Remote Agent successfully planned DS1 activities on-board and then carried out the plan without ground intervention. The software detected, diagnosed and fixed simulated problems, showing that it can make decisions to keep the mission on track. (M.5).
- The ARGOS technology mission (M.1, launch Feb. 23, 1999) of DoD employs an on-board automated mission planning system to optimize on-board data handling and power.
- The UoSAT-12 minisatellite of SSTL (launch April 21, 1999) in Surrey, UK, carries a closed-loop autonomous control system that enables orbit operations to be performed without the need of any ground segment. The autonomous control system consists of a GPS receiver, an on-board propulsion system EPS (Electric Propulsion System), and an orbit maintenance software package of Microcosm Inc., El Segundo, CA, referred to as OCK (Orbit Control Kit).¹⁷⁸⁾ The objective of the control part of the software is to ensure that the orbital altitude of the satellite never falls outside of a prescribed window due to drag. The orbit is described using a set of epicycle parameters which provide an analytic model of LEO orbits. The parameters in this model are estimated onboard the satellite using a Kalman filter. In addition, the software provides control, and an estimation of the orbit parameters by including drag in the model. The satellite was maneuvered into an exact 7-day repeat (ground track) pass orbit for the technology demonstration. The new orbit maintenance software then maintained the satellite mean radius in its resonant orbit for a test period of 27 days within an error band of ± 5 m (3 sigma), and slowly maneuvered the S/C into a frozen orbit.¹⁷⁹⁾
- The EO-1 mission of NASA/GSFC (launch Nov. 21, 2000) requires demonstrations of autonomous navigation/instrument operation with an on-board software package referred to as EFF (Enhanced Formation Flying). EFF is capable of autonomously planning, executing, and calibrating routine spacecraft maneuvers to maintain satellites in their respective constellations and formations. The EFF features include an innovative use of fuzzy logic decision making capabilities and natural language to resolve multiple conflicting constraints.

178) G. Gurevich, R. Bell, J. R. Wertz, "Autonomous On-Board Orbit Control: Flight Results and Applications," Proceedings of AIAA Space 2000 Conference and Exposition, Long Beach, CA, Sept. 19-21, 2000

179) M. Aorpimai, Y. Hashida, P. Palmer, "Autonomous Control System for Precise Orbit Maintenance," Proceedings of the 14th AIAA/USU Conference on Small Satellites, Logan, UT, Aug. 21-24, 2000, SSC00-IX-6

- NASA's TIMED mission (launch 2001), designed and operated by JHU/APL, introduces operational autonomy by separating payload/instrument operations from all S/C system operations activities. In this way, the instrument teams are able to control all of the instrument modes, operations and science data return at their own choice without explicit interactions or approvals by the S/C project team. A combination of on-board GPS processing and the use of the Internet move the data from the APL ground station to each investigator's home site. In addition, the Internet is used by each investigator to control his instrument directly (the packetized messages are integrated into the uplink command structure in an automated fashion). The ultimate goal for TIMED is to develop a "lights-out" concept of operations as the missions progresses.
- ESA's PROBA minisatellite mission (launch in 2001, M.20). The attitude control and avionics subsystems accommodate the core technologies for S/C autonomy. Demonstration of autonomous operations for orbit and attitude determination with a GPS receiver (SRG-20). The other autonomous subsystem is ASC (Advanced Stellar Compass) of DTU, Denmark. ASC is capable to reconstruct autonomously the S/C inertial attitude starting from the condition "lost in space." The mission operations concept provides considerable flexibility in the allocation of on-board resources and in scheduling of operations.
- A NASA/GSFC technology initiative is developing (1998) a concept referred to as IA/GNC (Image-Aided/Guidance, Navigation and Control) to support S/C autonomy and to reduce operating costs.¹⁸⁰⁾ The IA/GNC scheme uses 2-D images from the S/C science instrument or a secondary low-cost camera and generates attitude control and image stabilization information that enhances pointing performance and ultimately permits autonomous onboard geo-referencing and geometric rendering of data. IA/GNC relies heavily on image correlation tracking (ICT) techniques which compute the translational offset between an instantaneous image and a stored reference image derived from a previous image or a model.
- The STEREO mission of NASA (launch 2004, K.26) will demonstrate the feasibility of autonomous solar navigation (the sun is used as a reference). The technique employs a dual-mode imaging system (designed by JHU/APL) for measuring the direction of the sun using a CCD camera which captures the image of the sun against a star background (the stars serve as a direction reference). The two-mode design, based on a DSAD (Digital Solar Attitude Detector) imaging system, permits the control of vast the brightness contrast differences. The S/C state vector is determined by on-board processing the solar observation data.¹⁸¹⁾
- Autonomous station keeping of S/C. Up to the late 1990s, the station keeping of satellites (in GEO and LEO) has primarily been ground based, involving the Control Center personnel in all phases of operations, including orbit maintenance and station keeping. Current GEO satellite operations have evolved so as to take advantage of the stationary nature of the satellite position relative to the ground stations. The favorable geometry provides a continuous window for ranging, tracking, and commanding, thereby minimizing the computational burden on the on-board processors. The LEO satellites (with intermittent ground contacts), on the other hand, always required an on-board processing capability to provide some limited autonomy in navigation. Functional capabilities in the direction of autonomy improved considerably with the availability of on-board GPS systems and advanced feedback control techniques. New orbit control designs are based on the concept of continually minimizing the position and velocity error between a satellite and its target orbital position.
- The Emerald two-spacecraft mission of Stanford and Santa Clara University within UNP (launch 2001) provides a two-level on-board autonomy. At the lowest level,

¹⁸⁰⁾ <http://gnctech.gsfc.nasa.gov/gto/library/staif/staif171.html>

¹⁸¹⁾ Y. Guo, "Autonomous Solar Navigation System," JHU/APL Technical Digest, Vol. 22, No 2, 2001, pp. 119121

formation-flying algorithms provide relative position determination and control. At the highest level, the on-board autonomy functions and fleet-level commanding are demonstrated. An expert system is used to execute model-derived analysis rules for robust anomaly management. The execution system provides intersatellite command synchronization and planning. The objective is to enable fleet-level commanding (i.e., a single high-level command to the fleet will cause coordinated fleet activity) and to support opportunistic observations (i.e., the ability of all S/C to detect “events of interest” and to react by starting coordinated observation activities). In addition, the distributed beacon system validates these methods by providing the anomaly notification function of the cluster to the ground.

Autonomous on-board control offers several operational capabilities not available to missions without this feature (according to reference 178):

- The position of the spacecraft at all future times is known as far in advance as desirable
- The ground track (or inertial track) of the spacecraft can be made to follow a predefined pattern which may be changed at user request
- The process for computing future positions is simple and can be included in any ground-based equipment that uses a general-purpose microprocessor
- There is a longer planning horizon dealing with the potential problems of RF or physical interference with other spacecraft or debris
- Disturbance torques are much lower than with more traditional orbit control processes, such that the size and responsiveness of control actuators can be lessened and restrictions on the timing of stationkeeping maneuvers can be reduced or eliminated.

In summary, autonomous on-board orbit control can fundamentally change the way space missions operate. It is a key component in extending the philosophy of “faster, better, cheaper” to 21st century ground operations.

Today’s requirements of future space-system functionality call for nothing less but **system intelligence** (error-tolerant systems) with the following characteristics: (see reference 7)

- Autonomy to think for themselves
- Self-reliance to identify, diagnose, and correct internal problems and failures
- Self-repair to overcome damage
- Self-assembly and evolvability to adapt to and explore new and unknown environments
- Extreme efficiency to operate with very limited resources and without input from mission control.

• **Internet access.** A demonstration of Internet access to flying spacecraft was first performed by SSTL (Surrey Satellite Technology Ltd) using its UoSAT-12 (launch April 21, 1999) minisatellite.^{182) 183)} The demonstrations consisted of uploading an IP (Internet Protocol) software stack to the UoSAT-12, including simple modifications to the SSTL ground station, and a series of tests to measure the performance of various Internet applications (UoSAT-12 was assigned an IP address). The UoSAT-12 S/C was reconfigured on-orbit. The initial tests included basic network connectivity (PING), automated clock synchronization with NTP (Network Time Protocol), and FTP (File Transfer Protocol) transfers.

The UoSAT-12 Internet demonstration was carried out in the time frame April-June 2000 within the OMNI (Operating Missions as Nodes on the Internet) project of NASA/GSFC. The UoSAT-12 spacecraft was selected because of its ability to support the HDLC (High-Level Data Link Control) framing in hardware for link-level protocol on space-to-ground links. This allowed simple and straightforward interfacing with existing commercial routers. UoSAT-12 was an ideal test platform because it already used HDLC framing for its AX.25 protocol. - Follow-on work is to demonstrate the following functions and additional proto-

182) J. Rash, R. Parise, K. Hogue, E. Criscuolo, J. Langston, C. Jackson, H. Price, “Internet Access to Spacecraft,” Proceedings of the 14th AIAA/USU Conference on Small Satellites, Logan UT, Aug. 21-24, 2000, SSC00-IX-4

183) <http://ipinspace.gsfc.nasa.gov/general/>

cols: http file delivery, mobile IP, security, store-and-forward commanding, data delivery using SMTP (Simple Mail Transfer Protocol), and VPN (Virtual Private Network) to enable automated, operational S/C communication.¹⁸⁴⁾

- Autonomous ground stations and systems.
- The first ground stations that could be operated autonomously were probably the APT (Automatic Picture Transmission) stations for NOAA satellite data reception. The APT broadcast service was first introduced with TIROS-8 (launch Dec. 21, 1963). Simple APT ground stations could soon be purchased to support autonomous data acquisition.
- The broadcast of HRPT data started with TIROS-N (launch Oct. 13, 1978). Along with this service came simple HRPT stations supporting autonomous data acquisition.
- True and continuous autonomous ground station operations has probably first been realized with the introduction of systematic spaceborne data collection services (DCS) from the ground segment. Each remote ground station (on land, on water, or in the air) had to be operationally autonomous to participate in such a venture. The first such system in LEO (polar orbit) was IRLS (Interrogation, Recording, and Location System), employing a range-only platform location technique and flown on Nimbus-3 (launch April 14, 1969, see M.17.3). The French-US Eole experiment measured ambient air temperature and pressure and determined 200 mb winds over the Southern Hemisphere by tracking constant-density balloons, employing a range and range-rate location technique (launch Aug. 16, 1971). A simplified approach, using only random-access range-rate data, was employed in the TWERLE (Tropical Wind Energy conversion and Reference Level Experiment) flown on Nimbus-6 (launch June 12, 1975, see M.17.6). These systems led eventually to the French-developed **Argos** Data Collection and Location System, first flown on TIROS-N (launch Oct. 13, 1978, see C.1). A similar system, COSPAS, was developed by the Soviet Union and first launched on June 29, 1982. The US, Canada, France, and the Soviet Union banded together to form COSPAS-S&RSAT (Search and Rescue Satellite Aided Tracking System), an international humanitarian search and rescue system that became fully operational in 1984 (see I.6). As of April 2001, over 11,000 persons have been rescued by COSPAS-S&RSAT services since its inception.
The first DCS in GEO orbit was flown on SMS-1 (Synchronous Meteorological Satellite-1, launch May 17, 1974). See chapter 1.8.
- Autonomy is also invading the mission control room. Traditionally, satellite operations have been preformed from a fixed set-up of computers in a dedicated control room at the space agency's or satellite owner's premises. The control room was staffed around the clock in order to continuously monitor and operate the spacecraft. This 24 hour staffing approach, however, was very expensive. For small scientific satellites on a constrained budget, this type of support may only be justified during the initial commissioning phase (typically a few weeks) and in case of contingencies or special campaigns.
- Future missions of satellites will increasingly rely on autonomy for routine operations and automatic downlinking of housekeeping and instrument data. Both the on-board computer and computers at the ground station or a dedicated control facility will continuously monitor the health of the spacecraft and alert the operator-on-call in case of anomalies.
- Increased use of Internet services in S/C (or mission) operations, in particular for small S/C to save costs over the conventional leased-line communications approach. Furthermore, with the first LEO commercial telephone networks in operation, S/C operators (in particular student developed satellites) are designing their prime communications

184) J. Rash, R. Parise, K. Hogue, E. Criscuolo, J. Langston, "Internet Technology on Spacecraft," Proceedings of the AIAA Space Conference and Exhibition, Long Beach, CA, Sept. 19-21, 2000

needs for uplink and downlink data transmissions entirely on the service provision of these distributed cellular telephone networks. This eliminates the conventional dedicated ground segment to space segment communication links for a space mission.

- Munin (N.9), a Swedish nanosatellite of IRF (Swedish Institute of Space Physics), students at Umeå University (RYP), and students at Luth (Luleå University of Technology) with a launch as a secondary payload on NASA's EO-1 mission (launch Nov. 21, 2000), feeds its science data (space weather parameters) directly into the Internet at reception, available to anyone.
- The ION-F (Ionospheric Observation Nanosatellite-Formation, three satellite constellation of USU (Utah State University), UW (University of Washington, and VT (Virginia Polytechnic Institute) with a planned launch in 2001, employs also commercial cellular phone communications in all links.
- etc.
- Spacecraft data transmission (telemetry and telecommand) using CCSDS protocols. The first recommendations for a CCSDS (Consultative Committee for Space Data Systems) standard were released in 1987, allowing information from different parts of a satellite to be placed into packets and to be sent to a ground station (or to be uplinked as telecommand data). By using a standard method of processing and distributing satellite data, one ground station can handle data from different satellites.¹⁸⁵⁾ - The ERS-1 mission of ESA was probably the first one to introduce CCSDS formats and protocols. The SAMPEX mission was the first in USA to implement the CCSDS communication standards. TEAM-SAT (launch Oct. 30, 1997) is the first ESA spacecraft flown with telemetry and telecommand systems both fully compatible with CCSDS standards; it is also the first spacecraft to exploit the self-adaptive asynchronous telemetry capabilities successfully that the CCSDS standards support. [The communication system excepts user data as randomly occurring squirts of various sizes or as fully asynchronous individual bytes. The bandwidth on the link is shared among the users according to allocation ratios. Any bandwidth not taken up by one user is offered to the other users in the proportionate ratios].

Satellite (Agency)	Launch Date
ERS-1 (ESA)	July 17, 1991
SAMPEX (NASA in SMEX program)	July 3, 1992
EURECA (ESA)	July 31, 1992, retrieval June 21-July 1, 1993

Aqua - formerly EOS/PM1 (NASA)	planned for 2001
ADEOS-II (NASDA)	planned for 2002
GP-B (Gravity Probe-B), NASA/Stanford	planned for 2002
SCISAT/ACE (CSA)	planned for 2002
MTSAT-1R (NASDA/JMA, Japan)	planned for 2003
Diamant-1 OHB-System, Bremen	planned for 2003
COSMO-SkyMed (ASI, ESA)	planned for 2004
MetOp-1 (EUMETSAT)	planned for 2005
Pléiades (CNES, ESA)	planned for 2005
TerraSAR (Astrium, ESA)	planned for 2006

Table 25: Some CCSDS protocol implementations on satellite missions

The CCSDS standard offers a number of significant advantages over the more traditional ‘mission-specific’, fixed-format data frames, such as:

- Very reliable uplink, with automatic retransmission capability
- Cost reducing, commercial off-the-shelf onboard components
- Potential for inter-operability with other ground stations/segments
- A CCSDS protocol design in combination with a MIL-STD-1553B communications bus can provide substantial advantages in terms of spacecraft/payload decoupling. Such a design is for instance implemented in the IMAGE satellite of NASA.

As commercial satellite manufacturers adopt the CCSDS standard, the scope for international inter-operability will offer significant opportunities for collaborative programs resulting in a reduction in ground control facility costs.

- The communications bus MIL-STD-1553B has become an established spacecraft bus standard with roots in military aircraft avionics.¹⁸⁶⁾ The bus was first introduced in 1973 and experienced a number of revisions. The structure of the bus consists of a single bus controller connected to remote terminals (up to 31 max can be used). The use of the MIL-STD-1553B communications bus in combination with CCSDS protocols is increasingly being used in the design of small satellite command and data handling systems. In this way, they function as standard spacecraft-to-payload interfaces and protocols. In addition, the IEEE 1394 high-speed and low-power serial bus standard (subsystem communications), in combination with MIL-STD-1553B, is gaining acceptance in spacecraft design. IEEE 1394 defines techniques for serial digital data communications among multiple nodes.¹⁸⁷⁾ Example of IEEE 1394 I/F: The VIIRS (Visible/Infrared Imager and Radiometer Suite) instrument of NPOESS (R.147.3) utilizes an IEEE 1394 cable.

- Store & Forward (S&F) satellite communication. The UoSAT-2 S/C (SSTL, launch March 1, 1984) carried the first digital S&F payload in orbit using a protocol suite by the name of PACSAT.

¹⁸⁶⁾ R. Killough M. McLelland, “Designing Command and Telemetry Systems Using MIL-STD-1553 and CCSDS,” Proceedings of the 14th AIAA/USU Conference on Small Satellites, SSC00-XI-4, Aug. 21-24, 2000, Logan, UT

¹⁸⁷⁾ M. E. Fraeman, “Advanced Spacecraft Architectures: 1394 Serial Bus,” JHU/APL Technical Digest, Vol. 22, No 2, 2001, pp. 114-115

- Automatic docking maneuvers in space. ETS-VII, a Japanese technology demonstration satellite (launch Nov. 28, 1997) of NASDA, conducted the first successful release, tracking, and capture of a subsatellite without help from the ground on Sept. 1, 1999. The ETS-VII system consists of two spacecraft: a chaser satellite (Hikoboshi), and a target satellite (Orihime). Engineers commanded the Orihime to float about 200 mm away from the Hikoboshi main satellite body. Then, using a robotic arm and grapple attached to the larger craft, Orihime was retrieved and held firmly in place. The entire capture procedure, including the activation of the robotic arm and extension, was conducted automatically without help from ground control computers.¹⁸⁸⁾ - Previous automatic docking activities, such as those conducted with the Russian Soyuz and Progress S/C, have used either operator assistance or ground control computers. On Oct. 30, 1967, the USSR accomplished the first docking of two unmanned satellites in LEO (Cosmos-186 and Cosmos-188).
- Communication downlink experiment. XPAA (X-band Phased Array Antenna) is a communication experiment on EO-1 (launch Nov. 21, 2000) of NASA/GSFC with the objective to demonstrate link-pointing capability with the use of a body-fixed low-mass and low-cost phased array antenna (data rate of 105 Mbit/s). XPAA is composed of a flat grid of 64 radiating elements whose transmitted signals are combined spatially to produce the desired antenna directivity. An inherent advantage of the body-fixed design (mass of 5.5 kg) is to permit simultaneous capture and transmission of data, avoiding perturbations to instrument measurements.
- **On-board data compression systems.** Vast amounts of source data, generated by satellite high-resolution data instruments, such as hyperspectral imagery or SAR imagery, require data reduction algorithms to alleviate data handling and processing problems. These problems are severe (a limiting operational factor) in particular for the functions of on-board storage and high-volume data transmissions to the ground segment. They also permeate throughout the ground segment in communications, data processing (memory) and archiving.

The development of compression algorithms requires a complete understanding of the characteristics and the use of the data. In particular, data compression techniques require internal redundancy in the data sequence if compression is to work.¹⁸⁹⁾ ¹⁹⁰⁾ Streamlined approaches of compression are in use by various reversible (lossless) as well as irreversible (lossy) methods for reduction of data. Statistical codes (e.g. Huffman, Shannon-Fano, etc.), statistical methods (e.g. runlength and arithmetic coding), vector quantization (e.g. block truncation coding, JPEG) encoding by transformations (e.g. Fourier and wavelet transformations) and fractal approaches (e.g. contracting mappings) depict some examples of the first, second and third generation approaches for data compression. As of 1999, JPEG-LS (JPEG lossless) is the new lossless/near-lossless compression standard for continuous-tone images, ISO - 14495-1/ITU-T.87.¹⁹¹⁾ ¹⁹²⁾ The standard is based on the LOCO-I algorithm (LOW COMplexity LOSSless COMpression for Images) developed at Hewlett-Packard Laboratories. - Speed is the overriding issue for all real-time compression applications. Some examples of data compression implementations in past, current, and planned spaceborne systems are:

¹⁸⁸⁾ http://www.space.com/news/international/japan_satcapture.html

¹⁸⁹⁾ P. Hou, M. Petrou, C. Underwood, "Advanced On-board Image Compression in Conjunction with Cloud Detection for Microsatellite Optical Imaging," Proceedings of the 13th AIAA/USU Conference for Small Satellites, Aug. 23-26, 1999, Logan UT, SSC99-IV-5

¹⁹⁰⁾ P. Trinadh, R. Seshaiiah, U. N. Das, V. Nalanda, "Effect of Transmission Channel Errors on ADPCM and JPEG Compression," Journal of Spacecraft Technology, Vol. 9, No 1, 1999, pp. 23-36

¹⁹¹⁾ Note: In "lossy compression" information is thrown away during compression, so that the original data cannot be recovered by decompression. The decompression produces an approximation to the original data, with the level of approximation dependent on the compression ratio. In "lossless compression" the original data is reproduced exactly by decompressing the compressed stream.

¹⁹²⁾ B. V. Brower, A. Lan, J. M. McCabe, "Hyperspectral lossless compression," Proceedings of SPIE, Imaging Spectroscopy V, Vol 3753, Denver, CO, July 19-21, 1999, pp. 247-257

- The SPOT series satellites of CNES employ DPCM (Differential Pulse Code Modulation) on the PAN data stream of the HRV instruments on SPOT-1, -2 and -3 (launch SPOT-1 on Feb. 22, 1986) and on the PAN and MS data streams of HRVIR on SPOT-4 (launch March 24, 1998). SPOT-5 (launch 2002) uses DCT (Discrete Cosine Transform).
- The MOMS-02 (Modular Optoelectronic Multispectral Scanner), a stereoscopic along-track imaging system of DLR - flown on Shuttle flight STS-55 in April/May 1993, followed by a MOMS-02 reflight on MIR/Priroda (launch of Priroda April 23, 1996) - employed DPCM to compress its data from 8 bit to 6 bits.
- PoSAT-1 (launch Sept. 26, 1993), UoSAT-12 (launch April 21, 1999), Tsinghua-1 (launch June 28, 2000) of Tsinghua University in Beijing, China - all S/C built by SSTL, use a compression algorithm by the name of AMPBTC (Adaptive Moment-Preserving Block Truncation Coding), achieving compression ratios of 2.5:1 and 4:1.
- TRACE of NASA/GSFC (launch April 2, 1998) uses a data compression scheme.
- KITSAT-3 of KAIST/SaTReC, Korea (launch May 26, 1999) uses on-board image data compression in JPEG, GIF and DPCM.
- Kodak developed an algorithm by the name of ADPCM (Adaptive Differential Pulse Code Modulation) for imagery compression. It is applied to Ikonos-2 (launch Sept. 24, 1999) and QuickBird-1 (launch Nov. 20, 2000 - launch failure) imagery. The real-time technique compresses 11-bit digital imagery to average values of 2.6 bits per pixel (reduction of 4.25 : 1) with little detectable loss in image quality. The compression rate enables more efficient on-board storage and downlink transmission of the data.
- The MTI (Multispectral Thermal Imager) mission of DOE (launch March 12, 2000) employs image data compression with the USES (Universal Source Encoder for Science data) chip for lossless compression (Rice coding algorithm, developed at JPL)¹⁹³⁾; the compression ratio is 2.5:1.
- The EO-1 satellite of NASA (launch Nov. 21, 2000) carries WARP (Wideband Advanced Recorder Processor) to demonstrate a number of high density electronic board advanced packaging techniques. Besides storage functions, it provides also a data compression of imagery.
- The MSG-1 (Meteosat Second Generation -1) satellite of EUMETSAT (launch in early 2002) uses encryption and JPEG compression on the HRIT (High Rate Information Transmission) data stream.
- IRS-P5 (CartoSat-1) of ISRO (launch 2002) uses an on-board ADPCM/JPEG compression algorithm of 3.2 : 1 to reduce the source data rate of 338 Mbit/s to 105 Mbit/s in the downlink.
- ESA sponsored the development of a quasi-lossless data compressor ASIC (Application Specific Integrated Circuit) which exploits the advantages of a wavelet-based data compression. The ASIC, developed by Saab Ericsson of Sweden, employs the Rice algorithm defined by CCSDS (with some additional features improving the functionality but maintaining the compatibility with the standard). The ASIC is baselined for use on the PROBA mission (launch in 2001) and considered for other projects as well.
- NASA/GSFC is developing a high-performance lossy data compression technique to support high-speed pushbroom frame-based imaging applications.¹⁹⁵⁾ The algorithm is based on MLT (Modulated Lapped Transform) and DCT techniques combined with bit-plane encoding. Flight qualified hardware implementations are in development. A functional chip set is expected by the end of 2001. The chip set is being designed to compress data in excess of 20 Msamples/s and support quantizations from 2-16 bits.

193) Note: "Rice" is an adaptive variable-length compression scheme on images, an algorithm developed by Robert F. Rice of JPL and implemented by Frank Rabe of the Technical University in Braunschweig, Germany for the Mars Pathfinder Lander IMP imaging system.

- Adaptive Spectral Signature Recognition. The NEMO S/C of NRL (see D.25, planned launch in 2003) employs **ORASIS** (Optical Real-time Adaptive Signature Identification System), an automated and patented end-to-end HSI (Hyperspectral Imaging) algorithm and advanced processing system that performs on-board processing, thereby significantly reducing (compression factor >10) the amount of source data for on-board storage and ground transmission. The approach is to analyze each spectra in the scene sequentially, discarding duplicate spectra, and working only with the unique spectra and a map of their location in the scene. The ORASIS algorithm preserves 97-98% of the data fidelity.¹⁹⁶⁾
- The ALOS satellite of NASDA (launch in 2003) uses a lossy data compression technique DCT (Discrete Cosine Transformation) and Huffman coding on PRISM (Panchromatic Remote-sensing Instrument for Stereo Mapping) to reduce the source data rate (1 Gbit/s) to about 240 Mbit/s in the downlink. DPCM is used on AVNIR-2 data (reduction from 160 Mbit/s to 120 Mbit/s in the downlink).
- Relay satellites for data communication from Earth observation and space exploration S/C. The introduction of space agency relay satellite constellations (in GEO) opened up entirely new coverage capabilities in data communication. Operationally, it represents a definite advantage (although more expensive) over the conventional distributed ground-station concept in combination with S/C recorders. Relay stations in space permit extended or continuous (three satellites) coverage between a S/C in LEO and the ground. This can be a decisive advantage to some missions (for instance to Shuttle missions, space station operations, etc.). Extended contact periods permit also the transfer of vast amounts of data.
- The TDRS (Tracking and Data Relay Satellite) series of NASA (built by TRW) pioneered this relay technology. The communication services provided by TDRS include such items as: a) simultaneous tracking of multiple satellites, b) multiple access schemes of S-band and Ku-band, etc. The TDRS antenna module consists of seven antennas: two single-access antennas that support both Ku-band and S-band user S/C communications (each 4.9 m diameter); a multiple access S-band phased array consisting of 30 helix-antenna elements; a 2 m diameter space-ground link antenna in K-band; an S-band omnidirectional antenna for TT&C support; a C-band antenna for commercial communications, and a K-band commercial communications antenna. Starting with TDRS-H (TDRS-8 in orbit, launch of TDRS-H on June 30, 2000), an additional link in Ka-band is provided to the existing S-band and Ku-band communication service capabilities. The receive data rates are 300 Mbit/s for Ku- and Ka-band and 6 Mbit/s for S-band. Transmit data rates are 25 Mbit/s for Ku- and Ka-band, and 300 kbit/s for S-band. The TDRS-8 S/C (dry mass = 2910 kg, 2.04 kW power) carries two steerable 5 m disk antennas for C-, Ku- and Ka-band support. In addition, a phased array antenna in C-band can receive signals from five different S/C simultaneously, while transmitting to one of them.
- Russia established also a relay satellite network, similar to NASA's TDRS system. The first satellite in the series, Luch-1 (Kosmos-1700), was launched Oct. 25, 1985. It was used to relay communication to the new MIR station (launched in 1986). A controlled reentry of MIR occurred on March 23, 2001 over the Pacific Ocean.
- Japan (NASDA, CRL, JST, etc.) started its geostationary data relay and tracking satellite (DRTS) system with the launch of a prototype satellite, COMETS (Communications and Broadcasting Engineering Test Satellite), on Feb. 21, 1998. COMETS provides S-band and Ka-band communication services. In addition, the satellite is used to test the following technologies: a) Inter-orbit communications for relay of communications between observation satellites or space stations in low-altitude circular orbits (LEO) and Earth stations; b) Advanced satellite broadcast technology for broadband region-specific broadcasts and high definition television (HDTV) broadcasts using Ka-band frequency bands. Note: a sec-

¹⁹⁶⁾ J. Bowles et al., "New results from the ORASIS/NEMO compression algorithm," Proceedings of SPIE, Imaging Spectroscopy V, Vol 3753, Denver, CO, July 19-21, 1999, pp. 226-234

ond-stage problem failed to put COMETS into GEO. - Two DRTS are being built, with planned launches in 2002 (DRTS-W) and 2004 (DRTS-E), to complement the system.

- ARTEMIS (Advanced Relay and Technology Mission Satellite) of ESA has been developed for testing and operating new telecommunications techniques in GEO environment, a prototype data relay system for the planned DRS (Data Relay Satellite) system. ARTEMIS features S-band and Ka-band communication services. In addition, ARTEMIS is used to test the following technologies: a) an L-band land mobile payload allows two-way communications, via satellite, between fixed Earth stations and land mobiles - trucks, trains or cars - anywhere in Europe and North Africa; b) a laser-optical payload with a relay terminal called SILEX (Semiconductor Intersatellite Link Experiment), M.2. - Some users of the ARTEMIS' communication services are: SPOT-4 (CNES), OICETS (NASDA), Envisat (ESA), and ISS.

Satellite	Comment
TDRS-1 (NASA), launch Apr. 4, 1983 (STS-6)	Position at 41° W, also support of VLBI experiment demonstrations
Luch-1 (NPO PM) Russia, launch Oct. 25, 1985	Position at 95° E
TDRS-B (NASA), launch Jan. 28, 1986 (STS-51L)	Challenger accident !!
TDRS-3 (NASA), launch Sept. 29, 1988 (STS-26)	Position at 171° W
TDRS-4 (NASA), launch March 13, 1989 (STS-29)	Position at 41° W, replaced TDRS-1. Introduction of commercial C-band services
TDRS-5 (NASA), launch Aug. 2, 1991 (STS-43)	Position at 174° W, replaced TDRS-3
TDRS-6 (NASA), launch Jan. 13, 1993 (STS-54)	Position at 46° W
TDRS-7 (NASA), launch Jul. 13, 1995 (STS-70)	Position at 150° W (deletion of K- and C-band packages)
COMETS (NASDA), launch Feb 21, 1998, H-II launch vehicle	Position at 121° E, a prototype data relay and tracking satellite (DRTS) system with S-band and Ka-band services
TDRS-8 (NASA) launch June 30, 2000 (TDRS-H)	Position at 47° W, S-band, Ku-band, and Ka-band
ARTEMIS-1 (ESA), launch July 12, 2001	Position at 9-16° E, a prototype DRS with S-band, Ka-band, and optical communication tests
DRTS-W (NASDA), planned launch in 2002	Position at 90° E (DRTS-W), S-band and Ka-band
DRTS-E (NASDA), planned launch in 2004	Position at 170° W (DRTS-E), S-band and Ka-band

Table 26: Overview of relay satellites operated by space agencies

- ETS-VIII (Engineering Test Satellite - VIII), a GEO technology spacecraft of NASDA (planned launch in 2003). The objective is to demonstrate mobile satellite communications and broadcasting system technologies (in S-band) with small-scale ground terminals such as hand-held terminals. ETS-VIII features LDR (Large-scale Deployable Reflector) to support the experiments.

- Disaster monitoring. Although a spaceborne (LEO) service of disaster monitoring is of great interest to a global community of civil protection authorities, there has been no satellite so far dedicated to the task of service provision during periods of natural disasters (volcano eruptions, floods, etc.). However, there have been imagery services, in particular for flood events, from a number of instruments on various satellites of existing space missions. Examples are: ERS-1/2 (AMI), JERS-1 (SAR, OPS), RADARSAT-1 (SAR), IRS-1C and -1D (LISS-3, PAN), Landsat-5 (TM), NOAA (AVHRR) series, and the SPOT (HRV) series. - Future missions are: BIRD a demonstration mission of DLR (planned launch in 2001); FOC/FUEGO (Fire Observation Constellation), in the definition phase by ESA and the EU, is planned to deal in particular with forest fire observations.

1.3.2 Special S/C Maneuvers and Rescue Operations: Examples

- S/C rotation maneuver of RADARSAT-1. During AMM (Antarctic Mapping Mission), in the time period of September to November 1997, the RADARSAT-1 spacecraft

underwent a successful maneuver to rotate its normally right-looking radar array into a left-looking attitude. The shift involved rotating the satellite by 180° in yaw. Although other missions do regular yaw maneuvers to reorient S/C, RADARSAT-1 was the first satellite in remote sensing history to perform this maneuver twice (back to nominal right-looking configuration at the end of AMM). The left-looking configuration allowed to map the entire Antarctic continent for the first time.

- S/C rescue operations - GOES-10. In May 1997, the solar array mechanism of NOAA's newly launched GOES-10 (launch April 25, 1997 as an orbit backup) satellite, designed to rotate once each day to keep itself pointed normally at the sun, slowed down and shortly thereafter stopped working entirely. The subsequent rescue work by NOAA and NASA engineers led to an unusual solution by turning the spacecraft into an upside down orientation (a yaw-flip maneuver). This maneuver turned out to be highly successful in saving the spacecraft for regular operations, because it permitted the solar array to work in a backwards-rotating orientation. As a consequence, the on-board software was changed so that data from the instruments are provided to users as if the spacecraft were in the normal upright position. GOES-10 was activated on July 21, 1998 to replace the GOES-9 spacecraft.¹⁹⁷⁾

- MIR accident. In the summer 1997, an emergency occurred that had considerable impact on MIR's fate. While docking with the MIR space station, a Progress cargo ship failed to respond to commands and rammed the Spektr module. As a result of this first collision between operating spacecraft, the Spektr module was punctured and leaked oxygen. The international crew aboard MIR retreated to a docked Soyuz spacecraft to prepare for emergency evacuation. However, the situation was brought under control. The punctured module's hatch was closed and the oxygen leak was stopped. - For the next two years, MIR crews did extensive maintenance and brought the space station back into full working order.

- SOHO rescue operations (launch of SOHO on Dec. 2, 1995).¹⁹⁸⁾ Operational control of the SOHO S/C was lost on June 25, 1998 (when SOHO spun out of control and communication was lost). Subsequent investigations by a joint NASA/ESA/MMS team showed that the loss of contact with SOHO had been preceded by a routine calibration of the spacecraft's three roll-control gyros. - On July 23, first S/C recovery operations were performed with the Arecibo radio telescope in Puerto Rico. The 305 m diameter dish antenna was used to transmit S-band signals to SOHO, while NASA's DSN at Goldstone functioned as receiver, thereby locating the spacecraft's echo. On Aug. 3, contact with SOHO was re-established and reception of the carrier signal by DSN. Attitude recovery was established on Sept. 16, 1998, resulting in a SOHO lock to the sun. SOHO was finally brought back to normal operating mode on Sept. 25. The only equipment failures at S/C level were in two of the three gyros. Instrument re-commissioning started on Oct. 5 with SUMER and ended with CELIAS on Oct. 24, 1998. - On Dec. 21, 1998, the last on-board gyro failed during the preparation of a routine orbit-correction and wheel management maneuver.

In January 1999, a **gyroless mode of operation** was devised and installed with a new software patch for a modification of the AOCS (Attitude and Orbit Control Subsystem), making SOHO the first three-axis-stabilized S/C of ESA to be operated without a gyro. The software patch was developed by MMS (Matra Marconi Space), now Astrium SAS of France (an ESA patent is pending). The software allows to determine SOHO's drift by measuring the changes in the speed of the spacecraft's momentum wheels (the software triggers the momentum wheels instead of the faulty gyroscopes).¹⁹⁹⁾ Final recovery from ESR (Emergency Sun Re-acquisition mode) and full S/C operation of SOHO was regained Feb. 1, 1999. A joint ESA/NASA investigation board came to the conclusion that the loss of the SOHO

197) G. J. Dittberner, "NOAA's Geostationary Operational Environmental Satellite (GOES) Systems and Plans," Proceedings of the EUMETSAT Meteorological Satellite Data User's Conference, Copenhagen, Denmark, Sept. 6-10, 1999, pp. 33-38

198) F. C. Vandenbussche, "SOHO's Recovery - An Unprecedented Success Story," ESA Bulletin, Nr. 97, March 1999, pp. 39-47

199) J. Bates, "Software Extends Satellite Missions When Gyroscopes Fail," Space News, Feb. 5, 2001, p. 8

S/C was a direct result of operational errors, a failure to adequately monitor S/C status, and an erroneous decision which disabled part of the on-board autonomous failure detection.

- **PseudoGyro** - is a software package of The Aerospace Corporation (El Segundo, CA) to save satellites from failure (US patent as of Feb. 1, 2000). The PseudoGyro package emulates a hardware gyro through software processes. The technique was successfully demonstrated in 1999 on a classified satellite of NRO (National Reconnaissance Office) which had experienced failures of its primary and secondary hardware gyros. PseudoGyro works in conjunction with orbital-attitude-estimation filtering techniques and takes advantage of all available sensors, including the vehicle itself, in determining attitude. It uses the principle of conservation of momentum to accurately determine the angular velocity of a spacecraft. It can be applied to virtually all types of space vehicles that are controlled by any type of momentum storage device. The technology can be integrated before or after a satellite is in orbit. In general, gyroscope-mimicking software might not replace the real thing, but it can reduce the workload on gyros, thereby extending their lives. PseudoGyro addresses also the need to reduce the risks and costs associated with new technology gyros.²⁰⁰⁾
- **S/C rescue operations - DS1 extended mission.** In November 1999, two months after the end of its extremely successful primary mission and early in its extended bonus mission, the star tracker of DS1, responsible for the spacecraft's orientation, ceased operating. Rather than abandon the project, NASA engineers managed a deep-space rescue. They sent new software to DS1 (at a distance of 321 million km from Earth), turning an onboard camera (MICAS) into a navigation instrument. The challenging task was completed in June 2000 to resume thrusting in time to give DS1 a chance to encounter comet Borrelly in September 2001.

1.3.3 Cooperative Distributed Systems, Satellite Formations

Distributed space systems are multi-satellite systems that work together to perform a unified mission. Such systems are an alternative to monolithic satellite missions in which all on-orbit activities are performed on a single platform. Distributed space systems can range from global constellations offering extended service coverage to clusters of highly coordinated vehicles that perform distributed sensing. Global constellations of communication and navigation satellites are considered "loosely coupled" systems, they are in existence for many years. On the other hand, the use of spacecraft clusters for remote-sensing applications represents a new and rather unexplored type of constellation, namely "tightly coupled" systems with a new quality of service and support capabilities.²⁰¹⁾

- **Virtual satellite** - a new paradigm for a distributed remote sensing space segment (cooperative constellation of satellites). The idea of the EO mission concept is to use LEO clustered microsatellites ($10 \text{ kg} < \text{S/C mass} < 100 \text{ kg}$) and nanosatellites ($1 \text{ kg} < \text{S/C mass} < 10 \text{ kg}$), capable to cooperate and to share resources and functions (processing, communications, payload, and/or observation/mission functions) with each other, in order to perform the functions of a large single satellite. Sensors on satellites, flying in formation, may function as a single large sensor, offering entirely new observation capabilities [more frequent coverage through wider swaths, stereoscopic observations of imaging instruments (multi-fold coverage of common target regions), parallel provision of similar measurements at higher time-and-space sample rates (altimetry applications), virtual large aperture radar, etc.]. Distributed S/C control architectures are characterized by interactions between S/C, cooperation between S/C, and collective behavior among S/C within a constellation or formation. The introduction of concepts such as decision making, hierarchical control, decentralized control, etc., within the management of the formation enables spacecraft to cooperate with one another. Autonomy is a critical technology in this scenario that impacts

200) <http://www.aero.org/news/current/pseudogyro.html>

201) J. Bistrow, D. Folta, K. Hartman, "A Formation Flying Technology Vision," Proceedings of AIAA 2000 Space Conference and Exposition, Long Beach, CA, Sept. 19-21, 2000

every level of the design, from the subsystem, to the instrument, the platform, as well as the entire constellation. If a cooperative constellation includes a variety of basic, versatile instruments, for example UV, VIS and IR spectrometers, then 'virtual platforms' for different applications can be formed in space, on the fly, and "disassembled" (or reconfigured) later for other uses - flexibility to adapt to the evolving science needs and to implement the newest technologies during the course of an on-going mission are the basic requirements. In this new observation concept of **formation flying**, GPS plays a key role as a navigation instrument in the maintenance and control of the constellation (measurement of formation states, i.e., the relative orientations, positions and velocities of the vehicles). The ultimate goal of "virtual satellite" is a **satellite on a chip** providing all functions of conventional S/C (telemetry, tracking, and control).^{202) 203) 204)}

Examples of planned S/C cluster missions are:

- A program initiative, TechSat-21 (Technology Satellite of the 21st Century), was started in 1998 by various US DoD departments/directorates, namely AFRL (Air Force Research Laboratory), AFOSR (Air Force Office of Scientific Research), and DARPA (Defense Advanced Research Projects), with the objective to exploit the new paradigm and enabling technologies, such as MEMS (Micro-Electro-Mechanical Systems) and overall component miniaturization and function integration - that "involves satellites flying in tight formation that operate cooperatively to perform a surveillance mission." Under this effort, a variety of application missions are being considered including surveillance, passive radiometry, terrain mapping, and communications. A University Nanosatellite Program (UNP) was set up for this purpose by AFOSR/DARPA/NASA to fund ten university 'research projects centered on the design and demonstration of nanosatellites.'^{205) 206)} The funded projects within TechSat-21/UNP are:
- Emerald (Electromagnetic Radiation and Lightning Detection), a two-satellite project of Stanford University and Santa Clara University. A launch on a Shuttle mission is planned for 2001.
- 3CSat (3 Corner Sat), a constellation of three nanosatellites in formation. 3CSat is a joint project of the University of Colorado at Boulder, ASU (Arizona State University), and NMSU (New Mexico State University). The cluster is to be launched in 2002 with the objective to cooperate on science experiments (stereo imaging). While most satellites use a dedicated radio link, these will be the first to utilize cellular phone technology to communicate.
- ION-F (Ionospheric Observation Nanosatellite-Formation), a three-satellite project of USU (Utah State University), UW (University of Washington), and VT (Virginia Polytechnic Institute). Formation flying is a primary objective. Introduction of new technologies including micro-thrusters, magnetic gimbaled attitude control, advanced tether system, and an Internet-based operations center.
- Constellation Pathfinder, a one to three satellite mission of Boston University.
- Solar Blade Heliogyro Nanosatellite, a mission of CMU (Carnegie Mellon University), Pittsburgh, PA to demonstrate the solar sail concept.

Further projects of planned cluster missions and formation flying are:

- GRACE (Gravity Recovery and Climate Recovery), a cooperative US-German dual-minisatellite mission with a launch in 2001. The mission concept makes use of measurements of the inter-satellite range and its derivatives between two co-planar satellites (in

206) <http://www.vs.af.mil/vsd/techsat21/>

low-altitude and polar orbits), using a microwave tracking system and a GPS receiver system for precision orbit determination.

- DMC (Disaster Monitoring Constellation), a five microsatellite constellation of SSTL (Surrey Satellite Technology Ltd), Surrey, UK. The overall objective is to provide global daily imagery at 36 m resolution for the monitoring and mitigation of natural and man-made disasters and dynamic Earth observation. DMC is planned for launch in late 2002.
- The cooperative missions of CloudSat and ESSP-3, flying active and passive instruments, will be launched in 2004.
- Demonstration of close-proximity formation flying and sparse aperture sensing. TechSat-21 of DoD/AFRL is a constellation of three microsatellites (each of about 120 kg) flying in formation, each equipped with an X-band radar instrument (the TechSat-21 system is being built by ITN Energy Systems Inc. of Denver, CO). The objective is to demonstrate the MTI (Ground Moving Target) capability by operating as a virtual satellite with X-band transmit and receive payloads on each platform to form a large, sparse aperture system. A crosslink system (with carrier phase differential GPS positioning, intersatellite ranging and communication, phased array antennas, etc.) as well as a micropropulsion PPT (Pulsed Plasma Thruster) system, is provided for each spacecraft. A launch of TechSat-21 is planned for 2003/4.
- Trailblazer/ST5 (Space Technology 5) is a NASA mission in the New Millennium Program of three microsatellites, flying in formation, with a planned launch in 2003. The objective is to test new technologies in hardware and software.
- ROCSat-3/COSMIC (Constellation Observing System for Meteorology, Ionosphere and Climate), is a collaborative US/Taiwanese (led by UCAR and NSPO) microsatellite constellation, planned for launch in 2005. In the scenario, a LEO constellation of six spacecraft collects atmospheric remote sensing data for operational weather prediction, climate, ionospheric (space weather monitoring), and gravity research (refractive GPS radio occultation measurements).
- ACE (Atmospheric Climate Experiment), an ESA Explorer mission to obtain profiles of atmospheric parameters with occultation measurements using a cluster of six LEO microsatellites. The baseline configuration of the cluster considers two orbital planes. A launch is planned for 2005.
- On the military side,²⁰⁷⁾ the US NRO (National Reconnaissance Office) awarded a contract in Sept. 1999 to Boeing Space & Communications Group, Seal Beach, CA, to develop a constellation of imaging (optical and radar) microsatellites, based on the "Future Imagery Architecture." Planned first launches are in 2005.
- NASA/GSFC is defining MagCon (Magnetospheric Constellation), a mission of about 100 nanosatellites (deployed from a single mother ship) to acquire vector images of the magnetic and plasma flow fields in highly elliptical orbits (from 3 to 50 R_E). Simultaneous, multi-point observations of the Earth's magnetospheric environment. The overall science objectives are to a) determine the equilibria of the magnetotail, b) understand the responses of the magnetotail to the solar wind, c) reveal the instabilities of the magnetotail. A launch of MagCon is planned for 2006.
- NASA/JPL is planning to fly its ST-3 (Space Technology 3, formerly known as Deep Space-3) mission in 2006, using two S/C in heliocentric orbit. In early 2001, ST-3 was renamed to StarLight. The objective is to demonstrate separated spacecraft interferometry (first long baseline optical interferometer in space). StarLight tests and validates technologies and concepts requiring precise formation flying (separation distances of up to 1 km - requiring accuracies in relative range and attitude of 1 cm and 1 arcmin, respectively) in order to act as one giant telescope system.
-

207) W. Ferster, "NRO Awards Giant Satellite Contract to Boeing," Space News, Sept. 13, 1999, p. 1

- Intersatellite communication.^{208) 209)} A prerequisite to formation flying is intersatellite communication (also referred to as cross-communication) for the control of the spacecraft cluster. Such a service may be provided by the GPS constellation offering a range of sensing options for a formation including: absolute positioning, relative vehicle positioning, attitude estimation, and precise timing. This approach is based on a combination of CDGPS (Carrier-phase Differential GPS) and GPS-like transceivers (the challenge of using CDGPS is in estimating the cycle ambiguity to sufficient accuracy). The transceivers are RF-based cross-communication devices that can also be used as local ranging systems. Examples of such transceivers include:

- CLT (Cross Link Transceiver) of NASA designed and developed by JHU/APL. The CLT provides both an absolute and relative navigation solution (position and velocity) as well as precision time recovery and a steered one pulse-per-second output. Orbit determination is provided by the reception of GPS signals and processing by an extended Kalman filter. In addition, crosslink signals support relative navigation, with the potential for both, direct solutions as well as relative GPS solutions which rely upon the computation of double differences of GPS data in a paired manner among spacecraft.²¹⁰⁾
- SPTC (Stanford Pseudolite Transceiver), a relative navigation and crosslink system for formation-flying spacecraft
- Star Ranger of AeroAstro Inc. of Herndon, VA.
- LPT (Low Power Transceiver) of ITT, Fort Wayne, IN (and NASA). The LPT integrates TDRS S-band two-way communications and GPS navigation in a compact package. The first demonstration flight is expected aboard the Shuttle in 2002.
- AFF (Autonomous Formation Flying) sensor of JPL. AFF is planned to be flown on the ST-3 (Space Technology-3) with a launch in 2003.
- NCLT (Nanosatellite Cross Link Transceiver) of CLT heritage is under development at APL. The UNP (University Nanosatellite Program) satellites (of DoD/NASA) employ this device as well as AFRL's TechSat-21 program and NASA's ST-5 (Space Technology-5) constellation. NCLT is a multichannel, stand-alone system that implements three fundamental functions: on-board processing, GPS receiver, and crosslink communications. NCLT supports multiple-access communications architectures (FDMA/CDMA).

The first onboard experiment with a relative GPS navigation receiver was probably conducted on the NASDA spacecraft ETS-VII (Engineering Test Satellite VII) with a launch on Nov. 28, 1997. The instrument RGR (Relative GPS Receiver) was used successfully in the docking demonstrations (see M.8.1).

- Other distributed observation strategies of formation flying. This category considers so-called "trains of satellites performing similar observation objectives with their payloads in closely spaced sequences." Their orbits are optimized to coincide (within a few minutes) with those of other satellites. Examples are:

- The Landsat-7, EO-1, SAC-C and Terra "morning constellation" train (in formation as of early 2001). There is 1 minute separation between Landsat-7 and EO-1, a 15 minute separation between EO-1 and SAC-C, and a 1 minute separation between SAC-C and Terra. The objective is to compare coincident imagery from the ETM+ and ALI instruments. The "paired scene" images are used to evaluate the performance of ALI.
- The TOPEX/Poseidon and Jason-1 spacecraft are planned to fly in tandem (as soon as Jason-1 is launched in 2001) with a one minute separation time enabling calibration to

be performed.²¹¹⁾ After the checkout/verification phase, the tandem mission will fly in an interleaved orbit (i.e., the TOPEX/Poseidon orbit will be moved to an orbit that produces interleaved groundtracks with a 1.4° longitude spacing from the Jason-1 tracks). The intent is to address the following topics: a) double the spatial sampling to enhance the resolution of the Rossby waves and eddies; b) quadruple the crossover points for the estimation of the current velocity vector; c) enhanced coastal tide models; and d) obtain improved global change detection.

- The Aqua, ESSP-3, PARASOL, CloudSat and Aura spacecraft will form the so-called “A-train” (Aqua in the lead and Aura at the tail) or afternoon constellation (formation flight starting in the 2004 time period). The objective is to provide a coincident set of data on aerosol and cloud properties, radiative fluxes and atmospheric state essential for accurate quantification of aerosol and cloud radiative effects.

1.3.4 Bistatic Systems in Remote Sensing

The bistatic remote-sensing concept refers to a measurement geometry in which the transmitter and receiver locations of an active system (radar, etc.) are separated by a distance comparable to that of the target distance. In addition, bistatic observations require accurate time synchronization; antenna pointing between transmitter and receiver may also be involved. In contrast, a **monostatic system** refers to a measurement arrangement, in which both transmitter and receiver are collocated, often the same antenna is used for both functions. The great majority of all radars (SAR instruments, Doppler radars, lidars, etc.) in use today (and flown on spaceborne missions) are of the monostatic type, providing their own illumination and measuring the echo at the same location. The dual monostatic or repeat-pass approach (for interferometric operation) has been demonstrated by the ERS-1/2 tandem mission (Aug. 1995 to May 1996). In a tandem mission in monostatic mode, the two spacecraft have equal status, there is no direct link between them. In the bistatic mode concept, one satellite (the master) generates the radar pulses, and the reception of the echoes by both master and slave must be synchronized.^{212) 213)}

It is interesting to note here that all early radar experiments, conducted by experimenters in various countries like in France, Germany, Italy, Japan, Russia, UK, and USA (from about 1905 on until after World War II), were of the bistatic type. In the USA, for instance, an observation of the radar effect was made in 1922 at the U.S. Naval Research Laboratory (NRL) in Washington, D.C. NRL researchers conducted an experiment by positioning a radio transmitter on one shore of the Potomac River and a receiver on the other. A ship sailing on the river caused fluctuations in the intensity of the received signals when it passed between the transmitter and receiver. Today, such a configuration is called a **bistatic** radar system. In spite of the promising results of this experiment, U.S. Navy officials were unwilling to support further work at the time. Practically all early military radar systems until the end of World War II) were of the bistatic type. - In the space age era, bistatic radar systems employing an orbiting transmitter and an Earth-based receiver have been used for lunar and planetary exploration.

Since the 1990s, bistatic systems are also finding ever increasing applications in the wide field of Earth observation. A typical example is atmospheric research where ground-based bistatic multiple-Doppler networks have significant scientific and economic advantages accruing from the use of only single sources of illumination. Individual spatial volumes are viewed simultaneously from multiple look angles, minimizing storm evolution induced errors. The passive receivers in a bistatic network do not require expensive transmitters, moving antenna hardware, or operators. Thus they require only a small percentage of the invest-

212) A. Moccia, N. Chiacchio, A. Capone, “Spaceborne bistatic Synthetic Aperture Radar for remote Sensing applications,” *International Journal of Remote Sensing*, Vol. 21, No 18, 2000, pp. 3395-3414

213) N. J. Willis, “Bistatic Radar,” Artech House, Boston, 1991, ISBN: 0-89006-427-X

ment needed to field traditional transmitting radars. In 1993, NCAR (National Center of Atmospheric Research) developed such a dual-Doppler weather radar network at its facilities in Boulder, CO. The network provides three-dimensional fields of full vector winds, including directly measured vertical precipitation particle velocities for numerous applications in meteorological research, aviation, forecasting, media, and education. ^{214) 215) 216)}

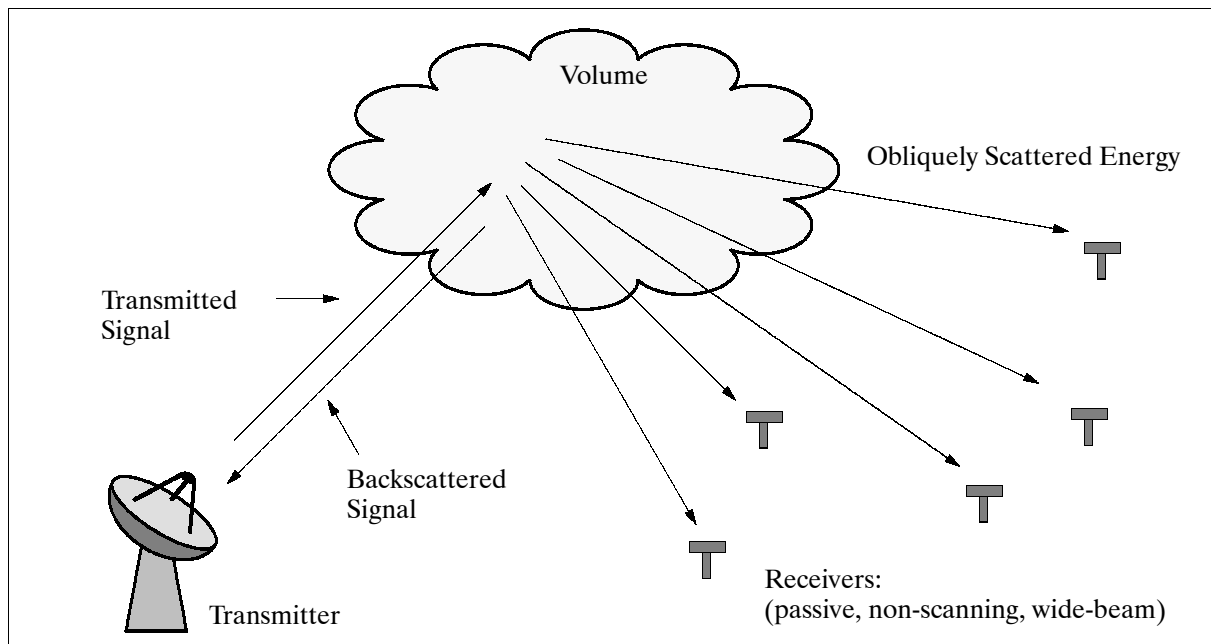

Figure 3: Schematic illustration of a ground-based bistatic multiple Doppler network

Bistatic or multistatic radar systems offer some advantages: ²¹⁷⁾

- A significant cost reduction can be achieved in the design and operation of a bistatic system (passive radiometers are significantly less expensive than active SAR instruments). Microsatellites may be used to accommodate the passive receiver antennas.
- The physical separation of the transmitter and receiver function permits for instance designs, in which the number of participating receivers can be any number in an observation system; thus, the receiver function is of a parasitic nature, simply passively participating in an observation environment/arrangement, it is in a sense “independent” of the transmitter function (not in the time domain for SAR applications). Systems with two or more receiving sites are also referred to as multistatic systems. They employ overlapping coverage of the illumination footprint and combine target data coherently and non-coherently at a central location.
- Bistatic systems offer the potential of upgrading existing monostatic missions. For instance, an existing SAR mission may be complemented with a constellation of passive receiver spacecraft in its neighborhood. This improvement results in added value to the master mission offering bistatic SAR data. Interferometric processing of the bistatic data may be unrealistic, due to rather large antenna separations; however, cross-track and along-track interferometry may be achieved. See also the Cartwheel mission below.

There may be also some disadvantages in upgrading an existing monostatic system: a) the transmitting antenna and satellite are non-cooperative; i.e., they are unaware of the new

 217) <http://aaron.ou.edu/bistatic/>

satellite with its receiver; in this case, time-synchronization of the receiving-only antenna may pose added complexities on the data processing side. Hence, long-term plans are needed for upgrading options.

- The GPS and GLONASS navigation constellations are also examples of bistatic systems. By its very nature, each navigation constellation provides the transmitter function while the “signal user community” at its numerous instant locations plays the role of the receiver function. The direct reception of GNSS signals can be used a) as navigation function, b) as timing reference, and/or c) as remote sensing function (for refractive sounding, etc.).
- Lately, indirect or reflected GNSS signals are also being used as information.²¹⁸⁾ In radar remote-sensing nomenclature, GPS reflection data (of the ocean surface or of any ground surface) can be characterized as a “bistatic radar scatterometer.” The forward scatter from the transmitter in the direction of the receiver is recorded. An entire new spectrum of remote sensing applications is beginning to unfold with the measurement of this new source of reflection data. Initial experiments with airborne GPS receivers were conducted in the early 1990s (see also “ocean reflection measurements of GNSS signals” in 1.7.5).
- Reflected ocean wave spectra, caused by Bragg scattering, were already performed with LORAN-A (Long-Range Navigation) radionavigation systems in the 1960s. The LORAN-A bistatic experiments demonstrated that the Doppler shift of the radar echo is exactly equal to the wave frequency; it is also related to the bistatic angle.²¹⁹⁾ See also LORAN in Glossary.
- **Bistatic SAR systems.** SRTM (Shuttle Radar Topography Mission), a cooperative project of NASA, DLR and ASI on STS-99 (Feb. 11-22, 2000, see J.25), was the first spaceborne bistatic SAR mission where both SAR systems operated with the main antenna of each instrument located in the open cargo bay of the Shuttle, and a second receive antenna mounted on a deployable outboard mast, respectively (a single-pass interferometer on a 60 m baseline).

Interferometric capabilities are becoming a key requirement at the turn of the 21st century to obtain topographic performance. A number of projects under development are planning to test the bistatic concepts in the spaceborne arena of close formation-flying satellite missions (offering larger baselines than SRTM). A viable option in such a distributed concept is for example a master-slave implementation. A single so-called master spacecraft is equipped with an active radar (i. e., a transmitter and receiver function), while the rest of the constellation (slave spacecraft) is outfitted with just a radiometer (receiver). All observation instruments of the constellation are directed to look into the same footprint. Thus, all passive instruments in the constellation are also able to detect coherently the bistatic responses from the single active radar of the master spacecraft as well.²²⁰⁾ The multi-location (or nodal) spacecraft data collected in this fashion provides automatically interferometric imagery after ground processing. The distributed apertures improve also the performance of the system with regard to detection and resolution capabilities. A wealth of independently sampled angle-of-arrival data can be collected, the constellation forms a large but sparse coherent array. By virtue of its sparseness, the independent apertures look through different parts of the ionosphere, thus temporal and spatial variations on the scale of their separation could adversely affect their operation. This innovative bistatic observation concept has the potential to reduce the mass, power and cost of the constellation as a whole.

Examples of the first collaborating constellations demonstrating the new bistatic SAR observation technologies are under intensive study at the start of the 21st century.

219) A. M. Peterson, C. C. Teague, G. C. Tyler, “Bistatic-radar observation of long-period, directional ocean-wave spectra with LORAN-A,” Science, Vol. 170, 1970, pp. 158-161

220) Note: Coherent detection requires synchronization between master and slaves. The synchronization may either be achieved using a crosslink from master to slaves, or by accurate synchronization of all involved to the same source.

- In Europe, CNES and DLR (in cooperation with ESA) are planning a so-called **Interferometric Cartwheel (ICW)** mission constellation of three passive microsatellites, each equipped with a receiver dish antenna (a slave receiver), to co-orbit with a soon-to-come conventional SAR mission (as host or “illuminator” or master satellite). A Cartwheel launch is planned for late 2004 followed by a four month commissioning phase prior to the operational phase in 2005. The candidate conventional SAR missions considered for Cartwheel are: Envisat, RadarSat-2, TerraSAR, and ALOS (in fact, any radar satellite mission provides a suitable context for a cartwheel mission). An “interferometric cartwheel orbit” of the passive constellation is employed. In such a cartwheel concept, the locations of the passive satellites are planned to be ahead or behind of the transmitter satellite at a fairly constant angle. Their orbits are the same as the transmitter spacecraft orbit, but with an eccentricity slightly different from that of the transmitter spacecraft orbit (the three passive satellites are moving relatively to a common reference point, in motion and coplanar with the transmitter S/C; the common reference is either lagging or preceding the transmitter S/C orbit at a constant angle). The new orbital concept is considered to offer a good geometric stability of the baselines, both vertically and horizontally, essential for interferometric processing (see O.12.8 for a definition of the Cartwheel orbit).^{221) 222) 223) 224)}
- The Canadian Space Agency (CSA) is implementing an interferometric SAR monitoring concept for its RadarSat-2 (launch 2003) and RadarSat-3 tandem missions (launch 2005). The interferometric capability (beyond 2005) is a key requirement on both missions. As a consequence, the RadarSat-3 design is based on that of RadarSat-2. As of 2001, either a bistatic or a “pursuit dual monostatic” implementation are still under consideration.
- GPM (Global Precipitation Mission), a follow-up mission to TRMM with a constellation of eight microsatellites and advanced rain-measuring radar instruments, is in the proposal state as of 2000/1 (NASA/NASDA). A possible launch date is 2007.

1.3.5 On-orbit Propulsion

- On-orbit chemical propulsion systems. Traditionally, low-thrust propulsion tasks are accomplished with cold gas or hot gas thrusters (bi-propellant technology). These thrusters, which are quite simple in principle, are perfectly suited to most of the applications (attitude control, etc.). There are some drawbacks to the system. Of course, all gases need to be stored in pressurized tanks. This means that extra weight is added to the spacecraft due to the heavy structure, hermetic seals, piping etc. The specific impulse (Isp) of cold gas thrusters is very low (in the order of two orders of magnitude lower than in electric propulsion systems). Low specific impulse means a relatively large amount of propellant to deliver a given total impulse. The total amount of propellant that can be carried poses a limit to the mission lifetime.
- **On-orbit electric propulsion systems** use electrical power provided by the spacecraft’s solar panels to accelerate a propellant to high velocity creating a reaction which causes the movement of the spacecraft. Although the thrust generated in this fashion is rather small, electric propulsion systems nonetheless provide the capability of raising a satellite’s orbit and/or to maintain platform attitude - thereby offering the potential for considerably extended mission life times. A further advantage is spacecraft mass reduction (the fuel load on

conventional propulsion systems is considerable for long-term missions). The electric propulsion technology can also be used for missions requiring drag compensation. Several thruster technologies have been demonstrated or are being demonstrated. A new era in space propulsion is evolving, gaining momentum in the late 1990s. The basic thruster technologies are: (see also chapter O.14)

- 1) Electrothermal propulsion systems: arcjets, resistojets
- 2) Electrostatic propulsion systems: Gridded ion engine, Hall-effect thrusters (free electron drift propulsion), FEEP (Field Emission Electric Propulsion)
- 3) Electromagnetic propulsion systems: Pulsed Plasma Thruster (PPT), Stationary Plasma Thruster (SPT), and Magneto Plasma Dynamic (MPD) thrusters.

Background/Applications:

- Research on Hall-effect thrusters started in the early 1960s notably in the Soviet Union. The first spaceborne plasma thruster was flown on the USSR satellite Zond-2 (launch Nov. 30, 1964). The Zond-2 S/C, on its way to Mars, was equipped with secondary electric thrusters. The Yantar-1 satellite (launch Oct. 1, 1966 from Kapustin Yar into a 400 km orbit), a USSR military surveillance S/C built by TsKB, flew the first argon ion engine. In Feb. 1972, the Meteor-1-10 S/C (launch Dec. 29, 1971) was the first satellite to correct its orbit with an SPT engine. Since 1971, Soviet/Russian spacecraft (more than 15 missions) have used low-power xenon plasma thrusters, referred to as SPT (Stationary Plasma Thrusters), for station-keeping and on-orbit maneuvering functions on the Express communication satellite series. The early SPT family engines (SPT-60 and SPT-70) were manufactured by Fakel Company of Kaliningrad, Russia.

- In 1964, a pair of NASA/LeRC ion engines were launched on a Scout rocket from Wallops Island, VA, under the name SERT-1 (Space Electric Rocket Test); one of the two thrusters onboard did not work, but the other operated for 31 minutes. A follow-up mission, SERT-2, which carried two ion thrusters, one operating for more than five months and the other for nearly three months.

- The navigation satellites of the US Navy (designed and built by JHU/APL), namely Triad-2 (also referred to as TIP-2, launched Oct. 11, 1975) and Triad-3 (TIP-3, launched Sept. 1, 1976), were each equipped with a redundant pulsed-plasma thruster (PPT) electric propulsion system, used for drag compensation (drag-free satellite).

- SCATHA (Spacecraft Charging at High Altitude) satellite of the USAF (launch Jan. 30, 1979) flew the first xenon ion engine, built by Hughes Research Laboratories in Malibu, CA.

- The Hall thruster technology has been under intensive [governmental and industrial (TsNIIMASH)] investigation in Russia since the early 1990s. The first US spacecraft with a Hall thruster is the STEX (Space Technology Experiment) mission of DoD (launch Oct. 3, 1998). STEX flies EPDM (Electric Propulsion Demonstrator Module), built by NASA/GRC, to provide orbit-raising and station-keeping functions (see O.14.2). The TAL-D55 (Thruster with Anode Layer) Hall effect thruster used in EPDM was developed by the Russian Central Research Institute of Machine Building (TsNIIMASH).

- DS1 (Deep Space 1) of NASA/JPL (launch Oct. 24, 1998) employs IPS (Ion Propulsion System), designed and built by the NSTAR team. It is the first time that IPS technology was demonstrated as the spacecraft's primary engine (smooth and continuous IPS operation from Nov. 24, 1998 for over 200 days) throughout the prime mission which ended in Sept. 1999. - The EO-1 spacecraft of NASA/GSFC (launch Nov. 21, 2000) uses PPT technology.

- ARGOS of DoD (SMC/TE at Kirtland AFB, NM), launch Feb. 23, 1999. The spacecraft uses arcjet propulsion technology for orbit transfer, maneuvering capability, and attitude adjustment. The electric propulsion system is ESEX (Electric Propulsion Space Experiment), built by TRW. Demonstration of the largest electric propulsion system (26 kW of power input) so far.

- UoSAT-12, the first minisatellite of Surrey (launch April 21, 1999), employs a resistojet electric propulsion system. The thruster can impart velocity changes of up to 10 m/s to the S/C.
- SNAP-1 (Surrey Nanosatellite Applications Program-1), launch June 28, 2000. SNAP-1 of SSTL carries a micro-propulsion system, the size of a pencil, using butane as a cold gas system. The propulsion system is used to maneuver SNAP-1 to rendezvous with Tsinghua-1 of the University of Beijing (see D.40.17).
- The AMSAT-P-3D [Amateur Satellite-Phase-3D, now called AMSAT-Oscar 40, launch Nov. 15, 2000 from Kourou into HEO (Molniya-type orbit)] spacecraft employs an arcjet thruster by the name of ATOS (Arcjet Thruster on OSCAR Satellite) for on-orbit fine control of the S/C. ATOS was developed at IRS (Institut für Raumfahrtssysteme) of the University of Stuttgart, Germany and funded by DLR. ATOS is a 750 W ammonia arcjet with a specific impulse Isp of 4600 m/s. Orbit maneuvers are achieved by a separate 400 N chemical thruster.
- EO-1 (Earth Observing-1) of NASA/GSFC (launch Nov. 21, 2000). A PPT (Pulsed Plasma Thruster) of General Dynamics, Ordinance and Tactical Systems, Aerospace Operations [formerly Primex Aerospace (formerly Olin (formerly Rocket))] is used to demonstrate on-orbit electromagnetic propulsion technology and to provide a spacecraft precision-pointing capability.
- The ARTEMIS data relay satellite of ESA (launch in 2001), built by Alenia Spazio of Rome, Italy, includes also a xenon electric propulsion thruster system (redundant systems: RIT-10 of DASA, Germany, and EIT of MMS, UK). The RIT-10 system was test-flown on the EURECA-1 mission (launch July 31, 1992 - retrieval July 1, 1993).
- The ESA mission SMART-1 (Small Mission for Advanced Research in Technology) to the moon with a planned launch in 2002, employs the STS (Stationary Plasma Thruster) concept, referred to as PPS-1350, to demonstrate electric propulsion as the primary engine of the S/C. The PPS-1350 electric propulsion engine of SNECMA Moteurs (Paris, France) has also been selected for France's Stentor technology demonstration satellite.
- On the commercial side (communications satellites), on-orbit electric propulsion makes great inroads. The Lockheed Martin S7000 platform series communication satellites, such as Intelsat-8, TelStar-IV, and Echostar, use hydrazine arcjets for station-keeping functions. Hughes is supplying xenon ion engines as an option on high-powered versions of the HS-601 platform. PanAmSat-5 (PAS-5) of PanAmSat Corp., a telecommunications satellite launched July 30, 1997 (and launch of PanAmSat-1R launch Nov. 15, 2000), use XIPS (Xenon Ion Propulsion System, built by HSC of Hughes Electronics Corp., Los Angeles, CA) on the HS-702 platform for station keeping and attitude maintenance. In the latter case, XIPS is the spacecraft's sole means of station keeping.²²⁵⁾ By the end of 2000, 12 communication satellites were using XIPS and variations thereof (Note: as of Oct. 2000 the Boeing Co. acquired three units within Hughes Electronics Corporation). SSL (Space Systems/Loral) and ASI (Alcatel Space Industries) are manufacturing communication satellites (Telstar-8 and Astra-1K, respectively) which use SPT (Stationary Plasma Thrusters) type electric propulsion systems to support such functions as stationkeeping. The Russian company Fakel Design Bureau in Kaliningrad produces the SPT-100 electric propulsion system for many applications in the commercial satellite market. The function of electric orbit raising is also being considered for large communication satellites. An arcjet electric propulsion system of General Dynamics (Primex) had its first flight in 1994. As of January 2001, there were over 100 Primex arcjets in orbit.
- **Solar sails** [refer to S/C concepts which utilize the momentum transfer of photons (solar radiation pressure) on large, highly reflecting sails in space for passive propulsion and

²²⁵⁾ <http://www.hughespace.com/factsheets/xips/xips.html>

orbit transfer functions]. In 1990 RSC Energia of Korolev (Moscow region), Russia, as the lead sponsor, formed SRC (Space Regatta Consortium - an association of 15 enterprises) with the objective to promote, develop and demonstrate satellite-based solar sails, so-called solarcraft (large deployable structures based on thin film sails). The first practical step toward this end was Znamya-2 (Banner), a demonstration experiment conducted on Feb. 4, 1993, when a segmented disk sail (20 m in diameter) was deployed by centrifugal forces from the Progress M-15 spacecraft, docked at the MIR space station (the experiment included verification of the system concept, stability and control of the structure, etc.). The Znamya-2 experiment represents the first solar sail deployment in space.

In parallel to the Znamya-2 deployment, a further experiment, “Novey Svet” (New Light) was conducted on the same solar sail structure with the objective to illuminate Earth from space. The first illumination from space took place in the early morning hours before sunrise over Western Europe. A reflected spot of light of about 5 km in diameter travelled from southern France through Switzerland, Germany, Czech Republic, and Poland, it then disappeared in the early sunlight of Belarus.

A second Znamya experiment, called Znamya-2.5, from MIR (actually the departing service vehicle Progress M-40) took place on Feb. 4, 1999 with a 25 m diameter sail (solar reflector) structure. The objective of Znamya-2.5 was to demonstrate beaming of solar power (reflected sun light) from space to Earth for artificial target illumination (spot light of 5-7 km in diameter) under controlled conditions; also test of film structure and test of prolonged illumination. However, a problem in the deployment mechanism resulted in an abort of the demonstration.

The Cosmos-1 Solar Sail Project, a privately funded venture of the Planetary Society, Pasadena, CA. The objective is to conduct a solar sail demonstration flight. In a first step, a sub-orbital test flight of an inflatable tube sail deployment system (600 m² of mylar sail) on a Volna launch vehicle (a converted SS-N 18 ICBM) took place on July 23, 2001 (submarine launch from Barents Sea). The Russian Babakin Space Center is the prime contractor and spacecraft integrator of the Planetary Society. The sub-orbital flight of the 40 kg S/C is from the Barents Sea to the Kamchatka peninsula (solar sail deployment at 400 km altitude). Initial flight analysis revealed a capsule separation failure (neither the solar sail deployment test nor the re-entry capsule inflation sequence that were planned for this sub-orbital test flight were carried out). The Cosmos-1 test craft was to separate from its capsule and unfurl its two 15 m long, wing-like blades before making a soft landing on Kamchatka. - In a second step, an orbital flight of Cosmos-1, also on a Volna launch vehicle, is planned for the end of 2001. ²²⁶⁾

A mission of CMU (Carnegie Mellon University), Pittsburgh, PA is called “Solar Blade Heliogyro Nanosatellite” (planned launch in 2002). The objective is to demonstrate the solar sail concept for attitude precession, spin rate management, and orbital adjustments. The mission is supported within UNP (University Nanosatellite Program) of DoD and NASA.

A NASA/JPL and DLR ²²⁷⁾ ²²⁸⁾ ²²⁹⁾ proposal of ODISSEE (Orbital Demonstration on an Innovative Solar Sail driven Expandable structure Experiment) plans a technology demonstration mission (ASAP microsatellite on Ariane-5). A solar sail ground deployment demonstration, conducted by a DLR, ESA and INVENT project team in Dec. 1999, was highly successful.

1.3.6 Space Environment Experiments

All spacecraft inevitably interact with their environments.²³⁰⁾ Besides the interactions one immediately thinks of in space (zero-g, solar heating, atmospheric drag, expansion into vacuum conditions, etc.) other interactions are also important. Those of interest to spacecraft designers so far may be grouped under several headings:

- Plasma interactions and spacecraft charging
 - Debris and micrometeoroids impact
 - Chemical reaction with neutral species
 - Radiation degradation
- Satellite surface charging experiments (see also Glossary). The ionizing radiation environment in space represents one of the most severe environment loads to space hardware and can cause a large number of problems such as spurious errors or permanent damage to electronics, erroneous signals in detectors, electrostatic charging of spacecraft or health damage to astronauts. In particular, the electrostatic charge on satellite surfaces can pose a hazard, when differential charging is leading to potential gradients. In some cases this potential build-up causes discharge arcing.²³¹⁾²³²⁾ Electrostatic charging by the natural space radiation environment is regarded as the most serious source of anomalies of S/C electronics. Hence, in-situ measurement of the space radiation environment is an important prerequisite for the enhancement of the static radiation environment models towards dynamic models which are required for the optimized design of future advanced systems. Examples of missions and experiments are:
- GEOS-1/-2 (Geostationary Satellite) missions of ESA, two reference S/C for IMS (International Magnetosphere Study). Launch of GEOS-1 on April 20, 1977; launch of GEOS-2 on July 14, 1978. The GEOS-1/-2 were the first S/C anywhere to carry a totally conductive coating - even over their solar panels. An electron beam experiment and a pair of probes, 40 m apart, provided independent measurements of the electric field surrounding the S/C. The S/C surface-treatment technology was confirmed. E.6
 - SCATHA (Spacecraft Charging at High Altitude), the S/C is also referred to as P78-2. A NASA/JPL mission (launch Jan. 30, 1979; orbit: 28000 km x 42000 km, 8.3° inclination, S/C mass = 360 kg).²³³⁾ Experiment SC1 (Engineering+ VLF and HF Receivers) measured surface potentials (RF waves between 0-300 kHz and 2-30 MHz) of various S/C materials. SC2 (Spacecraft Sheath Fields + Energetic Ions) measured low energy electrons and ions, energetic protons, and electrons. SC3 (High Energy Particle Spectrometer) measured high energy electrons and protons. SC4 (Satellite Electron and Positive Ion Beam System) used ion and electron beam guns to control spacecraft surface potential. SC5 (Rapid Scan Particle Detector) measured electrons and ions. .. SC11 (Magnetic Field Monitor) measured DC and ELF magnetic fields. ML12 (Spacecraft Contamination + Thermal Control Materials Monitoring) measured contamination rates and property changes of several thermal control material samples.
 - GEOTAIL
 - STRV-1a and -1b (Space Technology Research Vehicle, of DERA, UK, see M.25), launch June 17, 1994. Both S/C flew CAE (Charge Alleviation Experiment) to demonstrate an active S/C surface charge alleviation system. Other space environment instruments flown on STRV-1a are: SCDE (Surface Charge Detector Experiment), CID (Cold Ion Detector), LPI (Langmuir Probe Experiment), CREDO-II (Cosmic Radiation Environment and Dosimetry Experiment), and RDRS (Radiation Dose Rate Sensor). Other space environment instruments flown on STRV-1b are: SEE (Space En-

- vironmental Effects), and REM (Radiation Environment Monitor). Note: The REM instrument was also flown on the MIR space station starting in Nov. '94 until Nov. '96.
- STRV-1c and -1d (launch Nov. 16, 2000) are follow-up missions of DERA, UK with the environment objectives focused on emerging technology hardware.
 - Equator-S (launch Dec. 2, 1997, see K.9) carried PCD (Potential Control Device) to reduce the potential caused by the ambient plasma charging of the outer surfaces.
 - SPOT-4 (launch March 24, 1998, see D.37.2) carried SILLAGE to measure electrostatic potentials on the outside of the SPOT satellite which are due to the “wake” effect.
 - Cluster-II (launch July 16, 2000 of first pair of S/C; on Aug. 9, 2000 the second pair was launched, K.7). The four identical Cluster S/C feature conductive outer surfaces. An extremely low S/C-generated electromagnetic background noise is mandatory for accurate electric field and cold plasma measurements. The solar arrays consist of BSR (Back-Surface-Reflection) cells, arranged in self-compensating formations to minimize the generation of DC magnetic fields. The conductive coating on the cell cover glass minimizes the build-up of differential charge potentials.
 - TSX-5 (Tri-Service Experiments Mission 5) of AFRL (launch June 6, 2000) flies two payloads: a) STRV-2 (Space Technology Research Vehicle) of DERA and AFRL with SAMMES (Space Active Modular Materials Experiment System), and b) CEASE (Compact Environmental Anomaly Sensor) of AFRL.
- Radiation-hardened components. The adverse effect of the ‘space weather’ (solar wind acting against the Earth’s magnetic field, energetic particle flux, etc.) on space hardware, (in particular electronic components, sensors, power and communication systems) increases with radial distance of the S/C orbit. It implies that the long-term performance and reliability of hardware in GEO is much more subjected to a severe environment than a spacecraft in MEO or LEO orbits. - As a consequence, radiation-hardened components (CMOS chips, solar cells, etc.) were developed to account for the space weather and to improve hardware life times. The introduction of radiation-hardened components was first realized in GEO satellites.
 - Space environment experiments - collection of cosmic dust, particles and debris from platforms. Dust is ubiquitous in the solar system, with dust particles abundant in regions as diverse as interplanetary space, the terrestrial and martian atmospheres, comets, asteroids, satellite surfaces, and planetary rings. The dynamics of these short-lived particles are particularly sensitive to their environment, so they serve as probes of a variety of processes and are strongly effected by electromagnetic forces. - Since the early 1980s several programs were initiated with the aim of systematic collection and analysis/curation of cosmic dust. Also study of radiation degradation effects on some types of materials. Initial airborne dust collections (since 1981) were made with instruments mounted underneath a wing using NASA WB-57F aircraft from NASA/JSC. Several space agencies (NASA, ESA, NASDA, CNES, etc.) maintain special laboratories to analyze impact damage, instruments are being developed and flown to measure orbital micro-debris sources. Long-term data on the space environment and its effects on space systems and operations is a constant need of spacecraft and instrument designers. In addition, the study of recovered long-duration space structures like LDEF and EURECA, and other recovered hardware (solar array from Hubble, etc.), is of major interest. In particular, large surface structures such as solar arrays, can serve as passive detectors for the study of debris impacts. ^{234) 235)}

In 1995, NASA started its SEE (Space Environments Effects) program with the objective to collect, develop and to disseminate the technologies required to design, manufacture and operate more reliable, cost-effective spacecraft for the government and commercial sectors. In partnership with industry, academia, and other government agencies, the SEE program defines the space environments and advocates technology development to accommo-

date or mitigate these harmful environments on spacecraft. The ESEM (Evaluation of Space Environment and Effects on Materials) payload of STS-85, in cooperation with NAS-DA, is one of many experiments in SEE.²³⁶⁾

Mission or Instrument	Description
LAC (Large Area Collector), NASA/JSC	LAC is flown on NASA ER-2 aircraft since 1989, P.110
EURECA-1 launched on STS-46 July 31, 1992 and retrieved on STS-57 July 1, 1993	ESA mission. The experiment TICCE on EURECA-1 collected debris, meteoroids, and cosmic dust. See J.5.1
LDEF (Long Duration Exposure Facility) see J.8	NASA/LaRC S/C deployed from Shuttle in April 1984 (STS-41-C) and recovered on STS-32 Jan. 12, 1990 Exposure of many systems to cosmic radiation and collection of cosmic dust by Exp. A0138-2 of CERT/ONERA, and by Exp. A0201, S001, etc. of NASA/LaRC
MIR Space Station	On three occasions (1988, 1995, 1997) dust collection detectors were used on the outside of MIR.
Ulysses mission (ESA/NASA), launch Oct. 6, 1990	DUST experiment of MPIK (Heidelberg, Germany), see K.28
APEX (Advanced Photovoltaic & Electronics Experiment), S/C of DoD, launch Aug. 3, 1994 (no particle collection on APEX)	Study of long-term radiation effects in an orbit of 361 km x 2528 km, inclination = 70°. Experiments included: PASP (Photovoltaic Array Space Power Diagnostics), CRUX (Cosmic Ray Upset Experiment), and FERRO (Thin-film Ferro-electric Experiment)
MEEP (MIR Environmental Effects Payload) deployed on STS-76 (Mar. 22, 96) and retrieved on STS-86 (Oct. 1, 1997)	NASA/LaRC/MSFC conducted a series of experiments such as POSA-I & -II (Passive Optical Sample Assembly), PEC (Passive Experiment Carrier), PPMD (Polished Plate Meteoroid Detector), ODC (Orbital Debris Collector)
CDCE (Cosmic Dust Collection Experiment) and AOE (Atomic Oxygen Experiment), both on STS-85 (Aug. 7-19, 1997)	NASA/LaRC experiments in ESEM program. CDCE: Use of aerogel to capture cosmic dust. AOE: candidate materials for ISS (lubricants, paints, thermal coatings, etc.)
MightySat-1 of AFRL, launch Dec. 4, 1998, see M.11.1	MPID (Micro-Particle Impact Detector)
Stardust (NASA minisatellite in Discovery program), launch Feb. 7, 1999	Rendezvous with a comet and return of comet tail samples to Earth (encounter with comet Wild-2 in Jan. 2004), in 2006 return of interstellar dust grains in a reentry capsule to Earth
ARGOS (DoD, launch Feb. 23, 1999)	SPADUS (Space Dust Experiment)
SUNSAT-1 of Stellenbosch University, South Africa, launch Feb. 23, 1999	MIS (Meteoroid Impact Sensor) of NASA/LaRC
STRV-1c and -1d, DERA, launch Nov. 16, 2000	CDMS (Compact Debris and Micrometeoroid Sensor) characterizes of the debris and micrometeoroid environment in GTO
STRV-2 of AFRL and DERA (launch June 6, 2000) on TSX-5 mission of AFRL	MDIM (Meteoroid and Debris Impact Monitor) of NASA/LaRC.

Table 27: Overview of some cosmic dust/particle collection platforms

- **Orbital debris.**^{237) 238) 239) 240) 241) 242) 243)} The use of outer space presents a number of hazards to S/C owners and operators. Temperature extremes, radiation, solar flares, and micrometeoroids have long been essential elements to consider in spacecraft and mission design. Increasing use of space has brought a new source of risk collisions with manmade objects. The proliferation of debris in space generated by spacecraft and launchers is likely to become a serious issue in the near future. Such debris, originating from S/C, upper stage

explosions and from the rising number of non-operational and abandoned satellites, represent a hazard for all operational missions (manned and unmanned). The GEO and LEO orbits are in particular littered with debris. Some examples are:

- Micro-debris originating from objects launched from Earth were first encountered in 1976 on the US Skylab Space Station, where aluminum oxide exhaust from apogee kick motors was identified.
- In 1986, the spent third stage of the Ariane launcher, used to place SPOT-1 into orbit (launch Feb. 22, 1986), exploded after nine months in orbit (LEO). The explosion generated over 700 fist-sized fragments. In addition, thousands of micro-particles of all sizes were released.
- Meteoroid impact on a satellite. In 1993 a Perseid meteoroid (tiny grains of dust) hit a solar panel on the European Olympus communications satellite. The project management is convinced the hit caused a pulse that sent false signals to the control system of the S/C. As a consequence, the satellite went into the wrong automated sequencing causing the loss of the spacecraft (it took all the remaining propellant to regain control, resulting in the end of the mission).

Particle diameter class	Effects on S/C structure	S/C protection	Estimated Nr. of particles on orbit
<0.01 cm	Cumulative effect over long periods of time	Unnecessary	Very large number of micro particles
0.01 - 1 cm	Serious structural damage, perforations. Consequences depend on element affected	Shielding needed	35,000,000 objects
1 - 10 cm	Very severe damage	No solution so far	110,000 objects
>10 cm	Objects are cataloged, catastrophic consequences	Avoidance maneuvers	>8700 objects

Table 28: Overview of space debris classes that may impact on operational S/C

- On July 24, 1996, the French microsatellite CERISE collided with a piece of debris (a suitcase-sized piece of the old Ariane rocket of 1986 - the first official collision between two catalogued objects), cutting in half the 6 m long stabilizing boom of CERISE. Fortunately, the French ground controllers regained control over the satellite following the collision.
- On Oct. 26, 1999 ISS (International Space Station) made a maneuver to avoid a potentially dangerous piece of orbital debris (the US Space Command and NORAD had reported that a spent Pegasus upper stage would pass ISS to within 1.4 km). Hence, thrusters of ISS were fired to increase the stations altitude by about 1.5 km.
- A major contributor to the orbital debris background have been breakups of rocket upper stages and satellites. More than 150 breakups have been verified, and more are believed to have occurred. Breakups generally are caused by explosions and collisions. Explosions can occur when propellant and oxidizer inadvertently mix, residual propellant becomes overpressurized due to heating, or batteries become overpressurized.

These incidents show that all aspects of debris-related issues, including some regulation standards, have to be dealt with in the future. The SSN (Space Surveillance Network) of the US Space Command and NORAD (North American Aerospace Defense Command) in Colorado Springs, CO, maintains orbital element sets of some 8764 objects (of 10 cm diameter or larger) - still many more are too small or in too eccentric orbits to be cataloged. Of the 8764 objects being tracked (as of Oct. 20, 1999), there are 2634 satellites (any payload operational or non-operational currently in Earth orbit - meaning LEO, GEO, GTO, MEO, HEO, or any other Earth orbit), 6040 objects are termed “debris” (meaning all man-made objects in Earth orbit), and 90 objects are termed “space probes” (referring to payloads that are not in Earth orbit - such as deep space missions). The historical catalog status

of the US Space Command lists on Oct. 20, 1999: payloads decayed = 2,501, debris decayed = 14,680, total = 17,181 objects.²⁴⁴⁾ - In this context, it is also of interest to look at the estimated distribution of orbital debris in the following scheme: Operating satellites = 6%, spent satellites = 22%, upper stages = 17%, operational debris = 13%, and fragments (of rocket upper stages, etc.) = 42%.

The debris in orbit totals an estimated 4000 tons in 1999, with 175 tons added every year.²⁴⁵⁾ Complications will arise from the ever-increasing use of space. The operational networks of major commercial satellite constellations (initial launches started in 1998) increases the crowding of space in LEO very rapidly. The Iridium constellation has 77 in orbit (nominal of 66 operational), Orbcomm has 35 (constellation completed in Dec. 1999), the Teledesic constellation has 288, Globalstar 48, and Skybridge 64, when fully deployed. These are only a few of the commercial entries. In Earth observation the picture is pretty much the same. Constellations or clusters of small satellites are planned by a number of agencies to enter a new dimension of formation flight observations.

Debris in the geostationary ring.²⁴⁷⁾ Since the launch of Syncom-1 in Feb. 1963, more than 800 satellites and rocket upper stages have been inserted into GEO or its vicinity. As of 2000, only about 250-270 of these satellites are used operationally. GEO satellites are therefore increasingly at risk of colliding with uncontrolled objects. Contrary to the situation with LEO satellites, there are no effective natural removal mechanisms for GEO objects. Routine surveillance with ground-based radars of SSN (Colorado Springs, CO) is able to catalog objects of 1 m in size or larger in GEO. Observations with ESA's Zeiss telescope at the Teide Observatory in Tenerife, with an optimized debris-detection system, have shown that there is a significant population of about 1600 small-debris objects (10-100 cm size) in the geostationary ring.

Collision risk monitoring. Starting in about 1995, space agencies (CNES, ESA, NASA, etc.) are beginning to monitor close encounters of catalogued objects with their own S/C. CNES experienced in this process, for instance, that on average, an object passes within less than 1500 m of a S/C every two weeks. Even closer approaches (under 800 m) were observed on 19 occasions.

Debris, reentering the atmosphere, presents a further problem, in particular to population safety. In 1999, it is estimated that about 17,000 objects of debris have reentered the atmosphere since Sputnik - virtually all of them disintegrated in the reentry process, very few actually hit Earth, although some particularly large or well-shielded objects have been known to get through. Controlled de-orbiting and reentry procedures over oceans or sparsely populated regions are the rule for larger returning S/C that can still be steered. At the Skylab uncontrolled reentry in 1979, with a mass of 82 metric tons, fragments fell into the Indian Ocean and the western region of Australia. This uncontrolled reentry definitely caused many alerts throughout the world. The MIR space station of Russia (with 140,000 kg of mass) was deorbited in a controlled manner in March 2001 with a final reentry into the Pacific Ocean on March 23, 2001. Many governments had their national control centers working for several weeks. An atmosphere of "we are doing something, and everything is under control" was portrayed publicly to keep the people calm. Fortunately, the Russian Control Center did an excellent job to bring MIR to the intended splashdown region. [Russia had asked NASA (incl. radars of the US Space Surveillance Network) and ESA (incl. the radar facilities of FGAN near Bonn, Germany) for support, which was granted. ESOC was the

center of a data exchange network among technical centers (TSUP, NASA/JSC, FGAN, and other space centers in Europe)].

A principal forum for debating orbital debris issues and new practices (including debris mitigation measures) is the “Inter-Agency Space Debris Coordination Committee” (IADC), created in 1993 by government representatives from USA (NASA), Europe (ESA), Russia (RKA), Japan (ISAS, NASDA and NAL), India (ISRO), China (CNSA), and the Ukraine (NSAU).

- **Spacecraft removal from orbit at end-of-life.** In the late 1990s, NASA adopted a new policy, a “NASA Management Instruction” with regard to spacecraft development (concerning debris prevention and end-of-life disposition). A so-called “debris assessment” is needed to determine if requirements are met for waiving the controlled reentry at the end of mission life. Because of lack of global regulations, waivers are likely to be issued for expensive measures that effect the projects of the own agency. But this is not special for the US: most spacefaring nations behave in the same way. Sometimes the US government insists on the strict application of its standard (NASA Management Instruction) as in the case of the Iridium constellation (condition for obtaining the license). - The planned NPP (NPOESS Preparatory Project) spacecraft and the follow-up NPOESS series, for instance, are expected to have sufficient debris that survives reentry; hence, they feature the capability of a controlled reentry (propulsive maneuvers) to place the debris in a pre-determined location in the ocean.

ESA came out with an “ESA Space Debris Mitigation Handbook,” Release 1, April 7, 1999, and a draft of the “European Space Debris Safety and Mitigation Standard” in 2000 (Sept. 27, 2000, Issue 1, Rev. 0), which discusses the issues of in-orbit debris and gives various scenarios for end-of-life (EOL) disposal. - The two TerraSAR spacecraft of Astrium (XSAR and LSAR mission with a planned launch in 2006), within the framework of ESA Earth Watch missions, are planning thruster firings at EOL (using budgeted fuel) to obtain an elliptical orbit with a perigee of about 300 km or lower. This generates sufficient atmospheric drag to bring the S/C eventually into a reentry trajectory.

Further references on space debris are: “Position Paper on Orbital Debris,” of IAA (International Academy of Astronautics), Paris, 2001, and “Technical Report on Space Debris,” UN, New York, 1999. The problem with debris policies is that the standard in its entirety will only be applied when everybody in space will abide by the rules. Since no international regulation concerning space debris exists, this will take some time. Such a regulation must necessarily be issued by the UN, where the deliberations in the UN Committee on the Peaceful Uses of Outer Space (UNCOPUOS) on debris are ongoing since 1994. All agreements must be reached by unanimity. It took several years to reach agreement to have space debris on the agenda.

Among the space agencies there is practically a consensus that S/C and rocket upper stages in Low Earth Orbit (LEO - orbits <2000 km) should be removed from orbit within 25-50 years after mission completion. This is simply to avoid further proliferation and generation of debris (through collision). A regulation is however needed to force everybody, including commercial users/operators to apply the same rules. ²⁴⁸⁾

The situation is different with objects which will reenter at some time, but which will not completely burn up. There is already now international space law, the Liability Agreement, which clearly stipulates the liability of the owner in case of damage on ground or in air-space. Therefore, more and more satellites which could be a risk on ground, will be deorbited in a controlled way. Examples: MIR, Compton Gamma Ray Observatory.

-

1.3.7 Tether Experiments

- Tether experiments in space (M.27). Although the idea of using space tethers goes back to the 1960s, it was the launch of TSS (Tethered Satellite System) in 1993 on Shuttle mission STS-46, which gave a decisive impetus to tether technology development and projects, by realizing the potential of tethers to meet a broad range of applications in various fields.²⁴⁹⁾
²⁵⁰⁾ Tether deployment techniques and stable operations were the dominant themes of the early years including the 1990s. Potential tether applications include: propulsion (orbit changes), payload capture and release, power generation, atmospheric studies [a) reaching otherwise inaccessible flight regions with downward deployed tethers; b) active experimentation with the surrounding plasma], and gravity experiments.

Mission (Agency)	Launch (Timeframe)	Orbit	Tether Length	Comment
Gemini-11(NASA)	Sep. 11-15,'66	LEO	30 m	Spin-stabilized, 0.15 rpm
Gemini-12(NASA)	Nov. 11-15,'66	LEO	30 m	Local vertical, stable swing
H-9M-69	1980	Suborbital	500 m	Partial deployment
S-520-2	1981	Suborbital	500 m	Partial deployment
Charge-1	1983	Suborbital	500 m	Full deployment
Charge-2	1984	Suborbital	500 m	Full deployment
ECHO-7	1988	Suborbital		Magnetic field aligned
Oedipus-A (NRC/ NASA,CRC, CSA)	Jan. 30, 1989	Suborbital	958 m	Spin-stabilized, 0.7 rpm (Canada/USA)
Charge-2B	1992	Suborbital	500 m	Full deployment
TSS-1 (STS-46) (ASI/NASA)	Jul. 31-Aug. 8, 1992,	LEO	< 270 m	Electrodynamic tether, partial upward deployment and retrieval of tether
SEDS-1 (NASA)	Mar. 29,1993	LEO	20 km	Nonconducting tether, downward deployment, swing and cut
PMG (DoD) Plasma Motor Generator	June 26, 1993	LEO	500 m	Electrodynamic tether, upward deployment, tether current in both directions. Demonstration of hollow cathode plasma contactors for current collection and emission
SEDS-2 (NASA)	Mar. 9, 1994	LEO	20 km	Local vertical stable, downward deployment
Oedipus-C (NRC/ NASA,CRC, CSA)	Nov. 6, 1995	Suborbital	1 km	Spin-stabilized, 0.7 rpm (Canada/USA)
TSS-1R (STS-75) (ASI/NASA)	Feb. 22-Mar. 9, 1996	LEO	19.6 km	Electrodynamic tether, severed prior to full deployment
TiPS (NRO/NRL)	May 12, 1996 Jun. 20, 1996 deployment	LEO	4 km	Long life tether (tracking of one year)
YES (Technical Univ. of Delft)	Oct. 30, 1997	GTO	35 km	YES (of TEAMSAT) was not deployed to avoid a collision with other S/C (M.26)
STEX/ATEX (NRO/NRL)	Oct. 3, 1998 Jan. 16 1999 deployment	LEO	6 km	Nonconductive tether, planned demonstration of tether system stability and control. However, a deployment malfunction caused an experiment failure
PICOSAT1.0 of the Aerospace Corporation	Jan. 27, 2000 on OPAL of Stanford	LEO	30 m	PICOSAT1.0 was ejected OPAL on Feb 6, 2000. The system of two S/C operated for 3 days when battery power decayed.
PICOSAT1.1 of the Aerospace Corporation	July 19, 2000 on MightySat II.1 of AFRL	LEO	30 m	PICOSAT1.1 will be ejected from Mightysat II.1 one year after launch (in Sept. 2001) to test storage effects on the system.
METS (MIR Electrodynamic Tether System)	2001	LEO	5 km	First practical application of non-rocket propulsion in space

²⁴⁹⁾ Note: The objective of the Gemini tether missions was to see if tethers could be used for rendezvous and docking in preparation for the future moon missions. A parachute cable was used as the tether, which was attached to the Agena by a spacewalking astronaut. The other mission (Gemini-11) experimented with rotation about the CM (Center of Mass) to see if it was stable - it was. The Gemini missions were not electrodynamic in nature, nor were they performed for scientific purposes - as were the TSS missions.

²⁵⁰⁾ <http://infinity.msfc.nasa.gov/Public/ps01/ps02/table1.html>

Mission (Agency)	Launch (Timeframe)	Orbit	Tether Length	Comment
ProSEDS (NASA)	2001	LEO	25 km	Upward deployment (producing drag and electrical power)
TSE (ESA)	2002	LEO	35 km	Demonstration of ISS sample return

Table 29: Chronology of tether missions

As of the late 1990s spaceborne tethers are indeed a reality (there are numerous projects) and their potential is far from being fully appreciated.

1.4 ISS (International Space Station) Built-up

- The ISS (International Space Station) built-up era in LEO began in 1998. - The program of an international space station was first announced/initiated by President Reagan in his ‘State of the Union’ address on Jan. 25, 1984. A total of 45 US/Russian missions are planned up to 2005 to assemble more than 100 elements that will complete the International Space Station (total mass of 460 tons of structures and equipment). The ISS target orbit altitude is 410 - 450 km, orbit height when docking is lowered to 350 km, orbit inclination is 51.6°. - Other nations, participating in the ISS project (besides the USA and Russia), include: Brazil, Belgium, Canada, Denmark, France, Germany, Italy, Japan, the Netherlands, Norway, Spain, Sweden, Switzerland and the United Kingdom. ISS is the largest cooperative space research program in the history of space flight. When assembled ISS will have dimension of: 108 m in length and 74 m in width. The total mass will be more than 415 tons. - Three of the four operational Shuttles - Discovery, Atlantis and Endeavour - have been modified for increased lift capability (16,000 kg max payload into orbits of 51.6° inclination) to meet the projected needs of ISS.

- The first component of ISS, namely FGB (Functional Cargo Block), also referred to as Zarya (meaning ‘sunrise’), was launched Nov. 20, 1998 on a Proton vehicle from the Baikonur Cosmodrome in Kazakhstan. Zarya serves as the cornerstone of ISS, it is a 20,040 kg pressurized module. Zarya was built for NASA by KhSC ((Khrunichev State Research and Production Space Center) of Moscow in cooperation with Russian space industry, under contract with the US Boeing Company.

- The second component of ISS, Unity (11,800 kg, 11 m in total length), referred to as node 1, with six berthing ports, was launched Dec. 4, 1998 on Shuttle (STS-88, Endeavour) and mated to Zarya three days later.

- The STS-96 Shuttle flight on Discovery (May 27 - June 6, 1999) carried a) internal logistics and resupply cargo for station outfitting, and b) an external Russian cargo crane that was mounted to the exterior of the Russian station segment and used to perform spacewalking maintenance activities.

- The STS-101 flight on Atlantis (May 19 - 29, 2000) services were: a) prepared the station for the arrival of the Zvezda Service Module, b) installed four new batteries, 10 new smoke detectors and four new cooling fans on the Zarya module, c) installed the final parts of the Strela crane on Pressurized Mating Adapter 1, d) removed and replaced the early communications system antenna, and e) installed handrails on the Unity module.

- The Russian-built Zvezda (meaning “star”) Service Module was launched on July 12, 2000 by a Proton-K vehicle from Baikonur (ISS 1R flight). Zvezda was docked to ISS on July 26, 2000. The Zvezda Service Module provided a) the first primary living quarters for three-person crews, b) primary docking port for Progress-type cargo resupply vehicles, c) power and steering (propulsive attitude control and reboost) capability to keep ISS in a safe orbit.

- Aug. 6, 2000 launch of Russian Soyuz-2 from Baikonur on ISS flight 1P with the Progress M1-3 resupply ship for ISS. Progress docked with ISS on Aug. 9, 2000.

- The STS-106 flight of Atlantis (Sept 8-20, 2000) provided a) internal logistics and re-supply cargo for station outfitting, b) a space walk was conducted to perform maintenance on the station.
- STS-92 flight of Discovery (Oct. 11-24, 2000, ISS-05-3A flight) provided: ITS (Integrated Truss Structure) Z1, PMA-3 (Pressurized Mating Adapter-3), a Ku-band communications system, and CMGs (Control Moment Gyroscopes) for non-propulsive attitude control. ITS-Z1 is an early exterior framework to allow first U.S. solar arrays on flight 4A to be temporarily installed on Unity for early power. The Z1 truss is the first permanent lattice-work structure for ISS.
- A Russian Soyuz rocket (launch Oct. 31, 2000) lifted the first expedition crew to ISS from Baikonur, referred to as ISS-2R.²⁵¹⁾ Objectives: a) to establish the first station manning with a three-person crew (Commander Bill Shepherd; Soyuz Commander Yuri Gidzenko, Flight Engineer Sergei Krikalev), b) provides Russian assured crew return capability without the Shuttle present, c) **the “permanent” habitation of ISS has begun.**
 - STS-97 flight of Endeavour (Nov. 30 - Dec. 11, 2000). The ISS assembly flight 4A provided the P6 Integrated Truss Segment, a 7700 kg package containing the PV (Photovoltaic) Module, plus S4 and S5 radiators. The US-provided power system increases the available electrical power of ISS by a factor of five. The P6 consists of two identical PVAAs (Photovoltaic Array Assembly), each of which is made up of an SAA (Solar Array Assembly) and a SAW (Solar Array Wing). The two SAWs have a total power generation capability of about 64 kW. Each SAW has a structure size of 35 m x 11.58 m and a mass of 1087 kg. Each SAW contains 33,000 solar arrays, each of size 8 cm x 8 cm with 4,100 diodes. The entire assembly represents the largest structure deployed in space so far (73 m from tip to tip) as well as the largest space-installed power supply.
 - STS-98 flight of Atlantis (Feb. 7 - 20, 2001). The ISS assembly flight 5A carried the Destiny Laboratory Module, an aluminum structure of 8.5 m in length and 4.3 m in diameter. The module provides an initial US user capability in the field of near-zero gravity research.
 - STS-102 flight of Discovery (March 8-21, 2001). The ISS logistics and resupply flight 5A.1 provided the Leonardo MPLM (Multi-Purpose Logistics Module). The module is about 6.4 m long and 4.6 m in diameter containing equipment racks. Exchange of first crew by a new crew.
 - STS-100 flight of Endeavour (April 19 - May 1, 2001). The flight 6A provided the Raffaello MPLM (lab outfitting) for the US Lab, the UHF antenna (for EVA support), and delivery/installation of the Canadian SSRMS (Space Station Remote Manipulator System), the cornerstone of ISS’s Mobile Servicing System (MMS), also referred to as Canadarm2 (Canadarm1 is on Shuttle). SSRMS, is currently attached to the Destiny module and used as “construction crane” of ISS, lifting payloads and performing maintenance work.. With the installation of Canada’s Mobile Base System (MBS) in 2002, SSRMS will be able to slide along the main truss of the station (lateral mobility), providing an additional functional capability with four Power Data Grapple Fixtures. A further upgrade of Canadarm2 is planned for 2003/4 with SPDM (Special Purpose Dextrous Manipulator). This smaller two-armed robot has the capability to perform even more delicate tasks at ISS. SSRMS is 17.6 m long when fully extended and has seven motorized joints. This arm is capable of handling large payloads and assisting with docking the Shuttle.
 - A Russian Soyuz spacecraft arrived at ISS on April 30, 2001 with the first space tourist ever on-board, namely Dennis Tito, a well-to-do US citizen who paid \$20 Million to Rosaviakosmos, the Russian Space Agency (one week stay at ISS). There was considerable criticism and protest from NASA officials prior to the launch, but Rosaviakosmos insisted on Tito’s mission. The agency wanted and needed the cash badly due to the abysmal lack of

²⁵¹⁾ <http://spaceflight.nasa.gov/station/assembly/flights/2000/2r.html>

governmental funding for its space programs. Further space tourists are waiting in the wings for a flight to ISS.

- STS-104 flight of Atlantis (July 12-24, 2001). Installation of an ISS Joint Airlock. The airlock is the primary path for ISS space walk activity (entry and departure of astronauts or cosmonauts). The airlock is a pressurized flight element consisting of two cylindrical chambers attached end-to-end by a connecting bulkhead and hatch. The airlock structure, built at MSFC, is 6 m in length and 4 m in diameter with a mass of about 6500 kg. There are two main components to the airlock: a crew airlock and an equipment airlock for storing EVA gear and EVA preflight preparations. STS-104 also carries a spacelab pallet with four High Pressure Gas Assembly containers that were attached to the exterior of the airlock.

1.5 Overview of Operational Meteorological Missions

Spaceborne operational meteorological services, namely the measurement of short-term weather variations in the lower regions of the atmosphere (in particular the troposphere as well as the Earth's surface), are provided by two types of satellite constellations: LEO and GEO.

“Today we can make 3-5-day weather forecasts with nearly 80% accuracy. That’s fantastic. In 10 year’s time, with all we can learn from our upcoming missions, we intend to push that out to 7 to 10 days with the same accuracy. With the right investments in observations and computational modeling, we might even push that out to 14 days perhaps 20 years from now.” (Daniel Goldin, NASA Administrator, at JHU/APL address, Oct. 10, 2000, Ref. 7)

1.5.1 LEO (Low Earth Orbit) Satellite Missions

LEO S/C in polar sun-synchronous orbits provide wide-swath repeat observations (same sun illumination angles) of a given Earth surface region at the same time of the day (due to same latitudinal crossings).

- The first meteorological LEO services started with NASA’s launch of TIROS-1 (Television Infrared Observation Satellite) on April 1, 1960, the first true weather satellite. Since then, five generations of polar-orbiting meteorological S/C were developed by NASA and flown by NOAA as outlined in Table 30. - The NOAA 4th-generation polar program (ATN), which started in 1978 with the launch of TIROS-N, is based on the services of two operational satellites flying in complementary sun-synchronous orbits, one in a “morning or AM” orbit, and the second in an “afternoon or PM” orbit.

1st generation 1960 - 1965	TIROS series [TIROS-1 (1960) to TIROS-10 (1965)]
2nd generation 1966 - 1969	TOS (TIROS Operational System) series as pre-launch designation. The in-orbit satellite designation was ESSA [ESSA-1 (1966) to ESSA-9 (1969)], after the S/C operating agency.
3rd generation 1970 - 1976	ITOS (Improved TIROS Operational System) series as pre-launch designation. The in-orbit satellite designation was NOAA [NOAA-1 (1970) to NOAA-5 (1976)]
4th generation 1978 - 1994	ATN [Advanced TIROS-N] series. After TIROS-N (1978) the pre-launch designation changed to NOAA-A (the corresponding inflight name was NOAA-6). The pre-launch letter designation was kept throughout. NOAA-8 through NOAA-14 were designated ATN (Advanced TIROS-N) spacecraft, equipped for S&R (Search and Rescue) and growth instruments.
5th generation 1998 - 2007	NOAA-15 (pre-launch NOAA-K), NOAA-L, -M, -N, and -N’ incorporate advanced instrumentation and are designated “NOAA next.”

Table 30: Overview of the US civilian polar meteorological programs

- The US military services of DoD built their own polar-orbiting meteorological satellite series in parallel to the civil system of NASA/NOAA, referred to as DMSP (Defense Mete-

orological Satellite Program). The first generation of DMSP S/C started with the launch of a Block 4 series satellite on Jan. 19, 1965 and ended with the launch of a Block 5C S/C on Feb 19, 1976. The various generations of DMSP satellites are listed in Table 330. The OLS (Operational Linescan System) instrument on DMSP provides in addition to its normal daytime (visible) imagery also nighttime imagery with its IR channels.

Satellite Series (Agency)	Launch	Major Instruments	Comment
NOAA-2 to -5 (NOAA)	21.10. 1971, 29.7. 1976	VHRR	2580 km swath
TIROS-N (NOAA-POES)	13.10.1978	AVHRR	> 2600 km swath
NOAA-15 to -L, M, N, N'	13.5.1998 - 2007	AVHRR/3	> 2600 km swath
DMSP Block 5D-1 (DoD)	11.9.1976 - 14.7.1980	OLS	3000 km swath
DMSP Block 5D-2 (DoD)	18.6.1987	OLS, SSM/I	SSMIS replaces SSM/I
DMSP Block 5D-3 (DoD)	12.12.1999	OLS, SSM/I,	starting with F-16 (2001)
Meteor-3 series of Russia	24.10.1985	MR-2000M, MR-900B	3100 km, 2600 km swath
Meteor-3M series of Russia	2001 (Meteor-3M-1)		
FY-1A, 1B, 1C (CMA, China)	7.9.1988, 3.9.1990, 10.5, 2000	MVISR	2800 km swath
MetOp-1 (EUMETSAT)	2005	AVHRR/3, MHS, IASI	PM complement to NOAA-POES series
NPP , (NASA/IPO)	2005	VIIRS, CrIS, ATMS	(NPOESS Preparatory Project)
NPOESS (IPO)	2008	VIIRS, CMIS, CrIS,	Successor of NOAA-POES and DMSP series

Table 31: Overview of polar-orbiting meteorological satellite series

- The Meteor-1 series of the former USSR started with the launch of Meteor-1-1 on March 23, 1969; the 1st generation series lasted until 1978 with the launch of Meteor-1-28. This was succeeded by the Meteor 2 series from 1975 to 1990 (Meteor-2-1 to 2-21), and further by the Meteor-3 series from 1985 to the present time (see Table 361).
- The Chinese polar-orbiting meteorological program started in 1977 followed by the launch of the FY-1A (Feng-Yun-1) satellite of CMA (China Meteorological Administration) on Sept. 7, 1988 and FY-1B on Sept. 3, 1990.
- EUMETSAT, the European meteorological service provider, was planning on a polar-orbiting satellite series since the mid 1980s. Since the early 1990s, NOAA and EUMETSAT have been discussing/planning future polar cooperation with increased European responsibility for the “morning orbit” to ensure continuity of the POES (Polar-orbiting Operational Environmental Satellites) services. The basic intent is to join the space segment of the emerging MetOp program of EUMETSAT with the existing POES program of NOAA into a fully coordinated service, thus sharing the costs of a program for synergetic reasons. The plans came to a common baseline and agreement, referred to as IJPS (Initial Joint Polar System), in 1998. IJPS comprises two series of independent, but fully coordinated polar satellite systems, namely POES and MetOp, to provide for the continuous and timely collection and exchange of environmental data from space. EUMETSAT plans to include its satellites MetOp-1, -2 and -3 for the morning orbit, while NOAA is starting with its NOAA-N and N' spacecraft for the afternoon orbit of the coordinated system. Plans call for MetOp-1 to be launched in 2005. - In this context, Europe (i.e. ESA, EUMETSAT) refers to its application-oriented missions (this includes operational meteorological and climate monitoring missions) in LEO and GEO as “Earth Watch Missions” (MetOp, MSG). The Earth Watch concept was introduced in 1994/5, dealing in particular with prototype operational missions and serving applications-oriented needs in partnership of industry and/or public agencies. Long-term operational service provision is the ultimate aim of the ESA Earth Watch program.
- NPP (NPOESS Preparatory Project). NASA and IPO (Integrated Program Office) plan the NPP mission (launch in 2005) with the objective to demonstrate/validate the op-

eration of three advanced instruments (VIIRS, CrIS, ATMS) scheduled to fly on NPOESS. ATMS (Advanced Technology Microwave Sounder) is a NASA-provided instrument with the objective to combine the passive-microwave observation capabilities of three heritage instruments, namely AMSU-A1/A2 and MHS, into a single instrument with a correspondingly reduced mass and power consumption and with advanced microwave-receiver electronics technologies.

- NPOESS (National Polar-orbiting Operational Environmental Satellite System). NPOESS (G.10) represents the future US meteorological polar-orbiting system (merger of NOAA-POES and DMSP programs) with the objective to provide a single national remote-sensing capability for meteorological, oceanographic, climatic and space environmental data. The NPOESS data sets will contain a number of variables that are currently not included in operational measurements (such as: radiation budget, total ozone, wind speed and direction, ocean topography, and ocean color) and will offer improved quality for some variables now being measured (such as: atmospheric moisture and temperature profiles, all-weather SST, and vegetation indices). The IPO plan for NPOESS is to launch its first satellite in the time frame 2008. Initial plans for the merger of the two services started in 1993. The following NPOESS sensor payloads are under development: CMIS (Conical-scanning Microwave Imager/Sounder) of SSM/I (Special Sensor Microwave Imager), SSMIS (Special Sensor Microwave Imager Sounder) and TMI (TRMM Microwave Imager) heritage, CrIS (Cross-Track Infrared Sounder) of HIRS/4, AIRS and IASI heritage, OMPS (Ozone Mapping and Profiler Suite) of SBUV/2, TOMS and GOME heritage, VIIRS (Visible/Infrared Imager and Radiometer Suite) of OLS, AVHRR/3, MODIS, and SeaWiFS heritage, GPSOS (GPS Occultation Sensor) of GRAS and GPS/MET heritage, and SESS (Space Environment Sensor Suite) of SEM-2 heritage.

LEO meteorological instruments: An overview cannot be complete without giving credit to at least one workhorse instrument, AVHRR (Advanced Very High Resolution Radiometer).

- AVHRR (Advanced Very High Resolution Radiometer) of the NOAA-POES satellite series is the spaceborne instrument with the longest service period, the widest data distribution and data analysis in the history of operational meteorology, oceanography, climatology, vegetation monitoring, and land and sea ice observation. The instrument provides wide-swath (>2600 km, $\text{FOV} = \pm 56^\circ$) multispectral imagery of about 1.1 km spatial resolution from LEO polar orbits (nominal altitude of 833 km). The resolution of 1.1 km is still quite high for the wide-swath measurement of large-scale meteorological phenomena. The imagery is used in a great variety of applications, such as: investigation of clouds, land-water boundaries, snow and ice extent, sea surface temperature, day and night cloud distribution, vegetation index, etc. The benefit of AVHRR data lies in its high temporal frequency of global coverage. The AVHRR instrument was initially designed for meteorological applications. - It is of interest to note that initial objectives of AVHRR were to develop a system that would provide a more efficient way to track clouds, estimate snow cover extent, and estimate sea surface temperature. It wasn't until a few years after the launch of the first AVHRR instrument that its usefulness in monitoring global vegetation became obvious.

Three generations of AVHRR whiskbroom scanning instruments (built by ITT Aerospace of Fort Wayne, IN) provided daily global coverage starting from 1978 (TIROS-N) to the turn of the millennium and beyond. The first 3rd generation instrument (AVHRR/3) with six channels was launched on May 13, 1998 as part of the NOAA-15 sensor complement. Although described in G.14.1, G.14.11, and G.15.1, it is worthwhile to repeat some tables of this remarkable instrument.

AVHRR is of VHRR (Very High Resolution Radiometer) heritage, a two-channel instrument flown on the ITOS (Improved TIROS Operational System) series, starting with NOAA-2 (ITOS-D), launch of ITOS-D on Oct. 15, 1972. The last one of the series flying the VHRR instrument was NOAA-5 (ITOS-H) with a launch July 29, 1976.

Channel No.	TIROS-N	NOAA-6, -8, -10	NOAA-7, -9, -11, -12, -14	IFOV (mrad)	Principal use of channel
1	0.550 - 0.90	0.550 - 0.68	0.550 - 0.68	1.39	Day cloud and surface mapping
2	0.725 - 1.10	0.725 - 1.10	0.725 - 1.10	1.41	Surface water delineation, vegetation mapping
3	3.550 - 3.93	3.550 - 3.93	3.550 - 3.93	1.51	SST and fire detection
4	10.50 - 11.50	10.50 - 11.50	10.30 - 11.30	1.41	SST and night time cloud mapping
5	repeat of Channel 4	repeat of Channel 4	11.50 - 12.50	1.30	Surface temperature and day/night cloud mapping
	AVHRR/1		AVHRR/2		Instrument configuration/designation

Table 32: Spectral channels of AVHRR

Figure 4: Illustration of the AVHRR instrument

Channel	Center wavelength (μm)	Spectral Range FWHM (μm)	Channel Noise	Detector Type
1	0.630	0.58 - 0.68	SNR ≥ 9:1 @ 0.5% albedo	Silicon
2	0.862	0.725 - 1.00	SNR ≥ 9:1 @ 0.5% albedo	Silicon
3a	1.61	1.58 - 1.64	SNR ≥ 20:1 @ 0.5% albedo	InGaAs
3b	3.74	3.55 - 3.93	NEΔT ≤ 0.12 K @ 300 K	InSb
4	10.80	10.30 - 11.30	NEΔT ≤ 0.12 K @ 300 K	HgCdTe
5	12.00	11.50 - 12.50	NEΔT ≤ 0.12 K @ 300 K	HgCdTe

Table 33: Spectral parameters of AVHRR/3 (starting with NOAA-15)

S/C	Launch Date	Ascending Node	Descending Node	S/C Service Period	
TIROS-N	Oct. 13, 1978	15:00	03:00	Oct. 19, 1978	Jan. 30, 1980
NOAA-6	Jun. 27, 1979	19:30	07:30	Jun. 27, 1979	Nov. 16, 1986
NOAA-7	Jun. 23, 1981	14:30	02:30	Aug. 24, 1981	Jun. 7, 1986
NOAA-8	Mar. 28, 1983	19:30	07:30	May 3, 1983	Oct. 31, 1985

Table 34: Temporal AVHRR coverage of NOAA POES series satellites

- Sea Surface Temperature (SST) measurements from space (a physical parameter derived from microwave radiometer data). The analysis of SST observations is an important indicator of the coupling between the ocean surface and the atmosphere - used in climate modeling and in many other fields (meteorology/oceanography). The ability to monitor global and regional surface temperature has improved so that it is now possible to use SST observations as indicators of regional- to basin-scale change, as well as for forecasting stress on the natural flora and faunal assemblages. - The longest data set of SST observations is based on observations initially made from ships (capturing buckets of seawater from over the sides of ships and measuring the temperature with a thermometer). From about 1870 onwards the ship observations were sufficiently frequent to permit a global SST analysis.²⁵²⁾ - First spaceborne SST data was provided by the VHRR (Very High Resolution Radiometer) instrument flown on NOAA-2 (launch Oct. 15, 1972). Better spaceborne SST retrievals became available from channels 3 and 4 of the AVHRR/1 instrument flown on the TIROS-N S/C (launch Oct. 13, 1978). More accurate SST retrievals became available with the introduction of AVHRR/2, first flown on NOAA-7 (launch June 23, 1981) and subsequent NOAA/POES missions. The AVHRR/3 instrument generation (with 6 bands) was first flown on NOAA-15 (launch May 13, 1998). AATSR of ESA (of ATSR heritage on ERS-1) provides a radiometric resolution of 0.1 K, an SST accuracy <0.5 K, and a spatial resolution of 1 km.

The accuracy of SST data is of great importance for climate modeling and climate change detection/prediction. The energy (gas) transfer between the ocean surface and the atmosphere is highly dependent on the “skin temperature” of the surface waters (surface winds are another important factor). For illustration: An error of 0.1 K in SST knowledge corresponds to an error in the global flux of CO₂ of 15%, while an error of 0.5 K leads to an error of 75% in CO₂ flux.

Passive microwave radiometers offer an all-weather observation capability for measuring SST. The challenge with microwave instruments is to increase the spatial resolution of the data (which are in the ranges of 20-100 km depending on channel frequency). The first such instruments are: MSMR (Multifrequency Scanning Microwave Radiometer) on IRS-P4 (ISRO), AMSR-E on Aqua (NASA) and AMSR on ADEOS-II (NASDA). The CMIS (Conical-scanning Microwave Imager/Sounder) of the planned NPOESS series, an advanced instrument of SSM/I and SSMIS heritage of the DMSP (US/DoD) satellite series, is a dual- and single look passive polarimetric microwave radiometer. SST is going to be one of the CMIS data products with a medium-scale spatial resolution of about 25 km.

Mission	Instrument	Comment
NOAA/POES series starting with NOAA-2 (launch Oct. 15, 1972)	VHRR, AVHRR/1, AVHRR/2, AVHRR/3	Operational series
Meteor-2 series starting with Meteor-2-4 (launch Oct. 25, 89)	Klimat	Pre-operational instrument of PLANETA, Russia
ERS-1 (launch July 17, 1991)	ATSR	Pre-operational instrument
ERS-2 (launch Apr. 21, 1995)	ATSR-2	Pre-operational instrument
IRS-P4 (launch May 26, 1999)	MSMR of ISRO	Pre-operational instrument
FY-1B (launch Sept. 3, 1990)	MVISR (Multichannel Visible and IR Scanning Radiometer)	Pre-operational instrument of CMA, China
FY-1C (launch May 10, 1999)

Mission	Instrument	Comment
OKEAN-O-1 (launch Jul. 16, 1999)	Delta-2D (Conical Scanning Microwave Radiometer)	OKEAN-O-1 operations lasted until fall 2000
Terra (launch Dec. 18, 1999)	MODIS	Pre-operational instrument
Aqua (launch 2001)	MODIS, AMSR-E	Pre-operational instruments
Envisat (launch 2001)	AATSR	Pre-operational instrument
ADEOS-II (launch 2002)	AMSR (Advanced Microwave Scanning Radiometer), GLI	Pre-operational instrument
EPS-MetOp series (starting with MetOp-1, launch 2005)	AVHRR/3	Operational series
NPP (NPOESS Preparatory Project), launch in 2005	VIIRS (Visible/Infrared Imager and Radiometer Suite)	Pre-operational instrument
NPOESS (launch in 2008)	VIIRS, CMIS	

Table 35: Overview of spaceborne instruments suitable for SST retrieval

1.5.2 GEO (Geosynchronous Orbit) Weather Satellites

The geostationary orbit provides new observation concepts. Satellites in geostationary orbits exhibit a fixed-position, constant-signal and continuous-coverage relationship with large area coverage between the satellite and its ground segment. The observation data, provided by the S/C instruments from GEO locations (about 45 times further away than LEO systems at altitude of 800 km), are generally of coarse resolution (in the order of kilometers). However, the data are ideal to monitor large-scale weather phenomena. - Since the mid 1960s a global network of geostationary meteorological satellites has been built up continuously around the equator by the various national agencies of the world to provide an ever-increasing service to its user community. The data of the various satellite series also contribute to GARP (Global Atmospheric Research Program) of WMO.

S/C Series (Agency)	Launch	Major Instruments	Comment
ATS-1 to ATS-6 (NASA)	6.12.1966, 12.8.1969	SSCC (MSSCC ATS-3)	Tech. Demonstration
GOES-1 to -7 (NOAA)	16.10.1975, 26.2.1987	VISSR	1st generation
GOES-8 to -12 (NOAA)	13.4.1994, 23.7. 2001	GOES-Imager, Sounder	2nd generation
GMS-1 to -5 (JMA)	14.7.1977, 18.3.1995	VISSR	1st generation
MTSAT-1 (JMA, et al.)	Nov. 15, 1999 (launch failure of H-2 vehicle)	Imager (GOES heritage)	2nd generation
MTSAT-1R (JMA)	re-planned for 2003	JAMI	
Meteosat-1 to -7 (Eumetsat)	23.11.1977, 3.9.1997	VISSR	1st generation
MSG-1 (Eumetsat)	early 2002	SEVIRI, GERB	2nd generation
INSAT-1B to -1D (ISRO)	30.8.1983 - 12.6.1990	VHRR	Starting with -2E Communications only
INSAT-2A to -2E (ISRO)	9.7.1992 - 2.4.1999	VHRR/2	
INSAT-3B (ISRO)	21.3.2000	VHRR/2	Weather satellite only
INSAT-3A (ISRO)	planned for 2001		
MetSat-1 (ISRO)	planned for Oct. 2001		
GOMS-1 (Russia/Planeta)	31.10.1994	STR	1st generation
Electro-M (Russia)	2005/6		2nd generation
FY-2A to -2B (CMA), China	10.6.1997, 26.6.2000	S-VISSR	
AVStar (AstroVision Inc.), Pearl River, MS, USA	2003	Suite of 5 cameras	First commercial GEO weather satellite

Table 36: Overview of geostationary meteorological satellites

- The NASA ATS (Application Technology Satellite) series set the stage for demonstrations (in particular communication experiments, first meteorological observations, etc.) in geostationary orbits. ATS-1 (launch Dec. 6, 1966) flew SSCC (Spin-Scan Cloudcover Camera) to provide continuous cloudcover patterns of the full-disk Earth view. The telescope photomultiplier assembly could be tilted in discrete steps to $\pm 7.5^\circ$ to a north-south scan (equivalent to $\pm 52^\circ$ latitude). The east-west scan was provided by the S/C spin of 100 rpm. A ground resolution of about 4 km was obtained. SSCC operated on ATS-1 until Oct. 16, 1972.

ATS-1 (Applications Technology Satellite), a spin-stabilized S/C (mass of 352 kg), built by Hughes Aircraft Company, was the first experimental near-geostationary weather satellite (position at 150° W longitude) with the ability to “**see weather systems**” with SSCC, an instrument built by Hughes SBRC. The optical system consisted of a two-element Cassegrain-type telescopes. SSCC provided imagery of the Earth in the visible spectrum. Within the first month of the availability of ATS-1 imagery, a time-sequence movie of mesoscale cloud patterns in motion was shown on TV (the animated imagery revealed atmospheric motion and their potential use for research and operations). By the early 1970s ATS imagery was being used in US operational forecast centers.^{253) 254)} ATS-1 also served as a platform for several communication experiments:

- C-band communications experiment (also used for international TV broadcasts)
- VHF communications package. The VHF experiment tested the ability to act as a link between ground stations and aircraft, demonstrated collection of meteorological data from remote terminals, and evaluated the feasibility of using VHF signals for navigation.
- A WEFAX (Weather Facsimile) system experiment was flown for the first time with the intention to test satellite retransmissions of meteorological data products to participating ground stations.

The ATS-3 S/C (launched Nov. 5, 1967, positioned at 70° W, spin stabilized, mass = 365 kg, equipped with a mechanically despun antenna) flew for the first time the **MSSCC** (Multicolor Spin-Scan Cloud Camera) instrument (built by SBRC) providing full-disk Earth-cloud images in color.²⁵⁵⁾ A cartwheel mounting configuration was realized with MSSCC (the concept was first introduced on TIROS-9), i. e, the instrument was mounted with its optical axis perpendicular to the S/C spin axis, permitting to view the Earth through a special aperture in the S/C cylindrical wall.

- NASA's demonstration of two Synchronous Meteorological Satellites (SMS) began with the launch of SMS-1 on May 17, 1974. NOAA's operation of the GOES series followed with the launch of GOES-1 in October 1975. The SMS satellites carried VISSR (Visible Infrared Spin-Scan Radiometer) as prime instruments. VISSR provided high-quality day/night cloudcover data and made radiance temperature measurements of the Earth-atmosphere system. - The evolution of ATS into SMS and eventually into the GOES series permitted new services like the routine tracking of clouds with infrared imagery available for cloud height determination and nighttime tracking capabilities.

- Japan started its geostationary meteorological program with the launch of GMS-1 (Geostationary Meteorological Satellite-1, referred to as Himawari-1 in Japan) of JMA (Japan Meteorological Agency) and NASDA on July 7, 1977 (see F.3). The newest entry into the ring, MTSAT-1 (Multifunctional Transport Satellite-1) with a launch Nov. 15, 1999 (however, a launch failure of the H-2 vehicle occurred), provides the double service of an "aeronautical mission" (providing navigation data to air-traffic control services in the Asia-Pacific region) and a "meteorological mission." In the latter function, MTSAT is a successor program to the GMS series. A replacement satellite, MTSAT-1R, is planned for launch in 2003. The prime instrument of the meteorology mission on MTSAT-1R is JAMI (Japanese Advanced Meteorological Imager), see F.9.1.2.

- The METEOSAT program of Europe was initiated by ESA in 1972 followed by a launch of METEOSAT-1 (a demonstration satellite) on Nov. 23, 1977. The EUMETSAT convention was signed on May 24, 1983 by 16 countries. On January 1, 1987, responsibility for the operation of the METEOSAT spacecraft was transferred from ESA to EUMETSAT (F.7). The MSG (METEOSAT Second Generation) series with a first launch in early 2002 is expected to provide considerable improvements.

- India started planning of the INSAT series in the 1970s with a launch of INSAT-1B on April 30, 1983 (see F.6). INSAT is a multipurpose operational satellite system series (geostationary) employed for meteorological observation over India and the Indian Ocean, as well as for domestic telecommunications (nationwide direct TV broadcasting, TV program distribution, meteorological data distribution, etc.). The ISRO-developed prime instrument VHRR (Very High-Resolution Radiometer) was enhanced several times providing high-quality data of 2 km spatial resolution in the visible band and 8 km resolution in the IR and TIR bands.

As of 2000, the Government of India approved a dedicated GEO weather satellite named MetSat (Meteorological Satellite). The MetSat-1 launch is planned for October 2001. MetSat-1 is expected to fill the void caused by two important meteorological payloads, namely VHRR/2 on INSAT-2E which failed already in 1999. On Nov. 4, 2000, ISRO was forced to retire INSAT-2B, after it ran out of station-keeping fuel (in July 2000, INSAT-2B completed its design life of seven years of operation). This action stopped of course also the VHRR instrument on INSAT-2B, used for operational meteorology.

- Russia launched GOMS-1 (Geostationary Operational Meteorological Satellite-1) on October 31, 1994. STR (Scanning TV Radiometer) is the prime instrument to observe clouds and underlying surface in VIS and IR bands. GOMS-1, also referred to as Electro-1, ended operations in Nov. 2000. Russia plans to launch Electro-M (Modified) in the time frame 2005/6. Until that time, the Russian weather service is dependent on the services provided by Meteosat of EUMETSAT with regard to GEO data.

- China joined the geostationary meteorological club in 1997 with the launch of FY-2A (Feng-Yun-2A) on June 10, 1997. The prime sensor, S-VISSR (Stretched - Visible and Infrared Spin-Scan Radiometer) is an optomechanical system, providing observations in three bands (at resolutions of: 1.25 km in VIS, 5 km in IR and water vapor).

- As of 2000/1, a US commercial GEO weather satellite, AVStar, is being built by Astro-Vision Inc. (located at NASA's Stennis Space Center in Pearl River, MS).²⁵⁶⁾ The overall objective is to monitor the weather over the Americas (North and South) and to provide meteorological data products to a customer base. One goal is to produce quasi-live regional imagery with a narrow-field instrument to permit researchers to monitor quickly the formation of major weather patterns. A launch of AVStar-1 is planned for 2003. The sensor suite consists of five cameras: 1) a video camera, 2) wide-field camera with RGB imagery of the full disk, 3) narrow-field camera, a pointing capability exists to track weather phenomena of interest 4) a panchromatic low-light camera, and 5) a 10-channel multispectral camera.

1.6 Solar-Terrestrial Connection

- X-ray sensor technology and applications. Devices measuring in the X-ray spectrum are being used in a variety of applications. Examples are: to observe X-ray sources in the universe (astronomy, study of particle transport mechanisms in the interplanetary medium), to measure the sun's X-ray radiation (study of solar flares, warning services of solar flares for possible S/C damage, etc.), to diagnose the chemistry of a planet's surface, to monitor the Earth's atmosphere for nuclear explosions in support of the Nuclear Non-proliferation Treaty and the Atomic Test Ban, and to monitor the morphology and spectra of energetic electron precipitation and its effect on the Earth's atmosphere. The X-ray spectrum is generally considered from 60 nm to about 10^{-8} nm (Soft-band X-rays: 60 - 0.1 nm; medium-band X-rays: 10^{-2} - 10^{-3} nm; hard-band X-rays: 10^{-3} - 10^{-8} nm).

S/C Mission	X-Ray Instruments	Comment
ALEXIS (launch Apr. 25, 1993)	ALEXIS	Soft X-ray monitor (6 telescopes)
ARGOS (launch Feb. 23, 1999)	USA	X-ray timing, time-resolved spectroscopy, Feasibility tests of X-ray S/C navigation
Bhaskara (launch Nov. 20, 1981)	X-ray monitor experiment	Study of transient and long-term X-ray sources
CORONAS-I (Mar. 2, 1994) CORONAS-F (Jul. 31, 2001)	TEREK-C, RES-C, DIOGENESS, HELICON, IRIS,	Study of the solar atmosphere structure
DMSP series	SSB, SSB/X-2,	Array-based systems for the detection of X-rays emitted by the atmosphere
GOMS (launch Oct. 31, 1994)	RMS	Study of solar X-ray radiation
GPS/Navstar (Block-II satellites)	IONDS, CXD is follow-up sensor	Monitoring of nuclear explosions, CXD (Combined X-ray detector and Dosimeter)
HESSI (launch Jul. 4, 2000)	HESSI	Study of the sun
IMP-8 (launch Oct. 26, 1973)	CPME, EPE	Solar X-rays
Interball (launch Aug. 3, 1995)	SKA-2, DOK-2X, RF-15, SOSNA-2	Tail Probe instruments
IRS-P3 (launch May 21, 1996)	X-Ray Payload	Study of X-ray sources
ISEE-3 (launch Aug. 12, 1978)	ANH,	Study of solar flares
MTI (launch March 12, 2000)	HXRS	Measures solar X-ray emissions in 8 bands
NOAA-GOES series	SEM package, XRS, SXI (GOES-M)	Monitoring of the solar-terrestrial environment
POLAR (launch Feb 24, 1996)	PIXIE (pinhole camera concept)	Study of energetic electron precipitation on and its effect on the atmosphere
SMART-1 (planned for 2003)	D-CIXS, XSM	Moon surface chemistry, swept charge detector design, instrument mass of 3 kg
SMM (launch Feb 14, 1980)	GRS, HXBRS (study of electron acceleration of solar flares), HXIS, XRP	GRS made important contributions to the international study of Supernova 87A, which in Feb. 1987 provided astronomers with their first opportunity to study such an explosion
SNOE (Launch Feb. 26, 1998)	SXP	Monitoring of soft X-ray flux from the sun
SOHO (launch Dec. 2, 1995)	CDS, EIT, UVCS, LASCO	Study of the composition of the solar corona, etc.

²⁵⁶⁾ Information provided by Malcolm A. LeCompte of AstroVision Inc.

S/C Mission	X-Ray Instruments	Comment
Solar-A (launch Aug. 30, 1991)	HXT, SXT,	Study of high-energy solar phenomena
Solar-B (launch 2004)	XRT	Study of high-energy solar phenomena
SNOE (launch Feb. 26, 1998)	SXP	Solar soft X-ray flux measurement
SORCE (planned for 2002)	XPS (SXP heritage)	Solar EUV measurement
TRACE (launch Apr. 2, 1998)	TRACE	Study of coronal mass ejections, etc.
UARS (launch Sept 12, 1991)	AXIS,	Measurement of Bremsstrahlung X-rays from Earth
Ulysses (launch Oct. 6, 1990)	GRB	X-ray and gamma-ray measurement of solar and cosmic origin

Table 37: Overview of some missions flying X-ray instruments (alphabetical order)

- Solar observations are performed by a number of dedicated missions, normally with strong international cooperation (Section K). There are also some Earth-observation missions with instruments dedicated for sun observations. Coriolis of NRL with SMEI (Solar Mass Ejection Imager) is an example of such a mission.

1.6.1 Earth Radiation Budget and Solar Constant

The solar constant, also referred to as TSI (Total Solar Irradiance), is the radiative power received normally onto a unit area at the mean Earth/Sun distance. Along with Earth's global average albedo and the emitted long wave, it determines Earth's global average equilibrium temperature. It is the primary power source driving our climate system. Hence, knowledge of the long-term solar constant variability is essential in understanding the past and future climate changes. Solar irradiance varies slightly over an 11-year cycle. This cycle of the sun's magnetic activity alters its energy output, as well as the occurrence of sunspots, flares, and CMEs (Coronal Mass Ejections). - Since the 1880s, routine solar irradiance measurements were made from the ground to detect an eventual variability. The irradiance was referred to as the "solar constant" because atmospheric transmittance variability, of the order of several percent, prevented the detection of systematic irradiance changes from the Earth's surface.

The continuous observation of the solar irradiance at the highest possible precision and accuracy is an important objective of the Earth climate change program. It requires high quality metrology in the space environment linked to ground solar radiometric comparisons supported by laboratory characterization activities. ²⁵⁷⁾

The Earth radiation budget (ERB) is the difference between the Earth's absorbed solar radiation and the longwave radiation emitted by Earth and its atmosphere. The concept applies globally to the whole Earth and locally to any place, with important consequences due to its gradients. Similarly, the net radiation at TOA (Top of the Atmosphere) is derived as a function of the planetary albedo and the longwave radiation emitted by Earth into space. ERB measurements seek to contribute to two key scientific goals: 1) the determination of how long- and shortwave fluxes are distributed in the atmosphere and how they vary in time, and 2) the development of a quantitative understanding of the links between the radiation budget and the properties of the atmosphere and the surface related to the energy budget and its processes. ^{258) 259)}

First Earth radiation budget measurements of the space age go back to the late 1950s, with instruments flown on Soviet and US satellites, such as Explorer-6 (launch Aug. 7, 1959 - last meaningful data on Aug. 25, 1959). The 'TV Optical Scanner' flown on Explorer-6, an im-

258) R. B. Lee III, M. A. Gibson, R. S. Wilson, S. Thomas, "Long-term total solar irradiance variability during sunspot cycle 22," *Journal of Geophysical Research*, Vol. 100, No A2, pp. 1667-1675, Feb. 1, 1995

259) E. N. Parker, "The Physics of the Sun and the Gateway to the Stars," *Physics Today*, June 2000, pp. 26-31

proved version of the TV system first employed on Pioneer 2, can be regarded as one of the first instruments, providing at least some very crude data (low-resolution daylight cloudcover photographs) for initial Earth radiation budget estimation (because of the poor spatial and temporal sampling without Earth emitted radiation observations).

In the early 1970s, the importance of improving knowledge on the Earth's radiation budget was recognized [i.e., the balance between incoming energy from the sun and the outgoing thermal (longwave) and reflected (shortwave) energy from the Earth] and its relationship with the Earth's climate. NASA built a multichannel absolute radiometer instrument (blackbody calibrated) by the name of ERB (Earth Radiation Budget) which was flown for the first time on Nimbus-6 (launch June 12, 1975, M.17.6). However, the analysis of the ERB data failed to detect any irradiance variability due to degraded responses of the ERB radiometer. An improved version of ERB was subsequently flown on Nimbus-7 (launch Oct. 24, 1978, M.17.7). This radiometer was stable enough to detect short-term and long-term solar irradiance variability. ERB was the first long term solar monitor utilizing the ESCC (Electrically Self Calibrating Cavity) technique. The design of this absolute cavity radiometer technique is based on the principle of substitution of electrical power for radiative power (the idea of the cavity design is to come as close as possible to a "perfect absorber" of solar radiation). TSI data from ERB on Nimbus-7 were available until the end of 1993.²⁶⁰⁾

The success of ERB on Nimbus-7 resulted in the development of a number of TSI instruments for various missions. Since the solar constant is one of the prime determining factors of the Earth's climate (together with the cloud cover and the Earth's thermal emission), the data obtained is used in such applications as climate change, solar physics studies, and Earth radiation budget estimates. Solar-constant instruments ought to be very sensitive and accurate radiometers for the measurement of solar radiation. Most sensor designs employ the method of "active cavity detector geometry" pyrheliometers (detector in equilibrium with incident solar radiation) and variations thereof. Following is a survey of "Earth radiation budget missions," most of them with absolute or active cavity radiometers for the measurement of TSI; there are also instruments (such as HCMM, ScaRaB and GERB) that are not of the absolute radiometer type.²⁶¹⁾

- A first comprehensive thermal survey of the Earth's surface was provided by HCMM (Heat Capacity Mapping Mission, launch April 26, 1978, end of mission Sept. 30, 1980) of NASA. The satellite featured a Heat Capacity Mapping Radiometer (HCRM) for the measurement of the heat budget, in particular the thermal inertia of the land surface for geological studies.

- SMM (Solar Maximum Mission, launch Feb. 14, 1980,²⁶²⁾ ACRIM data until 1989) flew ACRIM-I (Active Cavity Radiometer Irradiance Monitor) of NASA/JPL and provided data until 1989. The ACRIM-I and ERB/Nimbus-7 instruments detected a short-term (less than 27-day solar rotational period) irradiance variability of as much as 0.2% and a long-term variability of about 0.1%.

- A new generation instrument was realized with ERBE (Earth Radiation Budget Experiment) of NASA/LaRC, first flown on ERBS (Earth Radiation Budget Satellite, launch Oct. 5, 1984), then on NOAA-9 (launch Dec. 12, 1984), and NOAA-10 (launch Sept. 17, 1986). ERBE was able to provide more accurate and systematic parameters for estimating the Earth's radiation budget. ERBE flew both wide-field-of-view, flat-plate radiometers and the narrow-field-of-view scanning radiometric telescopes measuring with three chan-

262) D. V. Hoyt, H. L. Kyle, J. R. Hickey, R. H. Maschhoff, "The Nimbus-7 solar total irradiance: A new algorithm for its derivation," *Journal of Geophysical Research*, Vol. 97, 1992, pp. 51-63

nels the “short wave”, the “long wave” and the “total” radiances. The improved spatial resolution of flux data achieved with this scanner, by taking into account the bidirectional reflection functions at the TOA, is perhaps the most important advance offered by ERBE, because it led to better estimates of the difference between cloudy and clear-sky fluxes and thus a better estimate of the effect of clouds on Earth’s radiation budget.²⁶³⁾

- The instruments ACRIM-II, SOLSTICE (Solar/Stellar Irradiance Comparison Experiment) and SUSIM (Solar Ultraviolet Spectral Irradiance Monitor), all with the objective to measure solar radiation, are flown on NASA’s UARS (Upper Atmosphere Research Satellite) mission. Launch Sept. 12, 1991, the S/C is operational as of 2001.

- EURECA-1 (European Retrievable Carrier). An ESA long-term free-flyer platform (J.5.1) launched on Shuttle flight STS-46 on July 31, 1992 and retrieved with STS-57 on July 1, 1993. Two instruments aboard EURECA were dedicated to solar observations, namely SOVA (Solar Constant and Variability Instrument) with D. Crommelynck as PI, and SOSP (Solar Spectrum Instrument) with G.Thuillier as PI.

- The ScaRaB (Scanner for Radiation Budget) program of CNES (France, Russia and Germany are program partners), started in 1987 with the objective to measure the terms of the Earth’s radiation budget. Two of three instruments, built by CNRS/LMD and operated by CNES, were flown already on Meteor-3-7 (launch Jan. 25, 1994, ScaRaB stopped operating March 5, 1995) and Resurs-O1-4 (launch July 10, 1998 - failure of the backup downlink on Apr. 8, 1999 causing a termination of ScaRaB operations), respectively. The third instrument is planned to be flown on a future mission (currently a CNES/ISRO climate mission in the tropics is considered the most likely candidate, namely Megha-Tropiques).²⁶⁴⁾ Note: ScaRaB performs no measurements of TSI. However, the overall radiation budget analysis of ScaRaB uses solar constant values from other sources (such as ISP-2).

- VIRGO (Variability of Solar Irradiance and Gravity Oscillations), an ESA AO instrument package flown on SOHO (launch Dec. 2, 1995, operational as of 2001). The subunits DIARAD (Differential Absolute Radiometer) and PMO6-V are the absolute radiometers in this assembly. Regularly updated observations of the solar constant can be found at the following reference:²⁶⁵⁾

- ISP-2 (Izmeritel Solnechnoy Postoyannoy-2 - a Solar Constant Instrument) flown on Russia’s RESURS-O1-4 (launch July 10, 1998). The intention is to complement the ScaRaB measurements.

- CERES (Clouds and the Earth’s Radiant Energy System), an instrument of ERBE heritage of NASA/LARC, is flown on TRMM (launch Nov. 27, 1997) as a single cross-track radiance sensor of short, long- and total wave. CERES is also being flown on NASA’s Terra mission (launch Dec. 18, 1999) as a dual-track scanner (two radiometers). Another CERES instrument is scheduled to fly on further missions such as Aqua (formerly EOS/PM1).

- ACRIM-III on ACRIMSAT (NASA), launch Dec. 20, 1999 (A.2)

- GERB (Geostationary Earth Radiation Budget) is an ESA AO instrument of the EU-METSAT MSG-1 (METEOSAT Second Generation) mission, a two-channel broadband radiometer, provided by a consortium led by the UK (NERC), Belgium (SSTC) and Italy (ASI). A launch of MSG-1 is planned for early 2002. The instrument measures the radiances leaving the Earth at TOA (Top of the Atmosphere); it will provide an image of the reflected sunlight and infrared radiation at a five-minute sampling rate, in particular the shortwave (0.32 - 4.0 μm) and longwave (4.0 - 30 μm) regions of the spectrum. The overall radiation budget analysis of GERB uses solar-constant values from other sources. Because

264) Information provided by M. Rouzé of CNES

265) <http://remotesensing.oma.be/solarconstant/solar.html>

the evaluation of the TOA Earth radiation balance terms (conversion of radiances to TOA fluxes) will be made available about three hours after observation by the IRMB, the GERB observations can make a unique contribution to the understanding of the Earth's climate balance (diurnal sampling), since such measurements have never been carried before from geostationary orbit (F.8). GERB instruments are planned to be flown on the MSG-2 and MSG-3 missions.

- NASA is sponsoring TIM (Total Irradiance Monitor), developed at LASP (Laboratory for Atmospheric and Space Physics) of the University of Colorado, to be flown on SORCE (Solar Radiation and Climate Experiment). SORCE is part of NASA's ESE (Earth Science Enterprise) program with a planned launch in 2002. Besides very precise and accurate solar irradiance measurements with TIM, the other instruments of SORCE, namely SOLSTICE (Solar/Stellar Irradiance Comparison Experiment), SIM (Spectral Irradiance Monitor), and XPS (XUV Photometer System), complement the solar spectral irradiance measurements at wavelengths extending from the far ultraviolet to the near infrared. - A TIM instrument, referred to by the name of TSIS (Total Solar Irradiance Sensor), is also planned to fly on NASA's NPP (NPOESS Preparatory Project) with a launch in 2005 and on NPOESS (National Polar-orbiting Operational Environmental Satellite System) of IPO (Integrated Program Office) with a first launch projected for 2008.

- NISTAR (National Institute of Standards and Technology Advanced Radiometer) is a three-channel cavity radiometer of the NASA mission Triana (planned launch in 2004) which measures the Earth's "irradiance" in the small angle as seen from a halo orbit at L1 (Lagrangian point 1), about 1.5 million km from Earth in the direction of the sun. The NISTAR TSI measurements offer a great opportunity to compare its radiances with instruments in LEO (Low Earth Orbit).

- Solar-A (Solar Monitoring Observatory) is an ESA experiment package consisting of three instruments, namely SOVIM (Solar Variability and Irradiance Monitor), SOLSPEC (Solar Spectral Irradiance Measurements), and SOL-ACES (Solar Auto-Calibrating EUV/UV Spectrophotometers). The overall objective is to measure the solar spectral irradiance with unprecedented accuracy (L.2.16). The three instruments cover the combined wavelength range from 17-3000 nm. The Solar-A package will be mounted on the ESA-developed CPD (Course Pointing Device), located on EPA of ISS. A launch of Solar-A is planned for the timeframe of 2004.

- Picard is a CNES solar-terrestrial microsatellite mission (launch in 2006). Two instruments measure the solar constant: SOVAP (Solar Constant Variability, Picard) of IRMB (Royal Meteorological Institute of Belgium) in Brussels, and PREMOS (Precision Monitoring of Solar variability) photometric spectral band measurements of WRC (World Radiation Center) of Davos, Switzerland. The measurement of the solar diameter is done by SODISM (Solar Diameter Imager and Surface Mapper), a CNRS/SA (Verrières-le-Buisson, France) instrument in collaboration with ESA/ESTEC.

- Periodic (short-term) measurements were conducted in particular with SOLCON (Solar Constant Sensor) on a number of Shuttle flights. The instrument is a cooperative effort of IRMB (Belgium), Space Science Dept. of ESA, and NASA/LaRC.^{266) 267)}

Launch Vehicle	Date	Mission	Instrument
STS-9 (Shuttle)	Nov. 28 - Dec. 8, 1983	Spacelab-1 (ESA)	SOLCON-1
STS-45	March 24 - April 2, 1992	ATLAS-1 (NASA)	SOLCON-2, ACRIM-II
STS-56	April 8-17, 1993	ATLAS-2 (NASA)	SOLCON-2, ACRIM-II
STS-66	Nov. 3-14, 1994	ATLAS-3 (NASA)	SOLCON-2, ACRIM-II
STS-85	Aug. 7-19, 1997	Hitchhiker (NASA)	SOLCON-2

1.6.2 Solar Wind Observation

The phenomenon of the solar wind is a discovery of the space age by data analysis first conducted from the Soviet Luna spacecraft series [Luna-1 (launch Jan. 2, 1959), Luna-2 (launch Sept. 12, 1959), and Luna-3 (Oct. 14, 1959)] on their flight to the moon. The first tentative evidence of the solar wind was observed with an experiment of Konstantin I. Gringauz (1918-1993, USSR) and his team onboard the Luna-2 and Luna-3 spacecraft. The total electric charge of arriving ions was measured in the “ion trap experiment.” Gringauz noted that the signal fluctuated as the spacecraft spun around its axis, suggesting an ion flow was entering the instrument whenever it faced the sun.²⁶⁸⁾²⁶⁹⁾ In 1961, James Dungey (UK) proposed a mechanism for transmitting solar wind energy to the magnetosphere by direct magnetic linkage between the two. The magnetopause, the boundary between magnetosphere and the solar wind, was observed for the first time by Explorer-12 in 1961. The first variations in the speed of the solar wind (27 days intervals) were observed in 1962 from the US Mariner-II on its way to Venus. The data analysis of the IMP-1 (Interplanetary Monitoring Platform 1, launch Nov. 27, 1963, the mission is also known as Explorer-18) revealed a large bow shock formed in the solar wind ahead of the magnetosphere, and a long magnetic tail on the night side of the Earth. In 1983, the ISEE-3 (International Sun-Earth Explorer 3) mission explored the distant magnetotail, before heading for comet Giacobini-Zinner.

Mission	Instruments	Comment
ACE, launch Aug. 25, 1997	SWIMS, SWICS, SWEPAM	Focus on solar wind composition and acceleration
AMPTE, launch Aug. 16, 84		Release of trace gases into the solar wind
Cluster-II, launch Jul. 16, 00	CIS, HIA, STAFF	Study of solar wind bow shock
DS1, launch Oct 24, 1998	PEPE	Solar wind energy spectrum
Equator-S, launch Dec. 2, 1997		Solar wind measurements with WIND and SOHO
Genesis, launch Aug. 8, 2001	Collector Array, Solar Wind Concentrator	Solar wind measurement, collection and return of solar wind samples. Halo orbit at L1
GEOTAIL, launch Jul. 24, 1992	LEP, CPI	Measurement of fluctuations in the solar wind
IMAGE, launch Mar. 25, 2000	LENA, MENA, HENA	Response of magnetosphere with solar wind
IMP-8, launch Oct. 26, 1973	GAF, MAP	Plasma field environment for magnetospheric studies
INTERBALL, launch Aug. 3, 1995 and Aug. 29, 1996	Monitor-3, etc.	Solar wind energy and interaction with the Earth's magnetosphere
ISEE-1, -2, launch Oct. 2, 77	SWE, EGD, OGM, SHM,	Study of Earth's bow shock
ISEE-3, launch Aug. 12, 78	BAH, OGH, SBH	Measurement of solar wind/plasma fields First ever cometary encounter 7800 km tailward of comet Giacobini-Zinner.
NOAA-15, launch May 13, 1998	SEM-2 package	An operational space weather warning system
POLAR, launch Feb. 24, 1996	MFE, TIMAS,	Coupling of the solar wind and magnetosphere, study of particle populations
SOHO, launch Dec. 2, 1995	UVCS, SWAN, CELIAS,	Study of solar wind and energetic particles, interaction with the Earth. First tracing of the slow-speed solar wind

Mission	Instruments	Comment
STEREO, launch in 2004	IMPACT, SWEA, PLASTIC, SWAVES,	Measurements of solar wind in a helio-centric elliptical orbit in the ecliptic plane at 1 AU
TIMED, launch in 2001	TIDI	Solar wind structure in MLTI region
TIROS-N, launch 1978 and on all S/C of NOAA POES	SEM (NOAA/SEC package)	Measurement of solar wind particle flux
Triana (2004)	PlasMag	Study of solar wind in halo orbit at L1
Ulysses, launch Oct. 6, 1991	SWICS, SWOOPS, UARP,	Study of the solar wind
Viking, launch Feb. 22, 1986	V1, V2, V3, V4L	Solar wind interaction with the magnetosphere
WIND, launch Nov. 1, 1994	MFI, WAVES, SWE, SMS, EPACT, PLASMA,	Study of solar wind mass momentum and energy. Halo orbit at L1

Table 39: Some solar wind experiments/studies (alphabetic order of missions)

- SEM (Space Environment Monitor). SEM is an operational NOAA instrument package with the objective to provide “**space weather**” on a regular basis to the user community by measuring the solar wind particle flux and its variations. The package is provided by NOAA/SEC of Boulder, CO. SEM-1 instruments were initially introduced on satellites in geostationary orbit starting in 1974. SMS-1, a predecessor of the NOAA-GOES series, was the first satellite to carry SEM. NOAA introduced SEM on the POES series (G.14.1) as well starting with TIROS-N in 1978. An upgraded instrument package, SEM-2, was introduced into the POES series with the launch of NOAA-K (NOAA-15) on May, 13, 1998 (G.15.2).
- The ISEE-3 (International Sun-Earth Explorer-3) mission, with a launch in 1978, orbited the Earth for nearly four years. It was then directed to study the geomagnetic tail for a first-ever exploration of that region. This resulted in the discovery of gigantic plasmoids that were ejected from the near-Earth magnetosphere. After exploring the nature of the geomagnetic tail, ISEE-3 was sent off for the first spacecraft encounter with a comet in September 1985. When ISEE-3 was near Comet Giacobini-Zinner, first measurements of the solar wind’s interaction with a comet were obtained.
- The Ulysses S/C (launch Oct. 6, 1991, K.28) of ESA/NASA is the first S/C having left the ecliptic plane to observe the poles of the sun (sling shot past Jupiter). The three major objectives are to study the sun, the solar wind, and interstellar space. Although Ulysses is the first S/C to probe the sun’s polar regions, it does not travel near the sun. In 1994, it was reported that near the south pole the solar wind is flowing away from the sun at nearly twice the speed that is typically observed near the sun’s equator.
- The IMAGE S/C (launch Mar. 25, 2000, K.15) of NASA carries three ENA (Energetic Neutral Atom) imagers (LENA, MENA, and HENA) whose combined energy coverage permits the detection of ENAs with energies ranging from 1 eV to 500 keV per atomic mass unit (amu).²⁷⁰⁾ Each neutral atom instrument generates images showing the intensity and spatial distribution of ENA emissions produced in the inner magnetosphere through charge-exchange reactions between geocoronal neutral hydrogen and various magnetospheric ion populations. Neutral atom imaging of the ionosphere and magnetosphere is possible because the Earth’s geocorona acts like an imaging screen for magnetospheric and ionospheric ions. [The neutral atoms in the space environment are measured against the large and ubiquitous UV background which can produce high noise count rates in MCP detectors]. To date, four different techniques have been developed to allow neutral atom detection and imaging against the UV background:
 - A thick foil which blocks the UV
 - An ultra thin charge conversion foil to ionize ENAs (which are then passed through an electrostatic analyzer)
 - A charge exchange surface from which ENAs can reflect as ions which are then analyzed

²⁷⁰⁾ D. J. McComas, “Two Wide-Angle Imaging Neutral-Atom Spectrometers,”

- Transmission gratings which block UV but allow ENAs to pass.

Mission	ENA Instruments
ATLAS-1 of NASA on STS-45 (launch Mar. 24, 1992)	ENAP (Energetic Neutral Atom Precipitation), of the University of Texas, Dallas
POLAR of NASA, (launch Feb. 24, 1996)	CEPPAD/SEPS (Comprehensive Energetic-Particle Pitch Angle Distribution / Source Loss Cone Energetic Particle Spectrometer)
SAC-B of CONAE (launch Nov. 4, 1996), the 3rd stage failed to separate from the S/C	ISENA (Imaging Spectrometer for Energetic Neutral Atoms) of CNR/IFSI, Italy
IMAGE of NASA (launch March 25, 2000)	LENA, MENA, HENA
TWINS of NASA, LANL, etc. (launch of 1st S/C in 2002, launch of 2nd S/C in 2004)	TEI (TWINS ENA Imager)

Table 40: Overview of ENA instruments flown on various missions

The IMAGE spacecraft and its sensor complement represent a new era of magnetospheric observation capability. While traditional instruments provide in-situ observations of the magnetospheric plasma environment, the new ENA devices are able to image the plasma motions by detecting the particles and their traveling directions (the imaging is done using “electromagnetic wave sounding”).

Using neutral atoms (hydrogen, helium, oxygen), which speed through the magnetosphere unimpeded by magnetic forces, to image the magnetosphere was an idea first realized by researchers at JHU/APL in the late 1980s.

- The Genesis mission of NASA (launch Aug. 8 2001) has the objective to collect solar wind particles at L1 (Lagrangian point 1) and return these particles to Earth (by a sample return capsule) after mission completion.
- The TWINS two-spacecraft mission of NASA (launch 2003) has the objective to demonstrate the new capability of stereoscopic imaging of the magnetosphere. By imaging the ENAs (produced by charge-exchange reactions between the geocoronal neutral hydrogen and the plasma) over a broad energy range (about 1-100 keV) using two identical instruments [TEI (TWINS ENA Imager)] on two widely spaced high-altitude and high-inclination spacecraft, TWINS will enable the three-dimensional visualization and the resolution of large scale structures and dynamics within the magnetosphere for the first time.

Mission	Instrument	Objective or Measurement
AE-C (NASA), Launch Dec. 16, 1973	VAE (Visible Airglow Experiment)	Measurement of airglow and aurora features
APEX (Active Plasma Experiment), launch Dec. 18, 1991	Suite of sensors	Study of auroral-ionospheric relationships
ARGOS (DoD), launch Feb. 23, 1999	EUVIP, HIRAAS, LORAAS, GIMI	Characterization of the aurora
Astrid-1 (IRF-K), Sweden, launch Jan. 24, 1995	MIO (Miniature Imaging Optics)	Auroral emissions
Astrid-2, launch Dec. 10, 1998	PIA of MP Ae	Auroral imaging
ATLAS-1 (NASA) STS-45, launch March 24, 1992	AEPI (Atmospheric Emissions Photometric Imaging)	Images of natural and induced aurorae and airglow
DE-1 (Dynamic Explorer) of NASA, launch Aug. 3, 1981	EICS (Energetic Ion Mass Spectrometer), SAI (Spin-Scan Auroral Imager)	Coupling of magnetosphere/ionosphere, auroral images in UV and VIS
DMSP series of DoD	OLS (Operational Linescan System), SSULI (Special Sensor Ultraviolet Limb Imager), SSUSI (Special Sensor Ultraviolet Spectrographic Imager)	OLS auroral images (nighttime) since the mid-1970s, SSULI and SSUSI starting with F-16 in 2001
DODGE (DoD) launch July 1, 1967	Dual Vidicon Cameras	Some measurement of airglow and aurorae
EXOS-A (ISAS, Japan) launch Feb. 4, 1978 EXOS-D, launch Feb. 22, 1989	UV-TV camera, UV Glow Spectrophotometer ATV (Auroral TV)	Measurement of auroral activity, with ATV auroral imagery in UV and VIS

Mission	Instrument	Objective or Measurement
FREJA (Sweden), Oct. 6, 1992	F5 (Auroral UV Imager)	Study of aurorae
GEOTAIL (ISAS/NASA), launch July 24, 1992	CPI (Comprehensive Plasma Investigation)	Auroral imaging for magnetotail plasma dynamics
HILAT (DoD) or P83-1, launch Jun. 27, 1983	AIM (Auroral Ionospheric Mapper) built by APL	Imaging of the sunlit aurora
IMAGE (NASA), launch May, 25, 2000	WIC (Wideband Imaging Camera), SI (Spectrographic Imager), MENA (Medium-Energy Neutral Atom Imager), HENA, EUV	Broadband auroral imaging, different types of aurorae, etc. Imaging of ENAs, substorms, and ion populations of the cusp
INTERBALL (Russia, etc.), launch of Auroral Probe Aug. 29, 1996	UFSIPS, UVAI	Study of aurorae
Lewis (NASA) launch Aug. 23, 1997, contact to Lewis was lost on Aug. 26, 1997	LEISA	Study of nightglow aurorae
MSX (DoD), launch Apr. 24, 1996	UVISI with 4 cameras and 5 imaging spectrometers	Study of aurorae in FUV-VIS, tomographic imagery
POLAR (NASA), launch Feb. 24, 1996	UVI (UV Imager), VIS (Visible Imaging System)	Study of dayside and nightside aurorae
ROCSat-2 (NSPO), launch in 2003	ISUAL (Imager of Sprite Upper Atmospheric Lightning)	Study of aurorae and airglow
SNOE (U. of Colorado) launch Feb. 26, 1998	AP (Auroral Photometer)	Study of auroral emissions
STS-39, launch Apr. 28, 1991	CIRRIS (DoD)	Study of aurorae and airglow
TIMED (NASA), launch in 2001	GUVI (Global UV Imager)	Horizon-to-horizon imagery in five bands with coverage of one limb (away from the sun)
TWINS (NASA, LANL, APL, SwRI, USC, etc.), planned launches in 2002 and 2004	TEI (TWINS ENA Imager)	3-D visualization of large-scale structures in the magnetosphere, study of geomagnetic storms, etc.
Viking (Sweden), launch Feb. 22, 1986	V5 (Auroral Imaging Experiment)	Study of dynamic behavior of aurorae

Table 41: Some space science missions/instruments relating to auroral imaging

1.7 Navigation

Navigation is the art of establishing position and velocity of an object in space (distances, angles and time to known references). The object (platform) attitude is also of fundamental importance, since it serves in general as a reference for most sensor observations. Of particular interest are the ground-based and on-board instruments which provide inputs for orbit and/or attitude determination. In general, orbit determination is an iterative process, building upon the results of previous solutions, and on tracking data inputs from various sources over significant time periods. In spite of these obstacles, orbit determination is becoming an increasingly automated process due to better computing capabilities and ever-improving algorithms (and filters) in the latter 1990s.

Spacecraft	Launch Date	Innovation
Sputnik-1	Oct. 4, 1957	Satellite Doppler tracking
Transit-1A	Sept. 17, 1959	Yo-Yo spin/despin mechanism
Transit-1B	Apr. 13, 1960	Dual-frequency Doppler tracking for correcting ionospheric error First attitude-controlled S/C using permanent magnets First solar attitude detectors
Transit-2A	June 22, 1960	First dual-payload launch (Transit-2A and Solrad-1 of NRL) and first piggyback separation, demonstrated before on Transit-1B
Transit-3B	Feb. 21, 1961	First satellite electronic memory in space (384 bits of magnetic core register - required to store its own orbit ephemeris)
Transit-4A	June 29, 1961	First nuclear power generator tested in a spacecraft (RTG)
TRAAC	Nov. 15, 1961	Damping of satellite vibration by lossy spring-and-mass technique. (TRAAC= Transit Research And Attitude Control) satellite
ANNA-1B	Oct. 31, 1962	First geodetic satellite (ANNA = Army Navy, NASA, Air Force) which also flew the first gallium arsenide cell in space.
Transit-5A-1	Dec. 19, 1962	First uplink authentication system
Transit-5A-3	June 16, 1963	First successful gravity-gradient stabilization (plus spring-and-mass damping) to maintain Earth pointing for one side of the S/C. - Automatic temperature S/C control
Transit-5C-1	June 4, 1964	Demonstration that hysteresis rods, used previously for damping magnetic stabilization, were also effective for gravity-gradient stabilization
DME-A	Nov. 29, 1965	Magnetic spin/despin system (DME=Direct Measurement Explorer)
SAS-1	Dec. 12, 1970	Dual-spin control of satellite pointing (Small Astronomy Explorer-1)
Triad (Transit-improved DISCOS)	Sept. 2, 1972	First satellite compensated for drag and radiation pressure. The drag-free concept was realized with DISCOS (Disturbance Compensation Device). First demonstration of single-frequency refraction-free satellite navigation using pseudonoise modulation.
DODGE	July 1, 1967	First yaw stabilization of a satellite using a 'pitch axis wheel' [constant-speed 'momentum wheel'] DODGE = DoD Gravity Experiment, M.4
GEOS-3	April 9, 1975	Demonstration of first satellite-to-satellite tracking. By closed-loop tracking with a S-band transponder, the position of GEOS-3 was measured relative to that of ATS-6 of known position.
TIP-II	Oct. 12, 1975	Crystal oscillator as on-board timing system with all drift removed by a programmable synthesizer. TIP = Transit Improvement Program
SeaSat SAR downlink	Jun. 27, 1978	Quadri-filar helix antenna with beam shaping to compensate for slant range
Magsat	Oct 30, 1979	First attitude and command systems using microprocessors
Landsat-4	Jul. 16, 1982	GPSPAC (see 1.7.8) the first spaceborne GPS receiver in history
Geosat-A	Mar. 12, 1985	Bifilar helix antenna
MSX	April 24, 1996	First spaceborne hyperspectral imager, UVISI (Ultraviolet/Visible Imaging and Spectrographic Imaging)

Table 42: Some technology innovations introduced by JHU/APL

1.7.1 Tracking Techniques

The two-way support of the communication function requires the satellite to carry a simple transceiver. In order to also accomplish the tracking function, the satellite must carry a

transponder which, in addition to providing two-way communications, also returns the tracking antenna's transmitted ranging signal, thus, permitting the quick determination of the distance between the ground antenna and the spacecraft. - Ground-based navigation is with us from the very beginning of the space age. The conventional tracking methods are "ranging," "Doppler velocity," and "angle-only" (when no transponder is on-board) determination along the line of sight.²⁷¹⁾ Ranging (radial distance) is derived from transit time, namely the round-trip light time of ranging signals from the spacecraft transponder, while the ground antenna pointing direction provides angular information. More precise angle measuring methods are those of "differenced Doppler" and VLBI. The Doppler shift is a measure of object velocity. A two-way coherent transmission mode permits the measurement of the induced Doppler shift to within 1 Hz, since the uplink frequency is known with great precision. The Doppler shift is directly proportional to the radial component of the spacecraft's velocity. - The measurement accuracy is dependent on the frequency band selected. Conventional ranging and Doppler measurement capabilities are in the microwave region, such as S-band with typical accuracies in the order of about 0.5 m. Satellite laser ranging (SLR) techniques between a ground-based laser station and a satellite use the much shorter wavelengths of visible light, resulting in a single-shot precision of <2 cm.

- Doppler tracking. Soon after the launch of Sputnik-1 (Oct. 4, 1957), JHU/APL (Johns Hopkins University/Applied Physics Laboratory) researchers W. H. Guier and G. C. Weiffenbach discovered that they could **determine a satellite's orbit solely from RF Doppler measurements** made on a single pass over their laboratory. In early 1958, F. T. McClure of APL inverted the problem: **if the position of the satellite were accurately known, then Doppler data could tell an observer on the ground his unknown position** (Note: the inverse problem became later known as the "navigation problem"). This led to the conceptual design of the first satellite Doppler navigation system, namely "Transit" for the US Navy (H.6).^{272) 273) 274) 275)}

- S/C tracking techniques, tracking system behavior and geodetic studies were the objective of three dedicated NASA missions, namely GEOS-1 (launch Nov. 6, 1965, E.7.1), GEOS-2 (launch Jan. 11, 1968) and GEOS-3 (launch April 9, 1975). Doppler instruments on-board and on-ground were employed for systematic range and range-rate measurements. Doppler shift measurements of a spaceborne Doppler instrument were also used to establish the structure of the Earth's gravity field to a fairly good accuracy.

- Satellite-to-satellite tracking technique (SST). The concept is based on tracking the "relative motion" between two satellites. SST is employed in particular in geodetic applications (gravity missions) to obtain highly accurate orbits for LEO satellites, and from these, by applying orbit perturbation analysis, the structure of the Earth's gravity field. The lack of sufficient coverage in ground station tracking capability requires such measures. SST was demonstrated for the first time ever in 1968, mapping the near side gravity field of the moon (with Earth being considered a satellite of the moon). With regard to the Earth's gravity field, SST was first demonstrated between GEOS-3 (in LEO) and ATS-6 (Applied Technology Satellite), a geostationary S/C of NASA in April 1975 (closed-loop tracking with a S-band transponder, the position of GEOS-3 was measured relative to that of ATS-6 of known position). However, few results were obtained due to the relatively high altitude of the lower satellite (E.7.3, GEOS-3 perigee of 818 km, apogee of 858 km). Later in 1975, there were SST measurements between the Apollo-18 S/C (launch of Apollo-18 ASTP on July 15,

271) Note: In the very early period of space flight, the technique of optical tracking was employed by the use of the Baker-Nunn camera.

272) E. J. Hoffman, "Spacecraft Design Innovations in the APL Space Department," Johns Hopkins APL Technical Digest, Vol. 13, No. 1, 1992, pp. 167-181

273) R. B. Kershner, "Technical Innovations in the APL Space Department," Johns Hopkins APL Technical Digest, Vol. 1, No. 4, 1980, pp. 264-278

274) Note: The very concept of being able to compute a location on Earth by observing the change in frequency of a spaceborne transmitter during a single pass was initially ridiculed by a number of reputable scientists.

275) The Legacy of Transit, Special issue of Johns Hopkins APL Technical Digest, Jan.-March 1998, Volume 19, No.

1975) in LEO and ATS-6. A further SST demonstration was conducted between the GPS constellation (in MEO) and the TOPEX/Poseidon altimeter satellite in LEO [the GPS receiver (6 channels, two frequencies, code and phase) aboard TOPEX/Poseidon is providing GPS-SST data since Dec. 1992; there exists an almost continuous data set for 1993. In addition to the GPS receiver, TOPEX/Poseidon was tracked with TDRS (Tracking Data Relay Satellite), DORIS (on-board the S/C) and SLR (Satellite Laser Ranging). Comparison of the tracking information from the four sources has demonstrated a satellite position determination capability in the <5 cm range. This level of accuracy is achieved through post-pass processing of the GPS data obtained from the satellite's GPS receiver.^{276) 277)} Unfortunately, the artificial anti-spoofing GPS signal degradation switched on again in 1994/5, permitted only occasional GPS observations, not advantageous for routine precise orbit determination]. The contribution of Topex/Poseidon GPS-SST data to existing gravity-field models were not very significant, due to the relative high altitude of the TOPEX/Poseidon (1334 km) orbit. But whenever anti-spoofing-off periods were available, then GPS observations provided an orbit restitution with centimeter-level accuracy, an essential requirement for the quality of an altimeter mission.^{278) 279)}

Note: SST methods for applications in gravity field recovery favor low-altitude orbits (referred to as low-low SST), in which two orbiters flying close-proximity circular trajectories, perform relative velocity or range measurements of high accuracy, at the lowest possible altitude (in the co-orbiting satellite approach, the basic observed quantity can be a distance or a Doppler frequency shift, or both). - The other viable approach (at the end of the 1990s) is continuous on-board GPS position measurements with high-quality receivers, providing a second and independent satellite-to-satellite tracking method, in combination with low-low SST. The global long-wave gravity field recovery by GPS is based primarily on the combined carrier phase measurement on-board the LEO S/C, and a network of ground receivers which allow the recovery of the GPS trajectories. High-low GPS SST is also applied for on-board navigation purposes.²⁸⁰⁾

1.7.2 Gradiometry , Accelerometry and Magnetometry

- Gradiometry. Measurement of the Earth's gravity field from space. Two basic and complementary approaches are in use: 1) SST (Satellite-to-Satellite Tracking Technique) and 2) SGG (Satellite Gravity Gradiometry). SGG measures some derivatives of the gravity vector, called gravity gradients, on-board a S/C in various directions with the use of a gradiometer, consisting of several accelerometers operated in differential mode. Gravity gradients are highly sensitive to the local features of the gravity field in the proximity of the measurement location. SST is best at providing the long and medium wavelength of the geopotential, while SGG performs best at the shorter wavelengths as a result of the measurement bandwidth characteristics of the accelerometers. Both approaches favor low-altitude orbits in which air drag modeling is critical, because the non-gravitational orbit perturbations have to be separated from the purely gravitational ones.
- Drag-free satellite. A drag-free satellite, free falling along a space-time geodetic, is the ideal test bench for some of the most advanced gravitation theories, from the general relativity validation to the search for experimental evidence of the existence of gravitational waves. - Triad-1 of the US Navy and built by JHU/APL (launched Sept. 2, 1972) is considered the first satellite to fly a completely gravitational orbit, free from all surface forces such as drag and radiation pressure. The orbit could in fact be predicted for up to 60 days (see

279) Information provided by P. Schwintzer of GFZ Potsdam

280) <http://www.estec.esa.nl/vrwww/explorer/GRAVITY.html#introduction>

also Table 42 and H.6). Triad-2 (launch Oct. 11, 1975) and Triad-3 (launch Sept. 1, 1976) were follow-up drag-free missions to Triad-1. The Gravity Probe-B mission (launch 2002), and the ESA GOCE (Gravity Field and Steady-State Ocean Circulation Explorer) mission with a launch in 2005, are further satellites employing the drag-free concept. In general, a drag-free system consists of accelerometers (a free-floating proof mass), micro-thrusters, and a corresponding control system, often referred to as DFC (Drag-Free Control) system, to measure the non-gravitational influences.

Mission	Comment
Triad series of US Navy (Triad-1 launch Sept. 2, 1972); Triad-2 launch Oct. 11, 1975	DISCOS obtained a residual acceleration of $5 \times 10^{-11} \text{ ms}^{-2}$. Triad-2 was equipped with a redundant pulsed-plasma thruster (PPT)
CHAMP of Germany, launch July 15, 2000	STAR of ONERA with a proof mass
GRACE, a dual minisatellite mission, launch 2001	SuperSTAR, a proof-mass instrument of ONERA to measure non-gravitational accelerations
GP-B (Gravity Probe-B) of NASA/Stanford, launch 2002	Drag-free control with proportional helium thrusters and a drag-free proof mass ($< 10^{-12} \text{ g}$).
Microscope of CNES (launch in 2004)	Drag-free S/C for a test of EP (Equivalence Principle) with an accuracy of one in 10^{15}
GOCE of ESA, launch 2005	DFACS compensates drag with thrusters
LISA (Laser Interferometer Space Antenna) of NASA, ESA, etc. with a launch in 2005/6	The LISA constellation of 3 S/C represents a giant interferometer to be used to detect gravitational waves. Each S/C contains a proof mass.

Table 43: Overview of some drag-free and non-gravitational measurement missions

- Accelerometry.²⁸¹⁾ The measurement of spacecraft surface forces requires ingenious designs due to various forces (drag, solar and Earth radiation pressure) and orientation knowledge needed for proper results. An accelerometer at the S/C center of mass can measure these forces that cause non-gravitational orbit perturbations. [A large accelerometer class employs the concept of force balance: a frame contains a moving proof-mass, the servo control detects its position and exerts a force to maintain the proof-mass motionless with respect to this frame. The combination of position sensing and force actuating results in accelerometer designs based on the following principles: piezoelectric, piezoresistive, acoustic, capacitive (electrostatic), and magnetic.] At the beginning of the 21st century, sensitivity requirements of accelerometers for space applications generally call for acceleration measurements below the pico-g (10^{-12} g) level. The electrostatic accelerometer type is seen as a most likely candidate to provide these performance levels.²⁸²⁾

- CACTUS. A first version of an electrostatic accelerometer (measuring differential accelerations between the external surface and a small ball placed at the center of mass), referred to as CACTUS (Capteur Accélérométrique Capacitif Triaxial Ultra Sensible), developed and built by ONERA of Chatillon, France, was flown on the CASTOR D-5B S/C (of CNES, launch May 17, 1975, with nominal S/C operations until 1979) for atmospheric density studies. The measured precision was 10^{-10} m/s^2 (or 10^{-11} g).²⁸³⁾

- Another ONERA accelerometer by the name of ASTRE (Accéléromètre Spatial Triaxial Electrostatique), was part of the ESA Microgravity Measurement Assembly (MMA), and flown on STS-55 (Apr. 26 - May 6, 1993), STS-83 (Apr. 4-8, 1997) and on STS-94 (Jul. 1-17, 1997). The resolution achieved by ASTRE was 10^{-9} g in the measurement bandwidth DC to 1 Hz (monitoring of the low-frequency acceleration environment). The ASTRE working principle is based on keeping a proof mass motionless in its nominal posi-

tion and attitude by means of electrostatic suspension, such that the required electrostatic forces are a direct measure of the three acceleration components. ²⁸⁴⁾

- In 1996, a Czech micro-accelerometer by the name of MACEK (Mikroakcelerometr), designed and developed at the Institute of Astronomy of the Academy of Sciences of the Czech Republic at Ondrejov, was flown as a technology experiment on Shuttle flight STS-79 (Sept. 16 - 26, 1996). MACEK was placed inside of Spacehab, about 2 m away from the center of gravity of the Shuttle (measurement of Shuttle vibrations during the orbital flight phase, performance tests of MACEK). MACEK employs the concept of an electrostatically compensated proof-mass with a measurement accuracy of 10^{-9} m/s². The first version of MACEK has been flown on the Russian satellite Resurs-F1 in 1992 (launch June 23, 1992, proof of concept flight for MACEK). ²⁸⁵⁾ - An upgraded version of the MACEK (10^{-10} m/s²) instrument is planned to fly on the Czech MIMOSA (Microaccelerometric Measurements of Satellite Accelerations) satellite mission in 2002 (see E.17).

- The GOCE (Gravity field and steady-state Ocean Circulation Explorer) mission of ESA with a planned launch date in 2005, flies EGG (Electrostatic Gravity Gradiometer), developed by ONERA, in an SGG (Satellite Gravity Gradiometer) configuration, combined with an SST configuration. See E.11.

Gravity/Mag.-field missions	Description
Cosmos-26 (Soviet Union)	Launch March 18, 1964. The USSR Cosmos-26 satellite provided the first global magnetic mapping of the Earth's surface.
Prognoz-6 (Soviet Union) Magnetic field measurements	Prognoz-6 (launch Sept. 26, 1977), IZMIRAN (data provider) Prognoz-7 (launch Nov. 11, 1978), IZMIRAN Prognoz-9 (launch July. 1, 1983), IZMIRAN
ISEE-1/2 (NASA/ESA)	ISEE-1/2 (launch Oct. 2, 1977). The RUM/RUD magnetometer experiment of UCLA studied the dynamic plasma field of the Earth
GEOS-2 (ESA)	GEOS-2 (launch July 24, 1978, E.6.2) into a near GEO. Objective: Measurement of fluctuations in the Earth's magnetic field and waves and particles. Two years of data.
MAGSAT (APL,NASA, USGS)	MAGSAT (launch Oct. 30, 1979, operated to June 1980) was the first mission to systematically measure the Earth's magnetic field. It provided the first IGRF (International Geomagnetic Reference Field) model based on global scalar and vector data of high accuracy, determining the core radius and mapping fluid motions at the core mantle boundary.
Interball (IKI, Russia)	Interball (launch Aug. 3, 1995) constellation of 4 S/C carries the FM-3I fluxgate magnetometers (solar wind interaction with the magnetosphere).
POLAR (NASA)	POLAR (launch Feb. 24, 1996) flies MFE (Magnetic Fields Experiment of UCLA to study the coupling of the solar wind and the magnetosphere
FAST (NASA)	FAST (launch Aug. 21, 1996) flies MFI (Magnetic Fields Instrument) of UCLA to measure the vector DC and AC magnetic fields.
ASTRID-2 (SSC, IRF-K, Sweden)	ASTRID-2 (launch Dec. 10, 1998) with the objective to perform high-resolution E-field and B-field measurements in the auroral region
Ørsted (TUD, Denmark)	Ørsted (launch Feb. 23, 1999) with the objective to perform highly accurate and sensitive measurements of the geomagnetic field
SACI-1 (INPE, Brazil)	SACI-1 (launch Oct. 14, 1999). The MAGNEX instrument investigates the phenomena related to current alignment with the trans-equatorial field and the plasma electrodynamics involving the Earth, specifically in the region of the South Atlantic Anomaly.
SAC-C (CONAE, NASA, DSRI, etc.)	SAC-C launch Nov. 21, 2000. The objective of Ørsted-2 (Magnetic Mapping Payload) instrument suite is to map the Earth's magnetic field.
IMAGE (NASA, SwRI)	IMAGE launch on Mar. 25, 2000. The objective is to study the global response of the Earth's magnetosphere to changes in the solar wind. NASA's first S/C for making ENA measurements of the terrestrial magnetosphere.
CHAMP (GFZ, DLR, Germany)	CHAMP launch July 15, 2000. Gravity field and magnetic field mapping (MIAS and DIDM). Use of SST/GPS + laser for orbit restitution and accelerometry for non-gravitational force measurements

²⁸⁴⁾ <http://esapub.esrin.esa.it/microgra/micrv8n2/natv8n2.htm>

GRACE (NASA/DLR)	A dual minisatellite mission (launch 2001) with accelerometers and GPS receivers for SST (+laser), like CHAMP plus ultra-precise low-low SST
FEDSAT (CSIRO) Australia	FEDSAT is due for launch in early 2002. The objectives of the NewMag instrument are to measure electrical currents and perturbations in the Earth's magnetic field.
Microscope (CNES, ONE-RA)	A microsatellite mission (2004) with the objective to measure EP (Equivalence Principle) to an accuracy of one part in 10^{15}
GOCE (ESA)	A gravity field mission (2005) with three-axis satellite gravity gradiometry (SGG) provided by EGG (Electrostatic Gravity Gradiometer) and SSTI (Satellite to Satellite Tracking Instrument) for SST
Planned but not flown missions	
Gravity/Mag.-field missions	Description (the listing of the following missions is kept for historical reasons). All the gravity objectives, concepts and goals which were elaborated for them are still valid.
GRAVSAT (NASA)	A mission defined in the 1980s and cancelled in 1987 due to technical difficulties and budget constraints
GGM (Gravity Gradiometer Mission), NASA also known as SGGM	Objective: to map the Earth's gravity and magnetic fields using two drag-free S/C orbiting in polar orbit at a very low altitude. The project was cancelled in 1987.
GRADIO (CNES) (a gradiometer instrument - not a mission)	Under study by CNES and terminated in the 1980s. GRADIO was a satellite gravity gradiometer experiment aimed at measuring the full set of gravity gradients (and separating it from the spacecraft attitude disturbances) by means of eight three-axis micro-accelerometers of a new generation.
ARISTOTELES (ESA/NASA)	Mission studies started in 1989 with the objective to fly a high-low SST mission using GPS and satellite gravity gradient measurements (GRADIO). ARISTOTELES was terminated in 1994/5 due to budget constraints
GAMES (NASA/CNES)	A two (co-orbiting) S/C mission was designed with laser measurements between S/C. A GPS receiver on one S/C was planned for LEO orbit determination. Also measurement of the magnetic field. GAMES was cancelled in the 1990s due to budget constraints.

Table 44: Overview of gravity/magnetic field missions flown (and not flown)

- Magnetometers are flown to measure the attitude of the S/C relative to the Earth's magnetic field. As such, they are normally part of the on-board attitude system. Magnetometers, in particular triaxial fluxgate instruments, are also flown as a science instrument to measure the geomagnetic field. Table 45 represents a chronology of fluxgate magnetometers flown as science instruments on various missions.

Mission	Launch	Instrument	Comment
DODGE (DoD)	July 1, 1967	Triaxial magnetometer	S/C was operational for over 3 years
GEOS-2 (NASA))	Jan. 11, 1968	Uniaxial fluxgate	
TRIAD-1 (US Navy)	Sept. 2, 1972	Triaxial magnetometer	
TRIAD-2	Oct. 11, 1975		
TRIAD-3	Sept. 1, 1976		
IMP-8 (NASA)	Oct. 26, 1973	GNF (triaxial fluxgate)	S/C was operational in 1997
GEOS-1 (ESA)	Apr. 20, 1977	S-331 (triaxial fluxgate)	S/C was operated until Apr. 1980 S/C operated until Oct. 1985
GEOS-2 (ESA)	July 14, 1978	S-331 (triaxial fluxgate)	
MAGSAT (APL, NASA, USGS)	Oct. 30, 1979	Scalar and vector magnetometers	
DE-1/DE-2 (NASA)	Aug. 3, 1981	MAG-1 (triaxial)	Combined launch of S/C
IRM (Germany)	Aug. 16, 1984	Triaxial magnetometer	AMPTE mission with 3 subsatellites
UKS (UK)	Aug. 16, 1984	Triaxial magnetometer	
CCE (USA)	Aug. 16, 1984	Triaxial magnetometer	
Viking (Sweden)	Feb. 22, 1986	V2 (triaxial)	End of mission May 12, 1987
EXOS-D (ISAS)	Feb. 22, 1989	MFG (triaxial)	Akebono mission (Japan)
Magion-2 (Czech)	Sept. 28, 1989	SGR-7 (triaxial)	Magion is subsatellite of ACTIVE
Ulysses (ESA/NASA)	Oct. 6, 1990	FGM/VHM	Boom-mounted magnetometers
UARS (NASA)	Sept. 13, 1991	VMAG part of PEM	
APEX (USSR)	Dec. 18, 1991	SGR-5 (triaxial)	Magion-3 is subsatellite of APEX
Magion-3 (Czech)		SGR-7 (triaxial)	
FREJA (Sweden)	Oct. 6, 1992	F2 (triaxial)	Boom-mounted

Mission	Launch	Instrument	Comment
POLAR (NASA)	Feb. 24, 1996	MFE (triaxial)	Two instruments
FAST (NASA)	Aug. 21, 1996	MFE (triaxial)	
ACE (NASA)	Aug. 25, 1997	Magnetic Field Monitor	Triaxial fluxgate
DMSP/F7 (DoD)	Dec. 18, 1983	SSM (triaxial)	NASA instrument
DMSP/F12 (DoD)	Aug. 29, 1994	SSM (triaxial)	
DMSP/F13 (DoD)	Mar. 24, 1995	SSM (triaxial)	
DMSP/F15 (DoD)	Dec. 12, 1999	SSM (triaxial)	
Equator-S (MPI)	Dec. 2, 1997	MAM (triaxial)	Boom-mounted
ASTRID-2 (Sweden)	Dec. 10, 1998	EMMA	
Ørsted (Denmark)	Feb. 23, 1999	Vector+scalar magnetometer	Both instruments are boom-mounted
SACI-1 (INPE)	Oct. 14, 1999	MAGNEX (triaxial)	Boom-mounted
OPAL (Stanford)	Jan. 27, 2000		
CHAMP (GFZ)	July 15, 2000	MIAS (scalar+triaxial)	Boom-mounted package of OVM and FGM
Cluster-II (ESA)	July 16, 2000 Aug. 9, 2000	FGM	Boom-mounted (2) on all S/C
SAC-C (CONAE)	Nov. 21, 2000	Ørsted-2	Boom-mounted
FedSat (CSIRO)	2002	NewMag	Boom-mounted

Table 45: Chronology of some fluxgate magnetometers flown on geomagnetic field missions

1.7.3 Satellite Laser Ranging

- The SLR (Satellite Laser Ranging) technique was first successfully demonstrated with a 'laser tracking reflector experiment' flown on the following NASA S/C (E.7.1): GEOS-1, (launch Nov. 6, 1965), GEOS-2 (launch Jan. 11, 1968) also referred to as Explorer-36, GEOS-3 (launch Apr. 9, 1975) and SEASAT (launch June 27, 1978). International cooperation and participation of many agencies has successively led to a global network of SLR ground stations (see H.4.3.6). - SLR measurements are applied to such fields as: global tectonic plate motion, regional crustal deformation near plate boundaries, Earth's gravity field and the orientation of its polar axis and its rate of spin. - A passive satellite laser-ranging measurement capability (entire S/C consists of laser corner reflectors) from ground to space was first provided with the CNES Starlette satellite (launch, Feb. 6, 1975).
- A future extension of the SLR (ground to satellite) technique inverts the traditional SLR system with the ranging hardware being placed onboard a satellite to range to the ground. This will be attempted with the GLAS (Geoscience Laser Altimeter System) instrument of the EOS program on ICESat (planned launch in 2001) for high-resolution ice and land topography mapping (realized already in the Mars Explorer Mission).

S/C or Mission (instrument)	Launch	Comment
GEOS-1 (Laser Tracking Reflector), NASA	Nov. 6, 1965	322 cubes were mounted on fiberglass panels on the bottom rim of the S/C
GEOS-2 (Laser Tracking Reflector), NASA	Jan. 11, 1968	Identical system as flown on GEOS-1
GEOS-3 (Laser Tracking Reflector), NASA and JHU/APL	Apr. 9, 1975	264 quartz cube corner reflectors mounted on a 45° conic frustum
Starlette, CNES	Feb. 6, 1976	First mission where the entire S/C consists of laser corner reflectors
LAGEOS-I, NASA, MEO orbit	May 4, 1976	
SEASAT (Laser Tracking Reflector), NASA/JPL	June 27, 1978	96 fused silica 3.75 cm hexagonal corner cube retroreflectors
EGS (Ajisai), NASDA, Japan	Aug. 12, 1986	318 mirrors and 120 laser reflector assemblies (1436 corner cube reflectors)
GEO-IK, NPO PM, Krasnojarsk, USSR The series of GEO-IK S/C is incomplete due to lacking information	May 30, 1988 Aug. 28, 1989 1990 Nov. 24, 1994	Orbit:1500 km altitude, inclin. = 73.6° Orbit:1500 km altitude, inclin.=73.6°
ETALON-1, USSR, MEO orbit ETALON-2, USSR, MEO orbit	Jan. 10, 1989 May 31, 1989	2140 laser reflectors

S/C or Mission (instrument)	Launch	Comment
ERS-1 (LRR), ESA	July 17, 1991	
TOPEX/Poseidon (LRA), NASA/CNES	Aug. 10, 1992	
LAGEOS-II of ASI and NASA, MEO orbit	Oct. 22, 1992	
Stella, CNES	Sept. 26, 1993	Stella is an exact twin of Starlette
MSTI-2 (RRA), BMDO/SMC	May 8, 1994	
GFZ-1 of GFZ, Potsdam, Germany	April 9, 1995	Low-altitude and slowly decaying orbit
ERS-2 (LRR), ESA	April 21, 1995	
Meteor-2-22, Russia	Aug. 31, 1993	Fizeau retroreflector array
RESURS-01-3 (RRA), Russia	Nov. 4, 1994	Fizeau retroreflector array
TiPS (Tether Physics and Survivability), DoD/NRL, see M.27	June 20, 1996	Retroreflectors are mounted on the exterior surfaces Ralph and Norton
ADEOS (RIS), NASDA, JEA	Aug. 17, 1996	Design of a hollow and flat cube-corner retroreflector
WESTPAC, EOS Australia (RESURS-O1-4)	July 10, 1998	Fizeau retroreflector array
Techsat/Gurwin-II (SLRRE), Technion Israel Institute of Technology, launched with RESURS-O1-4 satellite, see N.20	July 10, 1998	Array of laser retroreflectors, corner-cube mounted on the Earth-viewing panel
STEX/ATEX, DoD/NRL	Oct. 3, 1998	
SUNSAT, Stellenbosch University, SA	Feb. 23, 1999	Eight retroreflectors
CHAMP (LRR), GFZ, Germany	July 15, 2000	
Jason-1 (LRA), CNES/NASA	planned 2001	
REFLECTOR, US/Russian (AFRL),	planned 2001	Nanosatellite on Meteor-3M-1, retroreflector array of 32 corner cubes
Envisat (LRR), ESA	planned 2001	
ICESat (GLAS), NASA/GSFC	planned 2001	
GRACE (LRA), NASA/DLR/GFZ	planned 2001	
ADEOS-II, NASDA	planned 2002	
Gravity Probe-B, NASA, Stanford University	planned 2002	
VCL (RRA), NASA	planned 2002	
ALOS, NASDA	planned 2003	

Table 46: Chronology of some SLR systems

- Modulation of retroreflectors. The state of the art of modulating retroreflectors has progressed considerably in the 1990s. The advent of ferro-electric liquid crystals (FLCs) and the technology to produce MEMS (Micro-Electro-Mechanical Systems) make new electro-optical systems available. The most significant development has been the increase in the switching speeds that now allow data to be sent at tens of kilohertz up to multi-megahertz with very low power consumption. The technologies used for these devices are:
 - Ferro-electric liquid crystal (FLC) - Switches the polarization by reversing the polarity of the bias voltage
 - Multiple Quantum Well Device (MQW) - Switches resonance to pass or reject optical beam by electro-absorption
 - Atomic Absorption Cell (AAC) - Quantum electronic filter
 - MEMS Spoiled Corner Cube - Diffuse or specular surface reflection on one surface of the retroreflector
 - Switchable Gratings (PLZT) - Uses piezo-electric transducers to momentarily create diffracting surface on one surface of the retroreflector.

1.7.4 Attitude and Control Instruments

- From a historical point of view, the first on-board navigation instruments were mainly involved with the measurement of attitude and the provision of guidance. Early satellites were spin-stabilized to maintain orientation. Conventional attitude sensor types for the measurement of orientation are: gyroscope, horizon sensor, sun sensor, star sensor, magnetometer, etc; attitude control instruments (actuators) are: flywheels (reaction/momen-

tum wheels), magnetic torque rods, thrusters, etc. Satellites in the 1990s usually employ a multisensor navigation payload, this was not available technology in the early days of space-flight. At the turn of the century, there is a tendency to replace conventional Earth horizon sensors and also sun sensors of the attitude control system by star trackers. Stars provide a much finer reference (point source) thus keeping the satellite pointing more accurately. Examples of advanced star sensor systems are: a) ASC (Advanced Stellar Compass) flown on the Danish satellite Ørsted (launch Feb. 23, 1999) with an attitude precision of a few arcseconds; b) ATS (Autonomous Star Tracker) of the DoD/NRO STEX (Space Technology Experiment) satellite (launch Oct. 3, 1998). ATS provides attitude information to an accuracy of 0.005°; c) ASC and PASS (Payload Autonomous Star Sensor) are both flown on ESA's PROBA (planned launch 2001) mission. PASS has a wide FOV (19.3° x 14.4°) and about 3 arcseconds of pointing accuracy in pitch and yaw.

Present day (1997-2000) star sensors are designed to image only a portion of the sky and report the location of any stars that are tracked. Among other factors, the accuracy of these devices is historically limited by three design parameters: 1) A small FOV in the order of 8° x 8°, 2) The capability to track 5 stars simultaneously, and 3) A CCD detector array with a 512 pixel square imaging area. These choices have led to a limiting measurement accuracy of about 5 arcseconds per star and per frame.

As of 2000, AFRL at Kirtland AFB (Albuquerque, NM) is developing an "intelligent star tracker" with a pointing accuracy of better than 0.20 arcsec and NEA (Noise Equivalent Angle) better than 0.10 arcsec. The MEMS instrument mass is about 0.2 kg with a power consumption of <2 W. An adaptive optics catadioptric telescope design is used in combination with APPS (Active Pixel Position Sensor) detector technology.²⁸⁶⁾

- **Inertial sensors.** Gyroscopes and accelerometers are inertial sensors to obtain information on orientation (attitude) and accelerations relative to an inertial reference frame. Attitude measurements of a gyroscope provide angular information, while acceleration measurements (which are corrected for gravity and, integrated twice for distance) provide linear information.

The classical gyroscope is a mechanical device with a rapidly spinning mass (solid body or rotor of substantial moment of inertia), supported on a mount (e.g. a gimbal structure) that allows freedom of tilt of the spin axis relative to the base on which it is mounted. The momentum of such a rotor causes the gyro to retain its attitude when the mount is tilted. The ability of the gyro to maintain its orientation (due to the stored energy, namely the angular momentum) is employed in a number of applications (compass, direction finder, steering mechanisms, inertial guidance systems, etc.). - A practical gyroscope suffers from a phenomenon known as drift due to undesired torques resulting from imperfections in machining, bearing and lubrication frictional torques, material impurities, etc.

Since the early 1960s, new generations of gyroscopes were developed (in particular through research funded by the military), working on different principles than the conventional mechanical gyroscope. The Ring Laser Gyro (RLG) and the Fiber-Optic Gyro (FOG) are such new developments based on optical (interferometric) principles.^{287) 288) 289)}

- **RLG (Ring Laser Gyro).** RLG is a Sagnac effect optical gyro which uses an active HeNe lasing medium in a mirror-defined ring cavity. Two contra-rotating beams of coherent (laser) light circulate within the quartz ring cavity (the RLG technique was first demonstrated in 1962, it took another 20 years of testing for operational use of the system in commercial aircraft). The objective is the measurement of angular rate. The concept is

289) P. J. Klass, "Fiber-Optic Gyros Now Challenging Laser Gyros," Aviation Week & Space Technology, July 1, 1996, pp. 62-64

based on the principles of general relativity, which predict that the distance around a closed optical path in a rotating frame of reference depends on the direction the path is traversed. A beam of light traveling around the path in the direction of rotation has to travel farther than one traveling in the opposite direction of rotation. The pathlength difference (and frequency change) is used as a measure of angular rotation.

Some characteristics of an RLG are: 1) it offers long-term stability and it is insensitive to the environment; 2) it can operate continuously and has no start-up time; 3) it can withstand large angular rates ($800^\circ/\text{s}$); 4) it has a digital output; 5) it has no moving parts as the conventional gyro (however, in practice it is kept in motion to minimize some error sources); 6) it requires very little power for operation.

- **FOG (Fiber-Optic Gyro).** A solid-state device with no moving parts for the measurement of angular rate (first demonstrated in 1976). In a FOG, the two light beams rotate in a spool of optical fiber. The measurement concept is based on the Sagnac effect, which defines an optical phase shift between counter-propagating beams in a rotating coil of fiber. This phase shift is proportional to the rotation rate about the axis of the coil, with a scale factor related to the coil geometry and the optical wavelength. NASA's TR1-A rocket (a microgravity mission, Japan), launched in 1991, marked the first spaceborne experimental application of a FOG instrument. The Japanese MUSES-B (Mu Space Engineering Satellite - VLBI measurements in astronomy) mission of ISAS, launch Feb. 12, 1997, uses a hybrid FOG/radio-wave guidance system as well as an open-loop FOG for rate control (providing a drift rate of $0.05^\circ/\text{h}$). - In the late 1990s, performance range sensitivities (drift rates) of FOG devices vary from $0.001^\circ/\text{hr}$ to $100^\circ/\text{hr}$ with dynamic ranges (usable measuring range) of 10^4 to 10^5 .
- **Vibratory microgyroscope.** Starting in 1997, a new generation of microgyroscopes, based on MEMS principles, was developed out of a technology cooperation agreement between NASA/JPL, UCLA, and HSC (Hughes Space and Communications Company). The instrument (1999), an all-silicon chip, has a size of $4\text{ mm} \times 4\text{ mm}$ and a mass of less than one gram (the mass of the entire 3-axis microgyroscope is $< 30\text{ gram}$, power of about 1 W , size of $1.5\text{ cm} \times 1.5\text{ cm} \times 3\text{ cm}$, rate of $> 360^\circ/\text{s}$, etc.). The new microgyroscope is lighter, cheaper, higher-performing and less complex than its conventional counterparts, while uniquely designed for continuous and long-term space operation. The instrument concept is based on a cloverleaf design that is tied down and vibrates at a very high speed. The gyroscope senses the Coriolis acceleration, which results from the vibratory motion in a rotating reference frame, to detect rotation. The design represents a qualitative step forward in gyroscope development.

The applications of angular rate gyros include navigation of manned and unmanned platforms, location of fleet vehicles, and attitude heading measurements. Fiber-optic gyros can also provide antenna pointing and tracking. Following are some typical classes of gyro applications:

- General low-precision navigation (such as for automobiles) is done with gyros providing drift rates of $10^\circ/\text{hr}$ - $100^\circ/\text{hr}$
- Attitude and heading references for airplanes use gyros with drift rates of $1^\circ/\text{hr}$
- Precision inertial navigation as used in commercial airplanes and on some space platforms use gyros with drift rates of $0.01^\circ/\text{hr}$ - $0.001^\circ/\text{hr}$.
- High-precision inertial navigation with a drift rate of $< 0.001^\circ/\text{hr}$ is used for satellite pointing and tracking applications.

Three parameters define the performance of optical gyroscopes:

- Bias drift (a shift in the instrument zero point in the absence of rotation)
- Optical scale factor (a proportionality constant between applied rate and instrument output)
- Output noise (due to signal processing electronics, noise in the optical detection process, and thermal fluctuations in the optical fiber).

- The first spaceborne horizon sensor was flown on TIROS-2 (launch Nov. 23, 1960). A further new feature on this S/C was the introduction of magnetic attitude control, i.e., adjustment of spin axis orientation along the orbital path. The attitude device consisted of 250 cores of wire wound around the outer surface of the spacecraft. The interaction between the induced magnetic field in the spacecraft and the Earth's magnetic field provided the necessary torque for attitude control.
- Magnetic damping. In a satellite, magnetic damping can be realized with hysteresis rods (nickel-iron rods which are easily magnetized, even by the Earth's weak magnetic field. Such rods, rotated in a magnetic field, dissipate a fixed amount of energy for every revolution). The concept was invented by R. E. Fischell of JHU/APL and first flown on Transit-5A-3 in 1963. Such a rod produces a constant retarding torque which opposes any rotation. Since this opposing torque remains constant, even for a small rotation, hysteresis damping is effective even at low angular velocities.
- Improvements in spaceborne attitude control with instruments like star sensors and flywheels were introduced in the 1970s.
- Magnetometers traditionally have been used on spacecraft for sensing of coarse attitudes (in the order of 1°) and for input to the momentum control logic (magnetic torquers). However, in combination with accurate calibration and the availability of accurate gyroscope data, attitudes accuracies of better than 0.1° can be obtained using only magnetometer data and rate data. This was done at GSFC with UARS data (launch of UARS, Sept. 13, 1991).
- Programmed yaw steering of the S/C. The ERS-1 S/C (launch July 17, 1991) of ESA introduced the concept of yaw steering (a form of dynamic attitude control) to compensate for Earth rotation (about 4° per orbit). The vertical axis of the S/C is pointed towards the geodetic nadir to optimize the observation performance of its payload instruments. This involves a carefully controlled rotation about the yaw axis over the course of each orbit. As a result, the natural coordinate system of the radar instrument (AMI) remains orthogonal to the ground track of the S/C. In addition, ERS-1 introduced a roll-tilt mode in which the entire S/C can be rotated about its horizontal axis. This permits radar imaging at different incidence angles over limited periods of time.
- Spacecraft/platform and instrument pointing is an important aspect of navigation (see also same heading in Appendix A). The ability to locate a sensor measurement with the required accuracy on the Earth's surface (or to point at a faint celestial body from an orbiting platform) has made great strides in four decades of spaceflight. Precision pointing is a function of platform stability through suitable attitude sensing and control mechanisms. Early spacecraft had pointing accuracies of about $\pm 1^\circ$ which is in the same order of magnitude as spacecraft with gravity-gradient boom stabilization in the 1990s. Three-axis stabilized spacecraft, such as the NOAA/POES series (starting with TIROS-N) and the early SPOT series (SPOT-1,-2,-3) offer pointing accuracies of 0.1° . IPS (Instrument Pointing System) of ESA (built by Dornier, Friedrichshafen), first flown on Shuttle flight STS-51-F as Space-lab-2 in July/Aug. 1985, then on STS-35 as Astro-1 (Dec. 2-10, 1990), and again on STS-67 as Astro-2 (March 2-18, 1995), is providing a pointing stability within ± 1.2 arcseconds for all sensors on the platform (J.6).²⁹⁰ ²⁹¹ NASA/LARC conducted precision pointing experiments with MACE (Middeck Active Control Experiment) flown on Shuttle (STS-67, March 2-18, 1995). MACE consisted of three components: a multibody platform, experiment support module, and the handheld terminal. MACE-II (of AFRL) is a follow-up experiment to the original MACE flight. The AFRL objective is use adaptive control algorithms for preci-

²⁹⁰) <http://www.esrin.esa.it/htdocs/esa/progs/mg.html>

²⁹¹) <http://liftoff.msfc.nasa.gov/Shuttle/Astro2/description/ips/ips.html>

sion structural control. MACE-II is manifested on STS-106 (launch in 2003).²⁹²⁾ The imaging sensor OSA (Optical Sensor Assembly) on Ikonos-2 (launch Sept. 24, 1999) is providing an absolute ground location accuracy of 12 m (without the use of ground control points), the relative accuracy is 2 m. The imagery of such a sensor may certainly be used for cartographic applications (see Table 563). A separate class of pointing accuracy, namely <20 milliarcseconds, is required of Gravity Probe-B (Relativity Mission, planned launch in 2001), a spin-stabilized spacecraft. This is three orders of magnitude higher than IPS or close to five orders of magnitude higher than normal three-axis stabilized spacecraft.

- The ARGOS mission of DoD (launch Feb. 23, 1999) is flying an instrument by the name of USA (Unconventional Stellar Aspect) also referred to as NRL-801 experiment. USA conducts feasibility tests of X-ray satellite navigation and new computational approaches to autonomous parameter estimation that includes GPS inputs and a variety of redundant truth measures. There are reasons why X-ray navigation might prove to be attractive in the future. The advantages are associated mainly with drawbacks of optical methods or with potential advantages of X-ray characteristics that have no exact analogs in the optical wavelengths (M.1).

1.7.5 Altimetry

The third dimension in navigation, the measurement of changes in orbital height, is provided by such instruments as altimeters and accelerometers.

- Altimeters are active microwave instruments for the accurate measurement of vertical distances. The technology determines the two-way delay of the radar echo from the Earth's surface to a very high precision (in the 1990s to less than a nanosecond). It has also the capability to measure the power and the shape of the reflected radar pulses. The data provide in particular information on ocean topography [the gravity grids reveal also all of the major structures of the ocean floor. The "equipotential surface" of the ocean bulges outward and inward mimicking the topography of the ocean floor. The actual ocean surface deviates by up to 100 m from the ideal ellipsoid. The bumps and dips (troughs) in geoid height are caused by minute variations in the Earth's gravitational field]. - First spaceborne measurements of ocean surface heights started in 1973 with S-193 on Skylab at an altitude of 435 km. Using a pulse width of 0.1 microseconds this system was able to get a resolution of 15 m.

In altimetry the variation of the return signal strength (as the cube power of height) and the footprint area with the altitude requires the use of the pulse compression for higher altitudes.²⁹³⁾ Since GEOS-3 (launch Apr. 9, 1975), flying at an altitude of 840 km, all altimeters have used pulse compression - the resolution due to this compression has been improved. GEOS-3 offered significant improvements over the Skylab altimeter (S-193), including improved performance as well as greater global coverage. The SeaSat (1978) ALT instrument, designed and built by JHU/APL, is regarded the first high performance altimeter (first use of the full-deramp technique; introduction of the capability of waveform sampling). In contrast with previous designs, the samples are now an integral part of the altitude tracking process and are used in such a way that the system adapts as a function of wave height to tracker performances. Despite the premature demise of the SeaSat S/C after only 100 days in orbit, the altimeter performance clearly demonstrated the significance of the signal processing innovation, it was adopted as the standard approach for new radar altimeters. GEOSAT (1985 - 1990) altimetry introduced also measurements of sea-state and ocean surface winds. The "exact repeat mission" of GEOSAT, in which it retraced the SEASAT ground tracks, provided the first long-term high-quality altimeter measurements to the scientific community. More missions were launched in the 1990s: The RA-1 altimeter on ERS-1 (1991 - 1996)

and on ERS-2 (since 1995) was designed to optimize its performance over all types of surfaces. The ALT instrument on Topex/Poseidon (launch Aug. 10, 1992), designed to optimize performances over ocean surfaces, is regarded the first dual-frequency altimeter, permitting the estimation of ionospheric range delay. The Topex/Poseidon mission has demonstrated that the time variation of ocean topography (dynamic and thermodynamic) can be determined with an accuracy and precision of a few centimeters. For the first time, the seasonal cycle and other temporal variabilities of the ocean have been determined globally with high accuracy, yielding fundamentally important information for testing ocean circulation models. Topex/Poseidon was the first mission specifically designed for observing ocean circulation. The missions ERS-1/2 and TOPEX/Poseidon are part of international oceanographic and meteorological programs, such as WOCE (World Ocean Circulation Experiment) and TOGA (Tropical Ocean and Global Atmosphere), both linked to WCRP (World Climate Research Programme).

Table 47: Chronological survey of spaceborne radar altimeters

- Delay/Doppler radar altimeter. While the conventional altimeter technique is to measure the distance between the satellite and the mean ocean surface, the delay/Doppler method differs from those instruments in two ways:
 - Pulse-to-pulse coherence and full Doppler processing to allow for measurement of the along-track position of the range measurement
 - Use of two antennas and two receiver channels that allow for measurement of the across-track angle of the range measurement.

The central innovation of the delay/Doppler technology is that the returns from a group of transmissions along-track are coherently processed together, rather than incoherently as is customary. The coherent along-track processing allows much more of the instrument's ra-

diated power to be converted into height measurement data. - The phase between two otherwise identical coherent signals is a direct measure of the time shift between them (referred to as phase-monopulse technique). If the geometry of the observation space is known, then the observed phase shift can be inverted to an angular offset. The phase-monopulse technique uses this principle to estimate the angle of arrival between two signals collected through separated antennas. ²⁹⁴⁾

An airborne instrument named D2P (Delay/Doppler Phase-monopulse Radar) was developed and built by JHU/APL which demonstrated the technology in various test flights in the spring and summer of 2000 (P.62). In addition, a S/C mission (WITTEX) with the same objective was proposed. ²⁹⁵⁾ ²⁹⁶⁾ SIRAL (SAR Interferometer Radar Altimeter), the CryoSat mission altimeter of ESA (planned launch in 2003/4), will employ the concepts that have been demonstrated with the D2P radar. The SIRAL dual-beam concept offers for the first time some swath information, a significant advance over conventional pencil-beam altimeters (thus, offering a better capability of ocean current pattern recognition). ²⁹⁷⁾

- **Ocean reflection measurements of GNSS signals as sources of opportunity** (a passive altimetry technique). ²⁹⁸⁾ ²⁹⁹⁾ Background: The detection of GPS signals scattered off the ocean surface from the ground and from aircraft were obtained experimentally in 1991 and reported by a French team (Dassault Electronique) in 1994. ³⁰⁰⁾ Earlier work by Boeing had revealed the existence of such signals in connection with multipath effects (Boeing Co. report FAA-RD-73-57-V of 1973). In 1993, ESA/ESTEC presented a multistatic altimeter (see Glossary for “bistatic surface scattering”) ³⁰¹⁾ concept, referred to as PARIS (Passive Reflectometry and Interference System), based on an interferometric approach which combines the direct and ocean-reflected GNSS signals. That work included accuracy analysis and discussions of alternative altimetry constellations. ³⁰²⁾ ³⁰³⁾ Stephen J. Katzberg and James L. Garrison of NASA/LARC first analytically predicted the change in GPS signal structure following an ocean reflection. They then demonstrated the intentional tracking of reflected GPS signals with an airborne GPS receiver.

On the spaceborne side, GNSS reflections were first observed by a JPL team after the SRL-02 (Shuttle Radar Laboratory-02) mission (STS-68, Sept 30 - Oct. 11, 1994).

The concept of GPS (or better: GNSS) signal reflection measurements (as a source for bistatic surface scattering) is based on ocean surface roughness which results in multipath signal reflections emanating from the GPS and GLONASS satellite constellations. ³⁰⁴⁾ ³⁰⁵⁾ These signal reflections can in turn be picked up by a GPS receiver (a delay-Doppler-mapping receiver system) and may be used to determine such factors as wave height, wind speed, and wind direction. The strength of the reflected signals (normally regarded as surface clutter)

ter or simply as noise) is also a discriminator between wet and dry surface areas and, therefore, can be applied to coastal and wetland mapping. In this concept, high spatial resolutions are obtained with wide-beam and low-gain receiving antennas by using the GPS carrier phase and its PRN code modulation. This is similar to the SAR (Synthetic Aperture Radar) technique in which the Doppler frequency shifts and pulsed-signal time delays are used to create a small footprint on the mapped surface. - By combining code-range and Doppler measurements, a receiver can distinguish particular patches of the ocean surface illuminated by GPS signals.

In some ways, the above GPS applications discovery is similar to that of using GPS to map the ionosphere's TEC (Total Electron Content) by measuring propagation delay differences between the L1 and L2 frequencies.³⁰⁶⁾

The GNSS-based concept of altimetry with reflective pseudorange noise (PRN) operates in a bistatic geometry (i.e., the transmitted and received signals travel two different paths) with the following features:

- Up to 20 ocean height measurements are possible simultaneously with a single receiver for the measurement of reflected GNSS signals. In comparison, traditional altimetry is limited to looking in the nadir direction and obtaining one height observation at a time below the altimeter.
- GNSS reflection coverage is very dense but random, while in traditional altimetry, the coverage is regular according to a certain repeat pattern. However, the reflected signal retrieval produces only modest SNRs with low-gain antennas. Hence, exploitation of GNSS reflections observed from space is still rather speculative at the start of the 21st century. It will require high gain antennas (preferably >26 dB gain) with multiple independently steerable beams. A single platform might typically see 10-12 reflections at once over the oceans. Measurement precision will be modest (about 1 m in a few seconds for altimetry), hence, massive averaging is required to get to the 5-cm level that will be needed for ocean circulation, and that may require a dozen or so platforms at once.
- When the GNSS signal impinges on the ocean surface, it is scattered randomly with maximum power in the direction of the specular reflection. Since the ocean reflectance depends on the surface temperature and salinity, in principle, measuring the return power with sufficient accuracy could eventually be used to infer these parameters.
- The GNSS reflection relies on detecting the amount of energy return of the GNSS signal by correlating the pseudo-random code of the reflected signal and a delayed model of the same code generated in the receiver. By examining the power return at different delays and Doppler shifts, different parts of the ocean are sensed. The footprint of GNSS reflection is determined by the intersection of iso-Doppler and iso-range contours.
- The BlackJack GPS receiver configurations/implementations of the missions CHAMP (launch July 15, 2000) and SAC-C (launch Nov. 21, 2000) have the added capability of bistatic ocean reflection measurements, originating from the GPS and GLONASS constellations (besides refractive atmospheric occultation monitoring). This relatively new technique of "GNSS reflected pseudorange altimetry" recovery with on-board GPS (or GNSS) receivers will eventually permit applications such as oceanic circulation sensing (particularly eddy-scale currents that are missed by today's altimetry missions), and scatterometry (measuring the shape of the reflected pulse) for determining wind speeds. The CHAMP and SAC-C GNSS reflection experiments are considered simple engineering tests of opportunity with antenna gains of only 6-9 dB. Thus, long averaging times are needed just to detect the signals. - Essential to the success of GNSS-recovered altimetry and scatterometry is the ability to see multiple reflected signals si-

306) A. Komjathy, J. L. Garrison, V. Zavorotny, "GPS: A New Tool for Ocean Science," GPS World, April 1999, pp. 50-56

multaneously. Note: The Blackjack instrument on SAC-C is also referred to as GOLPE (GPS Occultation and Passive reflection Experiment).

1.7.6 Orbits

A number of different Earth orbit types were introduced to cover particular observational and/or operational requirements (see also O.12).

- 1) **LEO** (Low Earth Orbit - altitude range between 300 - 2000 km). The most common and natural orbit for Earth observation. The very first satellites, like Sputnik-1 and most successors, had LEO orbits and were launched in an eastward direction (thereby gaining a boost with the Earth's rotation), and obtaining an inclination of the launch site's latitude.³⁰⁷⁾

Global LEO observation coverage was an early requirement in spaceflight. This led to new strategies in mission planning - in particular with regard to orbital plane inclinations and to orbital altitudes.

- The US satellite Discoverer-1 (launch on a Thor vehicle from VAFB on Feb. 28, 1959, apogee = 968 km, perigee = 163 km, inclination = 89.7°, period = 96 min) was the first spacecraft in **polar orbit**. It flew a military payload. This was followed by the "Transit" navigation satellite series of the US Navy. Starting with the launch of Transit-5A-1 (and follow-up satellites of the series) on a Scout vehicle from VAFB, CA, on Dec. 18, 1962.
 - In the field of Earth observation, the orbital strategy of **polar orbit** was introduced with Nimbus-1 (launch Aug. 28, 1964), then with TIROS-9 (launch Jan. 22, 1965). The polar orbit enabled the provision of full repetitive global coverage. Depending on sufficient swath width, some sensors (such as AVHRR) were able to provide daily global coverage, while other sensors needed several days for a repeat cycle.
 - The **sun-synchronous polar orbit** was first realized on TIROS-10 (launch July 2, 1965). This new orbit introduced the concept of repeat observations (same sun illumination angles) of a given Earth surface region at the same time of the day (due to same latitudinal crossings), improving considerably the conditions for data analysis. An additional advantage of the sun-synchronous orbit resulted in a better power provision for the spacecraft.
- 2) **GEO** (Geostationary Earth Orbit - approximately 35,786 km above the Earth's surface at the equator).³⁰⁸⁾ The GEO orbit provides a fixed-position relation between the satellite and the ground, a continuous viewing capability of the same footprint is given (however, the polar regions of the Earth are not accessible from GEO). Although the GEO concept is quite extensively utilized by meteorological and communication satellites at the end of the 20th century, it still remains challenging for remote sensing applications in terms of proper spatial resolutions for Earth surface imagery due to its radial distance of at least 36,000 km. The great distance from Earth implies tougher constraints on imaging instruments and on communication systems.

The concept of a geostationary orbit seems to have several independent authors - men of vision and imagination:

- a) Hermann Potocnic [Dec. 22, 1892 - Aug. 27, 1929, born in Pola (Pulj), Moravia, Austrian-Hungarian Empire, an engineer (Vienna) and retired captain of the army] published his

³⁰⁷⁾ Note: Satellites (Ofeq series) launched from Israel (Palamchim Air Force Base south of Tel Aviv) orbit from east to west, as opposed to the traditional west to east direction, as Israel can only safely launch rockets to the west, over the Mediterranean Sea.

³⁰⁸⁾ Note: With regard to the GEO concept, credit is almost universally given to only one author in the literature, namely to A. C. Clarke, who published his first article almost 20 years after that of Hermann Potocnic. In fact, some space age historians talk about the "Clarke Orbit" when referring to a geostationary Earth orbit. This is an injustice to the accomplishments of Hermann Potocnic.

concepts of future space travel in a book with the title: “Das Problem der Befahrung des Weltraums - Der Raketen-Motor,” Richard Carl Schmidt & Co., Berlin W62, 2. Auflage, 1929.^{309) 310)} He used the pseudonym of Hermann Noordung for the publication, since he was afraid to be ridiculed by his peers. In the book (page 98), Noordung proposed a stationary orbit of a space station (referred to as “Raumwarte” for astronomical observations) at radius 42,300 km from Earth center (or about 35,900 km above the surface), in the equator plane, with a chosen orbital speed of about 3080 m/s - resulting in a free orbit with an angular velocity equal to that of Earth rotation. An orbiting body would seem to be stationary over a certain point at the equator.

b) Arthur C. Clarke (born Dec. 16, 1917 in Somerset, England) published an article in 1945 with the title: “Extra-terrestrial Relays: Can Rocket Stations Give World-wide Radio Coverage?” (Wireless World, Oct. 1945) where he described the principles of satellite communication in geostationary orbit. Clarke suggested that if a satellite were placed above Earth’s equator at just the right height - 35,888 km - it would orbit Earth exactly once in 24 hours - and seem to stay put in the sky above some point on the ground.

In 1947, Arthur C. Clarke proposed how three satellites, suspended in orbits 35,888 km above the equator, could serve as relay platforms for the entire Earth. He cautioned that the concept was based on the theory that microwave radio signals would not bounce off the atmosphere like shortwave signals, something that wasn’t known for certain in 1947.

- Syncom-2 (launch July 26, 1963 on a Thor Delta vehicle, built by Hughes Corp.) was the first successful experimental communication satellite to achieve geostationary orbit. Positioned over the Atlantic, it demonstrated the feasibility of geostationary satellite communications. Note: Syncom-1 (launched Feb. 14, 1963) achieved GEO orbit but contact was lost after it was placed in orbit.

- The objective of ATS (Applications Technology Satellite) program, a series of six NASA S/C, was to explore and test new technologies and concepts for communications, meteorological and navigation satellites (investigation of the geostationary orbit environment). Note: ATS-2 and ATS-4 were MEO satellites, the rest of the ATS program were GEO satellites.

- In the 1990s the geostationary orbit (GEO) is indeed the most densely populated orbit of satellites. This is due in particular to the needs of the communication industry.

3) **IGSO** (Inclined Geosynchronous Orbit), see O.12.2. A geosynchronous satellite with an inclination different from zero is not “stationary” when observed from the Earth. This particular orbit has the property of remaining stationary over a particular meridian (there is no longitudinal precession for successive orbits but latitudinal motion along the meridian). An inclination of 30° causes a latitudinal displacement of $\pm 30^\circ$ during one orbital period (one day). First applications of IGSO were considered in the planning phase with GalileoSat (Europe’s space segment of a navigation system).

4) **GTO** (Geosynchronous Transfer Orbit - an elliptical orbit with perigees usually between 300 - 600 km and an apogee of 36,000 km). In the normal case, GTO is the short-term initial orbit of a S/C after launch to be placed into GEO by a sequence of orbit maneuvers that are executed by the satellite’s own propulsion system to circularize the orbit into GEO - all GEO satellites (weather or communication) go through this procedure. Secondly, GTO may be used as a long-term orbit, usually selected by S/C with payloads that measure the harsh solar radiation environment. GTO implies that a S/C passes through the Van Allen radiation belts (these are regions located at about $1.4-1.5 R_E$ and $4.5-6 R_E$ where many energetically charged particles from the solar wind are trapped in the Earth’s magnetic field) four times per day, causing them to be exposed,

309) Note: A 1st edition of the book could not be located anywhere. The reprint of “Das Problem der Befahrung des Weltraums,” Ausgabe von 1929, is available at Turia + Kant Verlag: ISBN: 3-85132-060-3

310) <http://www.ijs.si/slo/country/culture/potocnik.html>

in a twelve month period, to levels of radiation equivalent to about 8-10 years in GEO or LEO. GTO gives also exposure to other environmental effects such as atomic oxygen erosion at perigee and electrostatic charging at apogee. - The accelerated life testing of radiation effects provided by GTO is a unique opportunity to evaluate new technology solar panels quickly and cost-effectively. Examples of S/C in long-term GTO are: CRRES of NASA/DoD (launch July 25, 1990, A.11); STRV-1a and -1b of DERA, UK (launch June 17, 1994, M.25); STRV-1c/1d of DERA (launch Nov. 16, 2000); MDS-1 of NASDA (planned launch 2000/1), and IMEX (Inner Magnetospheric Explorer) of the University of Minnesota at Minneapolis, (planned launch in 2001).

- 5) **MEO** (Medium Earth Orbit - altitude range of about 5000 km to about 25,000 km above surface) provide considerably longer contact times with the user. Examples of typical MEO S/C are:

- Some laser ranging satellites (passive systems) such as: LAGEOS-1 of NASA (launch May 4, 1976, altitude 5900 km). ETALON-1 of USSR (launch Jan. 10, 1989, altitude about 19,000 km).
- Navigation satellite constellations of GPS (GPS-1 launch Feb. 22, 1978, altitudes of about 20,000 km, period of about 12 hours) and GLONASS (GLONASS-1, -2, -3 launch, Oct. 12, 1982; altitudes of about 19,000 km, period of about 11.25 hours). Prior to the GPS constellation, the launch of NTS-2 (July 14, 1974) had a MEO orbit of 13900 km.
- Some communication satellites: Inmarsat-P series, ATS-2 and ATS-4.

- 6) **HEO** (Highly-elliptical Earth Orbit - a typical HEO has a perigee of about 500 km and an apogee of 5-10 R_E and more). The observation objectives in HEO orbits involve mainly investigations of the energy transport between the sun and the Earth in the interplanetary plasma (energetic particle fluxes, etc.), solar-terrestrial interactions (in particular in the auroral regions), as well as magnetic field studies. Examples of satellites in HEO are:

The IMP-4, -5, -6, -7 and -8 (Interplanetary Monitoring Platform series of NASA - also referred to as Explorers 34, 41, 43, 47, and 50, respectively). IMP-4 was launched on May 24, 1967 (apogee of 34 R_E , perigee of 250 km). IMP-8 was launched Oct. 26, 1973. A number of the Prognoz spacecraft series of the USSR (magnetospheric research, etc.) had apogees ranging from 200,000 - 800,000 km (or about 30-125 R_E) such as Prognoz-6 (launch Sept. 26, 1977, Prognoz-7 (launch Nov. 11, 1978), and Prognoz-9 (launch July 1, 1983). Onboard the Prognoz-9 spacecraft was also the Relict-1 experiment to investigate the large-scale anisotropy of relict radiation.. The ISEE-1 and -2 satellites (K.18) had a joint launch on Oct. 2, 1977 (apogee at 23 R_E). The AMPTE satellites (IRM, UKS, CCE, see K.4) were launched on Aug. 16, 1984. GEOTAIL, launch July 24, 1992. WIND, launch Nov. 1, 1994. INTERBALL (launch of Tail probe Aug. 3, 1995, Auroral Probe launch Aug. 29, 1996). POLAR, launch Feb. 24, 1996. Equator-S, launch Dec. 2, 1997. Chandra X-ray Observatory, launch on Shuttle flight STS-93 on July 23, 1999. The XMM (X-Ray Multi-Mirror Mission - Note: XMM was officially renamed to "Newton" in Feb. 2000) of ESA, launch Dec. 10, 1999 with an Ariane-5 vehicle from Kourou, has an operational orbit of: perigee = 7000 km, apogee = 114,000 km, an inclination of 40° and a period of 47.86 hours. The IMAGE (Imager for Magnetopause-to-Aurora Global Exploration) mission of NASA/GSFC (launch Mar. 25, 2000), has a polar orbit of: perigee = 1000 km, apogee = 7 R_E (44,647 km). The location of the apogee changes during the course of the two-year mission, both in latitude and, because of the Earth's revolution about the sun, in local time.

- 7) **Halo orbits** (an orbit around the sun/Earth Lagrangian Point (L1), about 1.5 million km from Earth (in the direction Earth - sun), in which the sun/Earth gravitational forces are balanced. L1 is an ideal outlook point for Earth observation as well as for monitoring of "space weather" parameters. Examples of satellites in L1 halo orbits are (see also

O.12.11): ISEE-3 (NASA/GSFC, launch Aug. 12, 1978); SOHO (ESA/NASA, launch Dec. 2, 1995); WIND (NASA, launch Nov. 1, 1994 - WIND was placed into a halo orbit in Nov. 1996); ACE (NASA, launch Aug. 25, 1997). Further planned missions into a halo orbit at L1 are: Genesis of NASA/JPL with a launch in 2001, Triana of NASA with a launch in 2004, Geostorm of NASA/NOAA with a launch in 2003.

Astronomy missions to L2 are (see Figure 394): a) MAP (Microwave Anisotropy Probe) of NASA/GSFC with a launch June 30, 2001; the objective is to probe conditions in the early universe by measuring the properties of the cosmic microwave background radiation over the full sky; b) FIRST (Far Infrared Submillimeter Telescope) of ESA with a planned launch in 2006.

Note: the L2 point is the same distance away as L1 but at the opposite side of the Earth. This implies that a spacecraft positioned at L2 is always located in the Earth's shadow. An advantage of L2 is astronomical viewing (looking toward the universe) due to constant lighting conditions. - The first three Lagrangian points of the sun/Earth system, namely L1, L2 and L3, lie along an axis with Earth and the sun, with L3 on the opposite side of the sun from Earth. The other Lagrangian points, L4 and L5, are in the same orbit plane around the sun as Earth; however, L4 is 60° ahead of Earth while L5 is trailing Earth by 60°.

- 8) **EEO (Elliptical Earth Orbits).** Refer to orbits chosen in such a fashion that maximum service provision (or viewing time) can be provided to a particular region of the Earth. A prominent example are the numerous Molniya-type orbits (apogee = 39950 km, perigee about 100-300 km, inclination = 63.4°) with periods of 12 hours, whose apogee (by far the longest duration period of the orbit) occurs always in the intended region, namely the northern hemisphere. The first launch of the Molniya-1 satellite series occurred April 23, 1965 (over 20 S/C of the series until 1974), followed by the Molniya-2 series with first launches in 1972 and countless S/C of the Molniya-3 series. The Molniya series represents also the first communication satellites of the USSR. The TWINS dual-spacecraft mission of NASA (planned launch in 2003) employs Molniya-type orbits to achieve long periods in apogee.

- Close encounters/rendezvous of satellites with celestial bodies. The art of satellite navigation has evolved steadily over the years, resulting occasionally in close flyby maneuvers. Examples are:

- On July 29, 1999, the DS1 spacecraft of NASA/JPL successfully performed a close flyby of asteroid 9969 Braille using the AutoNav system. At about 27 km separation, it was by far the closest flyby of an asteroid so far attempted.

- The NEAR (Near Earth Asteroid Rendezvous S/C)/Shoemaker satellite of NASA, in orbit around asteroid 433 Eros since Feb. 2000, experienced his closest encounter with Eros on Oct. 26, 2000.³¹¹⁾ The flyby, with corresponding surface observation, occurred at an elevation of about 5 km, planned and supervised by the mission control center at JHU/APL. The NEAR/Shoemaker S/C then performed year-long observations of Eros (322 million km from Earth). **On Feb 12, 2001, it was commanded by JHU/APL to land on the asteroid** (the S/C was not built for landing). The final touchdown speed of the craft was 1.9 m/s after some descent maneuvers. The S/C instruments kept operating after touchdown. The GRS (Gamma Ray Spectrometer) is detecting key chemical signatures of a “planetesimal” - one of the original building blocks of planets. NEAR/Shoemaker thus became the first spacecraft ever to land on an asteroid.

1.7.7 On-Orbit Servicing

Space logistics, the ability of on-orbit service provision, is a natural consequence of high-value assets in space (like HST and ISS) as well as of ever increasing satellite fleets in all

³¹¹⁾ http://spacescience.com/headlines/y2000/ast26oct_2.htm?list65492

fields of space endeavors. Without any logistics, satellites have severe limitations affecting their operational life and functional capabilities. The conventional practice in spacecraft and instrument building puts very high demands on reliability resulting in redundant and expensive satellites. With this approach, a spacecraft may still be lost even if the majority of its components are operational. Redundancy in turn produces heavy spacecraft which require extra lift capacity for launch services. The emerging technologies of the 21st century may change the conventional practices of the past (at least to some degree) with the introduction of on-orbit servicing capabilities. The solutions offered by the space industry must be affordable in order to be accepted.³¹²⁾

- Shuttle repair/service missions. The first Shuttle repair mission took place in April 1984 (STS-41C). The SMM (Solar Maximum Mission) S/C became the first satellite to be retrieved, repaired, and redeployed in orbit by a Shuttle crew. The first Hubble repair mission was launched Dec. 2, 1993 on STS-61 [the HST (Hubble Space Telescope) was launched April 24, 1990 on STS-31]. The second Hubble service flight was on STS-82 (Feb. 11-21, 1997). The third Hubble service flight was on STS-95 (Oct. 29 - Nov. 7, 1998). The fourth Hubble service flight on STS-103 took place Dec. 19-27, 1999. Objective: replacement of gyroscopes, a fine guidance sensor and a S/C computer. Installation of a voltage/temperature kit for the S/C batteries. Installation of a new transmitter, solid state recorder (12 Gbit), and thermal insulation blankets. - A further routine servicing mission to Hubble is planned for November 2001. Without periodic on-board servicing, Hubble would have been a disaster and would not have produced all of the great science it has.
- The capability of on-orbit servicing is of course not limited to Shuttle flights (based on manned servicing techniques developed in the 1980s) resulting in very high service bills for a single mission. Small robotic spacecraft in combination with new technologies may in fact be the answer to potential future servicing mission capabilities in such fields as: a) mission repair, b) maintenance and scheduled repair, c) replenishment of consumables, and d) pre-planned product improvements and upgrades. First experiments with on-orbit servicing have already been conducted.
- SVS (Space Vision System). SVS is a Canadian-built camera system, sponsored by CSA and NASA with its maiden flight (prototype) on Shuttle STS-52 (Oct. 22 - Nov. 1, 1992). Since then, SVS has completed four Shuttle flights. The Shuttle mission STS-88 (Dec. 4 - 15, 1998), an assembly flight with the module Unity to ISS, marked the first operational use of SVS. The primary objective of SVS is to help astronauts perform so-called blind mates of the space station modules. SVS is a computer-aided vision system that works in conjunction with four stationary cameras located inside the Shuttle's cargo bay and two cameras attached to the robotic arm itself.³¹³⁾
- AERCam (Autonomous EVA Robotic Camera), a free-flying space camera (of NASA/MSFC). The first demonstration occurred on STS-87 (November 19 to December 5, 1997). The free-flyer has a self contained cold gas propulsion system giving it the capability to be propelled with a 6 degrees of freedom control system. Onboard the free-flyer are rate sensors to provide data for an automatic attitude hold capability.
- Inspector platform family of Astrium GmbH (formerly DASA).^{314) 315)} The program started in 1993 as a joint project of DASA/Space Infrastructure, RSC Energia, and The Boeing Company. The objective was to monitor events in space (docking maneuvers, etc.) and to extend the inspection capabilities for MIR as well as for ISS. At the start of the 21st century the Inspector family consists of X-MIR and three more service struc-

312) G. Leisman, "Analysis of on-board Servicing Architectures using Microsatellites, Advanced Propulsion, Secondary Opportunities and the Military Spaceplane Concept," Proceedings of the AIAA 2000 Space Conference and Exhibition, Long Beach, CA, Sept. 19-21, 2000

313) B. Berger, "Astronauts Use Space Vision to Assemble Station," Space News, Feb. 1, 1999, p. 10

314) "The Inspector Product Family," brochure provided by F. Steinsiek of DASA/Space Infrastructure, Bremen

315) http://www.dasa.com/dasa/index_e.htm

tures (ISS Inspector, Visitor, and Operator) in varying phases of development:

X-MIR Inspector was launched on its first demonstration flight to the Mir station on Oct. 5, 1997. The prime objectives were to verify the video navigation system and the visual inspection capabilities of X-MIR in the neighborhood of MIR. On Dec. 17, 1997, X-MIR started its demonstration flight as a free-flying observer service module, by orbiting MIR. The successful X-MIR demonstration lasted from 1997 to 1998 providing high-quality video imagery of MIR as well as of the docking sequences of the service vehicle Progress. X-MIR consists of: a) space vehicle, b) monitoring and control station, and c) transport launch container.³¹⁶⁾ X-MIR was remotely controlled from MCS (Monitoring and Control Station) on-board the MIR station. MCS consisted of a laptop PC, a video display, a video recorder and an electronic module for radio communications, power distribution and navigation.

The prime objective of the ISS Inspector is the inspection of the surfaces of the ISS or visiting transportation vehicles (US Space Shuttle, Proton vehicle, etc.). In 1997 NASA selected the Inspector for the AETD (Advanced Engineering and Technology) program. The prime objective of the Inspector for ISS services is the inspection of space vehicle surfaces (video and infrared observations), this includes the ISS and visiting spacecraft. The Inspector payload performs also leakage, contamination and radiation environment monitoring of the ISS.

The Visitor concept is a co-orbiting multi-purpose platform of ISS to be used for various payload operations in the fields of science observations, technology or commercial applications. Visitor is able to carry various kinds of payloads under very low gravity conditions. The payloads are mounted onto standard payload modules, referred to as ORU (Orbital Replaceable Unit) or onto ExPA (Express Pallet Adapter).

- MMS (Mobile Servicing System) of ISS provided by Canada. MMS is a robotics system consisting of the elements SSRMS (Space Station Remote Manipulator System), SPDM (Special Purpose Dextrous Manipulator), and MBS (Mobile Base System). In April 2001, SSRMS was flown and installed on ISS. The system will be used to assemble and maintain the ISS (International Space Station).
- Inspection services during launch and early-orbit phases are already practiced with on-board miniature cameras providing visible proof to the mission operators of such functions as stage separation, antenna deployment, secondary vehicle deployment, and many other on-board activities and events. An example of inspection services is TEAMSAT (M.26), an ESA/ESTEC low-cost satellite demonstrator mission (launch Oct 30, 1997) with VTS (Visual Telemetry System).
- The SNAP-1 nanosatellite mission of SSTL (Surrey Satellite Technology Ltd), UK, with a launch on June 28, 2000 (along with Tsinghua-1 of China) is quipped with MVS (Machine Vision System) permitting SNAP-1 to function as a remote inspector.
- Most work on autonomous on-orbit servicing has been confined to very high-value assets such as ISS. Servicing spacecraft developments considered for ISS are: a) CTV (Cargo Transfer Vehicle) of NASA; b) ATV (Automated Transfer Vehicle) of ESA, a cargo resupply vehicle for ISS to be launched by Ariane-5; and c) HOPE of NASDA.
- Designs for on-orbit servicing of average Earth-orbiting satellites are in the proposal state as of 2001.³¹⁷⁾

1.7.8 Satellite Radionavigation Systems

Radionavigation systems employ the concept of triangulation with line-of-sight radio signals from different satellites to find position - in the same fashion that angular measure-

316) H. Günther, "From MIR to ISS - The Inspector Mission," Proceedings of the 4th International Symposium on Small Satellites Systems and Services, Sept. 14-18, 1998, Antibes Juan les Pins, France

317) E. Lamassoure, D. E. Hastings, "Generalized Metrics for Optimization of Space Systems Cost-Effectiveness," Proceedings of the AIAA Space Conference and Exhibition, Long Beach, CA, Sept. 19-21, 2000

ments of distant stars were made (and are still being made) throughout navigation history to find position.^{318) 319)} Instead of angular measurements to natural stars, the new systems use a radio-ranging measurement technique, a triangulation to a constellation of satellites. The first generation spaceborne navigation systems, Transit (USA) and Tsikada (USSR), were mostly reserved for military use; however, they were of pivotal importance due to the insights gained in the nature of navigation and the considerable advances in early space-age technology. These were followed by second generation navigation systems, namely GPS and GLONASS, which were again developed, built and operated by the military services; but their use was so revolutionary and universal, that the civil community was permitted to use this new utility as well.

- Transit navigation program (US Navy, see H.6). The first operational US navigation satellite was Transit-1B (designed and built at JHU/APL), launched April 13, 1960 aboard a Thor-Able rocket from Cape Canaveral. Starting with Transit-5A-3 (launch June 16, 1963), each satellite in the series featured a gravity-gradient boom for stabilization and had a total mass of about 55 kg (polar circular orbits at altitudes of about 1100 km). Transit is generally credited with demonstrating the feasibility of using artificial satellites as navigational aids. By the end of 1962, a first position fix could be performed by a Polaris vessel.³²⁰⁾ The Transit system was used by the US Navy in 1964, it became fully operational in 1966 (12 S/C constellation with seven operational and five stored S/C in orbit). The satellites broadcast their signals on two frequencies: 150 and 400 MHz. The dual-frequency method was introduced for the first time (on Transit-1B) to correct for ionospheric refraction effects (the 2nd frequency enabled the distortion to be cancelled out). - The Navy's Transit (2-D) navigation system allowed the user to determine position by measuring the Doppler shift of the received signal (constant tone broadcast - the frequency of 150 MHz was transmitted to correct for ionospheric delay). The 2-D system did not permit velocity determination. - In 1967 the system was released for non-military purposes, a benefit to broad ocean navigation. The Transit series reached a peak utilization of about 100,000 commercial and military users in the late 1980s, and was decommissioned on Dec. 31, 1996.^{272) 321)}

One of the technologies required to make Transit possible was a considerable improvement on time and frequency standards. To realize the fixed site survey accuracy of 1 m, the satellite Doppler signal at 400 MHz must be measured to 0.0005 Hz (a resolution of 5×10^{-12}). In 1960, the best standards of frequency were only good to resolve 5×10^{-10} and could only measure the 400 MHz carrier to 0.2 Hz. APL established a precision time and frequency facility to support the necessary development of various equipment needed for Transit.

- Timation (Time Navigation) program. A US Navy satellite navigation system, initiated in 1964, designed by NRL (Naval Research Laboratory), with the objective to explore the idea of continuous navigation - of providing both accurate position and precise time to passive terrestrial observers (passive ranging). Timation-1, a small (39 kg) gravity-gradient stabilized satellite, was launched May 31, 1967 (VAFB, Thor Agena-D) into a 810 km polar orbit (as a secondary payload, along with GGSE-4, -5, Calsphere-3, -4, NRL-PL-153, -154, and -159). Timation-2 was launched Sept. 30, 1969; both S/C flew with stable quartz oscillators. The STR (Side Tone Ranging) signals were transmitted with a continuous Doppler tracking beacon at about 400 MHz. The experience with the new time system of Timation was a technology demonstrator for future missions.
- In 1964, SAMSO (Space and Missile System Organization) of the USAF in El Segundo, CA initiated a parallel navigation system program to that of the Navy, referred to as

318) B. W. Parkinson, T. Stansell, R. Beard, K. Gromov, "A History of Satellite Navigation," Navigation, ION, Vol. 42, No. 1, Special Issue, Spring 1995, pp. 109-164

319) B. W. Parkinson, "GPS Eyewitness: The Early Years," GPS World, September 1994, pp. 32-45

320) Note: Some benefits of satellite navigation are: precise, all-weather, worldwide availability, timekeeping capability, and unified reference coordinates.

321) Note: To achieve the required accuracy of the Transit system position measurement, APL had to develop a time standard several orders of magnitude more precise than existing devices (time frame of 1958/59).

‘Project 621 B’, with the objective to use a constellation of satellites for navigation signal transmission from highly eccentric orbits of 24-hours periods. First signal propagation tests were conducted in 1969 using ATS-5 of NASA. Then in 1972, a four-channel airborne receiver was tested with signals transmitted from the ground (satellite signal simulation) at Holloman AFB, NM. The demonstration used a new type of signal, modulated with a PRN (Pseudo Random Noise) code, to provide ranging and timing data. The signal modulation technique used a repeated digital sequence of random bits - that permitted a navigation user device to detect a start (“phase”) of the repeated sequence. Recognition of the repeat sequence allowed to determine the range to the signal emitter (satellite). The PRN (spread spectrum) technology turned out to be a key ingredient for GPS signal ranging.

- Start of the NAVSTAR/GPS program in 1973 (a joint-services program on DoD direction) by merging of the Timation and 621 B programs. The proposed new system concept integrated the basic concept of Timation, employing passive ranging precision clocks (time-of-propagation measurements by the user), and the PRN signal technology of Project 621 B - for an eventual constellation of multiple satellites in circular orbits for global coverage. The new GPS measurement technique employs the “time difference-of-arrival” concept (requiring the simultaneous view of four satellites) rather than the Doppler shift of its predecessor system, Transit, to determine position.
- The first spaceborne atomic clocks were flown in the GPS pre-series concept validation program of NRL, referred to as NTS (Navigation Technology Program - previous name was ‘Timation’). NTS-1 (a renamed and modified Timation-2A satellite), a three-axis stabilized S/C, was launched on July 14, 1974 into a 13900 km orbit, the payload included two modified commercial rubidium oscillators (Efratom, Munich). The navigation signals were transmitted in L-band. NTS-2 was launched June 23, 1977 from VAFB and placed into a 12 hour (semisynchronous) orbit - later used by the GPS satellites. The NTS-2 payload included two cesium clocks (Frequency and Time Inc.) and the PRN code generator. The signals were in L-band and modulated with a PRN code. NTS-2 was actually the first test satellite that contained the basic system features of the soon-to-follow GPS satellites.
- Launch of the first GPS-series navigation satellite, called NAVSTAR-1 (built by Rockwell International), on February 22, 1978 and declared operational March 29, 1978 (see Table 396 of GPS launches). The first full GPS constellation with 21 operational satellites was reached in 1994. On February 17, 1995, the FAA announced that GPS is now operational and is an integral part of US air traffic control system. The US Air Force Space Command declared the GPS system operational as of July 17, 1995 for the international user community. At the end of the 1990s, GPS is rapidly becoming an integral component of an emerging global information infrastructure.³²²⁾ See also chapter H.4 for a description of GPS.
- Launch of the first three GLONASS-series navigation satellites, called GLONASS-1, 2 and -3 (Cosmos 1413, 1414 and 1415 deployed), on October 12, 1982 (see chapter H.3 and Table 394).³²³⁾ Note: The first USSR navigation satellite, Tsyklon, was launched into a circular orbit of 750 km, on Cosmos flight 192, November 23, 1967. Tsyklon navigation was based on Doppler shift techniques. Tsyklon was followed by a six-satellite constellation with the name of Parus (also Tsikada-M). A virtually identical civilian navigation network with the name of Tsikada began deployments in 1976 with Kosmos 883, the constellation employs four orbital planes separated by 45°.
- Position and time measurements with ground-based GPS and GLONASS receivers have been made with partial GPS and GLONASS constellations since the first launch in each constellation (first institutionally, then by the civil community as commercial receivers became available). The evolution of the GPS receiver: In 1978, Texas Instruments decided to make available one of the first GPS receivers for civil use. Its price tag was \$153,000. In

322) M. Shaw, P. Levin, J. Martel, “The DoD: Stewards of a Global Information Resource, The NAVSTAR Global Positioning System (GPS),” Proceedings of ION GPS-97, Sept. 16-19, 1997, Kansas City, MO, pp. 1237-1243

323) N. L. Johnson, “GLONASS Spacecraft,” GPS World, November 1994, pp. 51-58

1988, Magellan offered the first hand-held GPS receiver. Its cost was \$3,500. In 1997, Magellan offered the first GPS receiver to break the \$100 price barrier. Called the GPS Pioneer, it is a 12-channel, 7-ounce mobile unit powered by two AA batteries. The global GPS receiver market produced over 1 million units in 1997.

- Demonstration of GPS receiver position and velocity measurements from LEO satellites.³²⁴⁾ The Landsat-4 (launch July 16, 1982) and Landsat-5 (launch March 1, 1984) spacecraft are flying the first experimental GPS receivers referred to as GPSPAC [GPS receiver and processor Package (the first on-board GPS receivers in history had to cope with a partial constellation of GPS satellites)]. GPSPAC (designed at JHU/APL, NASA as co-sponsor, built by Magnavox) is an integrated GPS receiver/processor assembly (R/PA), whose tracking data is used for spacecraft time system synchronization and for post-event (on-ground) orbit determination. Despite the sparse GPS constellation in orbit, GPSPAC demonstrated navigational accuracy of better than 50 m over 10- to 30-minute arcs on 88% of the revolutions. Since those early days, many GPS receivers have been installed on all types of satellites.

- Introduction of the GPS carrier-frequency phase measurement technique.³²⁵⁾ In the pre-operational period of GPS service provision [Initial Operating Capability (IOC) of the GPS system was declared in December 1993], the civil user community had to live with measurement accuracies in the 50-100 m range provided by the SPS (Standard Positioning Service) signals. The pseudorange measurement technique (the intentional downgrading of GPS signal quality) for positioning services, introduced the errors caused by atmospheric effects and SA (Selective Availability). In the early 1980s, two MIT radio astronomers (Counselman and Shapiro) suggested to the GPS user community, to use the **carrier frequency to make phase measurements**, instead of using the prescribed pseudorange modulation technique. This change in measurement technique opened up a window of greatly increased accuracies - namely centimeter-range GPS - provided one could resolve the so-called integer ambiguity (integer number of whole wavelengths). In response to this new opportunity, a number of commercial receiver manufacturers developed high-precision geodetic GPS receivers capable of relative positioning accuracies of a few centimeters. As a consequence, new applications became possible in such fields as geodesy, oceanography, land surveying, astronomy and many others. By 1987 it was known (within a small community) that unclassified “quasi-codeless” receivers with broad-beam antennas could recover dual-frequency GPS phase with the requisite millimeter precision, and that a strategy of concurrent observing from multiple sites would permit “double differencing” and related techniques to eliminate selective availability and other clock errors.³²⁶⁾ Thus, in the 1990s, the technique of carrier phase tracking of GPS signals has resulted in a revolution in land surveying as well as in other fields such as refractive occultation monitoring.

With regard to occultation monitoring, it was then a small step to see that analog techniques could be applied directly to occultation processing to remove clock errors. It thus emerged that the one-way GPS observing constraint, which at first seemed to demand stable clocks everywhere in the system, could be artfully adapted through concurrent observations to eliminate stable clocks altogether. This enabled both accurate retrievals and a reduction in instrument cost. Moreover, it was becoming clear that the basic techniques of GPS geodesy could be extended to provide orbit determination on the level of a few centimeters for LEO spacecraft, adequate for occultation analysis.³²⁷⁾

- Introduction of DGPS (Differential GPS) services. DGPS is a further approach by the civilian GPS user community to overcome the large errors provided by pseudorange signal

measurements. The DGPS concept is based on the principle that a user is affected by satellite ephemeris, atmospheric propagation, SA, and clock synchronization errors to the same extent as a relatively nearby reference station. By predicting the reference receiver's position to a high degree of accuracy, one can set up a system that can be used to calculate corrections to the pseudoranges measured to the various GPS satellites and to transmit these corrections to a multitude of users in the vicinity (100 km radius and more) of the reference station. DGPS accuracies are generally in the range of 1-2 m. - Further advances by the civilian user community led to the development of RTK (Real-Time Kinematic) tracking, enabling the receiver to make carrier-frequency phase measurements while in motion. See also H.4.3, H.4.4.

- Demonstration of GPS high-precision orbit determination. ³²⁸⁾ The GPSDR (GPS Demonstration Receiver) of Motorola was flown on two missions: EUVE (Extreme Ultraviolet Explorer, launch June 7, 1992, of NASA/GSFC) and TOPEX/Poseidon (launch Aug. 10, 1992) to demonstrate/validate accurate orbit determination with GPS data. Two GPSDR instruments (dual-frequency receivers producing long cycle-slip free carrier phase passes as well as pseudorange measurements) on TOPEX/Poseidon were the first spaceborne receivers obtaining high-accuracy range measurements and demonstrated DGPS techniques with a set of IGS (International GPS Service) ground reference stations. A comparison of orbit parameters from three independent techniques (retroreflectors for SLR, DORIS and GPS), all available on TOPEX/Poseidon, obtained GPS orbit differences <25 cm (3D rms). These results of GPS orbit reconstitution are indeed impressive in terms of accuracy. ³²⁹⁾

- Spaceborne orbit determination with a GPS receiver (initial validation flight tests). The goal is the provision of a real-time service of autonomous on-board functions (orbit, etc.). The provision of mean orbital elements is a first step toward operational autonomy. The orbital elements are being used on the ground for ground station operations and other support functions; they are also being used on-board for S/C operations. In general, however, there are further functional services needed for autonomous on-board S/C operations, such as: position, velocity and time; GPS receiver data logging; S/C clock synchronization; data logging; instrument triggering by position; status monitoring, and more. - The introduction of on-board autonomy has certainly great potential of reducing operating costs of future missions.

Background: Orbit determination is generally based on two models, namely the dynamic model (describing the forces acting on the satellite), and the observation model (providing the relationship between the measurements of the tracking system). This requires considerable on-board processing and storage capability. ³³⁰⁾ A recursive Kalman filter algorithm provides a sequential approach to combine the inputs of both models, namely the satellite's motion (in the dynamic Earth model) with the GPS measurements (observation model) as they become available, resulting in best estimates of position and velocity (continuous comparison and update of actual with estimated values).

- PoSAT-1 (launch Sept. 26, 1993, built at SSTL, UK) ³³¹⁾ is the first microsatellite to make use of a GPS receiver in orbit, and to autonomously determine its orbit through the processing of GPS data into orbital elements. The GNU (GPS Navigation Unit) consists of a TANS Vector-II 6-channel C/A code receiver of Trimble and is operated with a software package run on a Transputer Data Processing Unit (a T800 32-bit RISC

³³¹⁾ M. Unwin, M. Sweeting, "A Practical Demonstration of Low Cost Autonomous Orbit Determination Using GPS," Proceedings of ION GPS-95, Sept. 12-15, 1995, Palm Springs, CA, pp. 579-587

microprocessor). The GNU is operated intermittently to conserve power. Some services demonstrated on PoSAT-1 are: a) orbital elements: they provide a prediction accuracy of 1-10 km for two weeks, and b) the variables of position, velocity and time can be requested at any time.

- Since 1993 NASA/JSC is conducting different GPS experiments to validate concepts required to fly GPS as an in-line avionics component on Shuttle missions.³³²⁾ A series of seven flights were conducted on Endeavour which started with STS-56 (April 1993) using a Rockwell Collins 3M receiver operating in SPS mode. The next phase of Shuttle/GPS operations used a PPS (Precise Positioning Service) receiver as a single string navigation device (Rockwell Collins MAGR receiver). The first flight was on STS-79 (Sept. 16-26, 1996). During flight the navigation data was downlinked in real-time for display. During landing, the GPS system performance was compared to TACAN, the primary Shuttle navigation device.
- The REX-II satellite of USAF (see below, launch March 9, 1996) provides GPS-generated orbital elements in the downlink.
- The ORFEUS-SPAS-II free-flyer payload on Shuttle flight STS 80 (November 19-December 7, 1996) flew the first GPS Tensor receiver system (SS/L and LABEN) capable of providing on-board orbit parameters with an adapted Kalman filter algorithm along with Earth model software.
- Autonomous navigation on DS1 (Deep Space 1). This on-board system enables a S/C to determine its location in the Solar System as well as its flight path without help from controllers on Earth. With the knowledge of on-board time, AutoNav computes the position of the asteroids. By measuring where the asteroids appear relative to the stars, it computes where the S/C must be. It then can project its path to its destination and use its propulsion system to make any course changes that are required.
- The first GPS attitude determination systems - proof-of-concept demonstrations - were conducted on research aircraft, and on a commercial airliner.
 - Three GPS attitude measurement flight tests were conducted in April/May 1991 on a DC-3 aircraft of Ohio University by using an Ashtech-3DF (Three-dimensional Direction Finding) 24-channel receiver configured in four 6-channel sections, and four microstrip patch antennas (fuselage and wing-tip mounted). Attitude data were computed, stored and displayed in realtime by two PCs.³³³⁾
 - A Stanford University attitude demonstration was conducted with a Trimble TANS Vector GPS receiver on a Piper Dakota aircraft in 1991.³³⁴⁾ Four strip-mounted antennas were used for attitude sensing. A 486 laptop computer provided both real-time display and data recording for post-flight analysis.
 - On January 12, 1993, a flight experiment was conducted on a NASA/Ames King Air 200 aircraft with the objective to evaluate the dynamic response of a GPS attitude system. The attitude equipment consisted of two independent systems: INU (inertial Navigation Unit) and a six-channel C/A code GPS receiver (TANS Vector) and four microstrip patch antennas (fuselage and wing-tip mounted).³³⁵⁾ Attitude data from both systems were recorded for post-flight analysis.
 - On Dec. 10, 1994, a test flight of a TANS Vector receiver on board a DC-10 commercial airliner (United Airlines) demonstrated the potential for SATCOM antenna pointing,

335) C. E. Cohen, B. W. Parkinson, D. McNally, "Flight Tests of Attitude Determination Using GPS Compared Against an Inertial Navigation Unit," Navigation ION, Vol. 41, No. 1, Spring 1994, pp. 83-97

by providing aircraft attitude measurements (Note: Proper antenna pointing requires knowledge of aircraft position, satellite position and aircraft attitude). The aircraft used a Honeywell SATCOM system beam-steering antenna, two INS (Delco Carousel IV - the Carousel is a free azimuth INU which contains four-gimbal IRUs), a vertical gyro and a compass. In addition to the TANS Vector receiver, the aircraft was equipped with two modified TNL-8100 GPS receivers. The TANS Vector receiver exhibited expected performance during all phases of the test flight when compared to the reference measurements.³³⁶⁾

- Demonstration of spaceborne GPS orbit and attitude measurements. A number of tests for attitude determination with “prototype GPS receivers” have been carried out (or are planned) on Shuttle and on various commercial and military satellites. Table 48 lists a chronology of these instruments (see also chapter H.4.3.4).
- The CRISTA-SPAS-1 mission of DARA/NASA on Shuttle fight STS-56 (Nov. 3-14, 1994) provided the first demonstration of real-time attitude determination on the SPAS free-flyer platform of DASA (one day receiver operation).¹³¹¹⁾ See also chapter J.1.2.
- The REX-II satellite of USAF (launch March 9, 1996), with a GPS experiment by the name of ADACS, can be regarded the first successful demonstration of closed-loop attitude control application using real-time GPS carrier phase-based attitude measurement as sensor input (first time on March 29, 1996). It is also the first mission to provide orbital elements in the downlink.

Launch Date	Mission	GPS Receiver	Comment
June 25, 1993	RADCAL (USAF)	TANS Quadrex (Trimble)	2 cross-strapped receivers, attitude solutions in post-processing
Sept. 12-22, 1993	ORFEUS-SPAS-1 (DARA)	Alcatel/SEL receiver,	Shuttle STS-51, free flyer C/A code + L1 carrier phase
Aug. 3, 1994	APEX (USAF)	TANS Vector	Trimble Navigation instrument
Nov. 3-14, 1994	CRISTA-SPAS-1 (DARA/NASA)	Alcatel/SEL Rx+ TANS Vector + IRU	Shuttle STS-66, SPAS free-flyer
Jan. 11-20, 1996	GADACS (NASA)	TANS Vector (2)	Shuttle STS-72, on SPARTAN
March 9, 1996	REX-II (USAF)	TANS Vector (2) named ADACS	First long-term mission with GPS orbit/attitude determination
May 19-29, 1996	GANES (NASA)	TANS Vector + IRU	Shuttle STS-77
Nov.19-Dec 7, 96	ORFEUS-SPAS-2 (DARA/NASA)	Alcatel/SEL Rx+ GPS Tensor (Laben) TANS Quadrex	Shuttle STS-80, SPAS free-flyer; also relative navigation experiment ARP of ESA/ESTEC
May15-24, 1997	ARP (ESA) Shuttle/MIR	GPS Tensor (Laben)	STS-84 Shuttle - MIR rendezvous
Sep. 25-Oct. 6, 97	ARP (ESA) Shuttle/MIR	GPS Tensor (Laben)	STS-86 Shuttle - MIR rendezvous
Aug. 23, 1997	SSTI-Lewis (NASA)	GPS Tensor (2) named GADFLY	Lewis could not be operated and reentered Sept. 28, 1997
Aug.7-19, 1997	CRISTA-SPAS-2	Alcatel/SEL Rx+ GPS Tensor	Shuttle STS-85, SPAS free-flyer
Dec. 24, 1997	EarlyBird-1 (Earthwatch)	Vector and Viceroy	S/C lost contact with ground
Feb. 14, 98 (1st four satellites)	Globalstar (constellation of 48 satellites)	GPS Tensor on SS/L LS-400 platform	Big LEO communication system of Globalstar L. P., San Jose, CA
1998	SSTI-Clark (NASA)	TANS Vector (2) named GADFLY	NASA cancelled the Clark mission in Feb. 1998
Feb. 23, 1999	ARGOS (USAF)	Embedded receiver	
Nov. 15, 2000	AMSAT-3D (AMSAT)	TANS Vector (2)	
2001	Gravity Probe B (NASA)	GPS Tensor	
1998-2003	ISS (NASA, ESA, CSA, NASDA, and RKA)	SIGI (Space Integrated GPS/INS)	Start of SIGI operation on ISS is planned for 2001

Table 48: Overview of early spaceborne GPS attitude receivers flown on various missions

³³⁶⁾ L. Kruczynski, J. Delucchi, T. Iacobacci, “Results of DC-10 Tests using GPS Attitude Determination,” Proceedings of ION GPS-95,

- The first spaceborne flight demonstration of **SIGI** (Space Integrated GPS/INS) took place on Shuttle flight STS-101 (May 19-29, 2000) under the name of SOAR (SIGI Operational Attitude Readiness). A reflight of SOAR occurred on STS-106 (Sept. 8-20, 2000). Two units of SIGI are planned to be installed on ISS., one on ISS itself, the other on CRV (Crew Return Vehicle). CRV is scheduled to become an operational part of the station in 2004/5 (CRV is designed to be used as a life-boat in case of an emergency evacuation from ISS). A short description of SIGI is provided in H.4.3.4. ³³⁷⁾

At the beginning of the 21st century it is expected that lightweight spaceborne GPS receiver systems, providing the functions of: position, velocity, attitude, attitude rate and time, are going to replace a number of conventional attitude measurement devices such as horizon sensors and sun trackers. The GPS orbit/attitude receiver in combination with a control scheme (actuator) offers sound technical and economical attitude-control solutions. Previous experiments with GPS attitude determination have demonstrated a potential for coarse attitude determination in the 0.1° range. Also spaceborne GPS receivers have demonstrated a time transfer capability of <100 ns, thus making very precise, coordinated time available to spacecraft systems.

- Flight demonstrations of relative navigation using GPS observables. ESA, in cooperation with NASA, DARA, and RKA (now Rosaviakosmos), conducted three flight demonstrations in its ARP (ATV Rendezvous Pre-development) program with proximity navigation approaches [ATV is the future Automated Transfer Vehicle, the ESA resupply vehicle for ISS (International Space Station)].
- Deployment and retrieval maneuvers of SPAS release/approach with Shuttle. ³³⁸⁾ ³³⁹⁾ The ORFEUS-SPAS-2 free-flyer on Shuttle flight STS-80 (Nov. 19 - Dec. 7, 1996) carried, in addition to its prime payload, an ARP secondary payload of ESA/ESTEC, consisting of a GPS Tensor receiver and R-GPS (Relative-GPS) navigation algorithms (developed by MMS). The Shuttle orbiter carried also a GPS receiver (TANS Quadrex), implemented on the fixed part of WSF (Wake Shield Facility) within the cargo bay, and an optical sensor TCS (Trajectory Control Sensor). TCS (of NASA, a laser based sensor) verified the R-GPS measurements by tracking a retro-reflector mounted on the x-face of ORFEUS-SPAS.
- Shuttle - MIR flight approach and departure phases. ARP proximity navigation approaches were demonstrated with an instrument package of GPS Tensor (Laben) in combination with the R-GPS algorithm, and a close-range laser sensor, referred to as RVS (Rendezvous Sensor), built by DASA Jena Optronik - on Shuttle flights STS-84 (May15-24, 1997) and STS-86 (Sep. 25-Oct. 6, 97). The GPS receiver of the MOMS-NAV payload (DARA) on MIR/Priroda provided GPS measurements from the other direction. The Shuttle RVS used three retro-reflectors installed on MIR.
- Integrated GPS+GLONASS receiver technology. ³⁴⁰⁾ The combination of GPS and GLONASS signals enhances the overall navigation solution in three ways: availability, integrity and accuracy. The GLONASS constellation has no deliberate signal degradation; hence, the GPS+GLONASS horizontal accuracy is 15-20m compared to 100m for GPS-only (with SA on).
- In 1996/7 first GPS+GLONASS receivers came onto the market. Some models: GG24 (Ashtech, Sunnyvale, CA), GePOS RG24 (Carl Zeiss Geodetic Systems, Jena, Germa-

³⁴⁰⁾ Note: Prior to measurement integration of GPS and GLONASS into one receiver, proper transformations must be established between the two time scales [UTC(USNO) and UTC(SU)] ,and the two coordinate systems [WGS84 and PE-90 respectively]

ny), ASN-22 (DASA, Ulm Germany), GSR2400 (Sokkia Corp., Overland Park, KS), GNSS-300 (3S Navigation, Laguna Hills, CA).³⁴¹⁾

- En-route navigation in civil aviation.³⁴²⁾ Airborne testing against a proven flight truth source (Z-12 dual-frequency GPS + ground-based reference station). In September 1996, Ashtech Inc. and Universal Avionics made the world's first transoceanic flight with GPS+GLONASS technology, using an Ashtech GG24 receiver for an overseas flight (from Shannon, Ireland to Teterboro, NJ, USA). During the flight the 24-channel receiver computed positions using up to 17 satellites. Horizontal positions within an accuracy of 16 m were achieved 95% of the time. The potential benefits to civil aviation (navigation and positioning operations) in general have become increasingly obvious.
- Spaceborne testing. a) A GPS+GLONASS receiver [LAGRANGE (Laben GNSS Receiver for Advanced Navigation, Geodesy and Experiments) of Laben S.p.A., Vimodrone, Italy] is part of the SAC-C satellite payload with a launch Nov. 21, 2000. b) an ESA GPS+GLONASS receiver by the name of GRAS (GNSS Receiver for Atmospheric Sounding) is part of the MetOp-1 satellite.
- Starting in about 1994/5, spaceborne/airborne GPS/GLONASS receiver applications developed into two major functional directions:
 - Use of the receiver as a navigation sensor - to determine relative and absolute spacecraft attitude, orbit and time. The receiver is expected to provide an engineering environment of real-time, autonomous onboard support to the spacecraft (mission-critical functions).
 - Use of the receiver as a science instrument in Earth observation - to perform atmospheric sounding measurements, gravity measurements, and ionospheric sounding measurements, etc. These science applications require extensive postprocessing of the data to achieve the desired results.

Receivers are included on virtually all new Earth-observation missions. Parallel to orbit determination, the technology opened new applications in atmospheric profiling (GPS/MET on OrbView-1/Microlab-1, launch April 3, 1995) and possibly in ocean altimetry (SAC-C). NASA/JPL-provided dual-frequency GPS receivers are part of four geomagnetic missions: Ørsted (launch Feb. 23, 1999), SUNSAT (launch Feb. 23, 1999), CHAMP (launch July 15, 2000), and SAC-C, launch Nov. 21, 2000) - and also of such missions as: SRTM (Shuttle Radar Topography Mission, launch Feb. 11-22, 2000), Jason, VCL (Vegetation Canopy Lidar), and GRACE (Gravity Recovery and Climate Experiment).
- Demonstration of GPS measurements in satellite orbits outside of the MEO GPS constellation of 20,000 km altitudes.
 - The Motorola GPS Viceroy receiver of the Equator-S (launch Dec. 2, 1997) satellite - with a near-equatorial HEO orbit of 10 R_E distance apogee and low perigee at 500 km - was able to measure carrier phase and/or C/A code of up to three GPS satellites at altitudes of 34,000 km (Dec. 3, 1997 while in transfer orbit). The GPS receiver measurements were considered for post-event (on-ground) orbit determination at GSOC. In addition, GPS side-lobe measurements were verified.³⁴³⁾
 - AMSAT-3D (launch Nov. 15, 2000) in a HEO orbit of 4000 x 47,700 km, inclination = 63.4°. The AMSAT-GPS experiment is to demonstrate real-time GPS attitude and orbit determination above the GPS constellation (two Trimble TANS Vector receivers

along with two sets of four GPS antennas, GEC Plessey front-end chipset and AMD 29200 embedded RISC processor board). An additional experiment is to map the GPS signal patterns outside the GPS constellation.

- GPS measurements in GEO. In general, GPS receivers in GEO cope with unfavorable conditions which are: 1) poor visibility and geometrical distribution of GPS signals, and 2) weak GPS signal power (low SNR). In spite of these handicaps, GPS pseudorange measurements were already demonstrated in GEO for orbit determination in US military applications.³⁴⁴⁾ Since geostationary orbit determination is a very attractive option for commercial GEO satellite operations, solutions are being introduced to a new generation of GPS receivers for any satellites in GEO. Two examples: Astrium GmbH offers an instrument, MosaicGNSS, using a software and hardware correlation.³⁴⁵⁾ The TOPSTAR 3000 GPS receiver of ASI (Alcatel Space Industries) employs a filter and integration techniques to analyze weak GPS signals. TOPSTAR (a 4-antenna 24-channel C/A code GPS receiver) is part of the STENTOR spacecraft (launch in 2001) to be used as a navigation tool for GEO spacecraft.³⁴⁶⁾
- Second frequency for civil GPS users (Block IIF series). Uninterrupted access to “carrier phase” of the L2 frequency will be provided as a second civil frequency. This agreement was announced Feb. 27, 1997, by DoT and DoD. The goal of the second civil frequency (designated L5) is to enhance GPS civil capabilities by: 1.) providing a redundant signal for civil use in the event that the GPS L1 were to become unavailable (due to jamming or interference), and 2.) enhancing civil GPS performance by providing a second civil frequency for ionospheric delay calculations, a critical design requirement for the FAA’s Wide Area Augmentation System (WAAS).
- The GPS-on-a-chip project (NASA) miniaturizes instrumentation.
- CDGPS (Carrier-phase Differential GPS), see H.4.3. CDGPS sensing techniques provide very precise measures of relative position (1-2 cm level) and attitude between vehicles in formation. Given GPS measurements at two nearby antennas, relative position between these antennas can be estimated to a high degree of accuracy based on tracking the relative phase. Sample implementations: 1) CDGPS is flown on the Orion microsatellite of Stanford University (planned launch at the end of 2001). The Orion CDGPS receiver (total instrument mass of 1.07 kg, including processors) consists of a single 6-antenna attitude and relative navigation receiver using carrier-differential GPS. 2) As of 2000/1, AeroAstro Inc. of Herndon, VA is developing “Star Ranger” for the TechSat-21 mission of AFRL. The Star Ranger design concept utilizes Ku-band for its operation (intersatellite communication), DSSS (Direct Sequence Spread Spectrum) for precise ranging, a two-PN code technique for multiple access within the three-satellite formation, and CDGPS for the determination of relative position and attitude between the formation flying satellites. The mass of Star Ranger is expected to be <2 kg.³⁴⁷⁾
- PRARE and DORIS are tracking systems requiring a host satellite (for the space segment instrument) and global ground-based tracking networks for precise orbit determination. Both systems (PRARE and DORIS) require an orbit determination process using conventional dynamic techniques (with physical models) whose accuracies depend on the quality of the models.

346) Ch. Mehlen, D. Laurichesse, “Real-time GEO orbit determination using TOPSTAR 3000 GPS Receiver,” Proceedings of ION GPS-2000, Sept. 19-22, 2000, Salt Lake City, UT, pp. 1985-1994

347) R. Zaenick, K. Kohlhepp, “GPS Micro Navigation and Communication System for Clusters of Micro and Nanosatellites,” Proceedings of the 14th AIAA/USU Conference on Small Satellites, Logan, UT, Aug. 21-24, 2000, SSC00-VI-8

PRARE (H.7.2) was initially installed on ERS-1 (launch July 17, 1991), but could not be operated. Further PRARE uses: Meteor-3-7 (launch Jan. 25, 1994), ERS-2 (April 21, 1995). PRARE is a two-way tracking system, broadcasting dual-frequency signals (2200 and 8500 MHz) from a transmitter on-board the host satellite to receiver-transponders on the ground. The signals are modulated by pseudonoise ranging codes to permit both range and range-rate measurements. The 8500 MHz signal is coherently transponded back to the host satellite (at 7200 MHz) for on-board range and range rate extraction. The 2200 MHz signal is received and tracked on the ground to provide an ionospheric correction.

DORIS was a prototype payload on SPOT-2 (launch Jan. 22, 1990) and SPOT-3 (launch Sept. 26, 1993); then flown on: Topex/Poseidon (launch Aug. 10, 1992). DORIS was initially a one-way Doppler system (E.21.1) which broadcasts continuously at two frequencies: 401 and 2036 MHz. A two-way upgrade is planned for use on Envisat (launch in 2001). The DORIS instrument on the host satellite observes individual ground beacons in sequence and measures the Doppler frequency of the received signals.

- Spaceborne GPS wide-area augmentation service. Japan is the first country to use a spaceborne GPS augmentation system to improve the management of its civil air traffic. The “aeronautical mission” of MTSAT (Multifunctional Transport Satellite) in GEO (launch of MTSAT on Nov 15, 1999, but a launch failure of the H-2 vehicle occurred) provides an operational system that satisfies every aspect of the ICAO (International Civil Aviation Organization) requirements in terms of reliability and accuracy to aviation enroute through precision approach navigation.
- GNSS-1 (Global Navigation Satellite System-1). The first generation GNSS-1 comprises the following elements: GPS, GLONASS and their augmentation systems [WAAS (Wide Area Augmentation System) of the US, EGNOS (European Geostationary Navigation Overlay System) of Europe, and MSAS (Multi-Transport Satellite Augmentation System) of Japan]. The three segments of GNSS-1 are expected to be operational by 2003.
- Galileo. In early 1999 the EU proposed a strategy with the goal to design, implement and operate its own (civil) constellation of navigation satellites with the appropriate terrestrial infrastructure within a program by the name of Galileo. The space segment of the overall Galileo program is referred to as GalileoSat. Galileo is considered an element in a future GNSS-2 (Global Navigation Satellite System-2) - currently comprising GPS, GLONASS and their future augmentation systems. The rationale for Galileo is the provision of a service with a certifiable service performance level, which neither GPS nor GLONASS can presently do. The goal is the support of safety-critical civilian applications, especially in civil aviation, marine navigation, and road transport. The goal is to complete implementation of the Galileo system by 2008.
- GNSS-2 (Global Navigation Satellite System-2). The second generation GNSS comprises all elements of GNSS-1 plus Galileo. GNSS-2 is planned to be operational by 2008.
- **Removal of the SA (Selective Availability) feature for the GPS constellation signal on May 2, 2000** (the SA levels were set to zero at 0400 UT).^{348) 349)} The Presidential Directive (of US President Bill Clinton) permits civil users worldwide general access to the highest-possible accuracy of GPS signals.³⁵⁰⁾ - Background: The SA service has been used to degrade the GPS signal for the civil community while retaining the higher-accuracy signals for US and allied military forces (as well as for approved receivers of NASA satellite projects). A 1996 Presidential Directive promised to review the SA issue every year starting in 2000, and to remove SA in 2007 at the latest.

- Joint GPS/LEO navigation receiver.^{351) 352)} As of 2000/1 new dual-use tracking concepts of GPS and LEO constellation signals are being considered by the communications industry. Commercial LEO satellite systems, such as Orbcomm, Iridium, and Globalstar, provide a global coverage of their data and/or voice services. In addition to these prime services, the LEO constellations may also serve as “guide posts in space” to complement and enhance the GPS navigation performance. The combined use of positioning and two-way communication in LEOs may eventually lead to such applications ranging from emergency roadside assistance to location-based merchandising. The overall objective is to achieve precision (cm-level) navigation performance using pre-existent LEO transceiver hardware. In this concept, the LEOs provide additional ranging signals, which improves GDOP, availability of navigation solutions, and availability of RAIM (Receiver Autonomous Integrity Monitoring) geometry. The geometric diversity, achieved mainly by the motion of the LEOs, enables the GPS/LEO receiver to resolve the integer cycle ambiguities on the GPS constellation signals as well as parameters related to the cycle ambiguities on the LEO signals. First experimental tests have been conducted with the Orbcomm constellation in conjunction with GPS.

1.8 Services

The rendering of any sustained or long-term service implies the provision of an operational capability. The early introduction of the NASA/NOAA broadcast service policy of free access to polar-orbit weather satellite data reception generated a totally new participative/co-operative research and application environment for a global user community (laboratories and research institutes in particular). Real-time data reception of AVHRR data became affordable to many with the installation of a simple receiving station. Eventually a network of thousands of small ground stations was realized, and the AVHRR sensor became the best known sensor in the world. The most important service aspect was probably the provision of a timely, reliable and repetitive data stream to the user community which in turn accelerated the pace of exploration and of technological development in the various fields of applications.

- TIROS-1 (launch April 1, 1960) is regarded the first true weather satellite.
- Starting with TIROS-8 (launch Dec. 21, 1963), real-time observational data were transmitted (broadcast) continuously in APT (Automatic Picture Transmission) mode to ground stations. Eventually, APT pictures could be received on fairly simple ground stations anywhere in the world.
- Introduction of APT and HRPT (High Resolution Picture Transmission) broadcast modes (VHF link for ATP and L-band link for HRPT) in parallel with TIROS-N (launch Oct. 13, 1978). Further broadcast services of ‘weather data’ followed:
 - The Terra satellite (launch Dec. 18, 1999) of NASA’s EOS (Earth Observing System) program introduced a direct broadcast in X-band for instrument data (MODIS) to the user community.
 - The Aqua (formerly EOS/PM-1) S/C of NASA (planned launch in late 2001) provides a direct broadcast in X-band for all its instrument data, including MODIS
 - MetOp-1 of EUMETSAT (planned launch in 2005) supports a real-time broadcast of instrument data to local users by means of LRPT (72 kbit/s in VHF for selected instruments) links and HRPT (3.5 Mbit/s in L-band) links.
 - NPP (NPOESS Preparatory Project) of NASA (planned launch in Dec. 2005) provides broadcasts of instrument data.
- WEFAX (Weather Facsimile) services. The first installation of WEFAX on ATS-1 (launch Dec. 6 1996) worked well until 1972. It demonstrated that WEFAX transmissions

351) M. Rabinowitz, B. W. Parkinson, K. Gromov, C. H. Cohen, “Architectures for Joint GPS/LEO Satellite Carrier Phase Receivers Designed for Rapid Robust Resolution of Carrier Cycle Ambiguities on Mobile Platforms,” ION GPS 2000, Slat Lake City, UT, Sept. 19-22, 2000, pp. 881-890

352) M. Rabinowitz, B. W. Parkinson, J. J. Spilker, “Some Capabilities of a Joint GPS-LEO Navigation System,” ION GPS 2000, Slat Lake City, UT, Sept. 19-22, 2000, pp. 225-265

were practical. The original transponder received on 149.22 MHz and transmitted on 135.6 MHz. Due to technological design improvements and interference with the aeronautical band, these frequencies were re-allocated to the S-band frequencies. The most pertinent one of these to date is the 1691 MHz WEFAX frequency.

- Presumably, NOAA-6 (launch June 27, 1979) is regarded as the first **operational** satellite of the TIROS-N series.
- The on-board store & forward data concept (with a data recorder and a data dump during a station pass) was introduced fairly early in the game (TIROS-1 with a launch in 1960 had a tape recorder). The lack of world-wide coverage (ground stations) for data downlinks dictated this strategy.
- Global coverage once per day was first provided by AVHRR on TIROS-N (launch Oct. 13, 1978)
- Introduction of search and rescue services on polar-orbiting satellites with the launch of COSPAS-1 on June 29, 1982 and with S&RSAT flown on NOAA-8, March 28, 1983. The first geostationary S&RSAT (demonstration) system, referred to as GEOS&R (Geostationary Search and Rescue), was flown on GOES-7 (launch Feb. 26, 1985).
- Introduction of spaceborne data collection systems (DCS). The first DCS anywhere was IRLS (Interrogation, Recording, and Location System) flown on Nimbus-3 (launch April 14, 1969, see M.17.3). DCS were also flown on the first three Landsat S/C, LS-1, LS-2, and LS-3 (LS-1 launch July 23, 1972). The first Argos DCS in LEO (polar orbit) was flown on TIROS-N (launch Oct. 13, 1978). The first DCS in GEO orbit was flown on SMS-1 (launch May 17, 1974). In the meantime all geostationary meteorological satellites series (METEOSAT, NOAA-GOES, GMS (JMA), etc. use DCS or variations thereof. The TEMISAT microsatellite (launch Aug. 31, 1993) of Telespazio represents further advancements in data collection services for the user community with regard to access scheme and functionality (see Table 133 for DCS).- The systematic collection of ground truth data from a large number of systems in the ground segment provides a reference (and verification) for the analysis of primary sensor data.+
- Satellite navigation data, such as position, velocity, and time, of GPS (GPS-1 launch in 1978) and GLONASS (first GLONASS launch in 1982) systems. The GPS constellation became operationally available in 1994 (officially in 1995). The real-time global availability of navigation data has spawned numerous positioning and navigation applications that have surpassed initial expectations. They are fast becoming an indispensable part of people's everyday lives. The navigation services on all levels (civil and military aviation, coastal and ocean ship navigation, automobile navigation, surveying, etc.) are becoming increasingly essential to the world's infrastructure. As a consequence, a large commercial market of equipment and service providers is unfolding, responding to the new needs of society.
- GPS time is being utilized as a cost-effective standard time source by many operators. Networks like Internet and many TTPs are being synchronized by GPS time. The GPS time service is provided by USNO (US Naval Observatory). GPS provides two types of time:³⁵³⁾
 - GPS time. Defined by its 'composite clock.' It consists of an ensemble of more than 20 GPS space and ground-based atomic frequency standards. GPS time is referenced to UTC (Universal Time Coordinated) as maintained by USNO. Time updates are maintained to within 1 μ s of UTC by the operators of the GPS Master Control Station at Falcon Air Force Base, Colorado Springs. Note: GPS time differs from UTC by the number of leap seconds accumulated since January 1980.
 - UTC. To obtain UTC from GPS, users must apply the GPS-UTC (USNO) correction, available in the navigation message, to transition from GPS time to an estimate of UTC (USNO). The estimate of UTC (USNO) is called UTC (GPS).

353) F. Vannicola, "The Time Is Now," GPS World Showcase, Dec. 1997, p. 40

Starting in the mid 1980s a number of commercial services have come into the Earth observation arena to complement (or replace) the institutional services.

- Spacecraft operators and data distributors like Eosat (Landsat-4, -5)
- In 1990, SSTL of Surrey (UK) started a unique microsatellite technology transfer program, providing on-the-job training of engineers and scientists of foreign national organizations in cooperative programs [KAIST (Korea), LNETI (Portugal), FACH (Chile), TMSC (Thailand), etc.]. Affordable access to space is the overall theme of the service. - The design, building and operating experience of their own microsatellites gave these organizations a means to start/continue their own involvement in national space programs. The ‘Surrey Space Centre’ of SSTL (since 1992) is a European center of excellence, a facility which accommodates the activities for the technology transfer service of academic and post-graduate research.
- Distributors of imaging data products from a particular spacecraft and sensor (SPOT Image, Eurimage, etc.)
- The RADARSAT-1 satellite of CSA, Canada, is an Earth observation mission for SAR data, operated on a commercial basis by RSI.
- Real-time ERS altimetry data are distributed via Internet. The NOAA/NODC Laboratory for Satellite Altimetry (LSA) receives ERS altimetry data and generates RGDRs (Real-time Geophysical Data Records). These RGDRs are distributed via Internet and may be used in oceanographic analysis and model assimilation studies. ³⁵⁴⁾

Mission	Data Availability	Sensor	Band	Spatial Resolution
Landsat-4,-5	1982	TM	0.45 - 2.35 μm (MS)	30 m
Landsat-7	1999	ETM+	0.50 - 0.90 μm (Pan)	15 m
SPOT-1, -2, -3	1986	HRV	0.51 - 0.73 μm (Pan)	10 m
Resurs-O1-1, 2, 3	1985	MSU-E	0.50 - 0.90 μm (MS)	45 m x 33 m
JERS-1	1992	OPS	0.52 - 2.40 μm (MS)	18 m x 24 m
IRS-1C, IRS-1D	1996, 1997	PAN	0.50 - 0.75 μm (Pan)	6 m

Table 49: Availability of long-term high-resolution imaging data of major Earth surface missions

- A multitude of commercial enterprises provide their services in the airborne arena, most with a full service (aircraft, sensor(s), data recording and processing, etc.).
- **Shuttle Small Payload Program (SSPP).** A flight service package offered by NASA for payload masses in the range between 23 kg to about 2270 kg. SSPP is for “small, self-contained payloads” with the objective to ensure divers user groups (educational, commercial, government, foreign experimenters, etc.) to have access to space at reasonable costs. Payloads are accommodated by providing various carrier systems [GAS, Hitchhiker, Hitchhiker Jr., and SEM (Space Experiment Module)] in the Shuttle’s unpressurized payload bay. SSPP started in 1984. ³⁵⁵⁾

Note: In general a S/C launch from Shuttle has advantages and disadvantages. Typically the low orbit implies a relatively short lifetime for the mission. This may be of interest in itself, as the orbital decay can be studied. But the Shuttle is the only launcher that really allows a payload to be viewed being released into space. In addition the g-loads are modest compared with other launchers.

- **GAS (Get Away Special).** GAS is a carrier system concept with standards and conditions relating to GAS payloads (they must fit in a standard container of 0.14 m³ in volume with a payload mass not exceeding 90 kg, two or more experiments may be included in a

³⁵⁴⁾ J. Lillibridge, “Real-time ERS altimetry at NOAA,” Earth System Monitor, Vol. 9, No. 3, March 1999, pp. 6-9

³⁵⁵⁾ <http://sspp.gsfc.nasa.gov/gas.html>

single container). In addition, GAS payloads must be self-powered and be easy to handle for the payload crew. The GAS container is made of aluminum with circular end plates. It can be pressurized (or evacuated) to suit experiment requirements.

GAS payloads are mounted during flight in the Shuttle payload bay, on the sidewall, or on a cross-bay truss structure (referred to as “getaway bridge”). The aluminum bridge fits across the payload bay of the orbiter and offers a convenient and economical way of flying several GAS canisters. The getaway bridge, capable of holding up to 12 canisters, made its maiden flight on STS-61-C (Jan. 12-18, 1986).

The service was initially announced by NASA in 1976, five years prior to the first Shuttle flight in 1981. The first GAS demonstration payload, FVP (Flight Verification Payload), was flown in 1982 on STS-3 (Mar. 22-30, 1982). The first customer GAS payload, G-001 of Utah State University, flew on STS-4 (June 27 - July 4, 1982). STS-95 (Oct. 29 - Nov. 7, 1998) is the 33rd Shuttle mission with the GAS payload service. Almost 200 individual GAS canisters have been flown in these 33 missions for a very diverse user community.

- **Hitchhiker carrier system.** The Hitchhiker concept is based on a modular and expandable carrier with the provision of extended functional features (standard power, data, and command services for customer equipment). The structure can carry equipment mounted in canisters but also has mounting plates of various sizes for user equipment (provision of options). The carrier provides electrical power (28 VDC), command signals (1200 baud), and downlink data interfaces (various data rates: 1200 baud asynchronous low-rate, 1-1400 kbit/s medium rate). Hitchhiker customers are able to operate their payloads from the ground segment (GSFC) using their own ground support equipment (usually a PC) to send commands and display data. The ACE (Advanced Carrier Equipment) package provides such standard services devices as: power distribution unit, remote interfaces unit, Hitchhiker central unit, digital storage unit, Hitchhiker video interface unit, and lightweight avionics plate. NASA initiated the service in 1984. The first flight was on STS-61-C (Jan. 12-18, 1986) with the Hitchhiker-G1 payload [consisting of IEH-1 (International Extreme Ultraviolet Hitchhiker, CAPL-2 (Combined Pumped Loop-2), TES (Thermal Energy Storage), etc.]. The SLA-1 (Shuttle Laser Altimeter) experiment on STS-72 (Jan. 11-20, 1996) was also a Hitchhiker payload.

- **Hitchhiker Jr. carrier system.** A limited Hitchhiker version, designed for payloads which do not need the functions of command and telemetry interfaces from the experiment to the ground (GSFC). The CONCAP-IV-3 payload on STS-69 (Sept. 7-18, 1995) was the first to use the Hitchhiker Jr. service package. The experiment was activated and de-activated by the Shuttle crew via a laptop computer. This requires autonomous payload operations for the duration of the experiment. The SOLSE/LORE (Shuttle Ozone Limb Sounding Experiment/Limb Ozone Retrieval Experiment), a NASA instrument package flown on STS-87 (Nov. 19 - Dec. 5, 1997), used also the Hitchhiker Jr. service version.

- **SEM (Space Experiment Module) carrier system.** The SEM program is an upgrade version of the GAS program. It uses GAS canisters with the added feature of installed power provision and more. On behalf of frequent student requests, NASA funded in 1995 the SEM program and designed a standard power supply. As a result, the standard SEM consists of subsystems which function together to provide containment, structural support, power, experiment command and data storage capabilities for experiment support. This new functional capability/availability of the carrier system permitted the students to focus their energies on creating their own experiments. The very first flight of the SEM system, SEM-1, took place on STS-80 (Nov. 19 - Dec. 7, 1996) with many experiments, built by students in cooperation with their mentors of various High Schools and Universities across the USA.

- Commercial spaceborne imaging missions with high-resolution data (1 m) are being introduced in the latter nineties (1998) by several companies and/or consortia (Space Imag-

ing EOSAT, Earthwatch, Resource 21, OrbView, etc.). The consortia provide also a full ground segment with corresponding archives and services. Their imaging products are being offered to anyone who pays for the service.

The provision of commercial imaging is considered a major shift in Earth observation policies - from government-sponsored research institutes toward private enterprise.

- Underwater/space launch. July 7, 1998, a Russian nuclear submarine of the Northern Fleet launched two environmental nanosatellites, TUBSAT-N and -N1 of the Technical University of Berlin, into Earth orbit (launch site of western Barents Sea). The launch represents the world's first underwater/space launch of a satellite into Earth orbit on the basis of a commercial service.

- First commercial satellite constellations in LEO (Low Earth Orbit). In 1998, the first two major satellite telephone systems, so-called "Big LEO Systems" of global handheld telephone service as well as mobile fax and data services, were launched. Iridium, a network developed by Motorola, completed its planned 66-spacecraft constellation in LEO, and started service. Globalstar, created by Loral, successfully launched its first 8 satellites. However, 12 other spacecraft were lost in a failure of Ukraine's Zenit rocket. In all, Iridium featured 10 launches and Globalstar had three.

On the "Little LEO Systems" front of non-voice messaging and data relay (i.e. store & forward) services, Orbcomm of Dulles VA, had the complete constellation of 35 satellites in orbit (with altitudes of 825 km) on Dec. 4, 1999. The initial launch of this constellation started on April 3, 1995.

1.9 Start of International Cooperation

The space age in general and Earth observation in particular turned out to be a natural field for all types of national and international cooperations/participations - unmatched in history. Initial cooperation (with NASA) started with permissions to operate ground stations in various countries. Later on, foreign ground station operators contributed to NASA missions through tracking and data receiving services. International cooperation in the early 1960s manifested itself also in such policies of flying sensors (experiments) of non-US scientists on NASA missions or in providing launches for foreign satellites. This evolved eventually in the common design and construction of spacecraft and instruments. In January 1970, NASA had official cooperations with agencies/institutes of 35 foreign countries (agreements of ground stations, exchange of personnel, etc. brought the total cooperations to 74 countries). Some of the first cooperations involving research satellites are listed below: ³⁵⁶⁾

- Ariel-1, a product of USA/UK cooperation, was launched April 26, 1962 on a Delta vehicle from Cape Canaveral (60 kg S/C, 389 km x 1214km inclined orbit at 54°) with the objective to measure parameters of the ionosphere and of the sun.

- Alouette-1, a Canada/USA cooperative venture, was launched September 29, 1962 from VAFB, CA aboard a Thor-Agena B launch vehicle (Alouette-1 mass = 145 kg) with the objective to investigate the ionosphere.

- San Marco-1 (mass of 24 kg), an Italian satellite, was launched December 15, 1964 with a US launcher (from a floating platform off Kenya) to investigate atmospheric densities.

- Asterix-1, the first French satellite launched on November 26, 1965 on a French launch vehicle, Diamant, from Hammaguir, Algeria (Elliptical orbit, apogee of 1736 km, perigee of 530 km, inclination of 34.3°). The 41.7kg satellite transmitted for two days. FR-1, the first operational French satellite, was launched into a 780 km orbit on Dec. 6, 1965 on a Scout launcher from Vandenberg AFB. The satellite was used to study the ionosphere.

- WRESAT (Weapons Research Establishment Satellite), an Australian/US S/C involved the development and launch from Woomera, Australia, of a small scientific satellite

³⁵⁶⁾ W. Buedeler, "Geschichte der Raumfahrt," Sigloch Edition, Künzelsau, 1979,

(mass of 50 kg) on Nov. 29, 1967 (reentry Jan. 10, 1968). The satellite was placed in a near-polar orbit (perigee = 198 km, apogee = 1252 km, inclination = 83.3°, period = 99.3 min) by a US Redstone rocket. The objective was to monitor solar radiation in the upper atmosphere and to demonstrate an Australian capability for developing a satellite.

- ESRO-1/Aurora, an ESRO (Europe)/NASA cooperative venture (86 kg S/C mass), was launched Oct. 3, 1968 from VAFB to investigate auroras and the ionosphere. Prior to this, ESRO-2 (a 75 kg S/C) was launched on May 17, 1968 on a Scout launcher from VAFB with a payload measuring cosmic rays and solar X-rays. - ESRO-1/Boreas, almost identical to ESRO-1/Aurora was launched Oct. 1, 1969 from VAFB and performed similar measurements simultaneously with its sister spacecraft Aurora.

- Azur-1, a German satellite (71 kg), was launched Nov. 11, 1969 on a Scout vehicle from VAFB (387 km x 3150 km sun-synchronous orbit inclined at 103°), to investigate radiation belts, solar particles and polar lights.

- ANS-1, Netherlands satellite (129 kg), launched August 30, 1974 on a Scout vehicle from VAFB, CA (258 km x 1173km inclined orbit at 98°). ANS-1 studied UV spectra of young stars, and hard and soft X-rays from cosmic sources.

- Intasat, Spain/USA satellite, was launched November 15, 1974.

- COS-B, the first ESA/NASA satellite, was launched August 9, 1975 to investigate stellar x-ray and gamma-ray radiation.

- Meteosat-1, the first geostationary ESA weather satellite, was NASA-launched on November 23, 1977.

- In the USSR, the program **Intercosmos** was created in 1967 with the objective to invite cooperation/participation of Soviet-affiliated countries in the Soviet space program with their own national contributions. An important area of participation was in remote sensing, building sensors for specific missions, dissemination and scientific interpretation of data, etc. The new policy fostered a number of collaborative science projects among its nine members as well as with other nations. The Intercosmos satellite series began with the launch of Intercosmos-1 on October 14, 1969. The payload featured, beside Soviet, also Czech and East-German instruments for the measurement of UV and x-ray radiation in the upper atmosphere. Up to 1991, there were a total of 25 Intercosmos satellites.

- The first foreign-built satellites launched from a Russian launch site, were from France.

- Aureole-1 was launched from Plesetsk by an SL-8 vehicle on Dec. 27, 1971 into an orbit of 410 km x 2500 km, inclination of 74°. S/C mass of 300 kg. Objective: study of the aurora borealis and ionosphere.

- SRET-1 was launched from Plesetsk on Apr. 4, 1972 along with the Molniya-1 spacecraft. The French satellite was placed in a 460 km x 39248km orbit and was used to study radiation effects on solar cells.

- Aureole-2 was launched from Plesetsk by an SL-8 vehicle on Dec. 26, 1973. S/C mass of 400 kg. Orbit: 400 km x 1975 km, inclination of 74°.

- April 19, 1975. Launch of the first Indian satellite, Aryabhata of ISRO, by a Cosmos launch vehicle.

- SRET-2, a technological research and study satellite, was launched piggyback on a Molniya satellite from Plesetsk on June 5, 1975. The 29.6kg satellite was used to test the passive cryogenic radiation system for Meteosat cooling, and to study of the aging of thermal casings and plastic films.

- The Soviet Union (A. Kosygin) and the USA (R. Nixon) signed formal agreements of cooperation on May 24, 1972 (of talks that started in 1969) in Moscow, concerning the Apollo-Soyuz Test Project (ASTP), leading to a common spaceflight (docking of both

spacecraft, Apollo 18 and Soyuz-19) on July 17, 1975 (the flight was from July 15 - 24). This represented the first international meeting of men in orbit. The main objects were to test the compatibility of rendezvous and docking systems for American and Soviet spacecraft, to open the way for international space rescue as well as future joint manned flights. The Apollo spacecraft was nearly identical to the one that orbited the Moon and later carried astronauts to Skylab. The Soyuz craft was the primary Soviet spacecraft used for manned flight since its introduction in 1967. A docking module was designed and constructed by NASA to serve as an airlock and transfer corridor between the two craft.

- First Shuttle docking at the MIR space station. A new era of international cooperation in space began on June 30, 1995 with the docking of both S/C. The event occurred on Shuttle flight STS-71 (Atlantis, June 27 - July 7, 1995).
- International partnerships have also been very successful in solar and space physics. NASA is the lead agency for the GGS (Global Geospace Science) program which includes the WIND and POLAR satellites, both of which have important international components. Conversely, ESA is the lead agency for Ulysses, SOHO (Solar and Heliospheric Observatory) and Cluster, while ISAS of Japan is the lead for Yohkoh (Solar-A), and Geotail. Within STP (Solar Terrestrial Probes) program, NASA has the lead with TIMED and STEREO while ISAS has the lead of Solar-B.
- In the latter part of the 1990s, the cooperations between partners in the Earth observation community have reached new dimensions. They are truly global in nature - a network of interrelations - they are so numerous and on so many levels (permeating many facets of society and affecting our every-day lives) - too complex for the scope of this writing.
- Public/private partnerships are vital for the continued growth and commercialization of the space sector. Historically, spaceborne systems have become a business only after the high-risk technologies and markets have been developed, most often through government initiatives and with public funding. First government/industrial project partnerships in the area of Earth observation were being introduced as early as 1985. The overall objective is cost-sharing of ever tighter government space budgets with commercial companies in projects that require new technology introduction. The investing companies are given some incentives (commercial data rights and/or ownership of the S/C, etc.) to recover their investments and to make a profit. An effective framework in such partnerships includes benefits to all partners. Some examples in satellite development are: ³⁵⁷⁾ ³⁵⁸⁾
 - In Sept. 1985 the US company Eosat was selected by NOAA (government) to operate the Landsat system (LS-4 and LS-5), to market LS data, and to build and launch LS-6.
 - SPIN-2 venture of Russia (since 1992). SPIN-2 is a joint venture (company), located in Washington DC, of Interbranch Association SOVINFORMSPUTNIK (Moscow, Russia), Aerial Images, Inc. (Raleigh, NC), and Central Trading Systems, Inc., (Huntington Bay, NY). The objective is to market high-resolution panchromatic imagery data (2 m) of past Russian missions, in particular data from the Resurs-F series.
 - RADARSAT-1 (launch Apr. 11, 1995) and RADARSAT-2 (launch in 2003) are jointly-funded SAR missions of CSA (Canadian Space Agency) and MDA (MacDonald Dettwiler Associates Ltd. of Richmond, BC). CSA is providing approximately 75% of the funding for the development of the satellites and MDA is investing the difference. MDA owns and operates the satellites. CSA's investment will be recovered through the supply of imagery to a number of Canadian government agencies during the mission lifetime.
 - OrbView-1/Microlab-1 and OrbView-2/SeaStar are commercially built and operated small satellites of OSC (Dulles, VA) flying government-sponsored instruments, OTD

357) D. L. Glackin, "International Earth remote sensing: overview 1980-2010," Proceedings of the SPIE International Symposium on Optical Science and Technology, San Diego, July 2000

358) "International Space Cooperation: Solving Global Problems," Report of an AIAA, UN/OOSA, CEAS, CASI Workshop, April 1999 (printed and distributed by AIAA)

of NASA/MSFC and GPS/MET of UCAR in the case of OrbView-1, and SeaWiFS of GSFC on OrbView-2. Data of these instruments is provided to government agencies as well as commercially sold (SeaWiFS).

- In Europe, CNES is introducing cost-sharing programs with commercial S/C builders. The SPOT-5 satellite development is such a joint venture of CNES with French industry, namely MMS (Matra Marconi Space), now Astrium SAS. Earlier S/C in the SPOT series of CNES (government) started data distribution arrangements with private companies like Spot Image.
- The US NEMO (Navy EarthMap Observer) satellite is sponsored by ONR (Office of Naval Research) and DARPA as well as with commercial investments. A consortium led by STDC (Space Technology Development Corporation) of Alexandria, VA is the S/C operator and commercial distributor of the imagery.
- The LightSAR project of NASA was conceived as a public/industry partnership. However, in July 1999, NASA cancelled the project due to lack of interest from industry. Industry officials could not see a sufficiently large commercial market for L-band imagery (a NASA requirement) to justify the required investments.³⁵⁹⁾
- ISRO of Bangalore, India,³⁶⁰⁾ announced in Nov. 2000 a new policy by inviting private sector investments with corresponding customer equipment and service-sharing arrangements on its GEO program of INSAT satellites. User demand is mostly expected in the field of communications.
- TerraSAR alliance. As of 2001, Infoterra/TerraSAR is a proposed cooperative Public-Private Partnership (PPP) program between the Infoterra Company (Astrium) and ESA. The fundamental objective of the Infoterra/TerraSAR initiative is to establish a self-sustaining geo-information business built on European strengths in SAR satellite technology, in SAR applications expertise and in the provision of services based on Earth observation data sources. TerraSAR is planned to be an element of the ESA Earth Watch program. The initial program calls for two satellites, featuring high-resolution X-band and L-band SAR imagery, respectively. A launch of TerraSAR-X1 and TerraSAR-L1 are planned for 2006.
- COSMO-SkyMed (Italy) and Pléiades (France) program alliance. France and Italy signed an agreement on Jan. 29, 2001 to jointly develop four radar satellites and two optical satellites. The first two COSMO-SkyMed high-resolution radar satellites will be launched in 2004. Pléiades is the SPOT successor program of CNES. The first two high-resolution optical satellites are planned for launch in 2005 and 2006. COSMO-SkyMed as well as Pléiades are also proposed PPP programs within ESA's Earth Watch and GMES initiatives.

Part A Atmosphere/Radiation/Aeronomy Missions

A.1 ACE (Atmosphere Climate Experiment)

An ESA Explorer mission, proposed in 1998, with the overall objective to obtain profiles of atmospheric parameters with occultation measurements using **a constellation of six LEO microsattellites**. The concept involves the systematic gathering of data over a five-year period. The profiles are used in such applications as climate modeling and climate prediction techniques to improve the understanding of the driving forces behind climate change and variability. The ACE science team is composed of researchers from the Meteorological Institutes in Denmark, Sweden, France and the United Kingdom. The ACE project is in phase A as of 2001. ³⁶¹⁾ ³⁶²⁾ ³⁶³⁾ ³⁶⁴⁾ ³⁶⁵⁾

The baseline configuration of the cluster considers two orbital planes. The six microsattellites are equipped with the GRAS receiver, flown on all S/C; they employ the technique of refractive radio occultation measurements of the GPS constellation, providing profiles of temperature, pressure, and humidity.

Figure 6: Illustration of the ACE spacecraft

The S/C bus is based on the SMART-1 bus of SSC (Swedish Space Corporation). The basic S/C body is trapezium-shaped with a size of 1 m x 0.62 m and a height of 0.6 m. Each S/C is nadir pointing and three-axis stabilized with a momentum bias system. Attitude is sensed by an Earth horizon sensor and a magnetometer; actuation is provided by a momentum wheel and three magnetorquers. The pointing accuracy is 1°, the rate error <0.025°/s. The S/C

mass is 87 kg, the solar power is 65 W (EOL) as orbital average provided by regulated solar arrays (unregulated bus of $28\text{ V} \pm 4\text{V}$). An NiCd battery of 6 Ah is used for solar eclipse phases. Orbit control is provided by an on-board propulsion system for constellation maintenance. The ACE avionics system is also based on the SMART-1 concept. This includes CCSDS compatible TM/TC, CAN bus for internal data handling, failure-tolerant design, FPGA (Field Programmable Gate Arrays) and an ERC-32 processor. The ERC-32 computer is able to support a number of on-board processing functions including science data processing.

Communication is provided by an S-band system with data rates of 4.8 kbit/s in uplink and 1 Mbit/s in downlink. An on-board storage capacity of 2 Gbit is available. The mission control is based on SCOS (Satellite/Mission Control System), a generic software package developed through ESA (by Terma A/S of Birkerød, Denmark) and configured for several on-going ESA missions. SCOS 2000 has the functionality to support automated execution of satellite, the ground segment commanding, evaluation of the S/C housekeeping telemetry, and the ground segment monitor function.

A launch of the ACE constellation is planned for 2005. Two launches inject the satellites (stacked launch of three S/C) into two perpendicular near-polar orbits.

Orbit: The six microsattellites fly in two orthogonal orbital planes (three satellites per plane) with an altitude of 700-800 km; inclination = 80-100°. An even time coverage is obtained with two orbits with each S/C sequentially spaced at 90°. In this arrangement each longitude can be revisited after six hours.

Sensor complement:

GRAS (GNSS Receiver for Atmospheric Sounding) of MetOp-1 heritage but with considerably reduced mass and power consumption. The instrument will be built by Saab-Ericsson Space and Austrian Aerospace. The instrument uses the occultation principle where the active instrument is mounted on a LEO satellite, and the monitored signal comes from the GPS and GLONASS constellations. The receiver will lock on transmitted GPS signals and monitor the phases of these signals. As the GPS satellite sets below (or rises above) the horizon, the influence of various layers in the atmosphere can be determined in the form of vertical profiles of density, pressure, humidity and temperature. GRAS is a 16-dual-frequency-channel GPS occultation instrument. It comprises two subsystems: the antenna subsystem with three antennas, GVA (GRAS Velocity Antenna), GAVA (GRAS Anti-Velocity Antenna), and GEU (GRAS Electronic Unit) with RF (Radio Frequency) front-end, RF/IF, A/D converter, frequency generation, channel processing, digital signal processor and power supply (see GRAS description under G.2). The GVA and GAVA are directed in the velocity and anti-velocity directions of the spacecraft, mechanically tilted by an angle of 30° below the horizontal plane to point to the Earth horizon. The zenith antenna is used for precise orbit determination. To enable the high degree of integration, the third generation AGGA-3 (Advanced GPS/GLONASS ASIC) chip will be developed. Each GRAS instrument has a mass of 8.2 kg with a power consumption of 20 W.

Ground segment: The ground segment is composed of two main facilities, the SDAC (Satellite Data Acquisition and Control) network and DPMCC (Data Processing and Mission Control Center). The SDAC consists of the main tracking and control station on Svalbard and the NMC (Network Management Center) at Kiruna, Sweden. The NMC supports alternative tracking and control stations especially during LEOP (Launch and Early Orbit Phase).

The DPMCC implements three main functional groups. The first group is mission control, which is based on SCOS 2000, a generic product developed through ESA. The second group is “application data acquisition and processing.” Data acquisition includes satellite data ingestion, validation and reformatting and also retrieval and similar processing of data from

ground based sources such as fiducial stations, such data being essential for the correction of occultation data before derivation of refraction profiles. Processing involves the use of a precise orbit determination tool based on the Bernese tool from the University of Bern, Switzerland, for the calculation of the orbits of the constellation satellites. This tool has been developed in the context of the ACE mission and the MetOp mission. In addition a clock extraction tool is developed for the precise estimation of the GPS and constellation satellite oscillator clocks. The third group is "data distribution and archiving," which makes different levels of data products available to meteorologists, e.g., for assimilation in weather prediction and climate models.

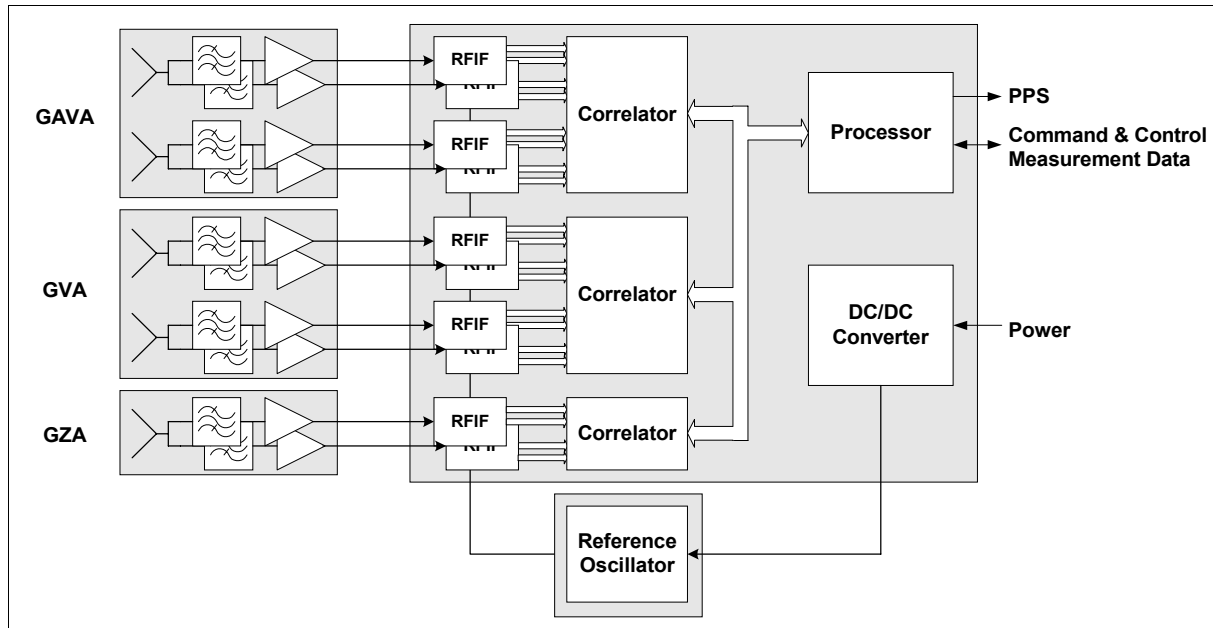

Figure 7: Electronic unit of GRAS

A.2 ACRIMSAT (Active Cavity Radiometer Irradiance Monitor)

ACRIMSAT is a NASA funded minisatellite to monitor the amount of total solar energy received (part of EOS program). The spacecraft builder/integrator is OSC of McLean, VA. The structure is based on the Ministar bus. In stowed configuration the S/C dimensions are: 79 cm in diameter x 69 cm in height. The S/C is sun pointing. It carries a flight processor used on previous missions. S/C mass = 213.3 kg, power = 47 W. The mission lifetime is 5 years. The communications links are in S-band, uplink frequency at 2065.5 MHz, uplink data rate at 2 kbit/s; downlink frequency at 2250.0 MHz with data rates of 3.6, 28.8, 57.6 or 115.2 kbit/s. ^{366) 367) 368)}

A launch of ACRIMSAT took place on Dec. 20, 1999 on a Taurus launch vehicle (together with KOMPSAT-1).

Orbit: Sun-synchronous circular orbit, altitude = 685 km, inclination = 98.13°, equator crossing at 10:50 AM on descending node.

Sensor complement:

ACRIM-III (Active Cavity Radiometer Irradiance Monitor), built at JPL. The ACRIM-III instrument has a heritage of ACRIM-I, flown on the SMM satellite (launch Feb. 14, 1980)

³⁶⁶⁾ Information provided by A. McLean of NASA/JPL

³⁶⁷⁾ <http://acrim.jpl.nasa.gov/mission/missionindex.html>

³⁶⁸⁾ <http://acrim.jpl.nasa.gov/>

and ACRIM-II, flown on UARS (launch Sept. 1991). The objective is to monitor the variability of total solar irradiance (TSI) with state-of-the-art accuracy and precision, thereby extending the high-precision database compiled by NASA since 1980 by other ACRIM experiments as part of the Earth Radiation Budget Program in the National Climate Program. Note: The first ACRIM sensor was flown on the Solar Maximum Mission (Launch: Feb. 14, 1980), follow-up missions: UARS, Spacelab-1, and ATLAS.

Figure 8: Illustration of the ACRIM-III instrument

Spectral coverage	0.2 - 2000 nm
Observation coverage	Minimum of 55 minutes per orbit of full solar disk data
View angle (FOV)	5°
Pointing accuracy	$\pm 0.25^\circ$ on S/C to sun line
Detectors (ACR)	Three, each with 30° right-circular cone painted specular black on the sun-viewing face
Accuracy	0.1% of full scale
Instrument mass, power	9.2 kg, 10 W
Instrument dimensions	Sensor housing: 18.5 cm diameter x 36 cm in length Central processing unit: 20.5 cm x 11.5 cm
Sampling interval	2 minutes (approx.)
Data rate	600 bit/s (about 600 kBytes of data are collected per day)

Table 50: Specification of the ACRIM instrument

The ACRIM-III sensor points toward the sun; the assembly is mounted on a two-axis tracker to observe the solar disk during each orbit. The instrument contains three independent active cavity radiometer (ACR) solar-monitoring sensors and a sun-position sensor. One ACR monitors solar irradiance, the other two are used to calibrate the optical degradation of the first instrument.

A.3 ADM (Atmospheric Dynamics Mission)

ADM is an ESA Earth Explorer Core Mission (a science-oriented mission) with the primary objective to provide wind profile measurements for an improved analysis of the global three-dimensional wind field. Such knowledge is crucial to the understanding of the atmospheric dynamics, including the global transport of energy, water, aerosols, chemicals and other airborne materials - to be able to deal with many aspects of climate research and climate and weather prediction.

The ADM mission makes use of a single observation instrument, referred to generically as DWL (Doppler Wind Lidar). The retrieval of wind speed relies on direct measurement along the LOS (Line-of-Sight) by lidar using Doppler shift information from atmospheric molecules and particles advected by wind.³⁶⁹⁾

The following description reflects the status of definition at the end of the phase A study.³⁷⁰⁾ The detailed design is under revision. The S/C structure, consisting of aluminum honeycomb elements, uses a conventional box-shaped spacecraft design with a central cone, upon which the observation instrument is mounted via three isostatic bipods. The electronic boxes of the bus and the associated satellite equipment are mounted on the side panels. The S/C is three-axis stabilized with AOCS (Attitude and Orbit Control Subsystem), using reaction wheels and magnetorquers as actuators, and magnetometers, star trackers, and a GPS receiver as sensors. The orbit is maintained by two 1 N thrusters. Electric power is provided by two fixed solar arrays of 8.4 m² of surface area (960 W power at EOL). A NiCd battery of 18 Ah is used for eclipse phases and the commissioning phase. The S/C mass at launch is 785 kg, including 100 kg of fuel. The design life is 3 years.³⁷¹⁾

Type	Equipment	Nr.	Main characteristics	Technology	Redundancy
Sensors	Magnetometer	2	Three-axis	Fluxgate	Cold redundancy
	GPS antennas & pre-amps	2	Half-space coverage	Patch antenna	Cold redundancy
	GPS receiver	2	C/A GPS receiver	RF ASIC and micro processor	Cold redundancy
	Star tracker	2	Large FOV	CCD	Cold redundancy
	Inertial reference unit (IRU)	1	3 measurement axis	HRG	Internal
Actuators	Reactions wheels	4	10 Nms/0.1 Nm	Ball bearings	3 among 4
	Magnetic torquers	3	100 Am ²	Windings	Cold redundancy

Table 51: AOCS elements of ADM

On-board data handling can be performed by an ESA-developed ERC-32 radiation tolerant processor; the subsystems are linked via serial links to the central processor. A solid-state memory provides a capacity of 2 Gbit on-board data storage. TT&C communications are based on standard S-band links, the uplink data rate is 2 kbit/s the downlink data rate is up to 64 kbit/s. The science data are dumped via a HRPT (High-Resolution Picture Transmission) link, as defined for METOP, in L-band at a data rate of 3.5 Mbit/s (an HRPT sta-

³⁷⁰⁾ "Atmospheric Dynamics Mission," ESA publication SP-1233 (4), July 1999

³⁷¹⁾ <http://www.estec.esa.nl/explorer/>

tion is a small remotely controlled facility with an antenna disk of 2.4 m and a G/T better than 6 dB/K). S/C operations are performed at ESOC using the Kiruna TT&C station. Two L-band stations at Kiruna (67.88° N, 20.25° E) and Barrow, Alaska (71.3° N, 156.7° W), are considered for science data dumps.

A Rockot launch vehicle has been baselined for a launch in 2006/7.

Orbit: Sun-synchronous orbit, altitude = 408 km (mean), inclination = 96.99°, local equator crossing time at 6:00 and 18:00 (dawn-dusk orbit).

The DWL (Doppler Wind Lidar) operation principle of ALADIN: The DWL sensor is an active instrument which fires laser pulses towards the atmosphere and measures the resulting Doppler shift of the return signal, backscattered at different levels in the atmosphere. The frequency shift results from the relative motion of the scatter elements along the sensor line of sight. This motion relates to the mean wind in the observed volume (cell). The measurement volume is determined by the maximum ground integration length of 50 km, the required height resolution and the width of the laser footprint. The measurements are repeated at intervals of 200 km.

Light is scattered either by interaction with aerosol or cloud particles (Mie scattering) or by interaction with air molecules (Rayleigh scattering). The two scattering mechanisms exhibit different spectral properties and different wavelength dependencies such that instruments evaluating only one signal type or both in separate processing chains can be constructed.

There are two detection techniques to measure the Mie and Rayleigh backscattering effects, namely a coherent-detection heterodyne system, and an incoherent or direct-detection interferometric system. The operation of each system exhibits profound differences in principle (see Chapter O.4.1 for heterodyne definitions).

- Coherent-detection heterodyne systems combine the weak (observed) optical signal at nominal frequency f_1 with a strong optical reference beam, the frequency-stable LO at frequency f_2 , on a wideband square-law detector, thereby producing radio frequency beats at the frequency difference $f_1 - f_2$. The resultant beat-frequency signal is analyzed in a post-detection step to provide the Doppler frequency.
- Incoherent-detection heterodyning refers to direct detection of an optical signal on an optical detector, with no LO present. The backscattered optical signal field is analyzed and dispersed in an interferometric filter (or in diffraction grating) prior to detection. The measurement accuracy of a direct-detection interferometric system depends only on the total scattered signal, it is not dependent on the energy of individual pulses, but on the total laser energy.

Observation configuration: The satellite is flown with the instrument pointing toward Earth in a plane quasi-perpendicular to the flight path and 35° offset from nadir in the anti-sun direction. The measurement geometry is depicted in Figure 606. The LOS is oriented such that the relative velocity at the intersection with the Earth is zero (yaw steering). All measurements are taken along the LOS. The Doppler shift of the backscatter signal reflects the relative wind speed along the LOS and has to be processed to a horizontal wind speed component (HLOS) referenced to the ground.

The measurement volume of the return signal from a single shot is defined by the lateral extension of the transmitted beam (a few meters in diameter) and the time gating of the receiver, which is adopted to the desired vertical resolution (several 100 m to 2 km). Due to the fact that the signal from a single shot is too weak for the evaluation, several shots along a ground track of up to 50 km have to be accumulated and integrated.

Measurement profile: The on-board instrument is operated at a duty cycle of 25% to obtain wind profile separation. An active operation cycle lasts 6.93 seconds (equivalent to a 50 km ground track), followed by a gap in observations of 20.79 seconds (equivalent of 150 km ground track). Winds can be measured in clear air (i.e., above or in the absence of thick clouds), and within and through thin clouds (e.g., cirrus).

Figure 9: Nominal measurement geometry and coverage of ADM

Sensor complement:

ALADIN (Atmospheric Laser Doppler Instrument).^{372) 373)} ALADIN is an incoherent direct detection lidar incorporating a fringe-imaging receiver (analyzing aerosol and cloud backscatter) and a double-edge receiver (analyzing molecular backscatter). The lidar emits laser pulses towards the atmosphere, then acquires, samples, and retrieves the frequency of the backscattered signal. The overall ALADIN instrument architecture is based on a 130 mJ diode-pumped frequency-tripled Nd:YAG laser operating in the ultraviolet (solid-state laser technology); the instrument consists of three major elements: a transmitter, a combined Mie and Rayleigh backscattering receiver assembly, and the opto-mechanical subsystem (a 1.1 diameter telescope).

Transmitter configuration: The power laser is composed of a medium power oscillator, a single amplifier, and a frequency tripler. The oscillator is actively Q-switched by a Pockels cell. A seed laser is used as frequency reference. The injection seeding technique is used to achieve a single frequency mode with a low-power continuous wave (CW) single frequency laser. The power laser is conductively cooled via heat pipes.

Receiver configuration: A combined Mie and Rayleigh backscattering receiver is implemented.

- The Mie receiver consists of a Fizeau spectrometer. The received backscatter signal produces a linear fringe whose position is directly linked to the wind velocity. The resolution of the Fizeau interferometer is 100 MHz (equivalent to 18 m/s). The wind value is determined by the fringe centroid position to better than a tenth of the resolution. The backscattered signals are detected by a thinned back-illuminated silicon CCD detector working in an accumulation mode which allows photon counting.

372) F. Fabre, A. Heliere, et al., "Direct Detection Doppler Wind Lidar Prototype: Design and Preliminary Results," Proceedings of the 2000 EUMETSAT Meteorological Satellite Data Users' Conference, Bologna, Italy, May 29-June 2, 2000, pp. 239-242

373) D. Morancais, F. Fabre, "Incoherent Doppler Wind Lidar ADM Concept and Related Prototype," Proceedings of the EUMETSAT Meteorological Satellite Data User's Conference, Copenhagen, Denmark, Sept. 6-10, 1999, pp. 85-92

- The Raleigh receiver employs a double Fabry-Perot etalon with a 2 GHz resolution and 5 GHz spacing. It analyzes the wings of the Rayleigh spectrum with a CCD. The etalon is split into two zones, which are imaged separately on the detector. The wind velocity is proportional to the relative difference between the intensities of the two etalons.

The optomechanical subsystem of ALADIN uses a Cassegrain afocal telescope for both functions of laser emission and backscatter reception. The telescope design employs iso-thermal and lightweight techniques based on e.g. SiC (Silicon Carbide) type ceramic mirrors and structures. This concept provides the needed optical quality and stability without a focusing or alignment mechanism. Star trackers for attitude sensing are mounted on the telescope structure to minimize the misalignment between the optical axis and the telescope's line-of-sight.

Parameter	ADM requirements			ADM predicted performances		
	Planetary Boundary Layer (PBL)	Troposphere	Stratosphere	PBL	Troposphere	Stratosphere
Vertical domain	0-2 km	2-16 km	16-20 km	0 - 2 km	2 - 16.5 km	16.5-26.5 km
Vertical resolution	0.5 km	1.0 km	2.0 km	0.5 km	1.0 km	2.0 km
Horizontal domain	global coverage			80° S to 85° N

Instrument mass, power	263 kg, 304 W average power (25% duty cycle)
Instrument data rate	11 kbit/s (max)

Table 53: Major instrument parameters of ALADIN

The instrument transmits raw source data consisting of the accumulated spectra from the Mie receiver and the flux intensities from the Rayleigh receiver. These data are provided for strips of 50 km length and a horizontal resolution down to 3.5 km. In the vertical direction, many layers or volume cells of the various altitude bins (-1 km to 16.5 km height for the Mie channel, and 0.5 km to 26.5 km for the Rayleigh channel) are measured; the instrument looks into a fixed direction (quasi perpendicular to the flight path and 35° away from nadir) and provides a vertical wind profile along the line of sight. In addition to these source data, laser internal calibration and attitude data are transmitted, as well as the receiver response calibration data.

The instrument performance considers the SNR error for each channel at the indicated altitude range. In addition, systematic bias errors are taken into account. When no ground echo is retrieved, the measurement bias is not cancelled; the total measurement error is slightly deteriorated. - For the Mie channel, the LOS (Line-of-Sight) wind error is below the requirement of 0.6 m/s for altitudes from 0 to 2 km in height. For the Rayleigh channel, the LOS wind error is below the requirement (except a marginal performance around 16 km).

	Mie channel @ 2 km	Rayleigh channel @ 10 km	Comment
Measurement accuracy (noise + bias)	0.67 m/s 0.85 m/s	1.05 m/s 1.23 m/s	LOS with ground echo LOS without ground echo

Table 54: ALADIN instrument overall LOS performance

A programmable sequencer is implemented for the detector permitting configuration changes with regard to vertical altitude resolution and range coverage. The vertical resolution can be varied from 250 m to 2 km or more. However, the measurement accuracy is only obtained for the nominal vertical resolution of 1 km. The altitude range is limited to 35 km. The horizontal (along-track) accumulation length can also be changed (nominal of 3.5 km) - from 100 m (Mie or Raleigh) to 50 km without significant performance degradation for the required along-track integration length of 50 km.

In addition to the line-of-sight (LOS) velocity measurements, ALADIN is able to provide information on cloud characteristics over the depth of the atmosphere, as well as aerosol measurements in the troposphere. These include:

- Cloud top height (notably cirrus top and base)
- Cloud cover
- Cloud and aerosol extinction and optical thickness
- Identification of multi-layer clouds
- A measure of clear air turbulence or wind variability
- Lower troposphere aerosol stratification
- The height of the tropopause
- The height of the PBL (Planetary Boundary Layer).

A.4 AE (Atmosphere Explorer)

A NASA satellite program (with two aeronomy and three atmosphere S/C) within the early Explorer Program. The main objective was the study of the upper atmosphere (ionospheric and thermospheric densities, temperatures, winds/drifts, and radiative emissions).³⁷⁴⁾

The satellites AE-C, -D, and -E were flying nearly identical in-situ experiments in complementary orbits, thereby producing a global database of many ionospheric and thermospheric parameters. Mass spectrometers were flown in each mission to determine the response of the lower thermosphere and ionosphere to radiation. In addition to determining the gas

³⁷⁴⁾ <http://nssdc.gsfc.nasa.gov/nmc/sc-query.html>

composition, consisting of helium, atomic oxygen, atomic nitrogen, molecular nitrogen, molecular oxygen, and argon, a modification of the mass spectrometer instrument allowed wind and gas kinetic temperature to be measured over an altitude range of 130 to 500 km.

A.4.1 AE-A (Aeronomy-A, Explorer 17)

A NASA/GSFC aeronomy satellite, a spin-stabilized sphere of 0.95 m in diameter. The S/C was vacuum sealed to prevent contamination of the local atmosphere. The battery power failed on July 10, 1963. Launch of AE-A (Explorer 17) from Cape Canaveral on a Thor-Delta vehicle on April 3, 1963. The AE-A S/C mass was 183.7 kg.

Orbit: Elliptical orbit, perigee = 255 km, apogee = 916 km, inclination = 57.6°, eccentricity = 0.04743, period = 96.39 minutes.

Sensor complement:

Neutral Mass Spectrometer (PI: C. A. Reber). Two identical double-focusing magnetic mass spectrometers were used. Objective: measurement of the concentrations of the major neutral particle constituents of the upper atmosphere - atomic and molecular oxygen, atomic and molecular nitrogen, helium, and water vapor. The neutral particles were ionized by electron bombardment. Measurements of the six different ion currents and the total current were made sequentially for four seconds in high sensitivity and for four seconds in low sensitivity (64 s for the entire measurement cycle). Included in the cycle was an operation to correct for any dc drift of the zero voltage level in the output signal. One spectrometer produced useless data due to malfunction. The other detector system experienced intermittent degeneration of the amplifier output. Consequently, the data were good only during certain periods.

Langmuir Probe (L. H. Brace). Two Langmuir probe systems were flown. One was used to provide measurements of the positive ion density, the other measured the electron temperature. Each system used a two-element sensor consisting of an outer cylindrical guard electrode of 10 cm length which was concentric with an inner collector electrode of 0.056 cm in diameter and 23 cm in length. The potentials of the electrodes were varied with respect to the satellite shell. The electron temperature probe was swept at 10 sweeps per second over two voltage intervals, 0 to 0.75 V and 0 to 1.5 V. The ion density probe was swept from -3 to +2 V in 2 seconds. The instrument operated nominally until July 10, 1963, when the S/C batteries failed.

Pressure Gauge (G. P. Newton). The instrument consisted of two Redhead (cold cathode) and two Bayard-Alpert (hot filament) ionization vacuum gauges to measure the neutral particle density and ambient pressure of the upper atmosphere between 260 km and 960 km (pressure range from 10^{-4} torr to 10^{-11} torr). The instruments were operated for 4-minute periods during a pass over a ground station. The neutral particles were ionized by electron bombardment, the resulting ion currents were detected and converted to voltages suitable for telemetry.

A.4.2 AE-B (Aeronomy-B, Explorer 32)

A NASA/GSFC aeronomy satellite with the objective to measure temperatures, composition, densities, and pressures in the global upper atmosphere. The S/C was a spin-stabilized stainless steel (spin axis normal to the orbit plane, spin rate = 30 rpm), vacuum-sealed sphere of 0.9 m in diameter. The on-board equipment included optical and magnetic aspect sensors, magnetic attitude and spin-rate control systems, and a tape recorder. Power was provided by silver-zinc batteries and a solar array. Two identical pulse-modulated telemetry systems and a canted turnstile antenna were used for communication. The S/C was launched from Cape Canaveral on a Delta vehicle on May 25, 1966. S/C mass = 224.5 kg.

Orbit: Elliptical orbit, perigee = 276 km, apogee = 2725 km, inclination = 64.67°, eccentricity = 0.15532, period = 116 minutes.

Sensor complement:

RF Ion Mass Spectrometer (PI: H. C. Brinton). Objective: Measurement of the ion species concentrations (atomic hydrogen, helium, nitrogen, and oxygen) in the topside ionosphere as a function of time, location, and solar and geomagnetic activity. The spectrometer consisted of a 5-3 cycle ceramic tube with 5 mm grid spacing and an external guard ring assembly. Two RF frequencies, 3.7 MHz and 9.0 MHz, were used to cover the ion mass range 12 to 19, and 1 and 4 atomic mass units (amu) assuring detection of the prime ionic constituents of the topside ionosphere. A mass scan was done in 208 seconds followed by a recycling of the sweep voltage and a second measurement of the high mass range. The stopping potential and the guard ring potential controlled the sensitivity of the spectrometer. The ion current of the spectrometer was measured by a series of five-decade amplifiers with a particle sensitivity range from about 10 to 10^6 ions/cm³. An automatic calibrator functioned once during each turn-on to supply two known signals to the amplifier system and to the sweep monitor. - The useful S/C lifetime of 10 months permitted a global study of the diurnal variation of the atmosphere during nearly two complete diurnal cycles, since the orbit plane precessed one revolution each 5.5 months.

Neutral Particle Magnetic Mass Spectrometer (PI: C. A. Reber). Two double-focusing mass spectrometers were used to measure the composition of the neutral atmosphere between 285 km and 1000 km. One instrument was mounted on the equator the spherical S/C normal to the spin axis, the other instrument was mounted on the top of the S/C, parallel to the spin axis. The neutral particles were ionized by electron bombardment and separated according to the mass-to-charge ratio (m/q) in the analyzer of the instrument (one collector cup for each of the seven ion species). An electrometer amplifier with two sensitivity ranges differing by a factor 100, sampled the seven collectors sequentially. The dwell time on a specific mass and sensitivity range was 2.4 s. The first four of the fifteen 2.4 s steps of a cycle were used to correct any zero drift of the electrometer and to record the low- and high-sensitivity zero levels. The ion currents were then measured in the high sensitivity for m/q equal to 2 (molecular hydrogen), 4 (helium), and 14 (atomic nitrogen), and in high and low sensitivity for m/q equal to 28 (molecular nitrogen), 32 (molecular oxygen), 16 (atomic oxygen), and 18 (water vapor). The time for a complete cycle was 36 seconds. - Electronic malfunctions caused one instrument to fail after four days in orbit, the other failed after 7 days.

Atmospheric Drag (PI: Wulf-Mathies). The spherical shape of the S/C permitted to determine the upper atmospheric density as a function of altitude, latitude, season, and solar activity. Density values near perigee were deduced from sequential observations of the S/C position, using optical and radio and/or radar tracking methods.

Electron Temperature and Density (L. H. Brace). The objective of this experiment was to measure the distribution of electron temperature and densities from 10^3 to 10^6 electrons/cm³ using a swept voltage electron tube.

Pressure Gauge (G. P. Newton). Three cold-cathode magnetron type density gauges (Red-head ionization gauges), each with its own high voltage supply and output electrometer, were flown to measure the density of the neutral atmosphere as a function of altitude, time, latitude, and solar and geomagnetic activity. One gauge was designated as NRC-528, the other two as GCA-R5 to reflect different origins. Mounted on the satellite equator was one gauge of each designation, with the third gauge mounted 55° above the equator. The metal-ceramic GCA-R5 gauges had an internal magnetic field of about 0.1 T and contained radioactive material deposited on the anode to permit operation at low atmospheric densities ($<10^{-17}$ g/cm³) with the anode potential fixed at 3500 V. The GCA-R5 equatorially mounted gauge had a linear range switchable electrometer output, and high-resolution current measurements were obtained. The remaining two gauge outputs were through loga-

rhythmic electrometers. All electrometers were calibrated once each turn-on. The time resolution of the measurements was 2 s, which was equal to the satellite spin period and corresponded to a spatial resolution of 6 km along the orbit path.

A.4.3 AE-C (Atmosphere Explorer-C, Explorer 51)

A NASA/GSFC atmosphere mission with the objective to investigate the thermosphere with emphasis on energy transfer and processes. The S/C was a multi-sided polyhedron with a diameter of 1.4 m. The S/C could be operated in either of two modes: spinning at a nominal 4 rpm or despun to 1 revolution per orbit. The spin axis was perpendicular to the orbit plane. Power was supplied by a solar cell array. The S/C used a PCM telemetry data system that operated in real time or in a tape recorder mode. The S/C mass was 658 kg including 85 kg of instrumentation. The S/C was launched from Cape Canaveral on a Delta vehicle on Dec. 16, 1973.

Orbit: Elliptical orbit, perigee = 149 km, apogee = 4,294 km, inclination = 68.1° , eccentricity = 0.24086, period = 132.30 minutes. - The initial elliptical orbit was altered many times in the first year of life by means of an onboard propulsion system employing a 3.5-lb thruster. The purpose of these changes was to alter the perigee height to 129 km. After this period, the orbit was circularized and was raised periodically to about 390 km when it would decay to 250 km altitude. During the first year, the latitude of perigee moved from about 10° up to 68° north and then down to about 60° south. During this period about two cycles through all local times were completed.

Sensor complement:

CEP (Cylindrical Electrostatic Probe - PI: L. H. Brace). Two identical instruments designed to measure electron temperatures, electron and ion concentrations, ion mass, and spacecraft potential. One probe was oriented along the spin axis of the S/C (normally perpendicular to the orbit plane), and the other radially so that it could observe in the direction of the velocity vector once each 15-s spin period. Each instrument was a retarding potential Langmuir probe device that produced a current-voltage (I-V) curve for a known voltage pattern placed on the collector. Electrometers were used to measure the current. There were two systems of operation (one with two modes and another with three modes) using collector voltage patterns between plus and minus 5 V. Most modes involved an automatic or fixed adjustment of collector voltage limits (and/or electrometer output) such that the region of interest on the I-V profile provided high resolution. Each system was designed for use with only one of the probes, but they could be inter-switched to provide backup redundancy. The best measurements in the most favorable modes provided 1-s time resolution; electron temperature between 300 and 10^3 K (10% accuracy); ion density between 10^3 and 10^6 ions/cm³ (10-20% accuracy); electron density between 50 and 10^5 electrons/cm³; and ion mass at ion densities above 10^3 ions/cm³. Each probe had a collector electrode extending from the central axis of a cylindrical guard ring. The 2.5 cm long guard ring was at the end of a 25 cm boom, and the collector extended another 7.5 cm beyond the guard ring. The boom, guard, and collector were 0.2 cm in diameter.

MESA (Miniature Electrostatic Analyzer - PI: K. S. W. Champion). An atmospheric density accelerometer with the objective to measure the neutral density of the atmosphere in the altitude range of 120 to 400 km from the measurements of satellite deceleration due to aerodynamic drag. The instrument consisted of three single-axis accelerometers, mounted mutually at right angles, two in the S/C x-y plane and the other along the z-axis. The instrument determined the applied acceleration from the electrostatic force required to re-center a proof mass. The output of the device was a digital pulse rate proportional to the applied acceleration. The measurements allowed determination of the density of the neutral atmosphere, monitored the thrust of the orbit-adjust propulsion system (OAPS), determined the satellite minimum altitude, measured spacecraft roll, and provided some attitude-sensing

information. S/C nutations of less than 0.01° were monitored. The instrument had three sensitivity ranges: 8×10^{-4} Earth's gravity (g) in OAPS monitor mode; 4×10^{-5} g between 120 ($\pm 2\%$) and 280 km ($\pm 10\%$); and 2×10^{-6} g between 180 km ($\pm 2\%$) and 400 km ($\pm 10\%$). Numbers in parentheses represent errors; in addition, there may be a systematic error of up to plus or minus 5% due to drag coefficient uncertainty. The highest measurement altitude was determined assuming the instrument could sense to 0.2% of full scale.

PES (Photoelectron Spectrometer - PI: J. P. Doering). The experiment was designed to provide information on the intensity, angular distribution, energy spectrum, and net flow along field lines, of electrons in the thermosphere with energies between 1 and 500 eV. The instrument consisted of two identical oppositely directed hemispherical electrostatic analyzers, and 30 operating modes. Each spectrometer had a relative energy resolution of plus or minus 2.5% and a geometric factor on the order of $0.001 \text{ cm}^2 \text{ sr}$, independent of electron energy. Three separate energy ranges could be sensed: 0 to 25, 0 to 100, or 0 to 500 eV. Measurements from these intervals could be sequenced in five different ways. Data could be taken from either sensor separately, or alternately with time resolution varying from 0.25 to 8 s. There were two deflection voltage scan rates determined by spacecraft clock. This voltage was changed in 64 steps, and was done at 4 or 16 steps per telemetry frame. With 16 frames/s, this allowed a choice of either one 64-point spectrum, or four 16-point spectra in 1 s. The longest (8 s) cycle of data involved observations using increasing voltage steps for the lowest, middle, lowest, then highest energy ranges (in that order) for 1 s each. A repeat for decreasing voltage step completed the cycle.

RPA (Retarding Potential Analyzer/Drift Meter - PI: W. B. Hanson). The experiment was designed to determine vector ion drift velocities, ion concentration and temperature, and S/C potential. An ionospheric irregularity index was also obtained from the ion concentration sensor. The experiment consisted of a retarding potential analyzer with four planar sensor heads. The sensor head used for ion drift measurements was collocated with another head, and all were spaced nearly equally, looking outward from the satellite equator. Since the satellite spin axis was perpendicular to the orbit plane, these heads could observe along the spacecraft velocity vector in either the spin or despun mode of the S/C. The primary objective of this experiment was to provide accurate ion temperatures with other measurements being of secondary importance. Three of the sensor heads were similar. They had two grounded entrance grids, two retarding grids, a suppressor grid, a shield grid, and a collector. A linear sweep voltage (32 or 22 to 0 V, up or down) was normally applied to the retarding grids in 0.75 s.

ESUM (Extreme Solar UV Monitor - PI: D. F. Heath). ESUM made absolute broadband spectro-radiometric measurements of the solar EUV flux from 200 Å to Lyman-alpha at 1216 Å and made precise measurements of the temporal variability - approximately 1% per solar rotation. The instrument consisted of two identical windowless EUV photodiodes with aluminum oxide cathodes and a filter wheel containing two sets of unbacked metallic filters (aluminum, tin, indium) and an open position. A visible light diode measured the pin-hole transmittance of the filters to determine the white light background. The tilt angle of the instrument relative to the +z S/C axis was optimized for the maximum viewing time of the sun in both spinning and despun spacecraft modes. The instrument field of view was 60° . The nominal bandwidths (for 50% of signal) were 270 - 550 Å, 570 - 584 Å, 800 - 935 Å, and 1216 Å.

EUVS (Solar EUV Spectrometer - PI: H. E. Hinteregger). EUVS was used to observe the variations in the solar EUV flux in the wavelength range from 140 to 1850 Å and the atmospheric attenuation at various fixed wavelengths. This provided quantitative atmospheric structure and composition data. The instrument consisted of 24 grazing-incidence grating monochromators, using parallel-slit systems for entrance collimation and photoelectric detectors at the exit slits. Twelve of these monochromators had wavelength scan capability, each with 128 selectable wavelength positions, which could also automatically step scan

through these positions. The other 12 monochromators operated at fixed wavelengths with fields of view smaller than the full solar disk to aid in the atmospheric absorption analysis. The spectral resolution varied from 2 to 54 Å depending upon the particular instrument. The FOV varied from 60 x 60 arcmin down to 3 x 6 arcmin. All 24 monochromator-entrance axes were co-aligned parallel. A solar pointing system could point to 256 different positions, execute a 16-step one-dimensional scan or a full 256-step raster. The time resolution varied from 0.5 s for observing 12 fixed wavelengths up to 256 s for programming the EUVS through all possible modes.

OSS (Open-Source Neutral Mass Spectrometer - PI: A. O. C. Nier). OSS mass = 7 kg, power = 10 W. The objective of this experiment was to contribute to a study of the chemical, dynamic, and energetic processes that control the structure of the thermosphere by providing direct, in situ measurements of both major and minor neutral atmospheric constituents having masses in the range from 1 to 48 atomic mass units (amu). A double-focusing Mattauch-Herzog magnetic deflection mass spectrometer with an impact ion source was flown. Two ion collectors were included to measure ions differing in mass by a factor of 8, i.e., the two mass ranges covered were 1 to 6 amu and 6 to 48 amu. In the ion source the neutral species were ionized by means of electron impact. At altitudes > 380 km, ion currents were measured with an electron multiplier counting individual ions. Counts were accumulated for 1/20 s before automatically switching to a different mass number. While complete mass spectra could be swept, in the common mode of operation peak stepping was employed, with readings on the principal peaks in the mass spectrum being repeated approximately every 0.5 s and on other species less frequently. Data below 380 km were measured using an electrometer. In addition to the peak stepping mode, there were several other operating modes which were selected by ground command. In the fly-through mode, the ion source voltages were adjusted so that there was no electric field to draw ions out of the electron beam when they were formed. Ambient particles striking the ion source retained energies less than 0.1 eV, which was not high enough to overcome the negative space charge potential holding the ions in the beam. Those ambient particles that did not strike the ion source retained their incoming energy of several eV after ionization and escaped into the accelerating region of the analyzer. The electron accelerating potential was 75 eV in normal mode operation and was 25 eV in the fly-through mode.

CSS (Closed-Source Neutral Mass Spectrometer -PI: D. T. Petz). CSS mass = 8 kg, power = 18 W. CSS measured in situ the spatial distribution and temporal changes of the concentrations of the neutral atmospheric species. In addition, new insight into in situ measurement techniques was obtained from comparisons of these measurements with those obtained from other on-board experiments; namely, OSS, EUVS, and MESA. CSS had a gold-plated stainless steel thermalizing chamber and ion source, a hyperbolic-rod quadrupole analyzer, and an off-axis electron multiplier. Five different sequences of mass selections were available and, expressed in atomic mass units (amu); they were (a) geophysical -1, 2, 4, total, 16, 28, 32, selected, 40, (b) analytical -12, 14, 18, 20, 22, 30, 44, calibrate, zero, (c) individual -selected, selected, selected, (any mass 1 to 44), (d) sweep digital -1, 2, 3, 4, 5, .. 45 (in 3/16 amu steps), and (e) sweep analog -2, 3, 4, 5, ... 45 (continuous). Spatial resolution was determined primarily by the mode of S/C operation. In orbit, the pre-sealed spectrometer was opened, and the atmospheric constituents passed through a knife-edged orifice into the thermalization chamber and ion source. Selected ions left the quadrupole analyzer through a weak focusing lens and were accelerated into a 14-stage electron multiplier, where they were turned 90° to strike the first dynode. For each impacting ion, the multiplier output was a pulse of 2×10^6 electrons.

NATE (Neutral Atmosphere Temperature Experiment - PI: N. W. Spencer). NATE mass = 7 kg, power = 10 W. NATE measured the kinetic temperature of the neutral atmosphere by determining the instantaneous density of molecular nitrogen in a spherical chamber coupled to the atmosphere through a knife-edged orifice. Analysis of the measured molecular nitrogen density variation over a spin cycle with a knowledge of the satellite's motion and

orientation led to a determination of the ambient temperature, independent of scale height. A measurement of the ambient nitrogen density was also obtained. An alternate measurement of neutral temperature was also undertaken, using a baffle inserted in front of the orifice to intercept a portion of the gas particle stream entering the chamber. When the satellite was in the despun mode, the baffle was made to oscillate in the stepwise fashion to interrupt the particle stream seen by the orificed chamber. These chamber density variations were interpreted to yield the neutral gas kinetic temperature. A dual-filament ion source sampled the thermalized molecular nitrogen in the chamber and produced an ion beam density proportional to the nitrogen chamber density. From the source, this ionized nitrogen beam was directed from a quadrupole analyzer, tuned to pass those particles whose mass-to-charge ratio (m/q) is 28, on to an electron multiplier. The output pulses were amplified and counted in a 16-bit accumulator. The experiment also provided measurements of neutral atmospheric composition, when commanded into the appropriate mode and, for the first time measured the local wind (vertical motions). The wind values were determined by measurement of the "stream" position relative to the satellite velocity. When the S/C was in the despun mode, the nitrogen density was measured except when the particle stream was interrupted by the baffle.

MIMS (Magnetic Ion-Mass Spectrometer - PI J. H. Hoffman). MIMS mass = 7.5 kg, power = 6 W. The MIMS objective was to measure in-situ the concentrations of the ambient ion species in the mass range from 1 to 90 atomic mass units (amu). MIMS was mounted on the S/C equator normal to the spin axis, and the entrance aperture faced forward when the S/C was in the despun mode. The electric and magnetic fields were arranged to produce a mass spectrum along the focal plane following the magnetic analyzer. Three slits were placed along the focal plane in appropriate places to simultaneously collect ions in the mass ratios 1 to 4 to 16. Ionospheric ions were accelerated into the analyzer system by a negative voltage that varied from -1060 to -225 V. The three mass ranges measured simultaneously were 1-4, 4-16, and 16-90 amu. Following each slit was an electron multiplier and a logarithmic electrometer-amplifier detector. The detector output could be measured directly for an analog output, or it could be fed to a "peak" circuit that determined the amplitude of each peak in the spectrum. Only the amplitude of each peak was telemetered in the primary peaks mode, and in this mode the time required to simultaneously sweep all three mass ranges was 1 s.

BIMS (Bennett Ion-Mass Spectrometer - PI: H. C. Brinton). BIMS mass = 3 kg, power = 2 W. The BIMS objective was to measure, throughout the AE-C orbit, the individual concentrations of all thermal ion species in the mass range of 1 to 72 atomic mass units (amu), and in the ambient density range from 8 to 5×10^6 ions/cm³. Any combination of the following three mass ranges, expressed in amu, were selected by ground command: range A, -1 to 4, range B, -2 to 18, range C, -8 to 72. Each range was normally scanned in 1.7 s (approximately 12 km along orbit). Normal operation consisted in sequence ABCABC (1 to 72 amu in 5.1 s). Laboratory and inflight determination of spectrometer efficiency and mass discrimination permitted direct conversion of measured ion currents to ambient concentrations. The experiment's four primary mechanical components were guard ring and ion-analyzer tube, collector and preamplifier assembly, vent, and main electronics housing. The guard ring was normally at ground potential, but it could be placed at -6 V by command if desirable, e.g., if the S/C acquired a positive charge. A three-stage Bennett tube with 7 to 5 cycle drift spaces was flown and was modified to permit ion concentration measurements to be obtained at low altitudes. The frequency of the 30 V peak-to-peak RF voltage varied with the mass range measured: range A, -10 MHz, range B, -5 MHz, and range C, -2.5 MHz. Primary analog instrument output was a compressed ion current spectrum which displayed the full dynamic range of the amplifier system on a single telemetry channel.

LEE (Low-Energy Electron Experiment - PI: J. H. Hoffman). This experiment provided direct measurements of the energy input into the upper atmosphere due to electrons and protons in the energy range of 0.2 to 25 keV. The experiment acquired differential measurements of the energy influx and angular distribution. There were two detectors measuring

electrons and protons from 0.2 to 25 keV in 16 logarithmically spaced steps, and one detector measuring 5 keV electrons continuously. Each detector consisted of a cylindrical electrostatic analyzer for species and energy selection, and a Spiraltron electron multiplier for particle detection. Energy distributions were obtained by applying different fixed or stepped voltages to the deflection plates. Distributions in angle were measured using the spacecraft spin and the analyzers' positions on the S/C. In the despun modes, measurements were obtained at 45° to the S/C equator, and radially away from the Earth. Detector look angles were chosen to give optimum magnetic pitch-angle coverage when the S/C was moving either poleward or equatorward. All detectors were identical in construction and used 1 by 6 mm entrance apertures. Counts were accumulated over 55.7 ms and read out each main telemetry frame (62.5 ms). The two stepped detectors moved one energy step once each main frame with the same accumulation time, requiring about 1 s for a complete cycle of steps.

UVNO (Ultraviolet Nitric-Oxide Experiment - PI: C. A. Barth). UVNO consisted of a two-channel fixed-grating Ebert-Fastie spectrometer which measured the airglow in the (1, 0) Gamma band in a 15- Å region centered at 2149 Å. The observed intensity was produced by resonance fluorescence of sunlight by the nitric-oxide molecules in the instrument's FOV. The intensity profiles obtained yielded altitude profiles of nitric-oxide density as a function of time and location. Profiles were measured along-track of the S/C at times when it was on the sunlit side of the Earth. The remote sensing character of the UVNO experiment permitted measurements of nitric-oxide to be made at altitudes both above and below S/C perigee. As the S/C spun, the spectrometer, which looked outward through the rim of the satellite, repeatedly had its FOV carried down through the atmosphere onto the Earth's limb, and altitude profiles of the emitted airglow intensity were obtained. Below some altitude the measured signal at 2149 Å was contaminated by Rayleigh-scattered sunlight. To correct for this contamination, a second channel measured only scattered light intensity in a 12 Å region centered at 2190 Å. The two channels were optically and electrically independent. Nitric-oxide airglow intensity was determined by taking the difference between these two measurements. The sensor's spherical fused-quartz telescope mirror had a 125 mm focal length, and focused incident light on the entrance slit of the spectrometer. From this slit the light struck one half of the Ebert mirror and was collimated onto the grating. The 3600-lines-per-mm grating returned it collimated to the other half of the mirror, and the light was focused on two exit slits. The spectrometer FOV was 4° by 0.25°, with the long axis parallel to the S/C spin axis, and therefore parallel to the viewed limb. In normal operation each channel was integrated for 20.8 ms and was read out alternately at 10.4 ms intervals.

VAE (Visible Airglow Experiment - PI: P. B. Hays). The experiment contained a filter photometer designed to measure various airglow and auroral features in the spectral range between 3000 and 7500 Å. The primary information obtained from this experiment was the rates of excitation of the atomic and molecular constituents of the thermosphere. For the AE-C mission, the following six specific lines and bands were chosen for study since they play an important role in the photochemical energy balance of the atmosphere: 3371, 4278, 5200, 5577, 6300, and 7319 Å. The emissions were measured in pairs: 5577 and 6300, 7319 and calibration, 3371 and 5577, 5200 and 7319, 4278 and 3371, calibration and 5200, and 6300 and 4278. Two optical systems viewed at right angles to each other. Each one employed a combination of a simple objective lens and field stop to define the FOV, and each contained a multistage light baffle. The wide-angle high-sensitivity system (designated channel 2) had a FOV of 3° half-angle, and was used to measure the nightglow, dayglow above the S/C, and other weak emission features. The less sensitive system (designated channel 1) had a FOV of approximately 0.75° half-angle and was used for dayglow and nightglow horizon measurements, as well as discrete auroral features which showed strong spatial gradients. Both optical channels had a diameter of 2.2 cm. They shared a filter wheel that contained six interference filters at the wavelengths identified above, and two other positions. One was a

dark position for noise measurements, and the other was a calibrate position. The dynamic range of the instrument was 10^{16} photons/m² (10^6 Rayleigh).

PSA (Pressure Sensor A - PI: C. J. Rice). PSA, the cold cathode ion gauge, was primarily an engineering experiment to provide data on S/C operation. However, data from this experiment was correlated with accelerometer and capacitance manometer data to evaluate satellite drag performance. PSA measured atmospheric pressure in the region between 120 and 370 km above the Earth's surface for values of atmospheric pressure between 1.3×10^{-3} to 1.3×10^{-7} mb. The estimated accuracy of the PSA was $\pm 20\%$. The cylindrically shaped sensor package consisted of a wedge-shaped orifice, a cathode near ground potential, an anode operating at about 1300 vdc, and a permanent magnetic field of about 1600 gauss. The gage contained no primary source of ionizing electrons. The discharge was initiated by field emission and was self-sustaining at a pressure above 1.3×10^{-7} mb. The ion current was collected at the cathode. The sensor was mounted on the S/C, with the orifice perpendicular to the S/C spin axis which was normal to the orbital plane. The instrument could be operated in two modes, spinning or despun. When the S/C was in a spinning mode, the PSA alternately sampled the ram and wake pressure. When the S/C was in the despun mode, the PSA faced 30° from the direction of motion.

PSB (Pressure Sensor B - PI: C. J. Rice). PSB mass = 1.14 kg, power = 3 W. The capacitance manometer was primarily an engineering experiment to provide data on S/C operations. However, data from this experiment were also correlated with accelerometer and ion gauge data in evaluating satellite drag. PSB measured atmospheric pressure in the region below 200 km. The accuracy of the PSB gauge varied from about 10% at 120 km to about 40% at 180 km. The PSB consisted of two spherical, thermally controlled chambers, separated by a thin membrane stretched flat and under radial tension. Any deflection of the diaphragm caused by a pressure differential between the two sides caused a change in capacitance between the diaphragm and an adjacent electrode which was measured by a ac bridge circuit. Air was permitted into one of the chambers through two ports 180 deg apart and perpendicular to the spacecraft spin axis. Thus, the wave-ram pressure differential was sampled twice each spacecraft revolution.

Temperature Alarm - PI: P. S. Caruso. The engineering experiment measured the impact temperature during low perigees. ³⁷⁵⁾ ³⁷⁶⁾

A.4.4 AE-D (Atmosphere Explorer-D, Explorer 54)

A NASA/GSFC mission with the objective to continue the investigation begun by AE-C of the chemical processes and energy transfer mechanisms that control the structure and behavior of the Earth's atmosphere and ionosphere in the region of high absorption of solar energy. This mission was planned to sample the high latitude regions at the same time that the AE-E mission was sampling the equatorial and low latitude regions. The same type of spacecraft as AE-C was used, the payload consisted of the same instruments except for deletion of EUVS and BIMS. They were part of the AE-E payload. The AE-D S/C was launched Oct. 6, 1975 on a Delta vehicle from Point Arguello, USA. The AE-D S/C mass was 681 kg.

Orbit: Polar elliptical orbit, perigee = 154 km, apogee = 3,816 km, inclination = 90.1° , eccentricity = 0.21881, period = 126.9 minutes. The polar orbit provided the sampling of all latitudes and the perigee moved through all latitudes in 3 months and all local times in 4 months. Unfortunately, a failure in the solar power panels resulted in the termination of operations on January 29, 1976, after slightly less than 4 months of useful life. However, all the regions at the perigee altitudes were sampled during this time. The S/C re-entered the

³⁷⁶⁾ P. S. Caruso Jr., C. R. Naegeli, "Low perigee aerodynamic heating during orbital flight of an Atmosphere Explorer," NASA TM D-8308, Sept. 1976

atmosphere about 1 month after cessation of telemetry. To continue the correlated observations with the AE-E mission, AE-C was reactivated on February 28, 1976, to replace AE-D.

Sensor complement: all sensors from AE-C (deletion of EUVS and BIMS). Note, the CSS instrument of mission AE-C was renamed to **NACE** (Neutral Atmosphere Composition Experiment) - PI: A. E. Hedin).

A.4.5 AE-E (Atmosphere Explorer-E, Explorer 55)

A NASA/GSFC mission with the objective to investigate the chemical processes and energy transfer mechanisms that control the structure and behavior of the Earth's atmosphere and ionosphere in the region of high absorption of solar energy at low and equatorial latitudes. The simultaneous sampling at higher latitudes was carried out by the AE-D S/C until its failure on January 29, 1976, and then by AE-C, until it reentered on December 12, 1978. The same type of spacecraft as AE-C was used, and the payload consisted of the same types of instruments except that the LEE and UVNO experiments were deleted and a backscatter UV spectrometer was added to monitor the ozone content of the atmosphere. The two experiments that were deleted were more appropriate for the high-latitude regions. The perigee swept through more than six full latitude cycles and two local time cycles during the first year after launch when the orbit was elliptical and the perigee height was varied between 130 and 400 km. The circularization of the orbit around 390 km was made on November 20, 1976 and the S/C was raised to this height whenever it would decay to about 250 km. AE-E reentered on June 10, 1981

The AE-E spacecraft was launched on Nov. 20, 1975 on a Delta vehicle from Cape Canaveral (operational for 5 1/2 years). The AE-E spacecraft mass was 735 kg.

Orbit: Elliptical orbit, perigee = 156 km, apogee = 2,983 km, inclination = 19.7°, eccentricity = 0.17774, period = 117.9 minutes.

Sensor complement: All sensors from AE-C (except LEE and UVNO) plus BUUV as described below.

BUV (Backscatter UV Spectrometer - PI: D. F. Heath). BUV monitored the spatial distribution of atmospheric ozone by measuring the intensity of the UV radiation backscattered from the Earth's atmosphere. To obtain this ozone distribution, the BUV subsystem measured direct solar radiation and backscattered UV radiation from the daytime sun-illuminated atmosphere. The instrument consisted of a spectrometer (monochromator) and a photometer. The monochromator measured the intensity of UV radiation backscatter and reflected radiation from the Earth's atmosphere in 12 wavelengths (2555 to 3398 Å) in which ozone attenuation occurs. The photometer measured the reflected UV radiation in a single wavelength span in which attenuation by ozone does not occur. The BUV had four operating modes.

A.5 AEM-2 (Applications Explorer Mission-2)

NASA/LaRC mission (also referred to as 'SAGE' or 'Explorer 60') with the objective to monitor stratospheric aerosol and its influence on the climate (study of aerosol sources and sinks, aerosol transport, aerosol radiative and climatological implications, etc.). Launch: Feb 18, 1979 by Scout vehicle from Wallops Island, VA. The S/C experienced power problems after May 15, 1979. However, operations continued until November 19, 1981.^{377) 378)}

Application: stratospheric chemistry related to aerosol, ozone, and nitrogen dioxide. Provision of almost global profiles by solar occultation techniques.

377) M. P. McCormick, P. Hamill, T. J. Pepin, W. P. Chu, T. J. Swissler, L. R. McMaster, "Satellite Studies of the Stratospheric Aerosol," Bulletin of the American Meteorological Society, Vol. 60, No. 9, September 1979, pp. 1038-1046

378) L. R. McMaster, M. W. Rowland, "SAGE-I Data User's Guide," NASA Reference Publication 1275, Aug. 1992

Orbit: Near-circular orbit, perigee = 548 km, apogee = 660 km, inclination = 55°, period = 96.8 min.

Sensor:

SAGE-I = Stratospheric Aerosol and Gas Experiment. The instrument is a sun photometer³⁷⁹⁾ [of SAM (on Apollo-Soyuz) and SAM-II (on Nimbus-7) heritage].

Objective: measurement of solar intensity profiles during each sunrise and sunset event (about 30 sampling opportunities per day, sunrise + sunset). The SAGE instrument is a radiometer (mass = 18 kg) consisting of a Gregorian telescope and a detector subassembly measuring the attenuation of solar radiation at four wavelengths (0.385, 0.45, 0.6, and 1.0 μm) during solar occultation. The sensor scanned the atmosphere from the horizon up, and measured the attenuation of solar radiation at different atmospheric layers as the S/C emerged from the Earth's shadow. This procedure was repeated during S/C sunset. Two vertical scanings were obtained during each orbit, with each scan requiring approximately 1 minute to cover the atmosphere above the troposphere. The instrument FOV was about 0.15 mrad, resulting in a vertical resolution of about 1 km.

The aerosol profiles can be interpreted to give concentrations of ozone, nitrogen dioxide, and total molecular density. A number of ground truth measurements in the US, Japan, Europe, and Nimbus-7 data are an integral part of the SAGE mission.

Data:

The instrument data include vertical profiles of stratospheric aerosol, ozone, and nitrogen dioxide. The SAGE-I aerosol data were validated by comparison with correlative lidar and dustsonde in situ measurements, the ozone data were validated by comparison with balloon electrochemical cell ozonesonde and sounding rocket measurements, the nitrogen dioxide measurements were compared with climatology data. All data are archived at NSSDC (National Space Science Data Center) at GSFC.

A.6 Aura Mission (EOS/Chem-1)

See description under D.11.3

A.7 CLOUDS (Cloud and Radiation Monitoring Satellite)

CLOUDS is a mission study (as of 2000), conducted by 12 European partners (7 institutes and 5 companies) and with NOAA/ETL participation, sponsored by the EC (European Commission) in its 4th Framework Program under the topic: "Environment and Climate." The study project lasted two years, from 1998 to 2000.^{380) 381) 382)}

CLOUDS is proposed as a monitoring mission to perform measurements (accurate, comprehensive, consistent and frequent information on cloud structures and associated radiative parameters) necessary to describe cloud-radiation interaction in operational models for climate and long-term weather prediction. Its strategic objective is to extend the overall European service of climate monitoring from Space, beyond what is achievable by the in-

³⁷⁹⁾ Note: A photometer is usually a broadband instrument capable of measuring thermal continuum radiation (i.e. flux) thereby permitting the study of energy balance and surface composition (also detection of infrared roughness of surface features)

³⁸¹⁾ B. Bizzarri, M. Desbois, C. Stanfuss, J. Murray, J. Russell, C. Naud, A. Gasiewski, K. Künzi, et al., "Scientific background for CLOUDS - a Cloud and Radiation Monitoring Satellite, the EOS/SPIE Symposium on Remote Sensing, Sept. 25-29, 2000, Barcelona, Spain, SPIE Vol. 4168-08

³⁸²⁾ <ftp://romatm9.phys.uniroma1.it/pub/clouds/report/>

strumentation presently foreseen for MSG and MetOp/EPS, whose mission definition has been driven by nowcasting and short-medium term weather prediction.

The CLOUDS bus is derived from the PRIMA bus of ASI for small-medium class satellites. Commonality of the ground segment with MetOp/EPS is envisaged.

Note: In 2000, the CLOUDS proposal was submitted to ESA in response to its “Call for Ideas” on future Earth Explorer Core Missions. But unfortunately, CLOUDS was not selected because of very tight budgets. Instead, the EarthCARE (Earth Clouds Aerosol and Radiation Explorer) mission proposal was selected (however, not yet approved) which is considered more promising because of its passive and active payload mix of instruments, expected to be “more advanced” and to yield a better observation data return. EarthCARE seems to be on its way to become a cooperative ESA/NASDA venture. - ESA stated that the CLOUDS proposal should again be submitted, but in the context of its Earth Watch program (the outcome will be known in mid 2002). In the meantime (2001), an attempt is being made to fly the various well-defined CLOUDS instruments on different smaller missions, all of which are in their proposal states. - Against my practice of including only “approved missions” into my documentation, I am including the CLOUDS project because of its clarity in concept and its balanced instrument complement on the topic of “clouds.” A lot of effort has been invested into the definition phase. The CLOUDS instruments will eventually show up in other missions. Hence, their description in this context may still be of benefit to all concerned.

Figure 10: Illustration of the proposed CLOUDS spacecraft

Payload resource requirements	
Payload total mass	350 kg (including payload data handling and transmission)
Electrical power requirement	400 W
Data rate at instrument output	747.8 kbit/s
Spacecraft parameters	
Spacecraft dimensions, design life	3.2 m x 2.0 m x 1.5 m, 5 years
Satellite mass	900 kg
S/C power	1600 W (peak), 1400 W (average), 10 m ² solar array size
S/C stabilization	Three-axis stabilized
Attitude sensors	2 magnetometers, 2 star sensors, 4 gyros
Attitude actuators	3 magnetic torquers, 4 reaction wheels
Pointing performance	Accuracy: 350 μ rad, stability = 20 μ rad/s

Communication capacity	
Mass memory of temporary storage	670 MByte (including RS-coding)
Data rate for global downlink	30 Mbit/s (X-band)
Uplink data rate	2 kbit/s (S-band)
Data rate of local read-out	1.1 Mbit/s in S-band (including Viterbi-coding)

Table 55: Overview of spacecraft parameters

Orbit: Sun-synchronous circular orbit, altitude = 840 km, inclination = 98°, period = 101.7 minutes, local equator crossing time at 10:00. The mission scenario calls for CLOUDS to co-orbit with MetOp, de-phased by 30 minutes.

Sensor complement:

The CLOUDS payload includes six radiometers, composed of four instruments integrated into one assembly, named CIOP (CLOUDS Integrated Optical Payload), and two MW/Sub-mm instruments. Use is made of: a) passive radiometry over a wide region of the electromagnetic spectrum (UV to MW), b) different polarizations to determine 2-3 Stokes parameters in a number of channels, c) fore- and aft-viewing capability for all channels and multi-angle viewing for one channel. For reasons of synergy, all instruments are of the conical-scanning type. In addition, all instruments feature in-flight calibration, and co-registration with accuracy requirement, ranging from 1/16 to 1/2 of a pixel.

Figure 11: Geometry of conical scanning

CIOP instruments: The four CIOP instruments, covering the range UV/VIS/NIR/SWIR/TIR/FIR, are integrated into a single rotating drum performing conical scanning with a scan speed of 1 scan per 8 seconds. The optical viewing geometry corresponds to: 45° off-nadir (MAVIR actually covers the range 21-57°) observing the target under a zenith angle ζ of 53.2° (MAVIR in the 23.9 - 71.7° range), with two arcs over $\pm 45^\circ$ fore- and aft-views for a swath width of about 1400 km (the MAVIR swath changes with viewing angle). When viewing the side arcs, calibration devices are observed.

CASIR (Clouds and Aerosol Shortwave Imaging Radiometer). The 10-channel instrument collects all narrow-band short-wave channels. The main objectives are:

- To perform basic clouds observations with emphasis on liquid/ice discrimination and drop size evaluation at the cloud top, and cloud optical thickness

- To observe aerosol over sea and land, with possible inference of gross vertical distribution
- To complement the broadband coarse-resolution Earth radiation budget observation in the short-waves, by observing components at finer spatial and spectral resolution.

Additionally, some Earth surface parameters are observed such as: albedo, PAR (Photosynthetically Active Radiation), FPAR (Fractional PAR), NDVI (Normalized Difference Vegetation Index), LAI (Leaf Area Index), and short-wave radiative fluxes (in association with BERIR and MAVIR).

1,610 nm, SWIR	30 nm	200	630	not required	-

Table 56: CASIR instrument parameters and expected performances

CASIR is composed of four different objectives, each with its detectors in the focal plane. The UV, VIS and NIR channels operate with 2-D array Si-CMOS detectors, the SWIR channels are cooled to -25°C, using 2-D CMT arrays. Band separation and polarization are obtained by bandpass filters and polarizers located closely to the FPA of each detector. Two UV bands feature the TDI (Time Delay Integration) scheme to meet the SNR requirements.

CIRIR (Clouds InfraRed Imaging Radiometer). The 10-channel instrument collects the narrow-band channel radiation in TIR and FIR. The objectives are:

- To observe clouds with emphasis on cloud top height, cloud emissivity, liquid/ice discrimination at cloud top, and thin cirrus cloud detection
- To observe layer-integrated water vapor, including low-level
- To complement the broadband coarse-resolution Earth radiation budget observation in the long waves, by observing components at finer spatial and spectral resolution.

Additionally, some Earth surface parameters are observed such as: SST (Sea Surface Temperature), ATI (Apparent Thermal Inertia), indicative of soil moisture, derived in association with CASIR and, in association with BERIR, long-wave radiative fluxes.

The CIRIR instrument features uncooled microbolometer detectors. However, long integration times are needed (>10 ms) with this design. For the WV (Water Vapor), TIR (Thermal Infrared) and FIR (Far Infrared) channels, an in-field bands separation is realized by means of different bandpass filters disposed close to different regions of each array detector. One blackbody and the view of space through a mirror provide calibration during the lateral arcs of the scanning path not used for measurements. In addition, CIRIR is able to view the calibration unit of BERIR for intercalibration.

The MIR channel of CIRIR is sampled at 5 km resolution to improve the co-registration accuracy between CIRIR and CASIR, all other channels have a 10 km spatial resolution. Full synergy (co-registration and identical observing conditions) with cloud observation in short-wave channels (CASIR) is preserved by the use of the same scanning and viewing scheme.

IFOV	Cha. 3.7 μm: 0.175°, providing a footprint of 6.5 km x 3.9 km, equ. to a 5 km circle All other cha: 0.35°, providing a footprint of 13 km x 7.8 km, equ. to a 10 km circle

Table 57: CIRIR instrument parameters and expected performances

BERIR (Broadband Earth Radiation Imaging Radiometer). The instrument features two broadband channels, one for total reflected radiation, the other for total energy measurement from UV to FIR. The overall objective is to observe the outgoing short-wave and long-wave radiative flux at the top of the atmosphere. Additionally, Earth surface radiative fluxes are observed in association with CASIR, CIRIR and MAVIR.

The BERIR design is derived from CERES of NASA. Since the detectors employed (bolometers) exhibit relatively slow response times and low detectivity, an integration time of 40 ms is needed along with an equivalent IFOV of 40 km. No polarizations are needed. The BERIR total-wave and short-wave (SW) channels are realized using two optical heads of CERES with minor modifications. Also, the CERES ICM (Internal Calibration Module) is used at each scan stroke. ICM contains a grooved blackbody source for the total-wave channel and a tungsten lamp for the short-wave channel. The total-wave channel also looks at the CIRIR blackbody and at a space reference during each scanning stroke for better offset evaluation and to permit an intercalibration between all infrared channels.

IFOV	1.4° providing a footprint of 52 km x 31 km, equivalent to a 40 km circle			
Scanning	Conical: ($\alpha=45^\circ$, $\zeta=53.2^\circ$), fore- and aft-views by $> \pm 45^\circ$ in azimuth, swath width = 1400 km			
Sampling	1 scan per 8 s, 1 detector/channel, readings at 40 ms intervals			
Optics	L=18 mm, f/1.8			
Detectors	One uncooled thermistor/bolometer per channel			
Data rate	0.6 kbit/s + HK			
Spectral parameters

0.3 - 100 μm , total	0.3 $\text{Wm}^{-2} \text{sr}^{-1}$	0.15 $\text{Wm}^{-2} \text{sr}^{-1}$	0.5 $\text{Wm}^{-2} \text{sr}^{-1}$	0.6 $\text{Wm}^{-2} \text{sr}^{-1}$

Table 58: BERIR instrument parameters and expected performance

Full synergy (accurate co-registration and identical observing conditions) with the narrow-band channels is maintained with the same scanning mode and viewing geometry.

MAVIR (Multi-Angle VIS Imaging Radiometer). MAVIR is complementary to BERIR. The instrument operates in a single, relatively broad channel, mostly covering the VIS range. Its objective is to complement the broadband and short-wave solar reflected radiation information by the measurement of bi-directional reflectance properties at a spatial resolution consistent with cloud structures. In addition, Earth surface radiative fluxes are observed in association with CASIR, specifically the short-wave radiative parameters: PAR, FPAR, NDVI, and LAI.

IFOV	0.175° providing a footprint of 6.5 km x 3.9 km, equivalent to a 5 km circle ($\alpha = 45^\circ$)		
Scanning	Conical, four viewing angles, fore- and aft-views by $> \pm 45^\circ$, swath changing with viewing angle (1400 km for $\alpha=45^\circ$)		
Sampling	1 scan per 8 s, 8 detector/channel, readings at 5 ms intervals		
Optics	L=3.2 mm, f/2.7		
Detectors	Linear CCD		
Data rate	86.4 kbit/s		
Spectral parameters			
Channel	Viewing angles	Radiometric accuracy (required)	Radiometric accuracy (estimated)
0.4 - 1.0 μm (VNIR)	$\alpha = 21^\circ, \zeta = 23.9^\circ$ $\alpha = 33^\circ, \zeta = 38.1^\circ$ $\alpha = 45^\circ, \zeta = 53.2^\circ$ $\alpha = 57^\circ, \zeta = 71.7^\circ$	SNR=200 @ 10% albedo	SNR=273 @ 10% albedo

Table 59: MAVIR instrument parameters and expected performance

MAVIR is implemented using a linear silicon CCD array in the FPA of a wide-angle telescope covering nadir angles in the range of 20° - 60°. Four series of eight detectors are active, centered in correspondence of the selected nadir angles. MAVIR synergy with BERIR and all other instruments is provided with one viewing angle being the same ($\alpha = 45^\circ$) for the conical scanning geometry.

MW/Sub-mm instruments: The two MW/Sub-mm instruments perform conical scanning at a uniform rate of 1 scan per 2 seconds. The viewing geometry is identical to that of the optical payload (45° off-nadir - observing the target under a zenith angle ζ of 53.2°, with two arcs over $\pm 45^\circ$ fore- and aft-views for a swath width of about 1400 km). The scan-rate of one scan per 2 s provides contiguous along-track coverage by a single feed for most channels. The 89 GHz channel, required at 5 km IFOV, implies the use of two parallel feeds. Along-track sampling assures a 10% overlap between adjacent IFOVs by using 1.25 ms intervals (5 km) or 2.5 ms (10 km). For low frequencies, the IFOV degrades with the diffraction law; hence, the integration time is progressively increased.

CIWSIR (Cloud Ice and Water-vapor Sub-mm Imaging Radiometer). The instrument objectives are:

- To observe cloud ice with a higher penetration capability than in the optical range
- To be able to discriminate the water phase in the cloud interior
- To infer convective penetration in the troposphere through differential water vapor optical depth.

IFOV	0.35° providing a footprint of 13 km x 7.8 km, equivalent to a 10 km circle			
Scanning	Conical ($\alpha=45^\circ$, $\zeta=53.2^\circ$), fore- and aft-views by $\pm 45^\circ$ in azimuth, swath=1400 km			
Sampling	1 scan per 2 s, 1 feed/channel, readings at 1.25 ms intervals			
Antennas	L=40 cm for channels 150-220 GHz, L=16 cm for channels 463-874 GHz			
Detection	Subharmonic Schottky mixers for mm-channels, pumped mixers for sub-mm channels			
Resources	Mass = 79 kg; cylindrical volume: 110 cm diameter, height=43 cm; electrical power = 110 W; data rate = 83.2 kbit/s + HK			
Channel center frequency (GHz)	Bandwidth $\Delta\nu$	Polarizations	NEAT (required)	NEAT (estimated)
874.38 \pm 6.0	3.0 GHz	two	1.0 K @ 240 K	2.0 K @ 240 K

150	4.0 GHz	two	1.0 K @ 300 K	0.6 K @ 300 K

Table 60: CIWSIR instrument parameters and expected performance

The CIWSIR instrument is a six-frequency, 13-channel microwave radiometer with seven channels in the mm-range (water vapor) and six channels in the sub-mm-range (ice in clouds). Two quasi-optical multiplexers are implemented for the beam-splitting function (one for mm channels, one for sub-mm channels) using dichroic plates. The separation of the two polarizations (H and V) employs wire grids which offer low losses and almost frequency-independent performance.

The instrument features also two built-in calibration systems utilizing ambient temperature loads and cold space (2.7 K) as references. The sub-mm channels employ pumped Schottky mixers for maximum sensitivity (quasi-optical diplexers are used for LO coupling). Subharmonic mixers are employed for the mm-wave channels. Synergy with the optical payload is provided with the same viewing geometry.

Figure 13: Schematic view of the CIWSIR instrument

Figure 14: Schematic view of the CLAPMIR instrument

CLAPMIR (Cloud Liquid-water And Precipitation Microwave Imaging Radiometer). The instrument includes MW channels in window and absorption bands. The main objectives are:

- To observe cloud liquid water, precipitating and non-precipitating, with inference of drop size
- To be able to discriminate the water phase in the cloud interior and to measure total-column vapor
- To infer a gross vertical profile of liquid/precipitating water cores as linked to air temperature.

The instrument features an offset parabolic reflector of 1.6 m x 1.4 m in size, illuminated by a cluster of feeds. The reflector and feed horn antenna are mounted on a drum containing the receivers, a digital data unit, mechanical balancing subsystem, and power supply. The drum assembly is rotated about the instrument axis by a coaxially mounted bearing and brushless DC motor. All information (commands, timing and telemetry signals) and power pass through the rotating part of the stator via a dedicated assembly. A calibration system with two calibration targets (cold space view and an internal hot blackbody load) permits a period end-to-end calibration of the receiving chains for all channels. The receiving channels are configured as total-power radiometers with direct detection. The polarimetric channels are designed to provide the third Stokes parameter by means of adding analog correlators. Synergy with the optical payload and with CIWSIR is provided with the same viewing geometry.

Table 61: CLAPMIR instrument parameters and expected performance

A.8 CloudSat

A NASA/CSA (USA/Canada) cooperative mission in the (ESSP) Pathfinder program. CloudSat's primary goal is to furnish data needed to evaluate and improve the way clouds are represented in global models, thereby contributing to better predictions of clouds and thus to their poorly understood role in climate change and the cloud-climate feedback [focused on understanding the role of optically thick clouds on the Earth's radiation budget (a

balance of solar energy reaching the Earth and lost to space that ultimately controls the temperature of the Earth)]. In the cooperative arrangement, NASA provides the S/C (a variant of the BCP 2000 bus of BATC), major portions of the cloud-profiling radar including integration and test of the radar system, and the S/C launch, while CSA (Canadian Space Agency) provides additional components of the advanced cloud-profiling radar. Other partners in the program are: CIRA (Cooperative Institute for Research in the Atmosphere) of CSU (Colorado State University) handles data processing and distribution during the mission operations phase (archiving after the mission will be the responsibility of a NASA DAAC); ground operations and communications are provided the USAF/STP (Space Test Program), and the U.S. Department of Energy provides ground and aircraft-based observations for validation. In addition, members of the Science Team, including non-USA members, are contributing additional ground and aircraft-based measurements for validation. The CloudSat mission and payload development is managed by NASA/JPL.

Figure 15: Illustration of the CloudSat spacecraft

CloudSat fills a significant gap in the existing and planned Earth observation missions by measuring the vertical profile of clouds using active remote sensing (94 GHz radar). The CloudSat S/C flies on-orbit in tight formation with a NASA lidar satellite, which carries a dual-wavelength backscattering (polarization-sensitive) lidar. The CloudSat orbit will be adjusted to hold a fixed distance of about 460 km (about 60 s delay) with respect to the lidar satellite, with an option to decrease this distance to a 15 second separation. The sensors of both S/C point into the same ground track. The footprint of the radar is expected to overlay the footprint of the lidar by about 50%, or more, of the time and will always be within 2 km. It is planned that the two satellites fly in formation with the Aqua S/C (EOS-PM) such that

384) <http://cloudsat.atmos.colostate.edu/cs.4.html>

385) G. L. Stephens, D. G. Vane, S. J. Walter, "The CloudSat Mission: A new Dimension to space-based Observations of Cloud in the coming Millennium," paper presented at the GCSS-WGNE Workshop, Fort Collins, CO, Nov. 9-13, 1998

386) <http://essp.gsfc.nasa.gov/cloudsat.html>

the radar and lidar footprints will always fall in the central 36 km of the Aqua-MODIS swath.

The CloudSat S/C (built by Ball Aerospace) uses a RS200 series bus of QuikSCAT and ICE-Sat heritage. The S/C is three-axis stabilized, the ADCS (Attitude Determination and Control Subsystem) uses a star tracker, reaction wheels, and a GPS receiver with C/A code; the pointing accuracy is $< 0.07^\circ$, two-axes, 99.7% probable; the geolocation knowledge of the radar footprint position is better than 1 km on the geoid, two-axes, 99.7% probable. The S/C mass is < 999 kg. The planned mission operational life of CloudSat is 2 years to enable more than one seasonal cycle to be observed. The design life of both the spacecraft and radar exceeds two years, and consumables are carried for a three-year mission, enabling an extended mission if funding is provided. A launch of CloudSat on a Delta 7420-10 launch vehicle, co-manifested with the NASA lidar mission, is projected for 2004.

Orbit: Sun-synchronous near-circular “frozen” orbit [same orbit as Aqua (EOS/PM)], altitude = 705 km, inclination = 98.2° .

Formation flying: Formation flying is a navigation strategy that enables CloudSat to closely track the groundtracks of the lidar spacecraft and Aqua in a very precise way. After launch, maneuvers within the first 45 days of the mission will bring the CloudSat spacecraft into formation with the other two spacecraft. The CloudSat orbit will be adjusted and monitored to hold the CloudSat spacecraft at a fixed distance/time from the lidar S/C. CloudSat will be controlled so that the mean separation between the satellites is approximately 460 kilometers which corresponds to approximately 60 seconds delay between lidar and radar measurements. The chosen delay is a compromise between the desire to minimize the time delay between the radar and lidar measurements and the need to hold the frequency of formation flying maintenance maneuvers to an interval of once per week or longer. In this way, the radar footprint will spatially overlay the lidar footprint much of the time, creating coordinated and essentially simultaneous measurements. It is believed that this time separation can, with further study, be reduced to as little as 15 seconds.

RF communications: CloudSat is controlled from a USAF facility using the Air Force Satellite Control Network (AFSCN). The payload data is downlinked at 1 Mbit/s and relayed to the control center, where it is sent to CIRA for processing into data products.

Sensor complement:

CPR (Cloud Profiling Radar), joint development by NASA/JPL and CSA. The objective is to provide information on the vertical structure of all cloud systems. CPR is a 94 GHz nadir-looking radar that measures the power backscattered by clouds as a function of distance from the radar. The overall design of the CPR consists of the following subsystems: RFES (Radio Frequency Electronics Subsystem), HPA (High Power Amplifier), Antenna Subsystem (Quasi-Optical Transmission Line), and DSS (Digital Subsystem). The RFES consists of an up-converter which generates a pulsed signal and up-converts it to 94 GHz. The signal is amplified to about 200 mW by a state-of-the-art MMIC power amplifier. The receiver portion of the RFES down-converts the signal to an IF (Intermediate Frequency). The IF signal is detected using a logarithmic amplifier (high dynamic range). The receiver noise level is critical in achieving the required sensitivity. The HPA consists of EIK (Extended Interaction Klystron) and a high-power voltage supply; it amplifies the transmitted pulse to a power level of 1.5 kW. This family of EIKs has been used extensively in existing ground-based and airborne 94 GHz cloud radars. The antenna is a fixed 1.85 m diameter reflector of composite graphite material to reduce mass. The antenna provides > 62 dBi gain, has a beamwidth of $< 12^\circ$, and has sidelobes < -50 dB for angles $> 7^\circ$ from boresight. The quasi-optical transmission line (QOTL) replaces the conventional waveguide and circulator for sending power from the HPA to the reflector and sending received power to the receiver subsystem. Waveguides are replaced by mirrors and free-space propagation, while the circulator duplexing function is handled by a polarizer and Faraday rotator. The advan-

tage of the QOTL over conventional waveguide and circulator is reduced loss, important for meeting sensitivity requirements. The DSS provides the command, control, and telemetry interface to the S/C. It includes a Control and Timing Unit and a data handling unit that accepts the analog signal from the RFES logarithmic detector. It digitizes it and performs the required sample averaging of 0.16 s.

To detect the low reflectivity of clouds, the CPR averages many samples of the measured power and subtracts the estimated system noise level. The number of independent samples can be increased by increasing the PRF (Pulse Repetition Frequency). However, the maximum PRF is given by the range ambiguity considerations. For CPR, the nominal range window size is set to 30 km, permitting the capture of the surface return and cloud return up to an altitude of 25 km. The system noise level is estimated using the clear air radar return from 25 to 30 km altitude. The radar footprint is 1.4 km, and is averaged over 0.16 seconds to produce an effective footprint of 2.5 km (along-track) by 1.4 km (cross-track).

Parameter	Short Pulse (SP) Operation
Nominal frequency	94 GHz
Pulse width	3.3 μ s
PRF	about 4300 Hz
Data window	0-25 km
Vertical range resolution	500 m
Cross-track resolution	1.4 km
Along-track resolution	2.5 km
Antenna size	1.85 m
Dynamic range	70 dB
Peak power	1.5 kW
Bandwidth	0.3 MHz
Integration time	0.16 s
Along-track sampling	1.1 km
Data rate	20 kbit/s
Instrument mass, power	230 kg, 270 W

Table 62: CPR instrument parameters

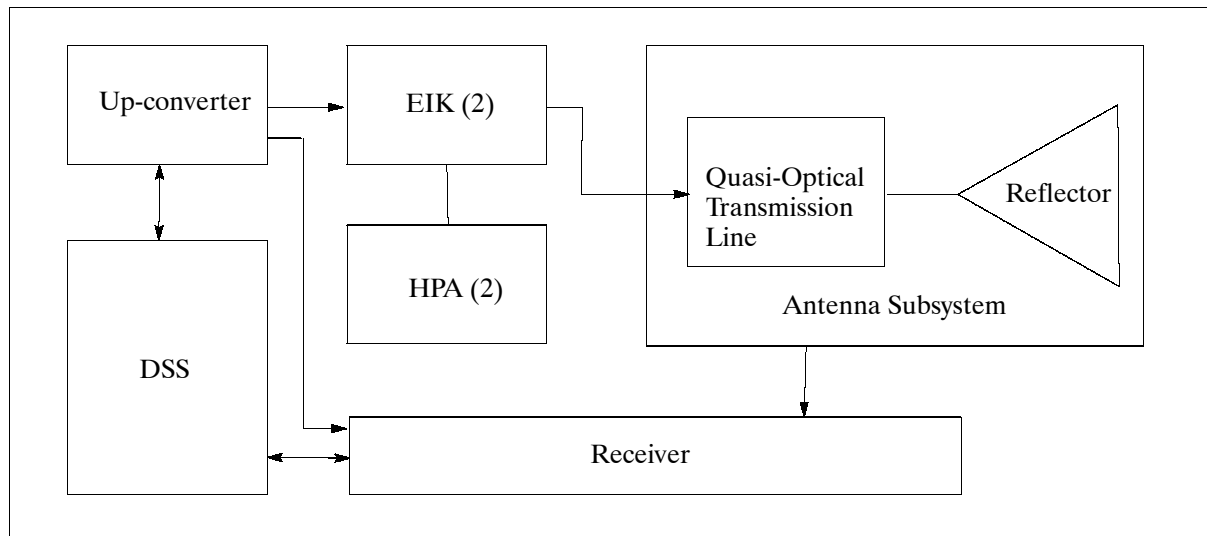

Figure 16: Simplified block diagram of CPR

Validation of the data products will use remote sensing measurements from surface and airborne platforms together with in-situ aircraft measurements of relevant cloud parameters as well as matching aircraft data with satellite data after launch. The validation strategy also involves the exploitation of existing cloud data bases. The CloudSat validation plan benefits

from the systematic measurement programs of ARM as well as selected sites within Europe, regular aircraft radar measurement activities within the USA, Japan and Europe, measurement capabilities at a number of universities, and field-experiment activities representing targets of opportunity are planned in the coming years.

A.9 COMPASS

COMPASS³⁸⁷⁾ is a Russian microsatellite mission, funded by Rosaviakosmos, the Russian Academy of Sciences, and the Science Ministry; it is designed and developed at IZMIRAN (Institute of Terrestrial Magnetism, Ionosphere and Radio Wave Propagation of the Russian Academy of Sciences), Moscow, and at Makeev's Federal Rocket Center. The overall objective is to demonstrate possible topside sounding techniques that may eventually lead to the forecasting of natural disasters such as earthquakes. Specific objectives are:

- To develop coordinated monitoring methods (spaceborne and ground-based) to observe pre-earthquake phenomena
- To develop methods to monitor man-made catastrophes in general
- To study the dynamic coupling of the atmosphere, ionosphere and magnetosphere systems
- To acquire technical experience and know-how in the design and development of low-cost microsatellite building.^{388) 389)}

Figure 17: Illustration of the COMPASS microsatellite

The COMPASS spacecraft bus has the shape of an inverted (nadir looking) pyramid containing the instrumentation. Two deployable solar panel wings (total area of 1 m²) are zenith facing. The S/C is three-axis stabilized. Attitude is sensed by sun sensors and by a DC

magnetometer. Actuation is provided by three magnetic torquers and by a gravity-gradient boom. A pointing knowledge of about 1° is provided. Real-time orbit determination and on-board timing services are provided by a GLONASS/GPS receiver system. The solar power provided is 50 W (EOL) and 27 V. The NiCd battery subsystem has a capacity of 4 Ah. The OBC (On-board Computer) provides all control and processing functions required. On-board data storage of 512 Mbit is available. The S/C mass is 64 kg. The design life is five years.

A launch of COMPASS is scheduled for 2001 on a Zenit-2 launch vehicle from the Baikonur Cosmodrome, Kazakhstan. The prime payload on this flight is Meteor-3M-1. COMPASS is a secondary payload along with Badr-2 satellite of Pakistan, Maroc-TUBSAT of Morocco, and REFLECTOR (USA/Russia).

Orbit: Sun-synchronous circular polar orbit, mean altitude = 830 km, inclination = 98.85° , period = 102 minutes; local time of ascending node is 9:15 AM

RF communication: A VHF (8 W, 137 MHz transmitter) amateur-standard data link is provided with a data rate of 64 kbit/s. The functions of data acquisition and mission control are performed at IZMIRAN, Troitsk (Moscow region).

Sensor complement:

NVK-ONCH (Low Frequency Wave Analyzer). The instrument is a cooperative development of IZMIRAN, Eötvös University, Budapest, and the Lvov Center of Space Research, Ukraine. The objective is the measurement of the electric and magnetic vector components of the low-frequency radiation in the range of 8 Hz to 20 kHz.

RFA (High Frequency Wave Analyzer), a cooperative experiment of IKI (Space Research Center), Moscow, the Polish Academy of Sciences, Warsaw, and IZMIRAN. The objective is the high-frequency spectrum analysis of the electromagnetic radiation in the range of 0.1 - 15.1 MHz.

FM-3K (Fluxgate Magnetometer), developed at IZMIRAN. The objective is the measurement of the three vector components of the magnetic field.

GIT-12T (GLONASS/GPS Receiver System) of IZMIRAN. The objective is to provide radio-tomography (measurement of the TEC distribution) and orbit determination (position to within 30 m, velocity to within 10 cm/s). GIT-12T has 12 channels to track 12 GPS or GLONASS satellites in parallel.

PR41/53 (UHF Receivers), developed at IZMIRAN and the Technical Institute, Athens, Greece. The objective is the measurement of radio waves at 41 MHz and at 53 MHz.

A.10 Coriolis

Coriolis is a US DoD satellite demonstration mission within STP (Space Test Program), sponsored by ONR (Office of Naval Research) and NPOESS/IPO, and managed and implemented by NRL (Naval Research Laboratory). The overall objective is to conduct an operational verification of new instrument technology, aimed at validating space-based multi-channel polarimetric radiometry as a reliable and cost effective means for achieving wind vector measurements that meet NPOESS requirements. A further objective of the Air Force is to monitor solar activity for better predictive models of solar storms.³⁹⁰⁾

Coriolis is a fully redundant three-axis stabilized spacecraft (nadir pointing) built by Spectrum Astro Inc. of Gilbert, AZ. The S/C bus is based on the SA-200HP catalog bus, an Al honeycomb/Al facesheet deck structure, as flown on DS1, with specific tailoring to suit the

³⁹⁰⁾ <http://www.spectrumastro.com/PDFs/Coriolis.PDF>

Coriolis requirements. The overall dimensions are: 4.69 m height (without solar array), 1.34 m diameter. Power is provided by a solar array assembly (1.174 kW) and by a single 50 Ah NiH₂ battery for ecliptic period operations. Attitude sensing is provided by autonomous sun acquisition using coarse sun sensors and magnetometers, actuation is provided by reaction wheels. A hydrazine propulsion system is used for orbit transfer. The S/C has a total mass of 827.4 kg (S/C bus of 377 kg), the design life is three years.

A launch of Coriolis is planned for spring 2002, aboard a Titan 2 rocket.

Communications: An on-board solid-state recorder of 30 Gbit capacity is provided. TT&C communications are provided in S-band. Instrument data are downlinked in X-band at 51.2 Mbit/s.

Orbit: Sun-synchronous circular orbit, altitude = 830 km, inclination = 98.7°, revisit time of 8 days, the longitude of the ascending node shifts westward by 138 km daily.

Figure 18: The Coriolis S/C model

Sensor complement:

WindSat (Wind Microwave Radiometer), a polarimetric microwave radiometer developed and built by NRL.³⁹¹⁾ WindSat is also considered a precursor instrument to CMIS (Conical-scanning Microwave Imager/Sounder), a radiometric polarimeter to be flown on NPOESS (National Polar-orbiting Operational Environmental Satellite System). The objective of WindSat is to conduct an operational demonstration of the WindSat system and to measure the ocean surface wind vector (speed and direction) for a number of practical applications (secondary measurements are sea surface temperature, rain rate and water vapor). WindSat also provides insight into such problems as the upwind/downwind asymmetry and boundary layer conditions.

³⁹¹⁾ <http://windsat.pxi.com/>

The measurement principle makes use of the natural microwave emissions of the sea surface which vary with the degree of sea surface roughness. The rougher the seas, the more intense the emissions. The wind direction is obtained from the relationship between the horizontal and vertical polarization characteristics of the received signal and the anisotropic distribution of wind-driven waves.

WindSat is a 22-channel polarimetric radiometer operating at the frequencies of 6.8, 10.7, 18.7, 23.8, and 37 GHz. The receivers at 10.7, 18.7 and 37.0 GHz are fully polarimetric; that is, they establish all four Stokes parameters by measuring the six principal polarizations. The 6.8 GHz channel is dual-polarimetric (vertical and horizontal) and provides sea surface temperature (SST) as a secondary product. The 23.8 GHz channel is also dual-polarimetric, its purpose is to correct for atmospheric water vapor which is unpolarized.. The WindSat frequencies are useful beyond the measurement of ocean surface wind vectors and SST. Other parameters can be extracted/estimated from the data such as: atmospheric water vapor, cloud liquid water, rain rate, sea ice (age, concentration, and boundary), snow cover extent, and water content of snow. ³⁹²⁾

Capability	NPOESS requirements	WindSat
Horizontal resolution	20 km	25 km
Mapping accuracy	5 km	5 km
Measurement range	3 - 25 m/s, 0 - 360° (direction)	3 - 25 m/s, 0 - 360° (direction)
Measurement precision Speed Direction	1 m/s 10°	1 m/s 10°
Measurement accuracy Speed Direction	greater of ± 2 m/s or $\pm 20\%$ $\pm 20^\circ$	greater of ± 2 m/s or $\pm 20\%$ 3-5 m/s: $\pm 20^\circ$

Table 63: Performance comparison of NPOESS requirements and WindSat parameters

Figure 19: Illustration of the WindSat instrument

³⁹²⁾ K. M. St. Germain and P. W. Gaiser, "Space borne polarimetric radiometer and the WindSat Coriolis mission," Proceedings of the IEEE Aerospace Conference, IEEE Catalog No. 00TH8484C, March 2000.

WindSat uses a conically scanned 1.83 m parabolic offset reflector with multiple feeds. A forward swath width of 1025 km is obtained from an orbital altitude of 830 km. The placement of external calibration targets allows for an aft swath of 400 km. The availability of fore and aft swaths enables evaluation of one-look versus two-look wind vector retrievals. The WindSat instrument has not-to-exceed limits of 340 kg for mass and 350 watts of power.

SMEI (Solar Mass Ejection Imager) is being designed and built by an international consortium comprising the University of Birmingham, UK, the US AFRL (Air Force Research Laboratory), and the University of California, San Diego (UCSD). Funding is provided by NASA, AFRL and the University of Birmingham. SMEI is an all-sky camera experiment capable of imaging CMEs (Coronal Mass Ejections) as they propagate from the sun through the solar wind. The objective is to monitor solar activity (detection of transient clouds of hot ionized gases - referred to as plasma) with the goal of more accurately predicting geomagnetic disturbances as they can have a serious effect on Earth-orbiting satellites, electrical power distribution networks, and long-distance radio communication. ³⁹³⁾ ³⁹⁴⁾ ³⁹⁵⁾ ³⁹⁶⁾

Figure 20: Illustration of the SMEI camera configuration

SMEI is designed to monitor solar optical radiation which is scattered off the plasma cloud as it moves out from the sun (measurement of the size, shape, speed, frequency, energy flux, mass, and momentum of CMEs). The SMEI instrument consists of three wide-angle CCD cameras each of which has a fan-beam field of view of size $3^\circ \times 60^\circ$. The cameras with their baffles are mounted onto the S/C in such a way that the combined 180° long fan-beam of the three cameras sweeps around the entire sky once per orbit. The baffles reduce the amount of scattered sunlight reaching a camera by about 10 orders of magnitude when it is viewing a region near the sun. The CCDs are cooled to about -35°C by passive radiators. A common data handling unit (DHU), interfacing to the S/C telemetry and telecommand systems, col-

³⁹³⁾ <http://www.sr.bham.ac.uk/instrument/smei.html>

³⁹⁴⁾ <http://www.vsbs.plh.af.mil/projects/smei/smei.html>

³⁹⁵⁾ <http://www.vs.af.mil/factsheets/SMEI.html>

³⁹⁶⁾ B. V. Jackson, A. Buffington, P. Hick, S. W. Kahler, S. L. Keil, R. C. Altrock, G. M. Simnett, D. F. Webb, "The Solar Mass Ejection Imager," *Phys. Chem. Earth*, 22, 441, 1997

lects the data from all three cameras and controls their operation (a MIL-STD-1553B bus is used for communications). The DHU includes a powerful processor system which is based around the digital signal processor SMJ320C50 of TI, operating at 19 MIPS making extensive use of field programmable gate arrays. The flight software controls the data transfer between the cameras, data compression, data transfer from SMEI to the S/C telemetry system, and operational commands to SMEI from the ground. - The SMEI data is used to estimate the outbreak of CMEs (success means that 1-3 day warnings can be given with regard to Earth-intersecting solar shocks, etc.).

After the contribution of stars is removed, SMEI's basic product will be a 100 minute (one orbit) cadence of all-sky maps of heliospheric brightness flux with an angular resolution of about 1° and a photometric precision equivalent to the brightness of a 12th magnitude star.

A.11 CRRES (Combined Release and Radiation Effects Satellite)

The CRRES program is a joint NASA/MSFC DoD/USAF mission in the field of solar-terrestrial energy transport with the objective to study ionospheric and magnetospheric transport phenomena and to study the effects of the natural radiation environment on micro-electronic components (DoD).^{397),398)} The satellite mass is 1753 kg (payload = 678 kg including the chemical canisters), nominal spin rate = 2 rpm. The spacecraft was launched on an Atlas/Centaur vehicle from Cape Canaveral on July 25, 1990. The nominal mission duration is 3 years, the extended mission is planned for 6 years [in support of the GGS (Global Geospace Science) mission]. The joint NASA/DoD mission is scheduled to last one year after launch, followed by a two year DoD science mission. After the third year of operation the CRRES mission will become part of the GGS program. The satellite failed on October 9, 1991.

Orbit: Initial elliptical orbit of 350 km x 35584 km, referred to as the Geosynchronous Transfer Orbit (GTO), inclination = 18.15°, orbit period = 10.56 hrs. The CRRES orbit plane is designed to precess in local time coordinates [taking advantage of perturbations (J2 perturbation due to the Earth's oblateness and the apparent 1°/day motion of the sun) resulting in a new rotation of the orbit perigee and apogee toward earlier local time, as the mission proceeds. Apsidal rotation also produces a periodic variation (36° peak to peak) in the latitude of perigee with a period of about 525 days. These two motions, given the initial local time of apogee, determined when and where, in local time and latitude, significant mission events such as the chemical releases occurred.

Investigation	Experiment Code	Mass (kg)	Data Rate (bit/s)	Principal Investigator
Chemical Releases	NASA	890		16 PIs from 13 institutions
Low Altitude Satellite Studies of Ionosphere Irregularities (LASSII)	NRL-701	28.5	13616	P. Rodrriguez, NLR

Table 64: The CRRES S/C science payload

CRRES carries a complement of chemical release canisters to be released at certain times over ground observation sites, and diagnostic facilities. These releases form large clouds of

397) R. A. Cooper, D. H. Burks, "Space Physics Missions Handbook," NASA, Office of Space Science and Applications, Feb. 1991

398) Special Section on CRRES, Journal of Spacecraft and Rockets, Vol. 29, No. 4 July-Aug. 1992, pp. 555-617

metal vapor that interact with the ionospheric and magnetospheric plasma and the Earth's magnetic field. These interactions will be studied with optical, radar, plasma wave and particle instruments from the ground, from aircraft, and from the CRRES spacecraft.

Figure 21: The CRRES S/C model

The experiments performed near perigee are intended to further understanding of the interaction of plasmas with magnetic fields, the coupling of the upper atmosphere with the ionosphere, the structure and chemistry of the ionosphere, and the structure of low-altitude electric fields. Those experiments which are performed near apogee in the Earth's magnetosphere are intended to study the formation of diamagnetic cavities, coupling between the magnetosphere and ionosphere, and the effects of artificial plasma injections on the stability of the trapped particles in the radiation belts.

The on-board scientific experiments consist of 46 electronic boxes, 10 booms, and 24 chemical canisters (Ba, Li, Ca, and Sr). There are 16 PI's responsible for the 16 separate chemical releases (24 canisters) at various times during the CRRES mission. The three chemical release campaigns were:

- 1) low-altitude releases (near perigee) over the South Pacific in September 1990.
- 2) high-altitude releases (from 6000 to about 33,500 km) over North America in January and February 1991.
- 3) low-altitude releases over the Caribbean in July and August of 1991.

Sensor complement:

LASSII = Low-Altitude Satellite Studies of Ionosphere Irregularities (PI: P. Rodriguez, NRL). Objective: monitoring naturally occurring and artificially produced ionospheric perturbations and the effects of ionospheric perturbations on communication paths. Measurements are conducted near perigee of selected orbits. LASSII is composed of three plasma experiments:

- P³ = Pulsed Plasma Probe. A Langmuir probe experiment that operates as two pulsed plasma probes, measuring ionospheric electron densities and temperatures.
- QIMS = Quadrupole Ion Mass Spectrometer. Measurement of the densities of positive ions in both the natural ionosphere and in the chemical release experiments. Energy range from 500 keV to 100 MeV.
- ELFWA = Extremely Low Frequency Wave Analyzer. Measurement of the spectrum of the electric and magnetic field fluctuations (electric field spectra from 10 to 250 Hz, and single-axis magnetic field spectra from 10 Hz to 125 Hz).

EPIC = Energetic Particles and Ion Composition Experiment. EPIC consists of four instruments:

- IMS-HI = Ion Mass Spectrometer - High/Medium Energy. Measurement of energy spectra and pitch angle distributions of magnetospheric ions and neutral particles.
- IMS-LO = Ion Mass Spectrometer - Low Energy. Two instruments measure the composition of plasmas that are the sources of radiation belt particles, and provide data on the origin and acceleration processes of these plasmas. $E/q = 0.11\text{-}35$ keV/e, and M/q from 1-32 amu/e.
- EPAS = Electron and Proton Wide-Angle Spectrometer. It covers the energy range from 21 - 285 keV, and for protons from 37 keV - 3.2 MeV. EPAS consists of two units to measure electrons simultaneously in ten directions and ions in four directions over a total angle of about 100°.
- SEP = Spectrometer for Electron and Protons. SEP measures the energy and pitch angle distribution of energetic electrons and protons throughout the S/C orbit.

A.12 Dynamics Explorers (DE-1 and DE-2)

NASA/GSFC program with international cooperation on the payload.³⁹⁹⁾ Combined DE-1 and DE-2 launch on Aug. 3, 1981 with Delta vehicle from Vandenberg. Objectives: Study of the flow of solar energy and matter from space through Earth's magnetic field into the upper atmosphere (coupling of energy, electric currents, electric fields, and plasmas between the magnetosphere, ionosphere, and the atmosphere). The DE S/C have a spin rate of 10 rpm, mass = 424 kg (at launch), payload mass = 105 kg

Figure 22: The Dynamics Explorer S/C model

³⁹⁹⁾ R. A. Hoffman, G. D. Hogan, R. C. Maehl, "Dynamics Explorer Spacecraft and Ground Operating Systems," *Space Science Instrumentation*, 5, 1981, pp. 349-367

Orbit: Coplanar polar orbits;

- DE-1 (high altitude mission) 464 km x 23370 km highly elliptical orbit ; inclination = 90°
- DE-2 (low altitude mission) of 309 x 1012 km; inclination = 90° ; period = 101 min; DE-2 re-entered the atmosphere on Feb. 19, 1983.

The orbits of the two spacecraft rotate in local time, precess and decay throughout the mission. This permits investigations in a multitude of constellations.

A.12.1 DE-1 Instruments (High Altitude Mission)

MAG-1 = Magnetometer (PI: Seguria, MSFC).⁴⁰⁰⁾

Measurement of the vector magnetic field. Objectives include: observation of field-aligned currents, magnetospheric equatorial currents, and ULF waves.

The instrument is a triaxial fluxgate magnetometer. Resolution = ± 1.5 nT in basic mode. In addition there are two modes of higher resolution: ± 0.25 nT and ± 20 pT. The sampling rate is 16 vector samples per second in all modes.

PWI = Plasma Wave Instrument (PI: S. D. Shawhan, NASA).⁴⁰¹⁾

Measurement of electromagnetic waves and electrostatic waves (PWI can distinguish between electromagnetic and electrostatic phenomena and determines wave polarization and wave propagation direction). The quasi-static electric fields are measured parallel to the spacecraft spin axis in a range of 2 mVm^{-1} to 2 mVm^{-1} , and perpendicular to the spin axis 0.5 mVm^{-1} to 2 mVm^{-1} at 16 samples per second. The AC electric field sensors include a 200 m tip-to-tip long wire antenna. Frequency range of AC fields: 1 Hz - 2 MHz. Integrated into this instrument is a Linear Wave Receiver (LWR, from Stanford) measuring wave amplitude in the frequency range 1.5 - 16 kHz.

HAPI = High Altitude Plasma Instrument (PI: J. L. Burch, SWRI).⁴⁰²⁾

Objectives: measurement of the velocity-space distributions of electron and positive ions. Information on the hot-plasma effects of the coupling of energy, mass, and momentum within the Earth's atmosphere, ionosphere, and magnetosphere. HAPI consists of five electrostatic analyzers mounted in a fan-shaped angular array at angles of 45° , 78° , 90° , 102° , and 135° with respect to the S/C spin axis, each making simultaneous measurements of electrons and positive ions at up to 64 energy steps from 5 eV to 32 keV.

RIMS = Retarding Ion Mass Spectrometer (PI: C. R. Chappel, MSFC).⁴⁰³⁾

Measurement of thermal ion density, temperature bulk velocity, and ion composition. RIMS consists of three nearly identical sensor heads which contain a retarding potential analyzer, followed by a magnetic ion mass spectrometer with two channel electron multiplier detectors.

EICS = Energetic Ion Mass Spectrometer (heritage of ISEE and GEOS-1,-2 spectrometers, PI: E. G. Shelley, Lockheed).⁴⁰⁴⁾ Objective: measurement of the ion composition [energy and pitch angle distributions of the principal mass constituents (O^+ , H^+) of the upward flowing ions from the auroral acceleration region]. EICS is a high sensitivity ($\approx 1 \text{ cm}^2\text{-sr-eV}$) high resolution ($M/\Delta M \geq 10$ FWHM at focus) instrument. It covers the entire mass range from $< 1 \text{ amu/e}$ to $> 150 \text{ amu/e}$ in 64 mass channels at each of 32 energy per charge steps covering the range from 0 to $\sim 17 \text{ keV/e}$. Data are used to investigate the coupling between the magnetosphere and the ionosphere via the auroral acceleration region.

SAI = Spin-scan Auroral Imager (PI: L. A. Frank, U. of Iowa).⁴⁰⁵⁾ Measurement of visual and UV global auroral images. The instrument consists of three spanning photometers to view the dim emissions from Earth in the presence of strong stray light sources. The rotation of the S/C and the instrument scanning mirror provide a 2-D array of pixels comprising an image frame.

A.12.2 DE-2 Instruments (Low Altitude Mission)

MAG-2 = Magnetometer. Measurement of the vector magnetic field (see MAG-1).

VEFI = Vector Electric Field Instrument (PI: N. C. Maynard, GSFC)⁴⁰⁶⁾

Measurement of the vector electric field. Instrument: Six 11 m cylindrical antennas are deployed along three orthogonal axes to form the sensor array. Measurements of the DC electric field are made 16 times per second. A 20 channel comb filter spectrometer monitors the AC electric fields, concentrating on frequencies below 1 kHz.

NACS = Neutral Atmosphere Composition Spectrometer (of Pioneer heritage, PI: G. R. Carignan, U. of Michigan). Measurement of the abundances of neutral species (atomic oxygen, helium, argon, molecular nitrogen) over an altitude range of at least 100 km to 300 km upward in the Earth's atmosphere. The NACS instrument is a quadrupole mass spectrometer with electron bombardment ionization (an electron multiplier in the counting mode is used for detection).⁴⁰⁷⁾

WATS = Wind and Temperature Spectrometer (PI: N. W. Spencer, GSFC).⁴⁰⁸⁾

Measurement of vertical, zonal and meridional components of neutral wind. In addition, measurements of the concentration and velocity of the ambient thermal ions are possible. Instrument accuracies: concentration of neutral particles $\sim 20\%$; their temperature ~ 5 K.

FPI = Fabry-Perot Interferometer (PI: P. B. Hays, U. of MI).⁴⁰⁹⁾ Objective: Study of cross-sectional views of the dynamic and thermodynamic state of the thermosphere. Measurement of drift and temperature of neutral and ionic atomic oxygen in the thermosphere. FPI has a FOV of 0.53° (semi-cone angle) defined by a doublet objective lens and a field stop.

IDM = Ion Drift Meter (PI: R. A. Heelis, U. of Texas).⁴¹⁰⁾

Measurement of the components of the ion drift normal to the spacecraft velocity. Data are used in studies of the convection pattern and energy deposition in the ionosphere.

RPA = Retarding Potential Analyzer (PI: W. B. Hansen, Univ. of Texas).⁴¹¹⁾

Measurement of bulk ion velocity in the direction of spacecraft motion, the constituent ion concentrations and the ion temperature along the satellite path. In addition, the spectral characteristics of irregularities in the total ion concentration are determined.

LANG = Langmuir Probe (PI: L. H. Brace, GSFC).⁴¹²⁾

Measurement of electron temperature and density and ion density in the Earth's ionosphere (heritage of Pioneer Venus mission).

LAPI = Low Altitude Plasma Instrument (PI: R. Hoffman, GSFC).⁴¹³⁾

Objectives: measurement of high-resolution velocity-space distributions of positive ions

and electrons from 5 eV to 30 keV, and from 0° to 180° in pitch angle. The instrument contains an array of 15 parabolic electrostatic analyzers and two Geiger-Mueller counters mounted on a one-degree of freedom platform.

Data: On-board tape recorder (2 for each S/C). Science data transmission rate of 16.384 kbit/s.

A.13 ERBS (Earth Radiation Budget Satellite)

ERBS = Earth Radiation Budget Satellite. NASA Earth Radiation Budget Experiment (ERBE) Research Program (at GSFC). Launch of the free-flyer ERBS satellite from Space Shuttle Challenger: October 5, 1984 (STS-41G). ERBS was a three-axis momentum-biased S/C (1° pointing using magnetic torquers and a hydrazine backup system) built by Ball Aerospace Systems of Boulder, CO. The ERBS S/C structure was composed of three basic modules: the keel module, the base module, and the instrument module. The keel module was a torque-box structure providing structural support for the propulsion system, the solar array panels, and the antennas. The base module provided a direct interface to the Shuttle. S/C mass = 249 kg, power = 470 W. ERBS subsystems included TCS (Thermal Control Subsystem), EPS (Electrical Power Subsystem) which consisted of two 50 Ah, 22 cell NiCd batteries; PCU (Power Unit) for regulating electrical power; C&DH (Command and Data Handling Subsystem) for collection of instrument and S/C data for real-time transmission; CS (Communications Subsystem), which included NASA TDRSS transponders and antennas; AC&DS (Attitude Control and Determination Subsystem), a three-axis, momentum system for attitude pointing, maneuvers, and thruster control; and OAPS (Orbit Adjust Propulsion System), a non-propellant hydrazine propulsion system used for raising ERBS to its operating orbit after launch from the Shuttle. ERBS was held primarily in the Earth-pointing mode for most of the mission. Downlink data rate at 128 kbit/s, uplink through TDRSS using electrically steerable spherical array antenna. ⁴¹⁴⁾

Objective: Measurement of reflected and emitted energy at various spatial levels. Observations provide useful data for studies of geographical-seasonal variations of the Earth's radiation budget. Data are correlated with NOAA polar-orbiting TIROS S/C.

Orbit: Non-sun-synchronous circular orbit, altitude = 600 km, inclination = 57°, period = 96.4 min.

Status: As of June 2001 the ERBS mission is still operational after more than 16 years in orbit. However, the S/C is operational on only one battery. SAGE-II is operational, ERBE is only operational in periods of enough sunlight. Of the ERBE instrument only the non-scanner portion is still functioning (the scanner portion failed Feb. 28, 1990). ERBE is no longer capable of movement to the internal calibration position. The ERBE nonscanner was a real value, since it outlived its design lifetime of 3 years by a factor of 5! It continues to acquire data. The non-scanning data will be processed until Sept. 2001. Although the ERBS spacecraft would probably function beyond 2010, de-orbit plans are being developed for 2003. ⁴¹⁵⁾

Sensor complement:

ERBE (Earth Radiation Budget Experiment). ERBE is a multimission system of NASA/LaRC to measure the Earth's radiation budget [i.e., the balance between incoming energy

412) J. P. Krehbiel, L. H. Brace, W. H. Pinkus, R. B. Kaplan, et. al., "The Dynamics Explorer Langmuir Probe Instrument," Space Science Instrumentation, 5, 1981, pp. 493-502

415) Information provided by Jack Paden and Bob Lee of NASA/LaRC

from the sun and outgoing thermal (longwave and reflected shortwave) energy from the Earth]. The instrument package (designed and built by TRW, Redondo Beach, CA) consists of a ‘scanner’ and a ‘nonscanner’ unit, providing measurements on several spatial and temporal scales.

Figure 23: The ERBS S/C model

The nonscanner unit features four Earth-viewing channels and a solar monitor used for solar calibration measurements. The Earth-viewing channels have two spatial resolutions: a horizon-to-horizon view (wide FOV or WFOV), and a FOV limited to about 1000 km in diameter (also referred to as medium FOV, or MFOV). For MFOV and WFOV there is a total spectral channel sensitive to all wavelengths, and a shortwave channel which uses a high purity, fused silica filter dome to transmit only the shortwave radiation from 0.2 to 5 μm . All five channels of the nonscanner are active cavity radiometers. Data rate: 160 bit/s.

Nonscanner			
Channel Nr.	Spectral bands (μm)	Filter	Field of View (FOV)
1 (Wide FOV)	0.2 - 50+	None	Horizon - Horizon
2 (Wide FOV)	0.2 - 5	Suprasil-W Dome	Horizon - Horizon
3 (Medium FOV)	0.2 - 50+	None	10°
4 (Medium FOV)	0.2 - 5	Suprasil-W Dome	10°
5 (Solar monitor)	0.2 - 50 +	None	18° conical
Scanner			
6	0.2 - 5 (shortwave)	Suprasil-W Dome	3° x 4.5° (IFOV)
7	5 - 200 (longwave)	Diamond plus shortwave cutoff	3° x 4.5° (IFOV)
8	0.2 - 200		3° x 4.5° (IFOV)

Table 65: ERBE instrument parameters

The scanner instrument package contains three co-planar detectors (longwave, shortwave and total energy). Each detector scans the Earth perpendicular to the groundtrack from ho-

rizon to horizon. The detectors are thermistors (bolometers) which use space on every scan as a reference point to guard against drift. They are located at the focal point of a f/1.84 Cassegrain telescope whose aluminum-coated filters have been coated to enhance UV reflectivity. The IFOV for each channel is hexagonal, with an angular size of 3° (across track) x 4.5° (along track). Data rate = 960 bit/s.^{416) 417)}

SAGE-II (Stratospheric Aerosol and Gas Experiment II). Earth limb-scanning grating spectrometer (with a Dall-Kirkham telescope, two-axis gimballed system capable of rotating in azimuth). Objective: monitoring of concentrations and distributions of stratospheric aerosols, nitrogen dioxide, and water vapor. SAGE-II is a 7 channel radiometer. Spectral range: 0.385 - 1.020 μm . Data rate = 6.3 kbit/s. The instrument provides self-calibrating near global measurements. - The measurements are inverted using the “onion-peeling” approach to yield 1 km vertical resolution profiles of aerosol extinction (at 0.385, 0.453, 0.525, and 1.02 μm). The focus of the measurements is on the lower and middle stratosphere.

A.14 ESSP-3 (Earth System Science Pathfinder-3)

ESSP-3 is the temporary name of the former PICASSO-CENA (Pathfinder Instruments for Cloud and Aerosol Spaceborne Observations / Climatologie Etendue des Nuages et des Aerosols) minisatellite mission, a collaborative NASA/CNES project in the ESSP (Earth System Science Pathfinder) program of NASA. A new name for the mission couldn't be found until manuscript submission (objections were voiced by the Picasso family). A launch of ESSP-3 is planned in 2003 (co-manifested with CloudSat on a Delta-II vehicle). Other project partners (algorithm development) are Hampton University in Hampton, VA, and IPSL (Institut Pierre Simon Laplace), Jussieu, France. The overall science objective of the mission is to profile the vertical distribution of clouds and aerosols and their role in the heating/cooling of the Earth (improve of estimates for direct and indirect radiative forcing, improve accuracy of long-wave radiative fluxes at the Earth's surface and within the atmosphere, assessment of cloud feed back in the climate system).^{418) 419) 420) 421) 422) 423)}

The mission is managed by NASA/LaRC. CNES supplies the S/C and an IR imaging sensor (of IASI heritage). NASA/LaRC provides the main instrument suite (a Ball-built lidar sensor) and S/C launch services aboard a Taurus launch vehicle. CNES provides S/C operations, the payload operations center is located at LaRC.

The S/C employs a Proteus bus, provided by CNES. It is three-axis stabilized. The S/C mass is 478 kg at launch, power = 232 W (average). An on-board data storage capability of 24 Gbit is provided.

Orbit: Near sun-synchronous orbit, altitude = 705 km, inclination = 98.05°. Observation strategy: The PICASSO-Cena orbit is optimized to form the so-called “A-train” (Aqua in the lead and Aura at the tail) or afternoon constellation (formation flight starting in the

2004 time period). The train will consists of the following S/C: Aqua, ESSP-3, PARASOL, CloudSat and Aura. The objective is to provide a coincident set of data on aerosol and cloud properties, radiative fluxes and atmospheric state essential for accurate quantification of aerosol and cloud radiative effects. The ESSP-3 orbit is maintained so that a target area can be observed within 6 minutes of each other (ESSP-3 and Aqua). The relevant Aqua instruments for ESSP-3 are: CERES, MODIS, AIRS, and AMSR-E.

Figure 24: Illustration of the ESSP-3 spacecraft

Sensor complement: The payload consists of four co-aligned nadir viewing instruments.

Lidar, provided by LaRC (built by Ball Aerospace). The objective is to acquire vertical profiles of elastic backscatter (distributions of aerosols and clouds, cloud particle phase) at dual-wavelength frequencies from a nadir-viewing geometry during the day and night phases of the orbit. Two orthogonal polarization components (parallel and perpendicular to the polarization plane of the transmitted beam) are measured at 532 nm. Vertical profiles are measured from -2 to +40 km with the 532 nm channel, with the upper region used for normalization/calibration. The other two channels span -2 to +26 km, covering the cloud and aerosol measurement region with polar stratospheric clouds occurring toward the top of the range. The maximum vertical resolution is 30 m, the footprint diameter on the ground is 70.5 m. The horizontal spacing between footprint centers is 250 m. At altitudes above 5 km, resolutions are reduced by on-board averaging.

Lidar type	Nd:YAG, diode-pumped, Q-switched, frequency-doubled
Wavelength (2)	532 nm and 1064 nm
Energy/pulse	105 - 115 mJ
PRF (Pulse Repetition Frequency)	27 Hz
Pulse width	24 ns nominal
Telescope aperture diameter	1.0 m
Horizontal/vertical resolution	250 m/30 m
Data rate	279 kbit/s
Instrument mass, power	135 kg, 190 W

Table 66: Parameters of the Lidar instrument

IIR (Imaging Infrared Radiometer), provided by CNES. IIR features a microbolometer array technology. The objective is to measure calibrated radiances at 10.5 and at 12 μm over a 40 km swath (the two wavelengths are chosen to optimize the joint Lidar/IIR retrievals of cirrus emissivity and particle size).

Spectral bands (2)	10.5 μm and at 12.0 μm
Spectral resolution	0.8 μm
Spatial resolution (IFOV)	624 m
FOV or swath width	42 km
Data rate	20.5 kbit/s

Table 67: IIR specifications

WFC (Wide-Field Camera), built by Ball Aerospace. The objective is to provide meteorological context and highly accurate spatial registration between the ESSP-3 and the Aqua mission. WFC has a spectral coverage of 620-670 nm providing images of a 25 km swath with a spatial resolution of 125 m. The source data rate is 28.3 kbit/s.

A.15 FBM (French-Brazilian Microsatellite)

FBM is a cooperative mission between CNES and INPE. The overall objectives are to study the Earth's plasma environment and to test several technologies.^{424) 425)} The FBM satellite design is part of the CNES Myriade series which encompasses the CNES microsatellite program with DEMETER, Microscope, PARASOL, and Picard. In this cooperative concept, INPE provides the launch of the S/C, the satellite structure, the TCS (Thermal Control Subsystem) and the PSS (Power Supply Subsystem); CNES provides OBDH (On-Board Data Handling), TMTC (Telemetry & Telecommand) and ACS (Attitude Control Subsystem).

Figure 25: Illustration of the FBM satellite

The FBM satellite is composed of the payload module and the platform module, the latter comprising the structure, TCS, ACS, OBDH, TMTC and PSS. The spacecraft is a three-axis stabilized (size of structure: 60 cm x 70 cm x 80 cm). ACS employs reaction wheels and torque rods for actuation, and a star sensor, a coarse sun sensor and a magnetometer for attitude sensing. A navigation software package supports various modes of operation. PSS comprises a solar generator (180 W at EOL) in two identical panels, a NiCd battery of 10 Ah capacity, a non-regulated bus power conditioning unit and a power distribution unit.

424) H. Carvalho, "The French Brazilian Microsatellite," Proceedings of the 51st IAF Congress, Rio de Janeiro, Brazil, Oct. 2-6, 2000, IAA-00-IAA.11.1.04

425) M. N. Barbosa, S. Plattard, "New opportunities for international cooperation - FBM, a French-Brazilian microsatellite to study the sun," CNES Magazine No 9, June 2000, pp. 33-34

OBDH consists of a computer (used also for ACS) and a 1 Gbit solid-state memory. The S/C mass is 93 kg, the design life is 13 months. A launch of FBM is scheduled for 2003 from the Alcântara launch site in Brazil on VLS (Veículo Lancador de Satélites), Brazil's launch vehicle.

RF communications are provided in S-band (redundant transmitter/receiver and antennas). The downlink data rates are 200 kbit/s (nominal) and 25 kbit/s in safe mode. The modulation is in QPSK, the downlink frequency is 2255.2 MHz. The uplink data rate is 20 kbit/s. The CCSDS protocol is used for all data transmission and formatting.

Orbit: Circular near-equatorial orbit, altitude = 750 km, inclination = 6°.

The FBM ground segment consists of a ground station in Natal (Brazil) and a SCC (Satellite Control Center) at INPE. CNES acquires the spacecraft science data to its users.

Sensor complement:

APEX (Alpha, Proton and Electronics Experiment) an INPE instrument with the objective to monitor alpha, proton and electron particle fluxes and their temporal variations in the inner magnetosphere.

- Flux measurements of He ion events in the energy range of 3.3 to 29 MeV/nuc, in 4 discrete channels
- Flux measurements of proton events in the energy range of 2.2 to 29 MeV, in 5 discrete energy channels
- Flux measurements of electron events in the energy range of 0.1 to 3.6 MeV, in 4 discrete energy channels

The APEX instrument consists of telescopes. Instrument dimensions: 20 cm x 10 cm x 14 cm, mass = 3 kg, power = 3 W.

PDP (Plasma Diagnostic Package), an INPE instrument in collaboration with Japan. The objective is to measure the temperature, density and structure of the ionospheric plasma at low altitude near the equator [study of the electrodynamics and nonlinear processes of the equatorial ionosphere-thermosphere system (EITS)]. The spaceborne observations are supported by ground-based ionospheric and thermospheric measurements in Brazil and in equatorial West Africa using a network of diagnostic instruments that include radars, digisondes/ionosondes, optical imagers and interferometers and the available GPS satellites. High-resolution measurements of the plasma density, plasma temperature, spectral distribution of the irregularities using the following experiments:

- HFCP (High Frequency Capacitance Probe) for measuring the plasma density
- A Langmuir Probe (LP) for measuring the electron density and temperature variations and the spectral distribution of plasma irregularities
- Electron Temperature Probe for measuring the kinetic temperature of the ionospheric electrons.

The PDP instrument mass is 3.2 kg, power = 5.5 W.

CPL (Capillary Pumped Loop) an INPE instrument. The aim is to space-qualify a capillary-pumped loop in microgravity conditions. CPL is designed to transport up to 40 W from the evaporator plate to the radiator, using ammonia as the working fluid. The absorber plate is designed to absorb up to 30 W of solar energy. The CPL is tested in the following modes:

- On/off power input of 3 W in the reservoir and solar power input up to 30 W during the entire mission of the satellite.
- On/off power input of 3 W in the reservoir, power input of 15 W in the electrical resistance of the capillary pump and a solar power input up to 30 W, during special modes reserved to the CPL experiment
- Testing of the CPL without any kind of external control (solar power input = 30 W).

The instrument operating temperature is 280-300 K, the pressures is 550-1061 kPa, the capillary pumping pressure is 3-10 kPa. The measurement accuracy is ± 0.5 K. The instrument mass is 2.9 kg.

Figure 26: Schematic diagram of the CPL experiment

CBEMG (Confined Boiling Experiment under Microgravity), an INPE package. The objective is to study nucleate boiling and critical heat flux under microgravity conditions. Transient and steady-state tests will be conducted. The measured data will provide very useful information for designing and selection of devices for thermal control of satellites which employ two-phase heat transfer processes like heat exchangers, heat pipes and capillary pumps.⁴²⁶⁾

FluxRad (Fluxmeter Radiometer), an INPE instrument package. The objective is instrument qualification and to measure the net flux and its distribution on the outer surfaces of the spacecraft. Several HFM (Heat Flux Meter) groups with distinct surface emissivities are mounted on the spacecraft surfaces (sunlit and deep-space directions); in addition there are slug radiometers. The mean HFM temperatures and the slug radiometer temperatures are measured by a thermistors. The mass of FluxRad is 0.270 kg, power = 2 W.

CHADOCC (Circuit Hydraulique a Ammoniaque Diphasique en Orbite a Pompage Capillaire et Centrifuge). A CNES technology experiment to test and qualify an active thermal control concept (able to transfer up to 10 W) that makes use of a capillary fluid loop. The experiment will test two capillary devices: a Loop Heat Pipe (LHP) and micro Heat Pipe (μ HP).⁴²⁷⁾

Debris, a CNES experiment to collect data about the distribution of orbital debris. The objective is to aid in the mapping of the space environment, modeling and to simulate it, besides the study of the effects on the specific mission.

Therme, a CNES experiment. The objective is to study the degradation of thermal coatings subjected to the space environment (charged particles, atomic oxygen, UV rays etc.).

MAGI, a CNES technology experiment to study and qualify a gyroscopic sensor that uses interferometric principles for angular measurements.

⁴²⁶⁾ Information provided by Himilcon Carvalho of INPE

⁴²⁷⁾ Information provided by Christophe Bastien-Thiry of CNES

A.16 FORTE (Fast On-Orbit Recording of Transient Events)

FORTE is a DOE-sponsored spacecraft designed and built by the Los Alamos National Laboratory (LANL) and by Sandia National Laboratories (SNL). The S/C features an advanced radio frequency (RF) impulse detection and characterization experiment. The prime objective is the measurement of electromagnetic pulses (EMP), primarily due to lightning, within a noise environment dominated by continuous wave (CW) carriers, such as TV and FM stations. The goal is to develop an understanding of the correlation between the optical flash and the VHF (30-300 MHz) emissions from lightning. Lightning is the main source of electromagnetic transients in this frequency range (nuclear weapon detonations produce also RF transients).^{428) 429) 430)}

FORTE also conducts ionospheric physics experiments. The effects of large scale structures within the ionosphere are being studied [such as traveling ionospheric disturbances and horizontal gradients in the total electron content (TEC) on the propagation of broad bandwidth signals.

Figure 27: Illustration of the FORTE satellite

The S/C, developed in partnership by LANL and COI (Composite Optics Incorporated), features an all-composite structure (of 42 kg). The primary structure consists of six major structural components: three structural trusses and three structural instrument decks, along with 24 solar array substrate (SAS) panels.

The S/C has a total mass of 236 kg and an average power of 50 Watt (body-mounted solar cells). The S/C is nadir-pointing with biased momentum wheel and gravity-gradient stabilization. The attitude is sensed by magnetometers and an Earth horizon sensor. Satellite op-

erations are conducted from SNL in Albuquerque, New Mexico. A Pegasus XL launch took place on Aug. 29, 1997 from VAFB, CA.

Communications: The S/C is operated in store&forward fashion with an on-board data recorder of 1.4 Gbit. The uplink and downlink communications are in S-band. The downlink data rate is 2 Mbit/s.

Orbit: near-circular orbit of 830 km x 800 km altitude, inclination = 70°, orbital period of about 100 minutes.

Sensor complement: The FORTE payload consists of a suite of instruments, each individually useful, and together very useful, for the study of lightning (simultaneous observation of optical and RF emissions of lightning activity in the electromagnetically noisy environment of near-Earth space).⁴³¹⁾

The observation of “lightning events” by an RF system and by an OLS (Optical Lightning Subsystem) requires an EC (Event Classifier) as part of the FORTE payload. In addition, the on-board data acquisition system must have the capability to be triggered by an RF trigger, an optical trigger, or by the FPC (Flight Payload Controller). The EC is connected to the FPC (Flight Payload Controller). The FPC triggers the EC only when it is needed by enabling power to the EC.⁴³²⁾

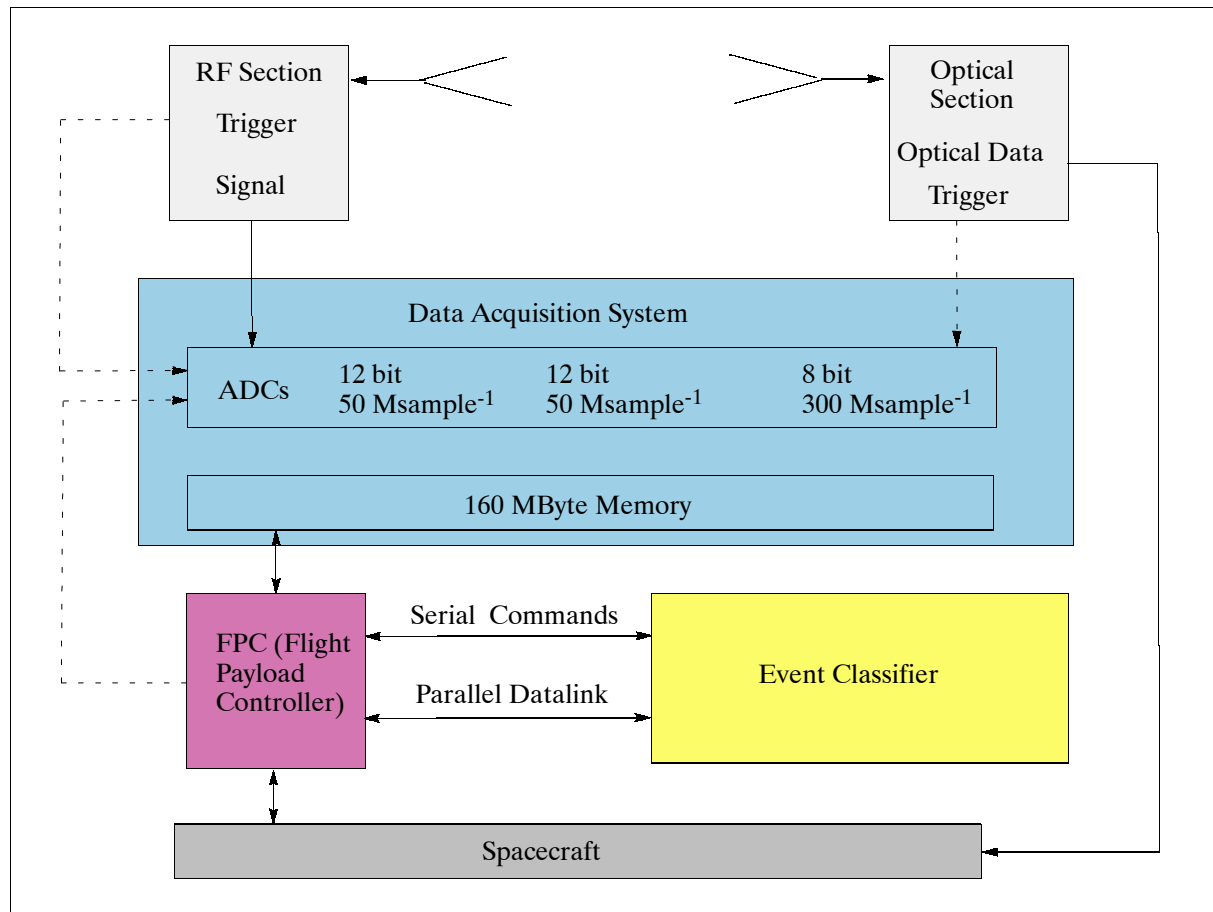

Figure 28: Schematic diagram of the FORTE experiment

EC (Event Classifier).⁴³³⁾ The EC is an experiment to determine the feasibility of telemetry reduction by onboard classification. The EC provides on-orbit characterization of im-

⁴³²⁾ K. R. Moore, P.C. Blain, et al., “Classification of rf transients in space using digital signal processing and neural network techniques,”. Applications and Science of Neural Networks, Proceedings SPIE, Vol. 2492, pp. 995-1006, 1995

pulsive RF events which satisfy the trigger criteria (extensive digital signal processing is involved). FORTE features a 10 m pseudo-log-periodic boom antenna coupled to a DSP (Digital Signal Processor) to capture the VHF (30-300 MHz) electromagnetic transients.

The EC, a DSP of TI (SMJ3320C30), executes neural network-based classification schemes. Communicating only with the FPC, the EC receives raw data and returns analysis reports via a 16-bit parallel port, it receives commands uplinks and state-of-health reports via a serial port.

There are three steps to EC demonstration testing: 1) Processing and classification algorithms are applied to digitized waveforms downlinked by the FORTE payload through the ground station to desktop computers. 2) Testing of promising algorithms in the FORTE engineering unit on the ground. 3) After successful ground testing, the EC is then commanded to perform the same analysis in space.

Successful demonstration of onboard event classification by the EC establishes confidence limits of classifications and enables follow-on missions to eliminate the costly data downlink and ground analysis steps.

RF (Radio Frequency) System. The RF system was developed and built by LANL. The RF system provides the following features: ⁴³⁴⁾ ⁴³⁵⁾

- Three broad bandwidth RF receivers (10 to 100 MHz bandwidth) covering the frequency range from 30 - 300 MHz. A multi-band coincidence trigger with perpetual recording of power background in all 16 trigger subbands (each 1 MHz wide).
- High-speed, low power digitizers (300 M samples/s)
- Broad bandwidth, dual polarization-selective VHF antenna
- Extensive on-board signal processing (adaptive discrimination, signal categorization by attributes)

The RF system derives its signals from either of two active monopoles, or alternatively from two mutually orthogonal, multi-element, passive, moderate-gain log-periodic antennas on nadir-directed deployed monopoles, or alternatively from two mutually orthogonal, multi-element, passive, moderate-gain log-periodic antennas on a nadir-directed deployed boom.

Both the RF System and the OLS (Optical Lightning Subsystem) are configurable for signal-triggered or for time-triggered digitization. There are also options for cross-triggering of PDD and LLS and for cross-triggering of PDD and the RF payload. With 160 MByte, there is ample memory on board for thousands of events to be stored and then downloaded. The downloading is done up to several times per day, at both Sandia and the University of Alaska.

OLS (Optical Lightning Subsystem), developed by SNL. The OLS instrument consists of:

- LLS (Lightning Location System) which employs a CCD imager with a ground resolution of 10 x 10 km (FOV = 80°, 500 frames/s)
- A fast time-response PDD (Photodiode Detector) for the recording of individual light curves. ⁴³⁶⁾ ⁴³⁷⁾

Photodiode/photometer systems are characterized by excellent temporal resolution (e.g. 10-100 μ s) and generally poor spatial resolution (100-1000 km). Conversely, CCD imagers are primarily utilized to provide accurate geolocation and 2-D imagery of lightning events.

436) D. M. Suszcynsky, T. E. Light S. Davis, J. L. Green, et al., "Coordinated Observations of Optical Lightning from Space Using the FORTE Photodiode Detector and Imager," Reg. LA-UR-00-341,

437) M. W. Kirkland, et al., "Observations of terrestrial lightning at optical wavelengths by the photodiode detector on the FORTE satellite," Rep. LA-UR-98-4098, LANL, 1998

They are characterized by excellent spatial resolution (1-10 km), low temporal resolution (1-10 ms), and a lack of waveform information.

The PDD employs an unfiltered, single element silicon photodiode with a sensing area of 1 cm². It is responsive to wavelengths of 400-1100 nm, with a peak response near 850 nm. A sunshade of 15 cm length provides a circular FOV of 80° (the total footprint is about 1200 km in diameter) to match that of LLS. The PDD measures the intensity of the incoming light and triggers on impulse events, thus providing a means to record the light-intensity time history. The PDD employs 12-bit sampling covering a dynamic range of more than four orders of magnitude. Two 128 x 128 pixel CCD (segmented array) detectors image the lightning; the input is the bright narrowband-filtered line emission centered at 777.4 nm wavelength.. In the “autonomous mode” operation, the instrument produces 1.92 ms long waveforms with 15 μs time resolution. The high temporal resolution of the PDD (about 15 μs) and the high spatial resolution of the LLS imager (about 10 km) combine to give a detailed satellite-based picture of both the spatial and temporal evolution of terrestrial lightning on both stroke (pulse) and flash timescales. OLS augments the RF system to develop high performance lightning discriminator/locator capability.

A.17 GCOM (Global Change Observation Mission)

GCOM is a NASDA program and a Japanese initiative with the overall objective to extend the observations (Earth climate monitoring), introduced by the ADEOS missions, on a long-term basis for the study and prediction of global-change phenomena to support the preservation of the environment. Three main goals are pursued: ⁴³⁸⁾ ⁴³⁹⁾

- Understanding of the energy cycle
- Study of the atmosphere/ocean interaction and radiative forcing, leading to the prediction of medium-to-long-term climate changes
- Understanding of the ozone and greenhouse gas circulation mechanism leading to the prediction of ozone layer and atmospheric composition variabilities.

The GCOM program, as defined in 2000, was previously referred to as ADEOS-III. The overall GCOM program consists of the GCOM-A and GCOM-B satellite series with their corresponding ground segments.

A.17.1 GCOM-A1

The emphasis is on atmospheric monitoring. ⁴⁴⁰⁾ ⁴⁴¹⁾ The mission objective is to support the Kyoto protocol that was adopted at COP3/UNFCCC (3rd session of the conference in the framework of climate change) in 1997. The protocol calls for a reduction of greenhouse gases, in particular CO₂; it requires all parties to reduce their emissions by 5% below the level of the year 1990, for the period of 2008-2012. - The GCOM-A1 mission calls for the study of the transport mechanisms of greenhouse gases (CO₂, methane, CFC and halon), transport process of ozone and ozone layer depletion.

The S/C bus is three-axis stabilized with a structure size of 2.6 m x 2.1 m x 3.0 m. The AOCS (Attitude & Orbit Control Subsystem) is based on a zero-momentum design, attitude is sensed by Earth sensors, a star tracker and a GPS receiver. The EPS (Electrical Power Subsystem) uses a 28 V unregulated bus, the solar panels are of rigid padpole design with 1300

W of power (EOL), and two NiCd batteries with energy of 35 Ah for solar eclipse operations. The overall S/C mass is about 1200 kg with an instrument mass of 256 kg. The overall design life is three years with propellant sized for five years. The planned launch date for GCOM-A1 is 2006.

Orbit: Non-sun-synchronous inclined circular orbit, altitude = 650 km, inclination = 69°, period = 98 min.

Communication: Science data is received and level-0 processed at NASDA/EOC (Earth Observation Center) in Hatoyama, Japan. The downlink is provided in X-band (8 GHz) with a data rate of 60 Mbit/s. The TT&C data link is DRTS compatible.

Sensor complement:

ODUS (Ozone Dynamics Ultraviolet Spectrometer). ODUS is a NASDA nadir-looking core instrument with the primary objective to measure the global total column ozone on a daily basis (target accuracy is 5% nominal and 2% after calibration/validation with a precision of 2%). Secondary objectives call for the measurement of volcanic sulfur dioxide (SO₂), of aerosols, NO₂, HCHO, BrO, and stratospheric OClO. In addition, cloud top heights are determined. ODUS employs the BUV (Backscattered Ultraviolet) technique to measure ozone and atmospheric trace gases. The design uses a Fastie-Ebert type spectrograph, measuring in the spectral range of 306 - 420 nm with 0.5 nm spacing. The spectral resolution is 0.5-0.7 nm. The instrument consists of a scanning subsystem, a spectrometer subsystem with detector assembly and calibration components, and a signal processing unit.

Instrument optics	Fastie-Ebert type grating (blazed holographic) monochromator
Spectral range, spectral resolution	306 - 420 nm, 0.5 nm
Detector, number of elements	CMOS type silicon photodiode array, 232 (with quantum efficiency >50%)
SNR	40 at 306 nm, > 100 at 310 nm
FOV, IFOV (spatial resolution)	1.8° x 120° (swath of 2500 km), 1.8° x 1.8° (or 20 km x 20 km at nadir)
Instrument mass, power, size	<50 kg, <100 W, 650 mm x 650 mm x 750 mm
Data rate	<100 kbit/s

Table 68: ODUS instrument characteristics

The whiskbroom scanning technique is used for wide-field global coverage (80° N to 80° S) on a daily basis.

SOFIS (Solar-Occultation FTS for Inclined-orbit Satellite), sponsored by the Ministry of Environment and developed by NEC as the prime contractor.⁴⁴²⁾ SOFIS is of ILAS (Improved Limb Atmospheric Spectrometer) and ILAS-II heritage, flown on ADEOS and ADEOS-II, respectively. SOFIS employs the solar occultation technique by measuring the vertical profiles of atmospheric constituents with a spectral resolution of 0.2 cm⁻¹ in the spectral range of 3-13 μm with 1 km vertical resolutions. The main science objective of SOFIS is to monitor ozone and its minor constituents, thereby obtaining the global distribution of the following constituents/parameters: O₃, HNO₃, NO₂, N₂O, CH₄, H₂O, CO₂, CFC-11, CFC-12, ClONO₂, aerosol extinction, atmospheric pressure and temperature. The combination of SOFIS and ODUS instrument measurements onboard GCOM-A1 provide in effect 3-D global ozone distributions.

The SOFIS instrument employs a dual-pass flexible blade Michelson FTS (Fourier Transform Spectrometer) design as well as a diode laser sampling system to reduce the instrument size and mass. Two photovoltaic (PV) HgCdTe detectors and a pulse-tube cooler pro-

442) A. Kuze, H. Nakajima, J. Tanii, Y. Sasano, "Conceptual Design of Solar Occultation FTS for Inclined-orbit Satellite (SOFIS) on GCOM-A1," Proceedings of SPIE 45th Conference, San Diego, Jul. 30 to Aug. 4, 2000, Vol. 4131-30 (Remote Sensing and Infrared Systems), 2000

vide high linearity and low-noise level performance. FTS acquires a two-sided interferogram for phase information and for accurate inverse-transform performance (there is in addition the capability of separate interferogram acquisitions in two directions). The FTS controller uses a laser fringe counter that is updated by the initial scan with a white-light lamp prior to any measurements to enable the FTS to sample at the same fringe position during the same occultation. The instrument features also a visible (O₂ A band) grating spectrometer for pressure and temperature retrieval. A sun-edge sensor is used for the detection of the tangent height position. The SOFIS gimbal mechanism provides an azimuth scan of $\pm 90^\circ$. A sun-tracking flat mirror and sun sensors are mounted on the two-axis gimbal. The sun sensors detect the radiometric center of the sun within $\pm 5^\circ$ and within $\pm 0.5^\circ$ at 875 nm and 1050 nm, respectively.

SOFIS configuration/accommodation parameters	
Measurement technique	Solar occultation of sunrise and sunset configurations
FOV	Altitude range of 5 km to 150 km (outer space)
IFOV	Tangent heights of 1.1 km (FWHM) at 6.5 μm , 0.8 km (interval)
Instrument calibration	Full level: pointing at the sun through outer space Zero level: pointing at deep space
Sun tracking	Radiometric center tracking with 2-axis gimbal
Instrument design life	3 years
Instrument data rate	45 Mbit/s
Instrument mass, power, size	190 kg, 250 W, 120 cm x 100 cm x 80 cm
FTS (Fourier Transform Spectrometer) parameters	
Spectral region -2 bands in PV-MCT design	3.25-6.5 μm or 3080-1540 cm^{-1} (no undersampling), 6.5 - 13 μm or 1540-770 cm^{-1} (interval 2 under sampling)
Spectral resolution (moderate)	0.2 cm^{-1} unapodized (interval), 0.24 cm^{-1} (FWHM)
Interferogram scan	0.23 s per interferogram, both sides, both ways
Zero path difference detection	White light
OPD (Optical Path Difference)	± 2.5 cm;
Scan direction detection	Two polarized phase-shifted diode lasers and InGa detectors
Scan speed stability	$\pm 1\%$ rms with servo control
SNR	>300 with 16 bit ADC
Sampling reference	Diode laser of 1550 nm wavelength
Beam splitter and compensator	ZnSe
FTS type	Double corner cubes, double path
Gimbal and telescope parameters	
Tracking range	Azimuth = 180° , elevation = 25°
Speed, acceleration	1°/s, 20°/s ²
Motor	DC brushless
Sun sensor	Coarse: Si position sensitive device Fine: InGaAs quadrant device
Resolver (data quantization)	18 bit
Telescope	Aperture diameter of 60 cm, F=5 Au coated
Sun edge sensor summary	
Image type	Reflected slit image
Detector	5000 pixel array using a silicon CCD (2500 pixels are used in elevation and 2500 pixels are in azimuth)
Data quantization	12 bit
Sun edge detection	Two images per interferogram
Solar image	Solar disk scan with gimbal elevation motion
Visible-range grating spectrometer parameters	
Spectral range, spectral resolution	753 - 784 nm, 0.06 nm
Optics, grating	Reflective (telecentric), 1800 grooves/mm (holographic)
Detector, data quantization	1024 pixels Si CMOS, 16 bit

Table 69: Overview of SOFIS instrument parameters

The FTS technique for solar occultation measurements requires a rapid interferogram acquisition method to achieve a high vertical resolution. The new technologies of high-speed A/D converters and precision linear motors offer such performance capabilities. By replacing the grating spectrometer with an FTS device and the uncooled thermal detector with a the cooled quantum detector, SOFIS is able to provide a 50 times higher spectral resolution than ILAS-II on ADEOS-II.

SWIFT (Stratospheric Wind Interferometer For Transport studies), sponsored by CSA (Canadian Space Agency) and designed/developed by a team from York University, Meteorological Service of Canada, and EMS Technologies Canada Ltd.. In 1998, the SWIFT concept was proposed to an ESA competition and was selected as one of five instruments for the Earth Explorer Mission series. ESA is supporting the accommodation of SWIFT on GCOM-A1, NASDA is providing the S/C and data acquisition. The scientific rationale for flying SWIFT is driven by the urgent need for global observations of vector-resolved vertical wind profiles between 18 and 40 km in the Earth's stratosphere. The intent is to address a) the factors/mechanisms influencing and controlling the stratospheric wind patterns, and b) to study stratospheric wind patterns and their role in controlling the global distributions of ozone and secular variations in ozone densities. The specific scientific objectives are:⁴⁴³⁾

- To study the ozone transport, including the Brewer Dobson circulation and horizontal ozone fluxes, from co-located wind and ozone measurements
- To determine the transport across the subtropical mixing barrier which is relevant to green house gases and halogen lifetimes
- To study tropical stratospheric winds, including QBO (Quasi Biennial Oscillation), SAO (Semi Annual Oscillation) and equatorial waves
- To assimilate the data with sophisticated GCMs (General Circulation Models), including model statistics, and a quality-controlled four-dimensional dataset.

The SWIFT wind and ozone measurements will be used to develop and refine general circulation models to provide more reliable predictions on global change phenomena. The SWIFT data are also used in data assimilation analysis to assess how stratospheric wind measurements would improve medium-term and long-term weather forecasts. SWIFT, combined with ODUS and SOFIS will provide major synergistic enhancements in the science return from all three instruments.

SWIFT is a spaceborne limb-viewing instrument (heritage of WINDII on UARS) designed to image the Doppler shift from thermal ozone emissions in the altitude range from 18 to 40 km (simultaneous observation of wind and ozone concentration profiles in the stratosphere). The operational concept employs optical Doppler imaging phase-stepping interferometry using a field-widened Michelson interferometer. Separation of the two components of the horizontal wind velocity of a given region on the limb is accomplished by having two fields of view at 45° and 135° to the spacecraft velocity vector. The measurements allow a reconstruction of the horizontal wind vectors from the two orthogonal components. A single thermal emission line from stratospheric ozone near 8.9 μm is isolated using two thermally stabilized and passively cooled 0.8 nm germanium Fabry-Perot etalons in series.

In the SWIFT concept, two off-axis telescopes view the limb in the fore and aft directions. Each has a FOV at the limb of 50 km x 100 km as seen from a S/C altitude of 600 km. Thermal radiation from the Earth's surface and warm baffles is prevented from entering the instrument via intermediate field stops and internal re-imaging of the telescope mirrors. The fore and aft FOVs are combined into one with a reflecting prism. This combined image is re-collimated and passed on to the Michelson interferometer with an optical path difference of 15 cm. For each wind measurement the mirror in one arm of the interferometer is piezoelectrically scanned over a single fringe in quarter-wave steps. The phase is then calculated for each pixel of the cryogenically cooled HgCdTe detector (128 x 128 pixel array,

443) G. G. Shepherd, I. C. McDade, W. A. Gault, Y. I. Rochon, A. Scott, et al., "The Stratospheric Wind Interferometer for Transport Studies (SWIFT)," 33rd COSPAR Scientific Assembly, Warsaw, Poland, July 16-23, 2000

cooled to 65 K using a mechanical Stirling cycle cooler), optimized for the observed wavelength, yielding a wind accuracy of 5 m/s. The instrument concept depends on a set of solid germanium etalon filters with clear apertures of 5 cm, bandwidths of 8 Å and 20 Å, finesse of at least 20, and which are cooled to about 150 K.

Figure 29: SOFIS instrument configuration

Limb observations are performed by a pointing mirror in SWIFT which directs the relatively narrow IFOV (1° vertical by 2° horizontal) towards the desired tangent height range (15 - 65 km) on the limb. Active pointing of the mirror ensures that the region of interest stays within the field of view. The mirror also periodically (as often as once every 12 s) turns the instrument's IFOV toward deep space to accurately monitor the thermal background flux. In addition, a periodic view to an internal phase calibration gas cell and to a radiometric (blackbody) calibration source is done to verify the instrument performance.

The volume of the SWIFT instrument is about 0.5 m^3 , its mass is 75 kg, the power consumption is 75 W. The data rate is about 100 kbit/s.

A.18 HCMM (Heat Capacity Mapping Mission)

NASA Mission, also known as **AEM-1** (Application Explorers Mission-1). Launch: April 26, 1978, end of operation: Aug. 1980. The S/C was launched on a Scout-F vehicle from VAFB, CA. ⁴⁴⁴⁾ ⁴⁴⁵⁾

The HCMM spacecraft was made of two distinct modules: 1) an instrument module, containing the heat capacity mapping radiometer and its supporting gear, and 2) a base module, containing the data handling, power, communications, command, and attitude control subsystems required to support the instrument module. The spacecraft was spin stabilized at a rate of 14 rpm. S/C mass = 134 kg. With no on-board data storage capability, only real-time data were transmitted when the satellite came within reception range of seven ground stations.

Orbit: Sun-synchronous near-polar orbit, apogee = 646 km, perigee = 558 km, inclination = 97.6° , period = 96.7 minutes, repeat cycle = 16 days, local equator crossing at 2 pm (ascending node). On Feb. 21-23, 1980 the HCMM orbit was lowered from 620 km to 540 km altitude to stop the drift of the orbit plane to unfavorable sun angles which in turn reduced the power collection capability of the solar panels.

⁴⁴⁴⁾ P. Slater, 'Remote Sensing' Optics and Optical Systems, Addison-Wesley, 1980, pp. 462 - 465

⁴⁴⁵⁾ HCMM System in 'Manual of Remote Sensing,' Second Edition, American Society of Photogrammetry, 1983, pp. 663-670

Application: Measurement of heat budget, surface temperature, soil moisture, urban heat islands, etc. HCMM was an experimental remote sensing mission to test thermal inertia to help discriminate between different surface materials, and to identify different states, such as degree of soil wetness.

Sensor:

HCMM (Heat Capacity Mapping Radiometer). Instrument mass = 38.9 kg. The radiometer was similar to the surface composition mapping radiometer (SCMR) of Nimbus-5. The HCMM had a small instantaneous geometric field of view (IFOV) of 0.83 mrad, high radiometric accuracy, and a wide 716 km swath coverage on the ground so that selected areas were covered within the 12 hour period corresponding to the maximum and minimum of temperature observed. The instrument operated in two channels and utilized a radiation cooler to cool the two Hg:Cd:Te detectors to 115 K. The experiment included an analog multiplexer that accepted the analog outputs of the detectors and multiplexed them in a form suitable for transmission by the spacecraft S-band transmitter. The instrument performed satisfactorily until the spacecraft operations terminated on September 30, 1980.

Spectral range (channel 1)	0.55 - 1.11 μm (solar reflection)	pixel size = 500 x 500 m
Spectral range (channel 2)	10.5 - 12.5 μm (thermal emission)	pixel size = 600 x 600 m
Image size	2016 lines (1680 pixels/line)	8 bit resolution

Table 70: Parameters of HCMM

HCMM data were stored and processed at GSFC. Data products: geometrically corrected and calibrated images of radiance or equivalent black-body temperature.

A.19 Megha-Tropiques

Megha-Tropiques⁴⁴⁶⁾ is a French/Indian cooperative mission of CNES and ISRO with the objective to study the convective systems (water cycle and energetic exchanges) that affect the intertropical zone.⁴⁴⁷⁾ The satellite uses the French Proteus bus, the S/C integration is performed at CNES while the payload integration is done at ISRO. On the operational side, CNES is providing the S/C operations via its own ground station; ISRO's ground station at Bangalore is used as the Mission Science Center. The science mission is also supported by CNRS/LMD (Laboratoire de Météorologie Dynamique) of Palaiseau, France. A statement of intent was signed on Nov. 21, 1999 in Bangalore between ISRO and CNES.⁴⁴⁸⁾⁴⁴⁹⁾⁴⁵⁰⁾

Data gathered by the mission will be used to predict tropical cyclones. The goals are to:

- Provide simultaneous measurements of several elements of the atmospheric water cycle: water vapor, clouds, condensed water in clouds, precipitation and evaporation
- Measure the corresponding radiative budget at the top of the atmosphere
- Ensure high temporal sampling in order to characterize the life cycle of the convective systems.

The satellite uses the Proteus bus of CNES/Alcatel. It is three-axis stabilized providing a pointing accuracy of 0.1°. The S/C has a mass of 570 kg (260 kg of payload mass), power =

446) Megha means "cloud" in Sanskrit; Tropiques is the French word for "tropics."

450) Illustration courtesy of Nadia Karouche of CNES

591 W (291 W for payload). The design life is 3 years. A launch on an ISRO PSLV launcher from SHAR is planned for 2006.

Orbit: Circular orbit, altitude = 867 km, inclination = 20°, period = 100 min.

Figure 30: Illustration of the Megha-Tropiques satellite

Sensor complement:

ScaRaB (Scanner for Radiation Budget), sponsored by CNES and developed at LMD. SCARAB is of Meteor-3-7 heritage. Its objective is the collection of data on shortwave and longwave radiation (reflected solar and emitted thermal radiation) to estimate the Earth’s radiation budget at the top of the atmosphere on global and regional scales. The instrument is a cross-track scanning radiometer featuring four channels. Channels 2 and 3 are considered the main channels, while channels 1 and 4 are auxiliary channels. The optical subsystem features four parallel telescopes, one telescope per channel, they are identical except for their filters. ^{451) 452) 453)}

Nr.	Spectral band (µm)	Band description	Filter	Signal W m ² sr ⁻¹	Noise W m ² sr ⁻¹
1	0.5 - 0.7	Visible channel: scene identification	Interference	120	<1
2	0.2 - 4	Solar channel: derivation of Earth radiation budget parameters	Fused silica	425	<0.5
3	0.2 - 200	Total radiation channel	None	500	<0.5
4	10.5 - 12.5	Atmospheric channel scene identification	Interference	30	<0.5

Table 71: Spectral bands of ScaRaB

ScaRaB uses BARNES pyroelectric detectors for all bands (placed at the focus of a spherical aluminium mirror), which are sensitive only to the AC component of the signal (i.e., the modulated energy). Hence, chopping is needed for each pixel. This reduces the influence of the self radiation of the telescope and filters. Two mechanical choppers are used (one for two channels), providing a 10 Hz chopping frequency. The four channels, the two choppers, and a filter wheel dedicated to channel 2 and 3, are mounted on a scanning optical bench

 452) J. L. Monge, R. Kandel, L. A. Pakhomov, B. Bauche, “ScaRaB Earth radiation budget scanning radiometer,” SPIE, Vol. 1490 , ‘Future European and Japanese Remote Sensing Programs,’ 1991
 453) J. Mueller, et al., “Ground Characterization of the Scanner for Radiation Budget (ScaRaB) Flight Model 1,” Journal of Atmospheric and Oceanic Technology, Vol. 14, No 4, pp.802-813, 1997.

(rotor). The telescopes are swiveled by the optical bench so that no extra mirror for the scanning is needed. This reduces the likelihood of offsets dependent on the scanning angle.

The spatial resolution of ScaRaB data is 48 x 48 mrad, scan angle = 100°, swath width = 3200 km. ScaRaB points to nadir and scans the full field of view (FOV) within six seconds. In this cross-track mode data are generated continuously.

Parameter	Value	Parameter	Value
IFOV (spatial resolution)	48 mrad x 48 mrad (60 km x 60 km at nadir)	Sampling interval	34 mrad
FOV (swath)	100° (3200 km)	Sampling period	62.5 ms
Pixels per scan	51	Scan period	6 s
Dynamic range (solar)	up to 425 W m ⁻² sr ⁻¹	Useful scan time	3.18 s
Dynamic range (total)	up to 500 W m ⁻² sr ⁻¹	Instrument mass, power	40 kg, 42 W (average)
		Instrument size (mm)	614 x 512 x 320

Table 72: ScaRaB instrument parameters

Calibration subsystem: Gray lamps and blackbodies are used for on-board gain calibration; deep space is used for offset calibration. That subsystem comprises a set of two reference blackbodies for channels 3 and 4, and a set of gray calibration lamps for channels 1, 2 and 3. There is continuous thermal control of the blackbodies. The gray lamps are turned on during the calibration session (typically once per day). In addition, there are short wave references, consisting of two lamps for the calibration of channels 2 and 3 (typical use is once per month). On the ScaRaB/Meteor-3-7 mission, however, the lamp system was damaged so that actual calibration was performed by using the instrument temperature and a pre-launch established gain-temperature law. The remaining lamps were then used to verify this calibration. During one year of operation, no significant sensor degradation was observed.

ScaRaB has a duty cycle of 100%, data rate = 3 kbit/s, data volume = 18 Mbit/orbit. An instrument mass memory provides data storage for up to 12 hours. The mass of the instrument is 20 kg, the maximum power use is 33 W.

The data processing system is based on algorithms for transforming the instantaneous measurements of radiances, filtered by the optics and detectors, into estimates of the monthly mean values of the radiant excitations in the solar and thermal domains, at the top of the atmosphere. This requires corrections for non-flat spectral response, anisotropic, and diurnal variations. The estimates are provided on a spatial grid of 250 km.

SAPHIR (Sondeur Atmospherique du Profil d'Humidite Intertropicale par Radiometrie), developed by CETP (Centre d'etude des Environnements Terrestre et Planetaires), by DEMIRM (Department de Radioastronomie Millimetrique de l'Observatoire de Paris), and by LMD. SAPHIR is a cross-track sounding instrument with the objective to measure water vapor profiles in the troposphere (water absorption band at 183.3 GHz) in six layers from 2-12 km altitudes and spatial resolutions of 10 km. The measurement sensitivity is 1.5 K with an inter-channel calibration of 0.5 K. The measurement polarization is H.

Cha. Frequency	Bandwidth	Spatial resolution	Measurement objective
18.7 GHz	±100 MHz	<40 km x 66 km	Rain above oceans
23.8 GHz	±200 MHz	<40 km x 63 km	Integrated water vapor
36.5 GHz	±500 MHz	<40 km x 63 km	Liquid water in clouds, rain above sea
89 GHz	±1 GHz	<10 km x 16 km	Convective rain regions over land & sea
157 GHz	±1 GHz	< 6 km x 9 km	Ice and cloud tops, window/SAPHIR

Table 73: Specification of the MADRAS channels

MADRAS (Microwave Analysis & Detection of Rain & Atmospheric Structures) developed by ISRO with CNES providing the RF assembly (dish, horns, receivers). The main ob-

jective of the microwave imager is to measure precipitation and cloud properties. MADRAS is a five-frequency (9 channel) conical-scanning radiometer. The frequencies of 89 and 157 GHz are responding to ice particles in cloud tops, thus permitting the detection of convective rain regions over land and sea. The lower frequency channels are employed over oceanic regions for the measurement of cloud liquid water and precipitation (absorption at 18.7 and 36.5 GHz, integrated water vapor at 23.8 GHz, and estimation of the sea surface wind speed with the 18.7 GHz channel. The polarization is in H + V, except for the 23.8 GHz channel which is H or V polarized. The sensitivity requirement is 1 K for the 89 and 157 GHz channels and 0.5 K for the other channels. Inter-channel calibration is 0.5 K. The dish effective diameter is 65 cm. The beam efficiency is 0.95. A single horn is used for the three channels: 18.6, 23.8 and 36.5 GHz. The incidence angle is between 50°-55° (upper limit for each channel). The mass of MADRAS is 150 kg, power consumption is 180 W.

A.20 ODIN

Odin is a Swedish minisatellite mission for astronomical and atmospheric research (previously named MOSES). The mission design life is 2 years minimum. The project is carried out jointly by the space agencies of Sweden (SNSB), Canada (CSA), Finland and France (CNES). Swedish Space Corporation (SSC) is responsible for system design and project management. A launch took place on Feb. 20, 2001 on a Russian Start-1 launch vehicle from the Svobodny Cosmodrome, Russia.

The S/C structure is of aluminum honeycomb with carbon reinforced plastic for the reflector support structure. ODIN is three-axis-stabilized with reaction wheels, star trackers and gyros; mass = 250 kg (80 kg payload); size: 2.0 m height, 1.1 m width stored and 3.8 m in flight configuration; power = 260 W from deployable fixed solar arrays, during eclipse ODIN is powered by 6-Ah NiCd batteries; cooling: closed Stirling cycle coolers; pointing = ± 15 arcsec in staring mode, ± 1.2 arcmin in scanning mode; datalink: S-band at 720 kbit/s to Esrange tracking station; on-board storage > 100 MByte in solid state memory.

Applications: astronomy and aeronomy (atmospheric research: stratospheric ozone chemistry, mesospheric ozone science, summer mesospheric science, coupling of atmospheric regions).^{454) 455) 456)}

Objectives: Measurements in the wavelengths of 0.5 - 0.6 mm and 2.5 mm. These contain emission lines from molecules such as water vapor, molecular oxygen, ozone and carbon monoxide which are important for the study of atmospheric processes as well as for the study of astronomical objects. Complementary information on the Earth's atmosphere comes from spectral lines at UV and VIS wavelengths. Major scientific issues relate to star formation processes, interstellar chemistry and atmospheric ozone balance.

Orbit: Sun-synchronous polar orbit; altitude = 625 km; inclination = 97.8°; with an ascending node at 18:00 hrs; period = 97.6 minutes.

Operating modes: For aeronomy the spacecraft follows the Earth limb, scanning the atmosphere up and down from 15 km to 120 km at a rate of up to 40 scans per orbit. When observing astronomical sources Odin continuously points towards the object for up to 60 minutes. Note: Both sensors point into the same direction.

Sensor complement:

SMR = Submillimeterwave Radiometer [Swedish instrument in cooperation with Finland (119 GHz channel), and France, provision of the AOS (Acousto-Optic Spectrometer) de-

454) F. v. Scheele, "Star Formation and Ozone Depletion: The Swedish ODIN Satellite to Eye Heaven and Earth," Nordic Space Activities, No. 5, 1994, pp. 44-46

456) <http://www.ssc.se/ssd/>

tector]. This is a passive microwave limb sounder with one receiver at a wavelength $\lambda = 3$ mm and additional four bands within the submillimeter range (0.5 - 1.0 mm). Antenna reflector type: offset Gregorian telescope [off-axis system, 1.1 m diameter, surface: 10 μ m rms, material: carbon fiber reinforced plastic (CFRP)]. SMR is used in the astronomy as well as in the atmospheric research mission to detect molecular transitions. The signal coming from the telescope is routed to the receivers, split and filtered by optics consisting of combinations of mirrors, grids and meshes. Diplexers and sideband filters are based on tunable polarizing Michelson interferometers.

Figure 31: The ODIN S/C model and observational configurations

The five single sideband heterodyne receivers in SMR are continuously switched between a reference source of known signal strength and the signal from the telescope. The telescope is periodically targeted towards well-known celestial objects. These procedures ensure both stability and good calibration.

Spectral lines: The SMR instrument covers transitions of aeronomical interest from the following molecules: ClO, CO, NO₂, N₂O, H₂O₂, HO₂, H₂O, H₂¹⁸O, NO, HNO₃, O₃, and O₂; and atomic and molecular transitions of astrophysical interest from: Cl, H₂¹⁸O, H₂O, H₂S, NH₃, H₂CO, O₂, CS, ¹³CO, H₂CS, SO, SO₂

Type	Single sideband heterodyne receivers,
Frequencies	118.25 - 119.25 GHz, 486.1 - 503.9 GHz, 541 - 580.4 GHz
Bandwidth	100 MHz to 1 GHz
Resolution	0.1 MHz to 1 MHz
Sensitivity	1 K in 1 MHz with S/N = 5 after 15 minutes
Mixers	Cooled Schottky mixers
Local Oscillators	LO based on Gunn diodes and frequency multipliers
LNA	Cooled HEMT low noise amplifiers
Spectrometers	two hybrid autocorrelators and one AOS (Acousto-Optic Spectrometer)

Table 74: Specification parameters of SMR

OSIRIS = Optical Spectrograph and Infrared Imaging System (Canadian sensor built by Routes of Kanata, Ontario, with funding by CSA).⁴⁵⁷⁾ OSIRIS has a dual-purpose objective of detecting aerosol layers and to detect abundances of species such as O₃, NO₂, OCLO, and NO. The instrument is a UV/VIS/IR limb sounder, in effect a double instrument, mounted in a common optical housing and supported by common electronics. The UV/VIS (optical) imaging spectrograph uses compact reflective optics (off-axis system, folded design, aperture = 36 mm x 36 mm) and an aspherical ruled grating along with UV-enhanced CCD arrays; the IR imager consists of three infrared telescopes. The Optical spectrograph measures species in the altitude range from 15 to 80 km (measurement of atmospheric airglow as well as utilization of the DOAS technique on scattered and subsequently absorbed moonlight). The FOV of the UV/VIS and the IR channels are aligned (and co-aligned with SMR) to produce simultaneous measurements. Instrument mass = 12 kg, power=20W. On-orbit spectral calibration for the UV/VIS instrument is done by observing artificial sources emanating from the Earth, such as discrete lines produced by mercury and sodium street lights. Radiometric calibration is not provided internally. For the IR imager, the IR shutter assembly contains a built-in incandescent lamp providing the radiometric calibration signal.

UV/VIS Spectrograph	
Wavelength	280 - 800 nm
Wavelength resolution	1 nm from 300-450 nm, <2nm from 450-800 nm
Slit orientation	perpendicular to the orbit plane (horizontal)
FOV	0.02° (vertical) x 0.8° (horizontal) or 1 km x 40 km
Spatial resolution	1 km at the limb
Pointing direction	aligned with SMR boresight
AD converter	14 bit
Detector type	Si CCD array (1353 x 143 pixels)
Species to be detected	O ₃ , NO ₂ , BrO, OCLO, O ₂ , aerosols
IR Imager	
Bandpass filter center wavelengths	1.263 μm, 1.273 μm, 1.520 μm
Bandwidth (FWHM)	10 nm (1.263 and 1.273), 40 nm (1.520)
FOV	118 km (vertical) x 2 km (horizontal)
Spatial resolution	1 km in the vertical direction
Telescope aperture	23 mm diameter
Detector type (linear arrays with hybrid multiplexers)	3 InGaAs, each detector has 128 pixels
Detector pointing direction	in the orbit plane (vertical)
Detector temperature	-40°C (or less)
Temperature stability during exposure	±0.1°C

A.21 OrbView-1/Microlab-1

See description under B.8.1

A.22 QuikSCAT (Quick Scatterometer Mission)

A NASA ESE (Earth Science Enterprise) program satellite built by BATC (Ball Aerospace & Technologies Corporation) of Boulder, CO. The QuikSCAT mission was initiated in the wake of the lost NSCAT instrument measurements aboard NASDA's ADEOS-1 satellite. The ADEOS-1 S/C ceased functioning June 30, 1997. The objective is to restart NASA's ocean-wind measurement program, needed for improved weather forecasts and climate research. The NASA/GSFC contract to Ball was awarded under its new Rapid Spacecraft Acquisition (RSA) procurement program. QuikSCAT is a mission designed to complete turn-around from conception to launch in a very short period of time (one year). JPL's NSCAT/SeaWinds Program Office has been assigned responsibility and provides overall project management, as well as science, ground processing systems, and the SeaWinds instrument. NASA/GSFC manages the satellite development and operation [data acquisition is facilitated at Wallops Flight Facility (WFF), Poker Flats (AGS), Svalbard Ground Station (SGS) Norway, and McMurdo (MGS) Ground Station, Antarctica, Hatoyama, Japan (contingency station)].

Figure 32: The QuikSCAT S/C model

The S/C uses a BCP 2000 (Ball Commercial Platform) series bus with dimensions: 2.2 m x 1.7 m x 1.4 m; it is three-axis stabilized, the ADCS (Attitude Determination and Control Subsystem) uses a star tracker, IRU, reaction wheels, and a GPS receiver with C/A code; the pointing accuracy is $< 0.1^\circ$ absolute per axis; the pointing knowledge is $< 0.05^\circ$ per axis. The propulsion system uses anhydrous hydrazine (N_2H_2) blowdown. S/C mass (wet) = 970 kg, power 874 W (average), payload mass = 205 kg, payload power = 250 W (average). Design

life > 2 years with 3 years for expendables. The on-board data recorder has a capacity of 8 Gbit. Downlink/uplink communications are provided in S-band at a data rate of 2 Mbit/s for payload data. Housekeeping data are at data rates of 4, 16, and 256 kbit/s, the uplink data rate is 2 kbit/s. The launch of the S/C took place on June 19, 1999 atop a Titan II vehicle (LM) from VAFB, CA.

Orbit: Circular sun-synchronous polar orbit with a local equator crossing time at the ascending node of 6:00 AM \pm 30 minutes, altitude = 803 km, inclination = 98.6°.

Sensor complement:

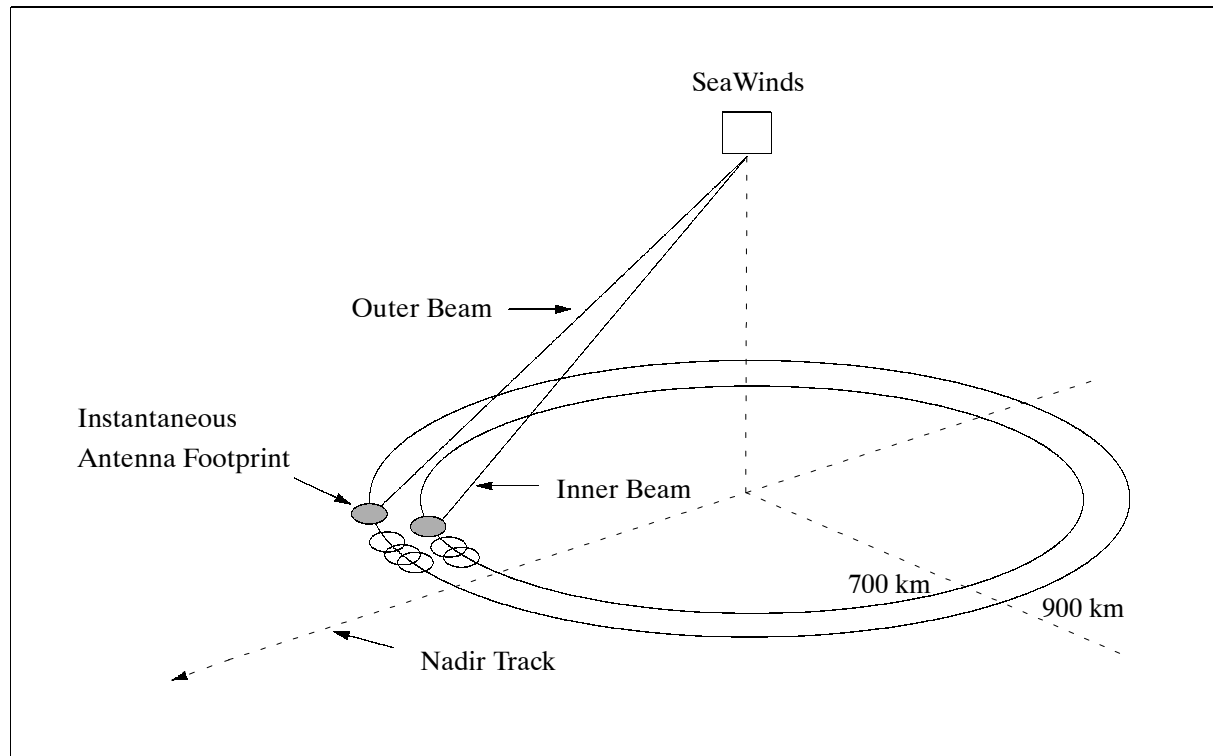

Figure 33: Illustration of the dual-beam scanning geometries

SeaWinds = NASA Scatterometer II (PI: M. Freilich, NASA/JPL and Oregon State University, Corvallis, OR).^{458) 459)} The old designation of the instrument was: NSCAT II. Objective: to acquire accurate, high-resolution, global measurements of sea-surface wind vectors in 1 to 2 day repeat cycles. Applications: studies of tropospheric dynamics and air-sea interaction processes, including air-sea momentum transfer. The instrument is an active microwave radar (a conically scanning pencil-beam scatterometer) with dual-beam, 40° (inner beam) and 46° look angle from nadir (outer beam), conical scan 1 m diameter reflector (rotating dish) antenna, operating in Ku-band at 13.402 GHz (110 W pulse at 189 Hz PRF). The antenna is conically scanned such that each point on the Earth within the inner 700 km of the swath is viewed from four different azimuth directions (twice by the inner beam looking forward then aft and twice by the outer beam in a similar fashion). Measurement of wind speeds between 3-20 m/s to an accuracy of 2 m/s, wind vector directions to an accuracy of 20°. The dish antenna is rotated about the satellite nadir axis at 18 rpm. Data is collected in a continuous 1800 km swath, centered about nadir (about 400,000 measurements daily covering 90% of Earth's surface). Spatial resolution = 50 km; FOV = $\pm 52^\circ$ from nadir; instrument mass = 200 kg; power = 220 W; duty cycle = 100%; average data rate = 40 kbit/s; thermal operating range is 5-40°C; pointing knowledge to 500 arcseconds. - SeaWinds data

458) B. D. Boller, et al., "The Development of the SeaWinds Scatterometer Electronics Subsystem (SES)," Proceedings of IGARSS'96, Vol. 1, pp. 269-272

459) <http://winds.jpl.nasa.gov/missions/quikscat/quikindex.html>

products consist of global multiazimuth normalized radar cross section measurements and 50-km-resolution ocean vector wind maps.

The antenna subsystem consists of a one-meter parabolic reflector antenna mounted to a spin activator assembly, which causes the reflector to rotate at 18 rpm. The activator assembly provides very accurate spin control and precise position or pointing information to the CDS (Command and Data Subsystem). The antenna spins at a very precise rate, and emits two beams about 6° apart, each consisting of a continuous stream of pulses. The two beams are necessary to achieve accurate wind direction measurements. The pointing of these beams was calibrated before launch for accurate echo location determination.

A.23 REX-II (Radiation Experiment Satellite II)

The REX satellites in STP (Space Test Program) of the USAF are designed to study scintillation effects of the Earth's atmosphere on RF transmissions. REX-I was launched June 29, 1991 on a Scout G1 vehicle from VAFB, CA (orbit: 770 km x 870 km, 89.6° inclination; S/C mass = 85 kg). Built by Defense Systems Inc. (DSI), the spacecraft was gravity gradient stabilized (approx. 5 degrees control) using a 6 m boom and 2.5 kg tip mass. Minor control was provided by three axis torque coils.

REX-II is the name of a minisatellite and a payload experiment, managed by SMC (Space & Missile Systems Center) at Los Angeles AFB. The objective of the mission is to study the physics of electron density irregularities that cause disruptive scintillation effects on radio signals. The S/C (built by CTA of McLean, VA) is stabilized using a passive gravity-gradient boom (6.4 m long) and two magnetic hysteresis rods for damping. In addition the S/C is actively controlled by electromagnetic coils and a pitch-axis reaction wheel which provides momentum bias. The S/C structure consists of an eight-sided box, 76 cm diameter, 56 cm height, total mass = 113 kg. Power (30 W) is provided by three NiCd batteries and by four solar arrays. Data transmission is via UHF-band during ground-station passes at rates of 2.4 kbit/s (uplink and downlink). The S/C was launched on March 9, 1996 on a Pegasus-XL vehicle from VAFB, CA.

Orbit: circular polar orbit, altitude=830 km, inclination=90°.

Experimental payload:

REX (Radiation Experiment) is the primary payload sponsored by the Rome Laboratory of the USAF/RL, Griffis AFB, NY. The objective is to study (and overcome) the physics of the electron density irregularities that cause disruptive scintillation effects on radio signals.

Three-axis magnetometer.

ADACS (Attitude Determination and Control Subsystem).^{460) 461)} The objective is to employ attitude knowledge in order to perform on-orbit attitude determination (maintaining a nadir pointing S/C orientation) using a GPS receiver/antenna system in closed-loop control with the ground control center. Three-axis attitude knowledge (0.3° on 1 m baseline) is provided by redundant TANS Vector receivers (Trimble Advanced Navigation Sensor) with software modifications/additions by GSFC and Stanford University. The GPS measurement concept uses four patch antennas, mounted coplanar with the S/C top plate. A multiplexed frontend allows the receiver to measure the differential carrier phase between the master and each of the slave antennas. - Several operating modes are defined within ADACS to coordinate attitude sensing and corresponding attitude control. Results

461) E. G. Lightsey, E. Ketchum, T. W. Flatley, J. L. Crassidis, et al., "Flight Results of GPS Based Attitude Control on the REX-II Spacecraft," Proceedings of ION GPS-96, Sept. 17-20, 1996, Kansas City, MO, pp. 1037-1046

of the technique (comparison with magnetometer measurements) indicate that the mean three-axis error of ADACS performance is 2.66° with a standard deviation of 1.16° , which is well within specifications (5° per axis).

A.24 ROCSat-3/COSMIC (Constellation of Six Microsatellites)

The ROCSat-3/COSMIC (Republic of China Satellite-3/Constellation Observing System for Meteorology, Ionosphere and Climate) is an international collaborative project between NSPO (National Space Program Office) of Taiwan and UCAR (University Corporation for Atmospheric Research) of the United States of America. Initiated in December 1997, the project will launch a LEO constellation of six microsatellites to collect atmospheric remote sensing data for operational weather prediction, climate, ionospheric (space weather monitoring), and geodesy research. NSPO is the prime sponsor and owner of the satellites. UCAR, located at NCAR in Boulder, CO, is primarily sponsored by NSF (National Science Foundation). Other partners in the project include JPL, NRL, USAF, NOAA, CWB (Central Weather Bureau of Taiwan), industry from both countries, universities, and other research organizations from the US, Taiwan, and other countries. ⁴⁶²⁾ ⁴⁶³⁾ ⁴⁶⁴⁾

Figure 34: The ROCSat-3/COSMIC spacecraft

The overall objective of ROCSat-3/COSMIC is to extend the low-cost research approach of refractive GPS radio occultation measurements (to derive important weather and climate research parameters, including atmospheric temperature, moisture, and pressure), that began with the GPS/MET instrument on Microlab-1 (launch April 3, 1995), to the next step by testing the ability of a constellation of six “ROCSat-3/COSMIC microsatellites with GPS/

MET heritage” to provide the data needed to fully evaluate the impact of this promising new observational tool. In addition to carrying an advanced version of the JPL-developed GPS receiver for occultation measurement, each satellite will carry two tiny, simple secondary instruments (tri-band-beacon and photometer) which synergistically enhance the accuracy and utility of the ionospheric observations. A global data collection network and operations center will process space and ground observations and deliver products to users in real-time for operational impact studies. The ROCSat-3/COSMIC constellation will be launched, using one Minotaur launch vehicle, in 2005, and be operated for at least two years.

Orbital Sciences Corporation (OSC) of Dulles, VA, is selected as the prime contractor for the satellites by NSPO. A joint team of the OSC and NSPO will design and manufacture the satellites, with the early phase of the work performed at OSC and integration and test performed at NSPO. Several local industry companies of Taiwan are selected to provide satellite components. The S/C structure is of cylindrical shape of 1 m diameter. All spacecraft are identical, with a mass of about 60 kg. Each S/C features on-board propulsion to reach its final destination orbit. The ADCS (Attitude Determination and Control Subsystem) provides attitude knowledge with an Earth limb sensor and a magnetometer. Power is provided by a solar array and 10 Ah batteries. The propulsion system consists of two tanks to store propellant (hydrazine) and 4 small monopropellant thrusters. The communication subsystem consists of an S-band receiver, an L-band transmitter, and a set of S-band and L-band antennas. ^{465) 466) 467) 468)}

Downlink Parameters		Uplink Parameters	
Receiver frequency	1690-1700 MHz (L-band)	Transmitter frequency	2025-2120 MHz
Polarization	Left Hand Circular	Polarization	Left Hand Circular
Data rates	Up to 2 Mbit/s	Data rate	Up to 32 kbit/s
Protocol	CCSDS compatible	Protocol	CCSDS compatible

Table 76: ROCSat-3/COSMIC communication characteristics

The ground segment of ROCSat-3/COSMIC consists of three ground TT&C stations and a MOC (Mission Operations Center). The three stations are located in Fairbanks (Alaska), Kiruna (Sweden), and Taiwan. The MOC is embedded into NSPO’s MMC (Multi-Mission Center). The MOC performs all S/C operations. All science and some telemetry data is sent to CDAAC (COSMIC Data Analysis and Archive Center) at Boulder, CO, and to TACC (Taiwan Analysis Center for COSMIC), a mirror site of CDAAC in Taiwan. The centers also receives data from a global network of ground GPS and TBB (Tri-Band Beacon Transmitter) receiving sites (the so-called fiducial network). The centers analyze the received data and distribute it to the principal investigators and to the science community for operational evaluation and research.

During the initial two years of the mission, the science data will be made available through the ROCSat-3/COSMIC project websites without charge.

Orbit: Circular orbit, altitude = 700 km, inclination = 72°. The six satellites are being positioned into six orbital planes .

The initial orbital altitude is 500 (-25/+100) km. Then different satellites will be boosted by

⁴⁶⁵⁾ Y. K. Kuo, L. C. Lee, “A Constellation of Microsatellites Promises to Help in a Range of Geoscience Research,” EOS Transcriptions, AGU, Vol. 80, No. 40, Oct. 5, 1999, pp. 467-471

⁴⁶⁶⁾ <http://www.cosmic.ucar.edu/>

⁴⁶⁷⁾ Information provided by Paul Chen of NSPO

⁴⁶⁸⁾ The GPS radio occultation technique is based on the following principles: As a signal travels through the atmosphere it is retarded and bent. This results in a phase and Doppler shift, which can be measured very accurately by the GPS receiver aboard the LEO ROCSat-3/COSMIC satellites. Since the transmitter and receiver positions and velocities are accurately know from precise orbit determination, the signal bending angle α as a function of impact parameter, can be computed from the Doppler shift observed at LEO. From the basic bending angle versus impact parameter data, vertical profiles of refractivity as a function of tangent point radius can be derived. Further analysis converts refractivity to electron density in the ionosphere.

on-board thrusters to different altitudes ranging up to 700 km. The corresponding different rates of orbit nodal precession will then gradually drift the orbit planes apart, until a more-or-less even distribution of six orbit planes is achieved. The orbit-adjustment process is estimated to take about 13 months, during which time the satellites will already start collecting atmospheric soundings.

Sensor complement:

The ROCSat-3/COSMIC constellation produces about 3000 soundings of bending angle and refractivity globally in all weather each day for at least one year after the spacecraft are placed in their final orbits. From these soundings, estimates of electron density in the ionosphere and temperature, water vapor and pressure in the stratosphere and troposphere will be derived. Desirable characteristics of these data include such items as: high accuracy, high vertical resolution, all weather (clouds and aerosols do not affect measurements), no calibration of instrument required, no instrument drift, require no first guess, modest cost.

Parameter	Science requirement	Comment
Vertical GPS occ. resolution	0.3-1.5 km	0.3 km near surface, 1.5 km at 45 km
Horizontal GPS occ. resolution	300-600 km	Smaller for fronts with large slope
Bending angle profile	1.5×10^{-6} rad	Limited mainly by residual ionospheric error and data noise
Refractivity profile	<1%	As good as 0.2% between 10-30 km
Temperature profile	1° C	In 0-40 km height range, assuming dry air
Water vapor profile	<1-10%	Between 0-5 km, assuming model temp. error of 1-2°, errors between 5-10 km are larger
Geopotential height vs pressure	10-20 m	Between 0-30 km (worse at solar maximum)
Electron density profile	<1-20%	Profile quality near the F2 peak, can be worse elsewhere; limited by horizontal gradients
GPS TEC	0.001 TECU	Relative TEC (absolute about 3-5 TECU)
TBB TEC	0.003 TECU	Relative TEC (absolute about 1-3 TECU)
TIP peak for F2 density, NmF2	<1-10%	Performs better at high electron densities Works only on the night side of the globe
Magnetometer measurement	10 nT	Precision at 1 Hz rate, 500 nT accuracy
Scintillation GPS	N/A	100 Hz SNR data used to determine S4
Scintillation TBB	N/A	50-1000 Hz SNR data
LEO position knowledge	about 10 cm	3-D rms position error (not critical)
LEO velocity knowledge	<0.1 mm/s	Relative velocity error for paired satellites

Table 77: Science requirements of the ROCSat-3/COSMIC constellation

Number of occultation measurements	About 2500 soundings/day on a global scale
L1/L2 phase measurements	About 2 mm (10 s interval for precise orbit determination)
GPS phase sampling rate	0.1-50 Hz
GPS vertical range neutral atmosphere	Surface to 60 km (50 Hz sampling)
GPS vertical range ionosphere	90-800 km (10 Hz sampling)
TBB phase measurement	<32 mm at 150 MHz (ground receiver)
TBB sampling rate	>50 Hz (ground receiver)
TIP measurement	<10% (uncertainty in photon count)
TIP footprint	125 km x 25 km (at 400 km height of F2 layer)
TIP resolution	0.1-10 s averaging
Magnetometer	10 nT precision, 500 nT accuracy

Table 78: Observational requirements of ROCSat-3/COSMIC

A **BlackJack GPS occultation receiver** is the primary science instrument of the ROCSat-3/COSMIC constellation. The particular receiver chosen for ROCSat-3/COSMIC is a refined version of the BlackJack occultation receiver developed by the Jet Propulsion Lab-

oratory for the CHAMP, SAC-C, and GRACE missions. The BlackJack receivers on ROC-Sat-3/COSMIC will be able to track all GPS satellites in view simultaneously, including two or more occulting satellites. It will operate fully autonomously, scheduling when to track which satellites and at what sampling rate based on its own known position and those of the GPS satellites. The instrument will report high-rate (50 Hz) dual frequency carrier phase measurements on the occulting links with sub-millimeter precision for accurate, high resolution profiling. Lower rate (0.1 Hz) phase measurements of all satellites in view will be collected for precise orbit determination at the 5-10 cm level. The receiver must track both GPS carrier frequencies to separate the frequency-dependent (dispersive) ionospheric delay from the non-dispersive refractive delay of the neutral atmosphere. A patented “semi-codeless” technique is used to obtain precise measurements of the L2 signal, both carrier phase and pseudorange, with anti-spoofing turned on. In addition to these measurements, the GPS instrument can record GPS signal amplitudes for on-orbit ionospheric scintillation monitoring and correction of signal diffraction effects in post-processing. The instrument mass is 3 kg; size of about 20 cm x 20 cm x 10 cm; power of 13 W, antenna inputs: 4.

TIP (Tiny Ionosphere Photometer), designed and built at NRL (Naval Research Laboratory), Washington, DC. TIP and TBB provide measurements of electron density, an important parameter of the upper atmosphere. The readings of TIP and TBB complement the primary BlackJack instrument so that 3-D fields of electron density between 90 and 750 km can be inferred.

In particular TIP provides horizontal gradients in electron density at the peak of the F2 layer, along the satellite orbit track. TIP measure the naturally occurring nighttime emission of neutral oxygen at 135.6 nm. This emission is produced by the recombination of O⁺ ions and electrons and is proportional to the square of the electron density in the ionospheric F region. Since horizontal gradients of electron density are a limiting error source for occultation inversions in the ionosphere, the combined analysis of TIP and GPS data promises improved retrievals of nighttime ionospheric profiles.

TBB (Triband Beacon Transmitter), designed and built at NRL. TBB transmits phase data measurements at 150, 400 and 1067 MHz which can be received at ground stations worldwide. These data are converted to line-of-sight total electron content (TEC) observations that can be processed with 2-dimensional ionospheric tomography techniques. TBB data can also be combined with the other ionospheric observations in tomographic and physical data assimilation models to compute global four-dimensional electron density fields.

The ROCSat-3/COSMIC instrument suite permits three-dimensional tomography of the ionosphere with unprecedented resolution and accuracy. ROCSat-3/COSMIC data will be highly complementary to other satellite sounding systems, including radiometric sounders on the POES and GOES series satellites of NOAA. The independence and the high-vertical resolution of the radio occultation soundings complement the high horizontal resolution of the radiometric soundings and together the two systems can likely be combined to yield composite soundings of temperature and water vapor with unprecedented accuracy, horizontal and vertical resolution, and global coverage.

A.25 SAN MARCO D/L

San Marco D/L^{469,470}) is a cooperative mission of CRA (University of Rome/Italy) and NASA/GSFC with sensor contributions from several agencies. NASA Scout launch vehicle, spin-stabilized satellite (axis parallel to Earth's axis), payload mass = 234 kg, satellite diameter = 0.940 m. Launch site: San Marco Range, Kenya; Mission duration: March 25, 1988 until Dec. 6, 1988.

469) Payload Definition Document for SAN MARCO D/L Satellite, CRA, Oct. 1987

470) G. Schmidtke, H. Doll, C. Wita, and S. Chakrabarti, “Solar EUV/UV and equatorial airglow measurements from San Marco-5,” *Journal of Atmospheric and Terrestrial Physics*, Vol. 53, No. 8, pp. 781-785, 1991

Objective: to explore the possible relationship between solar activity and meteorological phenomena by investigating the structure, dynamics, and aeronomy of the equatorial thermosphere, in particular:

- The relationship between density, composition, temperature, and airglow as a function of solar flux
- The interhemispheric transport of ions and neutral particles
- The dependence of neutral wind, ion drag, temperature, and particle densities on local time
- The relationship between neutral wind and the electric field
- Ionosphere irregularities and special events, and other parameters keyed to longitude
- The equatorial distribution of ozone
- Magnetic storm induced variations in the measured parameters
- The dependence of meridional wind and ion drift on the magnetic field
- The variation of the midnight temperature maximum

Orbit: Near-equatorial orbit, apogee = 619 km, perigee = 262 km, inclination = 2.9° .

Figure 35: San Marco D/L spacecraft model

Sensor complement:

DBI = Drag Balance Instrument (PI: L. Broglio, CRA). Measurement of the total aerodynamic drag force on the S/C.

ASSI = Airglow Solar Spectrometer Instrument (PI: G. Schmidtke, FhG/IPM, Fraunhofer Gesellschaft/ Institut für physikalische Meßtechnik, Freiburg, Germany).

Measurement of airglow, solar radiation, reflected solar radiation, and radiation from interplanetary and intergalactic sources. Four scanning spectrometers with solar pointing control cover a broad spectral range [from 20 - 700 nm (EUV - VIS)] using channels with 18 overlapping wavelength ranges with a spectral resolution of 0.7 - 4 nm (each spectrometer contains four or five detectors for a total of 18 detectors, there are two units of ASSI, namely ASSI-A and ASSI-B). Large dynamic ranges up to 10^{11} permit the measurement of very faint airglow or interplanetary radiation as well as intense solar emissions.

The ASSI-A and ASSI-B units are mounted on separate solar pointing devices, viewing 180° away from each other from the equatorial plane of the spacecraft.

WATI = Wind and Temperature Spectrometer (PI: N. Spencer, GSFC)

Measurement of two wind components (horizontal and normal to orbit plane), along with the kinetic temperature.

EFI = Electric Field Instrument (N. Maynard, PHG; T. Aggson, GSFC)

Plasma transport measurements. EFI consists of two orthogonal 40 m wire antenna pairs that are extended in the spin plane of the satellite, and a shorter antenna pair in the S/C spin axis. DC and electric field measurements.

IVI = Ion Velocity Instrument (PI: W. Hanson, University of Texas)

IVI measures the 3-D bulk velocity of the ambient ions in the S/C velocity frame. In addition IVI measures ambient plasma concentration and ion temperature.

Data: On-board recorder, VHF-band data link, data rate = 6 kbit/s. Sensor data at CRA and at World Data Center (GSFC).

The San Marco D/L mission is the fifth mission in Italy's San Marco program series.⁴⁷¹⁾

- San Marco 1 - Launch: Dec. 15, 1964 from Wallops. Orbit 194 x 697 km, incl. = 38° . Measured atmospheric density until its decay on Sept. 13, 1965
- San Marco 2 - Launch: April 26, 1967, Scout vehicle from San Marco (floating platform base in the Indian Ocean off the coast of Kenya). Orbit 185 x 211 km, incl. = 3° . Observation of atmospheric density. S/C re-entry: Oct. 14, 1967.
- San Marco 3 - Launch: April 24, 1971 from San Marco. Orbit: 222 x 718 km, incl. = 3° .
- San Marco 4 - Launch: Feb. 18, 1974 from San Marco. Orbit: 231 x 910 km, incl. = 3° . Observation of auroral zone over the equator. S/C re-entry on May 4, 1976.

A.26 SCISAT-1/ACE (Science Satellite/Atmospheric Chemistry Experiment)

In the time frame 1996/97 CSA (Canadian Space Agency) initiated the SCISAT program with the objective to provide opportunities for Canadian scientists to define and conduct space experiments in the following fields: Earth sciences, space astronomy, and solar-terrestrial relations. Mission selection procedures in the program are conducted via an AO (Announcement of Opportunity) process and peer reviews.^{472) 473) 474) 475)}

In addition, the SCISAT program is also part of a CSA/NASA collaboration program, consisting of two missions. Under the terms of the cooperative agreement, each agency provides a spacecraft and instrumentation, to be co-launched on an expendable vehicle. The AO for the Canadian elements of the first SCISAT (SCISAT-1) was released in 1997. The ACE mission was selected for flight in November of 1998.

475) P. Bernath, "Atmospheric Chemistry Experiment (ACE): An Overview," Spectroscopy from Space, J. Demaison, editor, Kluwer, 2001

The SCISAT/ACE mission is based at the University of Waterloo, Waterloo, Ontario (Mission Scientist: P. Bernath). The overall objective is to monitor and analyze the chemical processes that control the distribution of ozone in the upper troposphere and stratosphere. A comprehensive set of simultaneous measurements of trace gases, thin clouds, aerosols and temperature are being collected by solar occultation from low earth orbit. Detection of more than 30 molecules such as: O₃, N₂O, CH₄, HNO₃, H₂O, HCl, Hf, NO, NO₂, ClNO₃, CO, CO₂, CCl₃F, CCl₂F₂, and N₂O₅.

The ACE minisatellite structure, built by Canadian industry (Bristol Aerospace Ltd of Winnipeg, Manitoba), uses a circular instrument/component aluminum mounting plate (1.1 m in diameter) as the main structure of the three-axis stabilized platform. Attitude control is based on a bias momentum stabilization approach. The subsystem consists of a momentum wheel, torque rods along all three body-fixed axes, one fine sun sensor, a magnetometer and a set of six coarse sun sensors. All sensors and actuators are off-the-shelf components with flight heritage. In addition, the GyroWheel of Bristol is flown for technology validation (the GyroWheel has the ability to provide the S/C simultaneously with stored angular momentum, function as a 3-axis torque actuator, and measure the S/C angular rates in two axes). The S/C is always in a sun-pointing configuration. S/C power (71 W average) is generated by a single body-mounted solar panel. In addition, there are Lithium-Ion batteries for the orbital eclipse phase operations. On-board source data recording of up to 1.5 GByte is provided. The C&DH (Command & Data Handling) unit was developed for small satellites. It is responsible for all onboard data handling, monitoring and recording. The unit features low-power (<10 W), low-mass (<4 kg) and a radiation-tolerant core in a single string architecture (a UTMIC 80C196 16-bit processor is used to perform all S/C operations). A storage capacity of 1.5 Gbit is provided. The S/C mass is about 150 kg, the design life is two years with a goal of five years. A NASA-sponsored launch of SCISAT/ACE is scheduled for early summer 2002 on a Pegasus-XL vehicle.

Figure 36: Schematic illustration of the SCISAT-1/ACE spacecraft (two views)

S/C communications are provided in S-band using the CCSDS protocol (variable-rate telemetry up to 5 Mbit/s can be supported). The downlink uses OQPSK modulation, and the uplink is compatible with NASA's STDN (Satellite Tracking and Data Network) standards. The maximum data rate (occurring during an occultation) is about 9.6 Mbit/s, and almost all of it come from the ACE-FTS instrument. The uplink data rate is 4 kbit/s. Mission operations of SCISAT/ACE are conducted at CSA in St. Hubert near Montreal.

Orbit: Circular orbit, altitude = 650 km, inclination = 73.9°.

Sensor complement:

ACE-FTS (ACE-Fourier Transform Spectrometer), is being built by ABB Bomem Inc. of Quebec City, Quebec. The objective is to measure the vertical distribution of trace gases, in particular of the regional polar O₃ budget, as well as pressure and temperature (derived from CO₂ lines). The instrument is an adapted version of the classical sweeping Michelson interferometer, using an optimized optical layout. It consists of the following components: the FTS, a VNIR (Visible Near Infrared) imager, a sun tracker, the instrument electronics, and a power supply. An SNR > 100 is achieved; IFOV (FTS) = 1.25 mrad; an aperture diameter of 100 mm and a measurement period of 2 s. Instrument mass = 40 kg, power = 40 W operating, and 15 W in standby.

- The FTS spectrometer looks at the sun through the atmosphere (occultation or limb-viewing geometry) at different tangent heights, providing a series of spectra that are used to deduce the vertical distribution of trace gases and temperature. The spectral range of the instrument is from 2-13 μm (750 - 4100 cm^{-1}) in two bands, and the maximum resolution is 0.025 cm^{-1} . InSb (1800-4100 cm^{-1}) and HgCdTe (750-1800 cm^{-1}) detectors are used. Both detectors are cooled below 110 K. The spectrometer transforms the spectra into a modulated signal, the interferogram, in which all of the IR bands are present simultaneously. The spectrometer output consists of such interferograms for each observed scene. The interferograms are Fourier-transformed into spectra on the ground to provide vertical profiles of atmospheric constituents at resolutions of 3-4 km.

Parameter	Value	Parameter	Value
Spectral range	750-4100 nm	Noise equiv. radiance	<0.5% of the radiance of a blackbody at 5800 K
Spectral resolution cm^{-1}	<0.028, 0.056, 0.11, 0.55	Detectors	InSb, HgCdTe
Sweep duration	2, 1, 0.5, 0.1 s	Detector cooling	Passive cooling <110 K
Spectral stability (relat.)	3 x 10 ⁻⁷ rms for 180 s	FOV (Field of View)	1.25 mrad

Table 79: Characteristics of the ACE-FTS instrument

- VNIRI (Visible Near Infrared Imager). Objective: monitoring of aerosols using the method of extinction of solar radiation. VNIRI provides sun images in two spectral bands at 0.525 μm and at 1.02 μm . Refractive index distortion of the solar image for low altitude measurements is monitored with a large photodetector array of 128 x 128 effective elements covering 30 mrad with a pixel separation of 0.25 mrad (the IFOV is more than four times smaller than the IFOV of the FTS). These measurements have an SNR > 1000 for all sun-illuminated pixels in a two-second observation time. The sun tracker keeps the instruments (FTS and VNIRI) automatically pointed at the sun's radiometric center.

MAESTRO (Measurement of Aerosol Extinction in the Stratosphere and Troposphere Retrieved by Occultation), designed and built in a partnership between MSC (Meteorological Service of Canada) and EMS Technologies of Ottawa. MAESTRO is a dual optical spectrograph in the spectral region of 285-1030 nm. The objective is to measure ozone, nitrogen dioxide and aerosol/cloud extinction. The use of two overlapping spectrographs (280 - 550 nm, 500 - 1030 nm) improves the stray-light performance. The spectral resolution is about 1-2 nm. The detectors are linear EG&G Reticon photodiode arrays with 1024 elements. The instrument design is based on a simple concave grating with no moving parts. The entrance slit is held horizontal to the horizon during sunrise and sunset by controlling the spacecraft roll with a startracker and a momentum wheel on the satellite bus. The vertical resolution of the MAESTRO data is about 1 km; the SNR is > 1000. The high vertical resolution may help to distinguish between various atmospheric layers. The oxygen A-band at 762 nm (as well as the B-band and gamma-band) are used to make an independent determination of atmospheric temperature and pressure. MAESTRO is also able to make some near-nadir solar backscatter measurements with a separate backscatter port. The mass of the instrument is about 7 kg, power = 15 W (operating), 7 W (standby), the data rate = 3 Mbit/s.

A.27 **SORCE (Solar Radiation and Climate Experiment)**

SORCE is a NASA-sponsored microsatellite mission. The overall objectives to continue the precise, long-term measurements of TSI (Total Solar Irradiance) at UV and VNIR wavebands. The science objectives include:

- Daily measurements of the solar UV (120-300 nm) with a spectral resolution of 1 nm. To achieve an absolute accuracy of better than $\pm 5\%$, and a precision and long-term relative accuracy of $\pm 0.5\%$.
- To make the first precise measurements of the visible solar irradiance suitable for future climate studies - to obtain a daily measurement of the solar irradiance, between 0.3 and 2 μm , with a spectral resolution ($\lambda/\Delta\lambda$) of at least 1/30, an absolute accuracy of $\pm 0.3\%$ (3 sigma), and a precision and relative accuracy of better than $\pm 0.01\%$ /year.
- Improve our understanding of how and why the variability occurs at the Sun and how the variable irradiance affects our atmosphere and climate. To use this knowledge to estimate past and future solar behavior and climate response.
- To make precise and accurate measurements of TSI, connect them to previous TSI measurements to form the long-term climate record. To provide absolute accuracy of 0.03 % (300 parts per million) based on SI units and a relative accuracy of 0.001%/yr.

Figure 37: The SORCE S/C model

SORCE extends the broad data set gathered by the ACRIM instrument series while exploring a new capability to measure solar irradiance in two discrete spectral bands (ten-fold measurement accuracies are required over existing spaceborne radiometer and spectrometer performances). The SORCE project is designed, managed and operated by LASP (Laboratory for Atmospheric & Space Physics) of the University of Colorado in Boulder, CO (PI: G. J. Rottman). The payload instruments are designed and built by LASP.⁴⁷⁶⁾

The SORCE spacecraft is a three-axis stabilized, momentum-bias system using redundant reaction wheel assemblies, active magnetic control, and redundant sun sensors (provided by the instrument payload). The S/C is sun-pointed during the dayside orbit and star-

⁴⁷⁶⁾ <http://lasp.colorado.edu/sorce/>

pointed during the nighttime portion of the orbit. The S/C pointing values are: accuracy of 0.24 arc-minutes, knowledge of 0.20 arc-minutes, stability of 33 arc-minutes/min, and jitter of 3.0 arc-seconds/s. The slew rate is 2.2°/s. The S/C dimensions are: 1.48 m in height and 1.12 m in diameter; power = 730 W (EOL), provided by six fixed GaAs solar arrays; a 20 Ah NiH battery provides power during eclipse phases. The S/C mass is 268 kg, the payload mass is 86 kg, the S/C design life is six years. An on-board data storage of 1024 Mbit is provided. S/C communications are in S-band with an uplink of 2 kbit/s and a downlink of 1.25 Mbit/s (maximum data volume of about 570 Mbit/day). Mission operations are performed from LASP, using two ground stations located at Wallops and at Hawaii. Nominal SORCE operations include data downloads twice a day. A launch is planned for mid 2002 on a Pegasus XL vehicle from Cape Canaveral, FL.

Orbit: Circular orbit, altitude = 645 km, inclination = 40°.

Sensor complement:

TIM (Total Irradiance Monitor). TIM is an active cavity radiometer of ACRIM heritage, but with significant improvements in sensor and electrical design, particularly in thermal control. Objective: Measurement of TSI directly traceable to SI units (Système International d'Units) with an absolute accuracy of 0.03% and relative accuracy of 0.001% per year. The complete wavelength range is covered.

The TIM instrument consists of a cylindrical housing containing four identical, right circular, 15° apex angle, conical cavity detectors cantilevered from a single support. The mount provides thermal impedance between the cavities and the heat sink which surrounds them. One cone, the measurement cavity, views the total solar disk through a precision aperture, and any of the other cones may be used as the reference cavity. The cones are made from 1 mm thick electro-deposited 99.99% pure silver. The cone interiors and the heat sink are coated with a Ni-P black and etched to produce a diffuse black surface which has a nominal visible reflectance of 0.3%. - Six miniature (1 mm²) diamond-substrate chip heaters are soldered to the back of each cone. Gold electrode spinel chip thermistors mounted between the apex of each cone and its support structure are used as sensors for the electrical bridge circuit which controls the measurement cavity temperature. Baffles, located behind the primary aperture, shield the measurement cavity from earth albedo and off axis infrared radiation. Small Si and InAs photodiodes, located just behind the heat sink, view the measurement cavity at an oblique angle to measure the change in its reflectance. The heat sink is thermally isolated from the TIM channel case and its temperature is controlled to 0.001°C.

The ESR (Electrical Substitution Radiometer) of TIM has dual bolometers with autobalancing through an AC, digital, feedback loop.

TIM incorporates four cavities (cones) and adheres to the basic concepts of Electrical Substitution Radiometers (ESRs), but employs modern, state-of-the-art electronics and materials. The four cavities provide multiple redundancy and added duty-cycling capability. TIM looks at the sun every spacecraft orbit. Each measurement consists of multiple samples taken over the course of a single orbit, providing 15 measurements per day. The TIM shutters, one for each radiometer, are driven by brushless torque motors. In its normal operational mode, the TIM shutter is cycled 50% open and 50% closed every 100 seconds throughout the orbit. Periodic (approximately once per week) field of view maps are obtained by offset pointing the S/C by ±15° about the sun vector. - Instrument mass = 5.9 kg, power = 13.1 W (average), size = 17.7 cm x 27.9 cm x 27.2 cm (H x W x D), data rate = 1.661 kbit/s.

SOLSTICE (Solar/Stellar Irradiance Comparison Experiment). The 2nd generation instrument is of SOLSTICE heritage flown on UARS. SOLSTICE is a two-channel grating spectrometer with the objective to measure UV radiation in the spectral coverage of 115 to 320 nm with a spectral resolution between 0.1 nm and 0.2 nm. The device compares the ultraviolet output of the sun with similar radiation produced by about 20 stable, bright blue

stars. The stars constitute the standards (calibration) against which the solar irradiance is measured. The standard may therefore serve to directly compare the solar observations done by SORCE as well as by UARS, or by any other future SOLSTICE-type observation.

The SOLSTICE design features two identical spectrometers, mounted at right angles to each other to use perpendicular dispersion directions in order to facilitate verification of stellar pointing . A plane mirror reflects the beam onto one of two diffraction gratings mounted in a precision single-axis gimbal. Rotating the gimbal to a specified angle causes the illuminated grating to diffract a small wavelength band of the original beam toward a second plane mirror. The diffraction grating disperses the radiation and directs a specific wavelength onto one of the two photomultiplier detectors. - About 15 solar spectra and multiple stellar observations are provided each calendar day, resulting from about 15 orbits/day with measurements taken in the daytime (sun) and nighttime (stars) portions of the orbit.⁴⁷⁷⁾

Instrument type	Modified Monk-Gilleison spectrometers
Primary detector type	Photomultiplier tubes
FOV (Field of View)	1.5° x 1.5°
Wavelength range	115 - 180 nm and 170 - 320 nm
Spectral resolution	0.1 - 2.2 nm
Accuracy, precision	5%, <1% over mission life
Instrument dimensions (HxWxD)	18.3 cm x 38.7 cm x 84.6 (x2) cm
Instrument mass ,power, nominal data rate	36 kg, 33.2 W, 738 bit/s

Table 80: SOLSTICE instrument parameters

Figure 38: Optical layout of the SOLSTICE instrument

In-flight instrument calibration includes 1) long-term multi-wavelength observations of bright, blue stars, 2) redundant channel capability, and 3) anticipated underflight calibrations by almost identical instruments on sounding rockets. The wavelength calibration for

⁴⁷⁷⁾ William McClintock, “2nd Science Team Meeting for the Solar Radiation and Climate Experiment - SORCE,” The Earth Observer, Nov./Dec. 2000, Vol. 12, No 6, pp.22-27

the in-flight data uses the many well-known solar emission features to determine the wavelength scale.

SIM (Spectral Irradiance Monitor). Objective: Measurement of the solar spectral irradiance in the 200 to 2000 nm range. SIM is a dual-redundant spectrometer with a single optical element; it provides spectral measurements by rotating a small prism and recording the spectrum at the exit slit using a new high-sensitivity ESR (Electrical Substitution Radiometer). The ESR measurement technique measures heat flux. Two identical sensors, one active and the other used as reference, are connected so that they are in the same environment and at the same temperature. Joule heat is supplied to each sensor by an “actively controlled” heater circuit. The sensors have very high absorptivity in order to efficiently collect radiation, so that all photon energy incident on the detector is converted into heat. As radiation is allowed to fall on the active sensor, a corresponding amount of Joule heat must be removed from that sensor in order to restore the heat flux balance. This change in Joule heat to the active sensor is equivalent to the amount of radiation incident upon it.⁴⁷⁸⁾

The SIM instrument consists of two identical mirror-image spectrometers (A and B). This dual-channel design provides redundancy, self-calibration capability, and duty cycling necessary to meet the science objectives. In normal operation, spectrometer A is used for daily solar irradiance measurements while spectrometer B is used to make solar measurements on a much lower duty cycle (perhaps once per month). Additionally, a periscope system couples the two spectrometers and is used in conjunction with two photodiodes (Si and extended InGaAs) on a rotation turntable to provide an in-flight measurement of prism.

Parameter	Value	Parameter	Value
Spectral range	200 - 2000 nm	Spectral resolution	0.25 - 34 nm
Spectrometer f number	f/16	Solar f number	f/115
Prism aperture	25 mm x 12.5 mm	Effective focal length	400 mm
Prism vertex angle	34.5°	Front surface radius	435.3 mm
Back surface radius	445.4 mm (aluminized)	Scan range (focal plane)	40 mm
Optical aberration at exit slit	5 µm	Diffraction correction	0.3 - 2.2%
		Slit sizes	0.3 mm x 7 mm

Table 81: SIM instrument S-channel specification

In normal operation with the shutter open, sunlight enters the 0.3 mm x 7 mm entrance slit and follows a f/115 beam to the prism, 400 mm from the slit. The focusing prism forms a nearly flat spectrum at the focal plane. For each spectrometer, four separate detectors measure the solar irradiance; the primary detector is an Electrical Substitution Radiometer (ESR), and additional silicon and extended InGaAs photodiodes are used for the UV, Visible, and the IR portion of the spectrum respectively. The ESR and the photodiodes, behind separate exit slits, simultaneously measure radiation at four neighboring wavelengths.

Prism drive: The solar spectral intensity at S-channel resolution typically varies 3% per slit width (average value over the entire spectral range), requiring that the prism drive reproducibility be better than 1 µm (one slit width/300). The prism drive achieves 0.3 µm precision by rotating the prism on a flex pivot with a flex-suspended voice coil motor. Closed-loop control of prism rotation uses a small concave mirror on the prism table to focus a second, reference solar beam back to the focal plane and onto a 12,000 element (78 mm active length), 6.5 m² pixel size, 6.5 m² pitch linear CCD (Thomson TH7834C). The CCD detector at the focal plane compensates for motion and any bending of the optical bench. For ESR operation, spectra are measured in a step-stop-integrate mode with 3 steps per slit width (100 m² steps) to eliminate spectral aliasing of the integrated spectrum. The steep portions of the solar spectrum are benchmarks for wavelength adjustment, and the local maxima and

⁴⁷⁸⁾ G. Rottman, G. Mount, G. Lawrence, T. Woods, J. Harder, S. Tournois, “Solar spectral Irradiance measurements: visible to near-infrared regions,” *Metrologica*, Vol 35, 1998, pp. 707-712

minima in the spectrum provide the most reproducible measurements of spectral irradiance.

The ESR provides a long-term, absolute detector for the S-channel and maintains the sensitivity standard for the working photodiodes. The ESR optical head consists of dual bolometers each at the center of an optical quality isolation hemisphere, which reflects light back onto and thermally shields the detectors.

XPS (XUV Photometer System), of SXP (Solar X-ray Photometer) heritage flown on SNOE. The objective is to measure the XUV (Extreme Ultraviolet) solar irradiance from 1 to 35 nm. The instrument package consists of twelve silicon XUV photodiodes. Each photodiode has a thin-film filter to provide an approximately 5 nm spectral bandpass. These thin film filters are deposited directly on the photodiode to avoid using delicate metal foil filters which are difficult to handle, prone to develop pin holes, and degrade with time. The set of twelve XUV photometers is packaged together with a common filter wheel mechanism, which can rotate a closed aperture, a fused silica window, or an open aperture in front of any given photometer. The fused silica windows on this filter wheel permit accurate subtraction of the background signal, if any, from visible and near UV light.

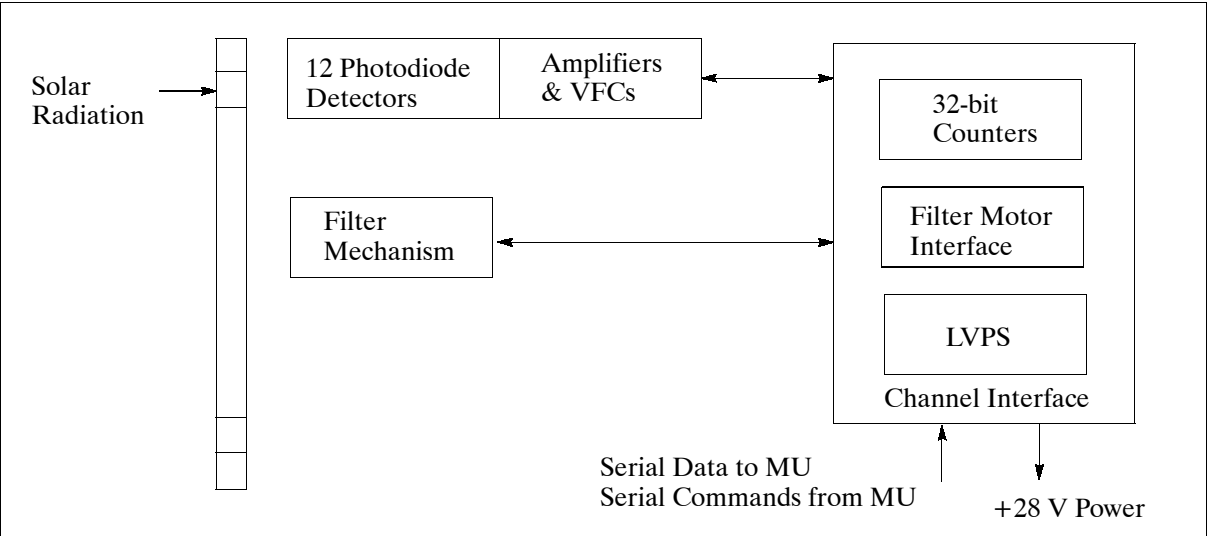

Figure 39: Block diagram of the XPS instrument

Instrument type	XUV photometer
Primary detector type	EUV photodiodes
Spectral range, resolution	0.1 - 31 nm, 5-10 nm
Accuracy, precision	20%, 4% over mission life
Instrument dimensions (HxWxD)	15.6 cm x 18.7 cm x 17.2 cm
Instrument mass, power, nominal data rate	2.6 kg, 8.6 W, 267 bit/s
FOV (Field of View)	8° (full cone angle)

Table 82: XPS instrument parameters

The 12 XUV photometers (XPs) are grouped into three sets. Each set of four XPs is arranged in a circle for use with the filter wheel mechanism. The filter wheel, which has 3 different rings of filters for the three sets of XPs, has 8 positions : four blocked for dark measurements, two clear for solar XUV measurements, and two with fused silica windows for solar visible background measurements. An observation run is a sequence of measurements from five consecutive filter wheel positions, normally starting and ending with dark measurements. The electronics for each photodiode include only a current amplifier and a voltage-to-frequency (VTF) converter.

Calibration: The XPs are silicon photodiodes with thin film filters to measure the integrated solar UV irradiance from 0.1 to 35 nm with a typical bandpass of 5 nm. The XPS instrument has redundant XPs in order to have a working photometer for daily measurements and a lower duty cycle (reference) photometer for degradation analysis of the working photometer. The reference photometer is used for a solar measurement every week; therefore, the cadence of the reference photometer is once per 105 measurements by the daily channel assuming 15 orbits per day.

A.28 TIMED (Thermosphere, Ionosphere, Mesosphere Energetics and Dynamics)

TIMED is a NASA exploratory mission, managed by JHU/APL (Johns Hopkins University/Applied Physics Laboratory) for NASA.^{479) 480) 481)} The primary objective is to investigate and understand the energetics of the Mesosphere and Lower-Thermosphere/Ionosphere (MLTI), the region in the Earth's atmosphere from about 60 to 180 km in altitude. The measurements of TIMED will provide data defining the basic states of the MLTI region and its thermal balance. Specific missions goals are:

- to determine the temperature, density and solar wind structure in the MLTI region, including the seasonal and latitudinal variations
- to determine the relative importance of the various radiative, chemical, electrodynamical, and dynamical sources or sinks of energy for an understanding of the thermal structure of the MLTI.⁴⁸²⁾

The TIMED S/C structure is an aluminum and framework/honeycomb design with a MIL-STD-1553B data bus; three-axis stabilization, attitude knowledge is 0.03° (3σ , all stellar), attitude control is 0.5° (3σ , three-axis momentum-bias); mission design life = 2 years; S/C mass = 660 kg, power = 426 W (solar panels, 50 Ah Ni-H₂ battery). Integrated Electronics Module (IEM) consisting of: 2 DC/DC converter, CMD&TLM processor, 2.5 Gbit solid-state recorder, GNS (GPS Navigation System), CMD&TLM interface, S-band uplink and S-band downlink (each consisting of a plug-in card). The transmission protocol is CCSDS compliant. Of particular interest is GNS, developed at APL. GNS is the spacecraft's navigation and timekeeping system. It is designed to autonomously provide position, velocity, time, sun vector, and defined orbital event notifications (e.g., terminator crossings and SAA (South Atlantic Anomaly) region encounters in real time. GNS consists of a zenith-oriented antenna, a preamplifier, RF downconverter, GTA (GPS Tracking ASIC - with a 12 channel GPS signal tracking capability), and a dual-processor-based computer system.^{483) 484)}

A launch of TIMED is planned for 2001 aboard a Delta-2 launcher from VAFB, CA (co-manifest with Jason-1).

Orbit: Circular orbit, altitude = 625 km; inclination = 74.1° with a 720° per year nodal regression (this means the local time of the equator crossing varies from dawn to dusk in three months).

Areas of applications: The MLTI is a very poorly understood region of the atmosphere. The results of the TIMED mission will enable the scientific community to establish the first quantitative MLTI baseline and will serve as a basis for future investigations.

Figure 40: The TIMED S/C model

RF communication: On-board storage capability of 2.5 Gbit in solid-state memory; communication in S-band (CCSDS standard). The scalable architecture of the S-band RF transceiver system is part of the IEM. The transceiver consists of two RF cards, each of size 15 cm x 22 cm. The IEM approach provides the integration of functionalities that are normally part of the system (inclusion of a real-time critical command decoder). The downlink card outputs a CCSDS-compatible downlink signal and support data rates up to 4 Mbit/s. The downlink card also includes an on-board data framer and Reed-Solomon encoder.

Non-coherent navigation: In addition, the transceiver system cards provide the capability for highly accurate Doppler tracking, using a two-way non-coherent technique. The APL-developed technique obviates the need for coherency between the uplink's carrier tracking oscillator and the downlink carrier. In this technique, the uplink carrier signal is received and compared with the receiver's on-board reference oscillator. This operation results in a set of phase comparison counts, placed in the telemetry and transmitted to the ground. There, the ground station continues tracking the S/C as if it were a coherent transponder. The uplink and downlink error counts are compared with the telemetered phase comparison counts. Tracking accuracies to 0.1 mm/s (velocity error) are achieved.

RF output frequency, output power	2214.97 MHz (S-Band), 3 W
High-rate modulation	4 Mbit/s with DQPSK modulation
Low-rate modulation	9 kbit/s residual carrier PM
Coding	Differential (select or bypass) Convolutional (select or bypass) Reed-Solomon (select or bypass)
Downlink framer	CCSDS compatible protocol
Bus interface	PCI
Card size, mass	15.3 cm x 23 cm, <0.6 kg
DC power	12.7 W conditioned power (transmit) 1.0 W conditioned power (standby)

Table 83: Downlink card characteristics

Mission operations are performed from JHU/APL in Laurel, MD. The payload operations concept requires each PI to perform his own instrument operations from his home site. A combination of on-board GPS processing and the use of Internet move the data from the APL ground station to each investigator's home site. By separating instrument operations from all S/C system activities, the instrument teams are able to control all of the instrument modes, operations and science data return at their own choice without explicit interactions or approvals by the S/C project team. In addition, the Internet is used by each investigator to control his instrument directly (the packetized messages are integrated into the uplink command structure in an automated fashion).

Sensor complement:

SEE = Solar EUV Experiment (PI: T. N. Woods; built by LASP of the University of Colorado).⁴⁸⁵⁾ The solar sensors in SEE are **EGS** (EUV Grating Spectrometer) and **XPS** (XUV Photometer System). The objective is to measure the absolute fluxes of solar UV, EUV, and XUV radiation and to determine the rates of energy deposition, dissociation and ionization. EGS features a Rowland-circle grating design; detector: 64 x 1024 MCP/CODACON (microchannel plates with coded anode position array); spectral range of 25 to 200 nm; resolution of 0.4 nm (0.17 nm per anode); FOV = 6° x 12°. - XPS has 12 XUV silicon photodiodes (thin film coatings on diodes) as detectors. The spectral range is 0.1 to 40 nm, the resolution is 0.4 nm above 25 nm and about 3 nm below 25 nm, FOV = 20° in diameter. Instrument mass = 26 kg, power=16 W (average). Look direction: solar pointing; data rate = 210 bit/s.

SABER = Sounding of the Atmosphere using Broadband Emission Radiometry (PI: J. M. Russell, Hampton University; instrument builder: SDL of Utah State University, Logan, UT). SABER (heritage of LIMS, SAMS, CIRRIS, ATMOS, HALOE, CLAES, ISAMS, and SME) is a 10-channel radiometer with the objective to measure the IR emissions emitted at altitudes generally below 100 km by limb scanning to drive vertical distributions of temperature and concentrations of energetically important species (O₃, H₂O, NO, NO₂, CO, CO₂) as well as radiative energy loss. The telescope is an on-axis Cassegrain design (rejection of stray light outside IFOV). Instrument mass=61.7 kg, power = 64 W; detector types: five HgCdTe (photoconductive mode of operation), two InSB (photovoltaic mode of operation), and three InGaAs (photovoltaic mode of operation). Spectral coverage: discrete ranges from 1.27 - 17 μm (7865 cm⁻¹ to 650 cm⁻¹). A scan depressing angle of -20.0° to -13.9° from the S/C horizontal is used; vertical resolution of 2 km; the telescope is cooled to 240 K; the focal plane assembly is cooled to 75 K; data rate: 4 kbit/s. SABER scans up and down the Earth's horizon once every 58 seconds, collecting data over an altitude range from about 180 km down to the Earth's surface (vertical profiles of elemental constituents) and temperature.

Instrument drifts due to changes in telescope and focal plane base temperatures are corrected by an in-flight calibration system.

Altitude range (km)	Parameter measured	Spectral range (μm)	Application
10-130	CO ₂	14.9 & 15.2	Temperature, density, IR cooling rates, P(z), non-LTE
15-100	O ₃	9.6	O ₃ concentration, cooling rates, solar heating and dynamics studies
50-105	O ₂	1.27	O ₃ concentration (day), inferred O at night, energy loss for solar heating efficiency
85-150	CO ₂	4.3	CO ₂ concentration, mesosphere solar heating, tracer
80-100	OH (v)	2.0 & 1.6	HO _y chemistry, chemical heat source, dynamics, inference of O and H, PMC studies
90-180	NO	5.3	Thermosphere cooling, NO _x chemistry
15-80	H ₂ O	6.9	HO _y source gas, dynamical tracer

Table 84: Overview of SABER measurements and applications

TIDI = TIMED Doppler Interferometer (PI: T. L. Killeen, U. of Michigan). Objective: investigation of the dynamics and energetics of MLTI. TIDI measures the VIS/NIR emissions emitted at altitudes between 60 and 300 km by limb scanning techniques to determine the temperature and horizontal winds with the use of the Doppler effect. The instrument makes also density measurements, mostly on the day side of the orbit. TIDI comprises three subsystems: four identical telescopes (off-axis Gregorian type, aperture 7.5 cm, f/2.2 FOV = 2.5° horizontal x 0.05° vertical), a Fabry-Perot interferometer (fixed-gap single etalon)

⁴⁸⁵⁾ http://lasp.colorado.edu/see/see_instrument.html

with a CCD detector (passively cooled), and an electronics box. TIDI views emissions from OI 557.7 nm, OI 630.0 nm, OI 732.0 nm, O₂ (0-0), O₂ (0-1), Na D, OI 844.6 nm, and OH to determine Doppler wind and temperature throughout the altitude range. Instrument mass=42 kg; power=19.3 W; spectral coverage: selected lines between 550 - 900 nm; look direction: limb scan; a scan depression angle of 23.2° to - 16.8° from the S/C horizontal is used; data rate = 2.336 kbit/s.

GUVI = Global Ultraviolet Imager (PI: A. B. Christensen, The Aerospace Corporation). The instrument is of SSUSI heritage and a joint collaboration between JHU/APL and The Aerospace Corporation, El Segundo, CA. The objective is to monitor three general regions: the daytime low- to mid-latitude thermosphere, the nighttime low- to mid-latitude ionosphere, and the high-latitude auroral zone. The goal is to obtain a detailed quantitative and predictive understanding of auroral phenomena. The instrument consists of the following elements: a scan mirror feeding a parabolic telescope and Rowland circle spectrograph, with a wedge-and-strip detector at the focal plane. GUVI is a FUV scanning imaging spectrograph providing horizon-to-horizon images in five selectable bands or “colors.” The colors chosen are: H 121.6 nm, O 130.4 nm, O 135.6 nm, and N₂ Lyman-Birge-Hopfield (LBH) bands at 140 to 150 nm and 165 to 180 nm. GUVI uses a scan mirror to sweep its FOV of 11.78° through an arc of up to 140° (scan from 80° to -60°) in the cross-track direction. This FOV is mapped via an f/3 Rowland circle spectrograph (with a toroidal grating) into 14 spatial and 160 spectral “pixels.” The scan sweep time is 22 s. The detector is a microchannel plate (MCP) intensified wedge-and-strip anode which provides a 2-D readout. The SIS (Scanning Imaging Spectrograph) of GUVI consists of a cross-track scanning mirror at the input to the telescope (a 75 mm focal-length off-axis parabola system with a 25 x 50 mm clear aperture) and a Rowland circle spectrograph. Two 2-D photon-counting detectors are located at the focal plane of the spectrograph. The operating detector is selected by a “pop-up” mirror that is moved into or out of the optical path to direct radiation from the grating onto one of two detectors. The detectors employ a position-sensitive anode to determine the photon event location.

GUVI has both cross-track disk and limb scan modes; it measures the UV radiation emitted at altitudes generally above 150 km up to 520 km by limb-scanning and imaging to determine during daytime conditions the concentrations of N₂, O₂, O, and the temperature; infers the fluxes of precipitating auroral particles. Instrument mass=19.2 kg, power=24 W; swath width of about 300 km; spectral coverage: 110 - 180 nm; look direction: cross-track scan (disk + limb); data rate = 8.0 kbit/s.

The GUVI observations are compared with data collected by the ground stations for “ground truthing.” GUVI products include maps of the auroral oval, the characteristic energy and flux of the electrons which excite it, F-region ionospheric electron density profiles, and dayside neutral composition information.

Parameter	H (121.6 nm)	O (130.4 nm)	O (135.6 nm)	N ₂ (LBH-1)	N ₂ (LBH-2)
Dayside limb	H profile and escape rate	O profile	O altitude profile	Solar EUV inputs	N ₂ , O ₂ , temperature
Dayside disk	H column	Composition	O/N ₂	O/N ₂	
Nightside limb	H column	F-region electron density profile			
Nightside disk	H column	F-region total electron content			
Auroral zone	Proton auroral boundaries	Auroral boundaries	Effective energy flux Q	Effective average energy of precipitating particles	

Table 85: GUVI environmental parameters measured by different colors

A.29 TOMS Missions

Within NASA’s Earth Probes Program several TOMS (Total Ozone Mapping Spectrometer) or TOMS/NSCAT missions are planned. The objectives are:

- to continue the global ozone data set that began in 1978 with the flight of TOMS on NIMBUS-7
- to continue observation of environmentally important areas such as the Antarctic ozone hole
- to observe sulfur dioxide clouds resulting from volcanic eruptions

A.29.1 TOMS-EP

TOMS-EP (Earth Probe) is a free-flying spacecraft (built by TRW, Redondo Beach, CA) with a payload of the TOMS instrument. It is nadir pointing and provides a contiguous survey of the Earth every day. The S/C bus is of modular design (TRW lightsat bus) with a stowed size of 1.16 m in diameter and 1.77 m in height, three-axis stabilized with a 3 sigma pointing accuracy of $<0.25^\circ$ (knowledge) and $<0.5^\circ$ (control). Design life = 2 years, S/C mass = 295 kg, power = 130 W. The S/C carries an orbit adjust module which fully integrates the propulsion subsystem (54 kg of propellant). In addition, the S/C features an autonomous operation/redundancy management providing 24 hours of autonomous operation and autonomous safing modes with ground-support recovery. Launch vehicle: Pegasus XL. Launch: July 2, 1996.

Communication: S-band (Omni-spherical coverage) with an uplink rate of 2 kbit/s and three downlink rates of 1.1 kbit/s, 50 kbit/s, and 200 kbit/s.

Orbit: circular, polar, sun-synchronous, altitude = 500 km, inclination = 99.3° , equator crossing time of 12 noon. - Starting Dec. 4, 1997, the TOMS-EP orbit was re-boostered during a 12-day period to an altitude of 750 km. The object is to: 1) increase the daily coverage, and 2) reach a stable orbit for a period of 4 years.

Sensor: **TOMS** (Total Ozone Mapping Spectrometer)

- 105° scan of $3 \times 3^\circ$ FOV, TOMS scanner is not pointed at sun
- Ebert-Fastie monochromator
- Wavelengths: 308.6 nm, 312.5 nm, 317.5 nm, 322.3 nm, 331.2 nm, and 360.0 nm
- Ozone trend measurement capacity: 0.1% yearly (goal)
- Swath width: 2722 km
- Spatial resolution: Nadir - 50 km x 50 km; average: 62 km x 62 km
- Dimensions: 15 x 30 x 27 cm
- Mass: 34 kg; power: 21 W
- Data rate: 600 - 700 bit/s (average). Data is available to the worldwide community of global change researchers through the National Space Science Data Center (NSSDC).

There is a new on-board calibration system involving illumination of the diffuser plate from a mercury lamp behind a fluorescing screen. - The electronics of TOMS have been modified/updated to include a reprogrammable microprocessor. Side-scanning can now be under the old 35 position mode or in a 37 position mode (used for ADEOS).

A.29.2 TOMS/NSCAT on ADEOS

TOMS and NSCAT instruments will be flown on the Japanese ADEOS mission in 1996 (see ADEOS mission).

Orbit: Sun-synchronous polar and circular orbit, altitude = 797 km, inclination = 98.6°

TOMS and NSCAT data will be available to the worldwide community of global change researchers through the Earth Science Data and Information System (ESDIS). Note: TOMS on ADEOS failed on June 30, 1997 when the S/C suffered several malfunctions and stopped functioning after an apparent loss of power (solar panel failed).

Figure 41: The TOMS-EP S/C and sensor

A.29.3 QuikTOMS (Quik Total Ozone Mapping Spectrometer)

A NASA mission, part of the Earth Explorer program, with the objective to continue long-term ozone measurements with the TOMS instrument beyond the TOMS-EP mission.⁴⁸⁶⁾ The TOMS-5 instrument on QuikTOMS was originally scheduled to be flown on the Russian Meteor-3M mission; however, constant delays of the Meteor-3M launch caused NASA to set up an alternate mission to avoid potential coverage gaps. NASA selected OSC of Dulles, VA, as prime contractor for the QuikTOMS mission. That includes S/C provision, sensor integration, launch and two years of mission operations.

⁴⁸⁶⁾ <http://quiktoms.gsfc.nasa.gov/>

The QuikTOMS S/C is a modified MicroStar platform of OSC. The bus is comprised of two rings stacked together vertically a core ring (a dual-faced cylinder consisting of a honeycomb structure) housing all primary spacecraft systems and a payload support module and the second ring carries four propulsion tanks and two solar arrays. The average payload power is 107 W (S/C power of 228 W EOL). Nickel hydrogen (NiH_2) batteries provide 10 Ah of energy. The S/C is three-axis stabilized with pointing control of 0.5° , a pointing knowledge of $< 0.25^\circ$, and a rate stability of $< 0.01^\circ/\text{s}$. The S/C design life is three years (with consumables of five years). The S/C mass is 166 kg. A launch of QuikTOMS as a secondary payload to OrbView-4 is planned for March 2001 on a Taurus launch vehicle from VAFB, CA.

Communications: The on-board data recorder has a capacity of 64 MByte SSR (Solid State Recorder). S-band communications is used for uplink (2 kbit/s) and downlink (500 kbit/s).

Orbit: Sun-synchronous circular polar orbit, altitude = 800 km, inclination = 98° , descending node equator crossing at 10:30 AM.

Figure 42: Illustration of the TOMS-5 instrument

Sensor complement:

TOMS-5 (Total Ozone Mapping Spectrometer), built by OSC, Pomona, CA (former Perkin Elmer subsidiary bought by OSC). TOMS-5 is a $f/5$ single grating Ebert-Fastie type monochromator with multiple exit slits for six different wavelengths centered at: 308.6, 312.5, 317.5, 322.3, 331.2, and 360 nm. The nominal bandwidth is 1.2 nm for each band. The wavelength is selected with a chopper wheel near the slit plate which gates the pair of the entrance and exit slits for each wavelength band. IFOV = $3^\circ \times 3^\circ$ or a footprint of about 42 km x 42 km. The instrument scans 18 scenes from the nadir to each cross-track direction in a 3°

interval to cover a swath of about 2300 km (max scan angle of $\pm 54^\circ$, scan cycle time = 6.3 s). The scanning axis of the scanner is 45° from the scanner normal and coincides with the optical axis of the instrument system so that the incidence angle on the scanner mirror is constant regardless of the scan angle. A depolarizer is placed immediately after the scanner mirror to minimize sensitivity to the polarization of the incoming radiation. A baffle with a square opening is placed before the objective lens as an aperture stop and the objective lens images the baffle to the grating. A PMT (Photomultiplier) detector is used for radiation detection.

The instrument employs a diffuser assembly to measure the solar flux and uses three on-board calibration features in orbit. The diffuser assembly has three ground aluminum surfaces, one of which is selected for sun illumination at the northern terminator. The diffuser surface generates a radiance source from the solar irradiance and the radiant source fills the field of view of TOMS-5. Two other surfaces are less frequently used for the solar viewing to minimize the degradation. The wavelength monitor is used to monitor a wavelength shift of the TOMS-5 bands using the mercury 296.7 nm line. Two narrow entrance slits, slightly offset, are imaged over the 312.5 nm exit slit when the 296.7 nm radiation illuminates them. The chopper wheel selects one of the two entrance slit images alternately. Any center wavelength change due to the image shift in the exit plane of the monochromator can be detected by comparing the relative strength of the two alternating signals. The electronic calibration (ECAL) is used to monitor the gain of the electronic amplifiers. A precision current source injects a current at several different levels to the front end of the electronics. The reflectance calibration (RCAL) is for monitoring the reflectivity of the diffuser surfaces. The Reflectance Calibration Assembly (RCA), a light source for RCA, is made of a mercury pen lamp with a reflector which has a window coated with a mixture of phosphors. This phosphor mixture produces a broad spectral emissions over the TOMS wavelength range when excited by the mercury ultraviolet radiation. The TOMS scanner mirror views the RCA lamp window and the diffuser surface illuminated by the RCA lamp alternately. The relative reflectance of the diffuser surfaces is monitored from the comparison of these two signals.

IFOV (scanner)	3° x 3° (42 km x 42 km)
Maximum scan angle, scan cycle time	$\pm 54^\circ$, 6.3 s
Scan dwell time, scan steps	150 ms, 37
Spectral bands: Band 1, Band 2, Band 3 Band 4, Band 5, Band 6	360 \pm 0.1 nm, 331.2 \pm 0.1, 322.3 \pm 0.1 nm, 317.5 \pm 0.1, 312.5 \pm 0.1, 308.6 \pm 0.1
Instrument mass, power	32 kg, average power is 25 W, peak power is 57 W

Table 86: Some parameters of the TOMS-5 instrument

A.30 Triana

A NASA mission named after Rodrigo de Triana, the sailor who first spotted the New World on Columbus's first expedition in 1492. Triana is a mission to L1, the Lagrangian liberation point (or balanced gravity point between the Earth and the sun), with the objective to continuously observe the sunlit Earth (full disk). The overall objective of the mission is to demonstrate the innovative use of a satellite to serve as a pathfinder to climate studies and global Earth scenes. The data products are planned to be made available on the Internet for global distribution, as one of Triana's goals is to provide high quality educational products that will aid in increasing public awareness about planet Earth. A Shuttle launch was planned for early 2002 from KSC (Kennedy Space Center).

However, with the new Bush Administration in office, launch plans of Triana were changed in the spring of 2001 (after all, the project was initially proposed by Al Gore who came in second in the 2000 US elections). Following is the official NASA version: "The constrained

Shuttle flight rate of six per year, established in the 2001 NASA budget planning process, requires that NASA give priority to the primary International Space Station (ISS) payloads, Hubble Space Telescope (HST) reboost, and Microgravity experiments. Consequently, it is not possible at this time to identify a definitive launch date for Triana. - As a result, NASA is working to complete the integration and qualification testing of the Triana Mission flight hardware and to place those assets into storage to await the determination of a future launch opportunity. Efforts associated with preparing for both the launch and operation of the mission are rapidly being suspended. System hardware qualification is anticipated to be completed by the end of September, 2001. No Fiscal year 2002 (FY 02) funding has been set aside for the project. Launch opportunities are being investigated within the Space Transportation System (STS) planning manifest process and additionally as a possible Expendable Launch Vehicle (ELV) payload. Restart plans will be dependent upon the definition of the mission launch date and approach.” 487) 488) 489) 490) 491)

Figure 43: Illustration of the Triana observatory (two views of the undeployed S/C)

A likely launch date of Triana could be in 2004.

The Triana spacecraft will have two major components within the Shuttle: a) the Observatory, and b) GUS (Gyroscopic Upper Stage). The Observatory design is based on the SMEX-

491) <http://www.earth.nasa.gov/ebn/triana/index.html>

Lite architecture bus which ties all the S/C functions together. The spacecraft is three-axis stabilized, equipped with solar arrays, a reaction-wheel-based GN&C (Guidance, Navigation and Control) subsystem [consisting of four reaction wheels, a gyro, a Startracker and sun sensors], and a hydrazine thruster system. The propulsion module is used to a) de-spin the Observatory (following its separation from GUS), b) to provide thrust for mid-course corrections and for L1 orbit maintenance. The OBC consists of a radiation-hardened 32-bit computer. Communications between the payload and the bus is provided by a redundant serial bus (MIL-STD-1553). The Startracker of Ball Aerospace contains an internal catalog of 2000 stars. The Startracker acquires, tracks and identifies stars, computes Triana's orientation, then transfers that information to the GN&C. The total mass of the Observatory is 564.5 kg, including the bus (461.3 kg) and the payload mass (103.2 kg).

GUS, also known as the kick stage, provides the power and thrust to boost the Observatory from LEO to the LOI (Lissajous Orbit Insertion) point. Once GUS has completed its solid rocket burn, it will separate from the Observatory. Prior to being deployed from the Space Shuttle, Triana will be spun up to 60 rpm by the IRIS (Italian Research Interim Stage) spin table, developed by Alenia Aerospazio of Italy (IRIS also provides the physical supporting structure for Triana while it's in the Space Shuttle Payload Bay). Approximately 45 minutes after Shuttle deployment, GUS fires its kick motor to begin the journey to L1. The total GUS mass at Shuttle deployment is 2424.4 kg.

Orbit: A halo orbit into the Lagrangian point L1, balanced gravitationally between the sun and the Earth. From this viewpoint, instruments have a continuous view of the entire sunlit face of the Earth, from sunrise to sunset and pole to pole. Every point on the Earth rotates under the view of the instruments providing a full day's data. L1 is located about 1.5 million km from Earth, amounting to 1/100 the distance from Earth to the sun. The Observatory will arrive at L1 approximately three months after launch.

Communications: The Observatory has three antennas, one high-gain and two omni antennas. The downlink data rates are 100-200 kbit/s, the uplink data rate is 2 kbit/s, both in S-band. The CCSDS protocol is used for all data transmissions.

Sensor complement:

EPIC (Earth Polychromatic Imaging Camera). This primary instrument on-board Triana is managed by SIO (Scripps Institution of Oceanography) at UCSD (University of California at San Diego) and designed and built by Lockheed Martin Advanced Technology Center (ATC). The objective is to measure ozone amounts, aerosol amounts, cloud height and phase, hotspot land properties (a view of the land from angles where shadows are a minimum), and UV radiation estimates at the Earth's surface. EPIC is able to view the entire sunlit Earth from sunrise to sunset at an almost constant scattering angle between 165-178°. The EPIC channels were selected to match closely with TOMS in the UV region and with MODIS in the visible range; hence, the data products will be very similar and can be directly compared. These comparisons will validate both the calibration and data reduction algorithms.

The EPIC instrument is of Cassegrain design (30.5 cm aperture diameter of telescope) featuring a ten-filter spectroradiometer with a spectral range of 0.317 to 0.905 μm (UV to NIR). The 10 filters are contained in two filter wheels. The sub-nadir spatial resolution of the observed data is 8 km. The measurement frequency is 15 minutes for RGB images (consisting of band 6, 7, and 8) and one hourly frame for the 10-channel radiometer data, each frame consisting of 4 million calibrated Earth-located radiances. Views of the moon are used to calibrate EPIC.

Band No	Center Wavelength (nm)	Bandwidth (nm) FWHM	Measurement Objective
1	317.5	1	Ozone, SO ₂
2	325	1	Ozone, SO ₂
3	340	3	Aerosols
4	388	3	Aerosols, clouds
5	393.5	1	Cloud height
6	443	10	Aerosols (blue)
7	551	10	Aerosols (green)
8	645	10	Aerosols (red)
9	869.5	15	Clouds, vegetation
10	905	15	Water vapor

Minimum image cadence	< 20 s
Image output format	Raw (bit map) and 12 bit JPEG/JFIF
Instrument power; total mass	32 W (electronics), 30 W (operational heaters); 63.2 kg

Table 88: EPIC performance parameters

NISTAR (National Institute of Standards and Technology Advanced Radiometer), developed by NIST and Ball Aerospace. The objective is to measure the radiance output from the sunlit Earth over a broad portion of the spectrum (UV and VIS as reflected radiation, IR as emitted radiation) in order to detect changes in the Earth's energy balance (climate studies). The instrument package consists of three active-cavity electrical-substitution radiometers and one silicon photodiode channel to measure the "total Earth reflected and emitted radiant power" in the direction of the Triana spacecraft with a goal of 0.1% accuracy and a precision (relative changes) of 0.03% (at L1 the measurement of the Earth's reflected and emitted radiance is a true challenge due to its minuteness; it is in fact $<10^{-5}$ than that of the

sun). These levels of accuracy and precision are necessary for detecting the small changes in Earth’s radiances corresponding to small changes occurring now that can be of major importance for humankind far into the future. The accuracy goal is based on the high sensitivity of the NISTAR instrument and on the ability to use long integration times (minutes) at the L1 location. - Besides broadband measurements of the total Earth irradiance, filtered channels on NISTAR allow separation of the reflected solar from the Earth-emitted infrared radiation. Techniques developed at NIST for SNR improvements in active-cavity radiometers were essential in making feasible the NISTAR measurement performance.⁴⁹²⁾

NISTAR has a FOV of 1°, sufficient to see and image the full Earth disk whose FOV is approximately 0.5° as seen from L1. The photodiode channel has been included in order to obtain a faster time series (<1 s) than what can be obtained by the cavity radiometers. The channel is used to provide for the tracking stability of the filters, to verify co-alignment of NISTAR and EPIC, and to continuously observe the solar reflected broadband radiation from Earth with high temporal resolution. - A PTC (Positive Temperature Coefficient) thermistor and a wire-wound low-temperature coefficient heater are bonded to the outside of the 30° conical receiver cavity. The absolute cavity radiometers are designed for optimum power measurements (in the tens of μW range). The optical signal incident on the receiver is only 1 μWcm⁻², however, the emission from the receiver cavity to space is estimated to be 30 μWcm⁻² when the shutter is open. There are four digital control loops, three receiver cavity control loops and one for the heat sink. The PTC temperature sensor resistance measurements are performed with AC-bridge circuits operating between 35 and 155 Hz. The NISTAR absolute cavity radiometers are designed for a noise floor of less than 10 nW (defined as the level at which the SNR is equal to one for a single one second measurement). The NISTAR electronics have a measurement resolution of 10 mΩ and internal equivalent noise of less than that. - The NISTAR total instrument mass is 23.5 kg.

The NISTAR halo orbit data will complement the large database of LEO Earth radiation budget measurements of such instruments as: ERB, ERBE, ScaRab, CERES, and ISP-2, as well as those of the GERB instruments flown on EUMETSAT’s MSG series in GEO. The NISTAR radiance measurements will be used in several ways:

- To make integrative measures of global change (longwave channel)
- To estimate the Earth albedo
- To attempt to interpret the near-infrared to visible albedo ratio
- To test CERES algorithms in an integral sense
- To provide an extensive integral test of how well radiative transfer in the Earth-atmosphere system is understood.

Channel	Range	Comment
UV+VIS+ FIR Band-A	0.2 - 100 μm	Total radiant power in the UV, VIS and FIR wavelengths (long-wave channel). Band-A is unfiltered
UV+VIS+SWIR Band-B	0.2 - 4 μm	Solar channel to measure reflected solar radiance
NIR+SWIR Band-C	0.7 - 4 μm	IR channel to measure reflected IR solar radiance.
VIS+NIR	0.3 - 1 μm	A non-absolutely calibrated silicon photodiode channel to calibrate the spectroradiometer

Table 89: Overview of NISTAR spectral bands

PlasMag (Plasma Magnetometer). The objective of this sun-viewing instrument is to measure the solar wind and magnetic field parameters (composition and energy) at high time resolution. The instrument serves also as an early-warning device for solar-event storms that could damage satellites and electrical equipment on Earth. The PlasMag instrument

⁴⁹²⁾ J. P. Rice, S. R. Lorentz, T. M. Jung, “The next generation of active cavity radiometers for space-based remote sensing,” 10th Conference on Atmospheric Radiation, Madison, WI, 1999, American Meteorological Society

suite is an advanced but smaller version of the ACE instrumentation (NASA S/C with a launch on Aug. 25, 1997). The PlasMag instrument package has a mass of 16 kg. The instrument suite was designed and developed (optimized for small size, low power, and very large dynamic range) by GSFC and MIT, consisting of a Faraday cup, a magnetometer and an electron analyzer.

- The Faraday cup measures the 3-D distributions of proton and alpha particles of the solar wind with a time resolution of 90 ms. The Faraday cup has a 60° FOV and uses multiple detectors, permitting the measurement of the full range of solar wind deflections (about 15° in all directions), allowing a full 3-D velocity distribution in parallel. The entire distribution function remains in the FOV, so that more accurate measurements can be made, especially at high densities.
- The triaxial fluxgate magnetometer provides magnetic vector field measurements in 30-40 ms intervals. The objective is to investigate solar-wind magnetic fields with a sensitivity of >0.1 nT. The instrument achieves a dynamic range of almost 8 orders of magnitude in field measurement capability.
- The tophat electron analyzer provides 3-D electron velocity distributions in intervals of 800 ms in the energy range of 3 eV to 2 keV. The 3-D measurements are accomplished by electronically simulating the data sampling of an electron spectrometer on a spinning S/C. The instrument has a set of anodes distributed uniformly in azimuth, each with a FOV of 50° x 70° in azimuth and elevation.

In addition to studies of the sun and solar wind, the PlasMag data are also being used to provide early warning (less than 1 hour) of solar events that might cause damage to power generation, communication, and other satellites.

A.31 TRMM (Tropical Rainfall Measuring Mission)

TRMM ⁴⁹³⁾ ⁴⁹⁴⁾ is a joint NASA/NASDA mission and program with a low-inclination (equatorial) orbit. NASA/GSFC provides the satellite, four passive sensors, and mission operations, NASDA the launch vehicle (H-II rocket) and the precipitation radar instrument. Each agency processes the data from its own instruments. Design life = 3 years. The launch of TRMM [along with ETS-7, composed of two spacecraft: Chaser (Orihime) and Target (Ikoboshi)] took place on Nov. 27, 1997 from Tanegashima Space Center (TNSC), Japan.

TRMM S/C mass = 3620 kg (including 725 kg of fuel); three-axis stabilization, power = 1100 W; data rate = 170 kbit/s average and 2 Mbit/s on playback; TDRSS S-band communications (8.5 minutes/orbit playback time).

Orbit: Non-sun-synchronous circular orbit, altitude = 350 km (approx.), inclination = 35°, period = 96 min. An observation coverage of the tropics was chosen since the volume of rainfall in the tropics accounts for about two-thirds of the total rainfall on the earth.

Operational status as of June 2001: TRMM is fully operational after 3.5 years in orbit. In fact, the project expects to be operational for at least another five years.

Objectives: Global change studies, especially in developing an interdisciplinary understanding of atmospheric circulation, ocean-atmospheric coupling, and tropical biology. General circulation models require detailed data on the latent heating of equatorial air masses, and the forcing and propagation speed of waves involved in the 30- to 60-day tropical oscillations.

- Measure diurnal variation of precipitation and evaporation in the tropics to provide increased understanding of how substantial rainfall affects global climate patterns.

⁴⁹³⁾ "The Early Observing System Reference Handbook, ESAD Missions 1990-1997," NASA/GSFC, pp. 62-64

⁴⁹⁴⁾ T. Keating, T. Ryan, "Tropical Rainfall Measuring Mission (TRMM): US/Japan Science Operations," AIAA-92-0594

- Obtain a minimum of three years of climatologically significant observations of rainfall in the tropics.
- In tandem with cloud models, provide accurate estimates of the vertical distributions of latent heating in the atmosphere.

Sensor complement:

PR = Precipitation Radar (NASDA instrument in cooperation with CRL, Japan).^{495), 496)} Active phased array microwave radar operating with horizontal polarization (orbit permits monthly sampling over the complete diurnal cycle), minimum measurable rain rate of 0.5 mm/h. Objective: 3-D rainfall distribution over land and oceans (combined with TMI sensor). Periodically the PR performs an external calibration with ARC (Active Radar Calibrator) and an internal loop calibration to measure the transfer function of the PR receiver.

Figure 45: The TRMM S/C model

The radar echo of the instrument consists of the following three components: rain echo, surface echo, and mirror image echo. The surface echo is measured for estimating the total path attenuation and for providing the range of the surface along the radar beam. The mirror image, which is the rain echo received through the double reflection at the surface, may be useful to estimate rain rate retrieval; it is measured at nadir incidence.

⁴⁹⁵⁾ T. Kozu, M. Kojima, K. Oikawa, K. Okamoto, T. Ihara, T. Manabe, "Development Status of Rain Radar for Tropical Rainfall Measuring Mission," IEEE IGARSS '92, Volume II, pp. 1722-1724

⁴⁹⁶⁾ NASA paper provided by ESAD and OSSA.

Type of radar echo	Description
Nominal rain and surface echoes	Surface to 15 km altitude, 250 m interval, all scan angles
Mirror image	0 - 5 km altitude, 250 m interval, at nadir only
Oversampled surface echo	Surface echo peak ± 0.5 km, 125 m interval, scan angles within $\pm 10^\circ$
Oversampled rain echo	Surface echo peak to 7.5 km alt., 125 m interval, scan within $\pm 3.5^\circ$

Table 90: PR radar echo collection parameters

The PR is a 128-element active phased array system. The transmitter/receiver consists of 128 Solid-State Power Amplifiers (SSPA) LNAs and PIN-diode phase shifters. Each transmitter/receiver element is connected to a 2 m slotted waveguide (WG) antenna (2 m x 2 m planar array). The PR uses a frequency-agility technique to obtain 64 independent samples (N_S) with a single PRF of 2776 Hz, in which a pair of 1.6 μ s pulses - having two different frequencies at 6 MHz apart from each other - are transmitted. There are 49 angle bins with the angle-bin interval of 0.71° over the swath width; 32 pairs of pulses are transmitted for each angle bin.⁴⁹⁷⁾

Item	Value	Item	Value
Frequency	13.796 and 13.802 GHz	Antenna type	128 element WG planar array
		Beam width	$0.71^\circ \times 0.71^\circ$
		Aperture	2.0 m x 2.0 m
		Scan angle	$\pm 17^\circ$ (cross track scan)
		Samples cross-track	49
		Samples vertically	80
Sensitivity	≤ 0.7 mm/h	Transmitter/receiver	SSPA & LNA (128 channels)
		Peak power	≥ 500 W (antenna input)
		Pulse width	1.6 μ s x 2 channel
		PRF	2776 Hz
Swath width	215 km	Dynamic range	≥ 70 dB
Observable range	Surface to 15 km	N_S (No. indep. sample)	64
Horizontal resolution	4.3 km (nadir)	Data rate	93.2 kbit/s
Range resolution	250 m (nadir)	Instrument mass, power	465 kg (max), 250 W (max)

Table 91: Instrument parameters of PR

Instrument Mode	Description
Observation	Nominal science observation $\pm 17^\circ$ cross-track scan
External calibration	Special oversample scan (center scan angle $\pm 1.1^\circ$) or fixed beam position
Internal calibration	Internal-loop calibration for receiver I/O transfer function measurement
Standby	Temporal RF radiation stop, phase shifter data load and dump
Analysis	LNA functional check using surface return
Health check	On-board computer ROM/RAM function check
Safety	Instrument power off

Table 92: Summary of PR operational modes

VIRS = Visible Infrared Scanner (NASA/GSFC instrument, built by Hughes SBRC) a passive cross-track scanning radiometer which measures scene radiance in five spectral bands: $0.63 \mu\text{m}$ (± 0.05), $1.6 \mu\text{m}$ (± 0.03), $3.75 \mu\text{m}$ (± 0.05), $10.8 \mu\text{m}$ (± 0.05), and $12 \mu\text{m}$ (± 0.05). Horizontal resolution = 2 km at nadir. Telescope=2-mirror Cassegrain-type focusing the image onto five collocated detectors, each with its own bandpass interference filter. Spectral separation: discrete filters mounted on a cooled focal plane. Swath width = 720 km (FOV = $\pm 45^\circ$). Applications: Data will be used in conjunction with data from CERES to determine cloud radiation. VIRS will enable “calibration” of precipitation indexes derived from data of other sources (rain estimation from brightness temperature). Data rate = 50 kbit/s (day) = 28.8 kbit/s (night), instrument mass = 34.5 kg, power = 40 W. In-flight radio-

⁴⁹⁷⁾ T. Kozu, et al., “TRMM Precipitation Radar: Calibration and Data Collection Strategies,” Proceedings of IGARSS '94, Volume IV, pp. 2215-2217

metric calibration is provided by an on-board blackbody, a solar diffuser, and a space view for a zero radiance calibration reference. Radiometric accuracy of at least 5% in the thermal bands and 10% in the visible region.

Channel	1 & 2	3 & 4	5	6 & 7	8 & 9
Frequency (GHz)	10.65	19.35	21.3	37.0	85.5
Polarization	V, H	V, H	V	V, H	V, H
Bandwidth (MHz)	100	500	200	2000	3000
IFOV (km x km)	63 x 37	30 x 18	23 x 18	16 x 9	7 x 5
Samples/scan	104	104	104	104	208

Table 93: Performance parameters of TMI

TMI = TRMM Microwave Imager (NASA instrument). TMI is a passive multichannel/dual-polarized microwave radiometer (heritage of SSM/I on DMSP series) with frequencies in five discrete channels at 10.65, 19.35, 21.3, 37.0, and 85.5 GHz. Resolution (IFOV): 7 km x 5 km to 63 km x 37 km depending on the frequency used. Swath width = 760 km. Applications: Data is related to rainfall rates over oceans (vertically integrated rainfall distribution). Data rate = 8.8 kbit/s, instrument mass = 65 kg, power = 50W.

CERES (Clouds and the Earth's Radiant Energy System), an EOS program funded NASA instrument. See CERES description in chapter D.11.1.

Sensor	Observation Objectives	Frequency	Horizontal Resolution	Swath Width
PR	3-D rainfall distribution	13.8 GHz	4.3 km (nadir)	215 km
TMI	Vertically integrated rainfall distribution	10.7, 19.4, 21.3, 37, and 85.5 GHz	5-45 km	760 km
VIRS	Cloud distribution and height, rain estimates from brightness temp.	0.63, 1.6, 3.75, 10.7, and 12 μ m	2 km	720 km
CERES	Radiation from top of clouds and Earth, energy budget	0.3 - 5 μ m 8.0 - 12.0 μ m 0.3 - 50 μ m	10 km (nadir)	Scan angle: $\pm 78^\circ$ global
LIS	Lightning distribution	0.7774 μ m	4 km (nadir)	600 x 600 km

Table 94: Overview of TRMM sensor complement and objectives⁴⁹⁸⁾

LIS = Lightning Imaging Sensor (NASA/MSFC instrument, PI: H. J. Christian). ⁴⁹⁹⁾ LIS is an EOS-funded instrument. Objective: Measurement of lightning distribution and variability over the Earth, its correlation with rainfall, and its relationship with the global electric circuit. Measurement approach: LIS is an optical staring telescope/filter imaging system that detects the rate, position, and radiant energy of lightning flashes. LIS detects intra-cloud and cloud-to-ground lightning with storm-scale resolution. Applications: study of mesoscale phenomena such as storm convection, dynamics, and microphysics. These will be related to global rates, amounts, and distributions of convective precipitation, as well as to the release and transport of latent heat, which are all influenced by global-scale processes. Further applications are: cloud characterization, hydrologic cycle studies, storm convection, microphysics and dynamics, seasonal and interannual variability of thunderstorms.

The LIS instrument consists of two main elements: a) a telescope with a CCD detector matrix, b) the real-time data processing unit. LIS uses an expanded optics wide-FOV lens, combined with a narrow-band interference filter that focuses the image on a small, high-speed CCD focal plane.

- special filter to image at 777.4 nm (OI line) onto a 128 x 128 high-speed CCD array detector

⁴⁹⁸⁾ Courtesy of K. Maeda, NASDA

⁴⁹⁹⁾ EOS Reference Handbook, NASA/GSFC, 1993

- event processor to subtract out the bright background during daylight (sensor records data during day and night)
- location coverage of lightning flashes within 5 km over a FOV of 600 km x 600 km
- spatial resolution: 5 - 10 km
- temporal resolution: 2 ms

Accommodation parameters: view direction: nadir, instrument mass: 21 kg, power: 33 W, data rate: 6 kbit/s, FOV: 80° x 80°, IFOV: 0.7°⁵⁰⁰⁾ 501)

Primary products of TRMM mission data:

- Average monthly rainfall over the tropics and subtropics for at least 3 years

Secondary Products:

- Cloud cover (VIRS, CERES)
- Rain rates (TMI)
- Rain rate vertical profile (PR)
- Path-averaged rain rate and liquid water content (PR)
- Lightning distribution and variability (LIS)

Data Validation Program:

- Rain rate spatial distribution (surface radars)
- Rain rate point measurements (in situ measurements)

Application	Total Precipitation Rate		
	Spatial Aver.	Time Average	Accuracy
Climate models	500 x 500 km	monthly mean	1 mm/day (10% in heavy rain)
Diurnal cycle over ocean	20° longitude	bimonthly	10% first harmonic amplitude 20% second harmonic amplitude
General circulation model vertical distribution	500 m	N/A	N/A
Tropical rain systems structure and evolution	20 km	N/A	30 - 50%

Table 95: TRMM scientific accuracy requirements

A.32 UARS (Upper Atmosphere Research Satellite)

UARS = Upper Atmosphere Research Satellite.⁵⁰²⁾ The first NASA mission in the series: ‘Mission to Planet Earth.’ Launch date: Sept. 12, 1991 with Space Shuttle (Discovery, STS-48; deployment date: Sept. 15, 1991). UARS is a free-flying laboratory; three years nominal lifetime; GSFC = POCC. The UARS S/C has a mass of 6795 kg (size = 4.6 m diameter and 9.8 m length), it is three-axis stabilized via reaction wheels and torque rods (accuracy of 36 arcsec). Attitude knowledge to 20 arcsec using star trackers, Earth sensors, IRU, and sun sensors. The single solar array has a size of 1.5 m x 3.3 m, it generates 1.6 kW of power. In addition there are three 50 Ah batteries. A hydrazine propulsion system is used for orbit insertion and maintenance.

Status: as of 2001 the UARS spacecraft is operational.

Application: Measurement of energy flux (input and loss) in the upper atmosphere; global photochemistry in the upper atmosphere, in particular in the stratosphere and mesosphere (trace gases and temperature profiles); dynamics of the upper atmosphere; transport phenomena of the different processes; correlations between the upper and lower atmosphere and their changes.

Sensor complement: ⁵⁰³⁾ ⁵⁰⁴⁾

CLAES = Cryogenic Limb Array Etalon Spectrometer (Solid-hydrogen cooled spectrometer sensing atmospheric infrared emissions); NASA sensor, (A. E Roche, Lockheed Palo Alto Research Lab)

Measures with four Etalons and eight filters the following wave spectrum: $3.5\ \mu\text{m}$, $6\ \mu\text{m}$, $8\ \mu\text{m}$ and $12.7\ \mu\text{m}$. Because the detectors and optics generate their own thermal emissions, they must be cooled to temperatures which suppress this emission. The coolant inside CLAES is expected to be depleted after about 18 months of service.

CLAES measures concentrations of members of the nitrogen and chlorine families, as well as ozone, water vapor, methane, and carbon dioxide. To obtain a vertical profile of species concentration, CLAES utilizes a telescope, a spectrometer, and a linear array of 20 detectors to make simultaneous measurements at 20 altitudes ranging from 10 to 60 km.

Observables: N_2O , NO , NO_2 , HNO_3 , CF_4 , CF_2Cl_2 , CFCl_3 , HCl , O_3 , ClONO_2 , CO_2 , H_2O ,

⁵⁰³⁾ Portion of a UARS publication put out by NASA (provided by B. Needham of NOAA)

ClO, CH₄ and temperature.

Ops status: CLAES ran out of oxygen in May 1993, as planned.

ISAMS = Improved Stratospheric and Mesospheric Sounder (mechanically cooled spectrometer sensing atmospheric emissions); (PI: F. W. Taylor, Oxford University, UK).

This is a SAMS instrument successor using filter radiometry and pressure modulation techniques in the following ranges: 4.6 - 16.6 μm (medium infrared band). The ISAMS instrument is provided by UK (it is an improved version of SAMS, which operated aboard Nimbus-7 from 1978 to 1983).

ISAMS is a filter radiometer employing eight detectors. It observes infrared molecular emissions by means of a movable off-axis reflecting telescope. In addition to scanning the atmosphere vertically, the telescope can also be commanded to view regions to either side of the UARS observatory, thus providing increased geographic coverage. One feature of ISAMS is that it carries samples of some of the gases to be measured in cells within the instrument. Atmospheric radiation collected by the telescope passes through these cells on its way to the detectors (spectra matching).

The limb-sounding instrument, ISAMS, uses a combination of pressure-modulated and wide-band infrared channels to measure the concentrations of nitrogen chemical species, as well as ozone, water vapor, methane, and carbon monoxide in the middle atmosphere. Typically, ISAMS produces vertical profiles of constituents and temperature every 200 km along the tangent track, with an IFOV of about 2.4 km vertically. Data rate: 1.25 kbit/s. Observables: CO, H₂O, CH₄, N₂O₅, NO, N₂O, O₃, HNO₃ and aerosols.

Status: the ISAMS instrument experienced a chopper motor failure in late July 1992, preventing its collection of atmospheric chemistry data.

HALOE = Halogen Occultation Experiment (J. M. Russell, LaRC)

Gas filter radiometer correlation in sun occultations. Infrared range = 2.43 - 10.25 μm . Spatial resolution: vertical = 1.6 km at limb; horizontal = 6.2 km at limb. Measurement of the vertical distribution of hydrofluoric and hydrochloric acids as well as of methane, carbon dioxide, ozone, water vapor, and members of the nitrogen family. The HALOE experiment uses samples of the gases to be observed as absorbing filters in front of the detectors to obtain a high degree of spectral resolution.

During every UARS orbit, at times of S/C sunrise and sunset, HALOE is pointed toward the sun to measure the absorption of energy along this line of sight. There are 28 solar occultation opportunities per day, providing data for 14 different longitudes in each of the northern and southern hemispheres. Data rate = 4 kbit/s. Observables: HF, HCl, CH₄, NO, H₂O, O₃, NO₂ and pressure.

MLS = Microwave Limb Sounder (J. W. Waters, JPL). MLS is a microwave radiometer which measures atmospheric thermal emission from selected molecular lines at mm wavelengths. Three-channel heterodyne limb sounder. Measurement frequencies: 63 GHz (1 band), 183 GHz (2 bands) and 205 GHz (3 bands, corresponding to wavelengths of 4.8, 1.64, and 1.46 mm, respectively). Each band is 500 MHz wide.

MLS is a microwave radiometer providing global measurements of chlorine monoxide (key reactant that destroys ozone), hydrogen peroxide, water vapor, and ozone. The MLS observations will provide, for the first time, a global data set on chlorine monoxide in the upper atmosphere. MLS will also determine the altitudes of atmospheric pressure levels. Spatial resolution in each band: \sim 400 km horizontal and 4 km vertical; measurement are made along the tangent track of the limb view, with no cross-track scanning, swath width: 5 - 85 km (vertical limb coverage). Data rate: 1.25 kbit/s.

Observables: O₃, ClO, H₂O₂, H₂O and pressure.

Calibration: radiometric views of cold space, and an on-board ambient-temperature black-body target. Calibration stability: better than 1% over mission lifetime.

SOLSTICE = Solar/Stellar Irradiance Comparison Experiment (G. J. Rottman, University of Colorado at Boulder). Three-channel grating spectrometer for measuring solar and stellar irradiation (UV radiation in the wavelength range from 115 to 430 nm with a resolution of 0.12 - 0.25 nm). The device compares the ultraviolet output of the sun with similar radiation produced by 30 stable, bright blue stars. The stars constitute the standards against which the solar irradiance is measured.

The experiment consists of a spectrometer with three spectral channels, each with a separate grating and photomultiplier tube. SOLSTICE will be pointed toward the sun during the daylight portion of the orbit, and toward one of the calibration stars during most of the nighttime orbit. Data rate: 250 bit/s.

SUSIM = Solar Ultraviolet Spectral Irradiance Monitor (G. E. Brueckner, Naval Research Lab, Washington, DC). SUSIM is a double-dispersion scanning spectrometer which measures solar irradiance (UV radiation in the spectral range from 120 - 400 nm with a resolution of 0.1 nm). SUSIM incorporates two spectrometers, seven detectors, and a set of four deuterium UV calibration lamps. One spectrometer observes the sun and measures variation in solar UV flux as a function of time. The second spectrometer monitors independently the calibration lamps. Data rate: 2 kbit/s.

PEM = Particle Environment Monitor (J.D. Winningham, Southwest Research Institute). PEM represents a collection of four instruments called AXIS, HEPS, MEPS and VMAG. PEM is mounted at three separate locations on UARS, including the boom.

- **AXIS** (X-ray, proton and electron spectrometer). Measurement of Bremsstrahlung X-rays from Earth, solid-state detection. Energy range from 3 keV to 100 keV. Spectral band: 0.012 to 0.41 nm
- **HEPS** (charged particle spectrometer). Measurement of in situ electron energies from 0.04 MeV to 5 MeV, proton energies from 0.07 MeV to 139 MeV. Measurement technique: solid state identification.
- **MAPS** (charged particle spectrometer). Measurement of electrons and protons. Energy range of electrons: 1 eV - 32 keV, energy range of protons: 1 eV to 32 keV; measurement technique; electric deflection with mechanical separation.
- **VMAG** (three-axis fluxgate magnetometer). VMAG DC: center at 0 nT, width: ± 65500 nT. VMAG AC: center at 0 nT with width dependent on AXIS. Measurement of the Earth's magnetic field and the type, number and distribution of charged particles flowing into the upper atmosphere from space.

HRDI = High Resolution Doppler Imager (P. B. Hays, U. of Michigan).

Mapping of atmospheric winds at altitudes below 45 km. HRDI observes the Doppler shifts of spectral lines within the atmospheric band system of molecular oxygen to determine the wind field. There are no sharp emissions lines in the radiance of the Earth's limb at such altitudes, but the oxygen bands contain many lines that appear as deep absorption features in the brilliant spectrum of scattered sunlight.

A triple-etalon Fabry-Perot interferometer, serving as a high-resolution spectral filter, will ensure efficient rejection of the intense emission continuum outside the absorption lines. HRDI will exploit these daytime absorption features to provide wind data for the stratosphere and upper troposphere to an accuracy of 5 m/s or better.

At altitudes above about 60 km, HRDI observes emission lines of neutral and ionized atomic oxygen in the visible and near-infrared regions. Unlike the molecular absorption lines, however, the emission lines are observable both day and night. Mesosphere and thermosphere wind profiles to an accuracy of 15 m/s or better are observed.

Measurement in 13 spectral bands with center wavelength and bandwidth in brackets, all in nm: 557.5 (0.84), 630.0 (.74), 630.5 (1.48), 686.8 (0.88), 687.6 (0.88), 692.3 (1.06), 692.9 (1.36), 723.5 (0.85), 760.7 (0.92), 763.5 (1.45), 764.9 (0.86), 766.6 (1.01), 775.6 (0.93).

The interferometer is tunable within the spectral width and can simultaneously measure 31 samples in a 0.5 cm^{-1} spectral region at a resolution of 0.05 cm^{-1} . Data rate = 4.75 kbit/s.

WINDII = Wind Doppler Imaging Interferometer (G. G. Shepherd, York University, Canada; Canadian/French Sensor, 145 kg mass). WINDII is a field-widened Michelson interferometer measuring the Doppler shift and line broadening of atmospheric emission in the visible and near-infrared. The airglow emissions observed are: O¹S at 557.7 nm (green line), O¹D at 630 nm (red line), O⁺ at 732 nm, OH (8,3)P₁(3) at 734.1 nm, and O₂ Atm (0,0) at 763.2 nm. O⁺ is observed only on the dayside orbit while OH only during the nightside of the orbit. Measurement of airglow emissions rates and wind conditions in the thermosphere and upper mesosphere. Temperatures in the upper mesosphere are determined from the Rayleigh scattering of sunlight. 505) 506) 507)

WINDII utilizes emission lines for the basic Doppler-shift measurements. In addition to lines of neutral and ionized oxygen, these include two lines of the OH molecule and a molecular oxygen line. WINDII obtains measurements both day and night at altitudes above 80 km.

The instrument consists of a telescope, the interferometer, and a CCD detector array. The telescope has two fields of view, each 4° x 6° looking at the airglow above the Earth's limb at 45° and 135° from the S/C velocity vector simultaneously. In normal operation, the detector provides a vertical resolution of 20 km. Wind velocity accuracy is within 10 m/s in the altitude range between 80 and 300 km. Data rate: 2 kbit/s. The WINDII spectral filter is a high-resolution Michelson interferometer.

ACRIM-2 = Active Cavity Radiometer Irradiance Monitor (R.C. Willson, JPL; see ACRIM in EOS)

Data:

There are two on-board recorders available (each capable of recording two orbits of data at 32 kbit/s). Tape recorder playback = 512 kbit/s.

Data transmission via TDRSS with 32 kbit/s (R/T) and 512 kbit/s (P/B).

Correlative data sets are provided in parallel, in particular NOAA SUBV data sets, as well as ground truth measurements (balloons, sounding rockets, Shuttle flights) and meteorological data.

Part B Commercial Imaging Satellites

The provision of high-resolution imagery in the optical and/or microwave regions – on a commercial basis by several companies with their own space- and ground segments (spacecraft, sensor complement, control center, ground receiving stations, archives, distribution networks, and extensive software), and the operation of these entities along with the provision of general and/or customized service arrangements – represents a new milestone in the field of space-flight exploitation. The investment in each venture is considerable; every major player in this game forms a consortium (or international alliances) to pool expertise, technology, and resources – and to share the risks. The overall objective in every satellite-project constellation is the provision of low-cost and high-quality data products along with expedient services for a large customer base. The strategic approach taken by industry with regard to concept design is that virtually all major system components are based on proven technologies; experience from past defense contract engagements is of great value. The introduction of a sensor-pointing capability beyond its rather limited swath-width indeed represents a new concept outside of the defense community; it extends the potential imaging coverage to the so-called field of regard (FOR), in order to make data rates manageable. The consequence of this pointing capability is “scheduled instrument operation,” permitting the imaging of scattered targets to suit customer requirements. Industry is betting on a competitive market, whose demand for high-resolution imagery goes far beyond the utilization of the rather ‘coarse-resolution’ interpretations of current satellite data. The aim is to address the wide field of public/private applications (in particular cartographic use), as well as the needs of the research community. There is also a considerable demand for high-resolution imagery by the defense and intelligence agencies of the world.

An observation prerequisite for all optical imaging acquisition from space is a cloudless sky. This limitation is somewhat counterbalanced by the periodic revisit capabilities of polar-orbiting satellites; still, optical observation is rather constrained in high-latitude regions of the world due to almost permanent cloud cover. - Providing optical high-resolution imagery is obviously only the first step into the commercial data arena; an extension of services to other spectral ranges (microwave region for SAR imagery) is already on its way.

Reliable and consistent service provision in any business depends very much on back-up solutions in case of need. This proven concept also applies to the providers of high-resolution imagery. Every consortium in this game has a complete back-up satellite/payload in store for the contingency of a launch failure or for a terminal instrument malfunction in orbit; it is also a neat solution in the event of unexpected demand in imagery, to be able to launch a second satellite at short notice.

The Resource21 mission, a long-planned (and sometimes dormant) commercial project for spaceborne crop monitoring of Resource21 of Englewood, CO, is missing in this chapter (Resource21 was already part of the 3rd edition in 1996). As of the summer 2001, the company is planning a smaller-scale project (than previously planned), the new plans call for a one spacecraft mission for a launch not before 2003.⁵⁰⁸⁾

B.1 Condor Series of NPO Machinostroyenia

The Russian enterprise NPO Machinostroyenia (or NPO Machine-builder), headquartered in the Moscow suburban town of Reutov, has been engaged in the field of remote sensing and space exploration since the start of the space age. The Almaz-1 spacecraft (launch March 31, 1991) with its provision of SAR instrumentation and data was a major engagement and experience in this direction. With the drastically changed economic situa-

⁵⁰⁸⁾ J. Bates, “Resource21 Moves Ahead With Smaller-Scale Project,” Space News Aug. 13, 2001, p. 3 and p. 28

tion in Russia during the past decade, the company began to re-orient its market strategies and is working for some time now on modern service solutions and projects by utilizing a small/medium sized spacecraft family (up to 1000 kg), combined with new-technology instruments, operational concepts, and a low-cost launch option. The overall objective is to offer high-resolution imagery (SAR imagery and eventually also optical imagery) on a commercial basis to worldwide customers as well as to institutional users in Russia for a variety of applications. From a service provider commitment and view point, the Condor project offers a long-term and pragmatic perspective to the customer base.

The idea is to overcome the large-spacecraft philosophy/practice of the past, exemplified by the Salyut spacecraft of Almaz-1 and Almaz-1B, each with launch mass of over 18,500 kg. If Almaz-1B was going to be launched by a Proton heavy-lift launch vehicle today, such a payload would amount to launch costs of \$60-80 million, making any low-cost project unprofitable. Hence, the project Almaz-1B, a planned follow-up mission to Almaz-1 for a long period of time, was finally cancelled in favor of the new concept of Condor-E; it represents a first step into the light-weight and small-size direction.^{509) 510)}

Figure 47: Illustration of the Condor-E-1 spacecraft

B.1.1 Condor-E (Condor Experimental)

The Condor-E spacecraft employs a standardized bus, the S/C is three-axis stabilized. Attitude sensing is provided by a gyroscope and star sensors, actuation is provided by reaction wheels and torquers. The pointing accuracy of the S/C is equal to or less than 6 arcmin with an angular drift of $<0.001^\circ/\text{s}$. On-board orbit determination is provided by a GLONASS/GPS receiver. Electrical power is provided by two solar panels with a total surface area of 9.2 m^2 . The payload power consumption is in the range of 240-1500 W, depending on service provided.. In addition there are batteries for power provision during orbital eclipse phases. Condor-E-1 has a spacecraft total mass of 800 kg (250 kg of payload mass); the design life is 5 years with a goal of 7 years.

509) V. Viter, V. Petrovsky, A. Koutcheiko, "Space-based radars designed by NPO Machinostroyenia, Novosti Kosmonavтики (Cosmic News), Vol 218, No 3 (218), Jan. 31, 2001, Vol. 11

510) V. Viter, "NPO Machinostroyenia - Advanced technology, reasonable economic policy and addressing practical problems of developing countries," Russian Air Force, Aircraft & Space Review, No 17, June 2000, pp. 58-59

A launch of Condor-E-1 is planned in the 2003/4 time frame on a Strela ("arrow") launch vehicle from the Svobodny Cosmodrome in the Amur region (Russian Far East). The Strela launcher is a converted RS-18 ICBM (NATO code name SS-19 Stiletto) utilizing a silo launch.

Orbit: Sun-synchronous polar or inclined circular orbit (final orbit selection at a later date), altitude = 500-900 km, inclination = 52-98°. The revisit time capability is 2-3 days.

RF data handling and communications: The instrument source data rate is up to 960 Mbit/s. On-board data compression is provided prior to data recording onto a 192 Gbit solid-state recorder. Downlink communications are in X-band. The data rate is 61 Mbit/s to regional data centers, and 245 Mbit/s to the central data center, located at NPO Machinostroyeniya. The functions of spacecraft operations and data distribution are also performed at NPO Machinostroyeniya.

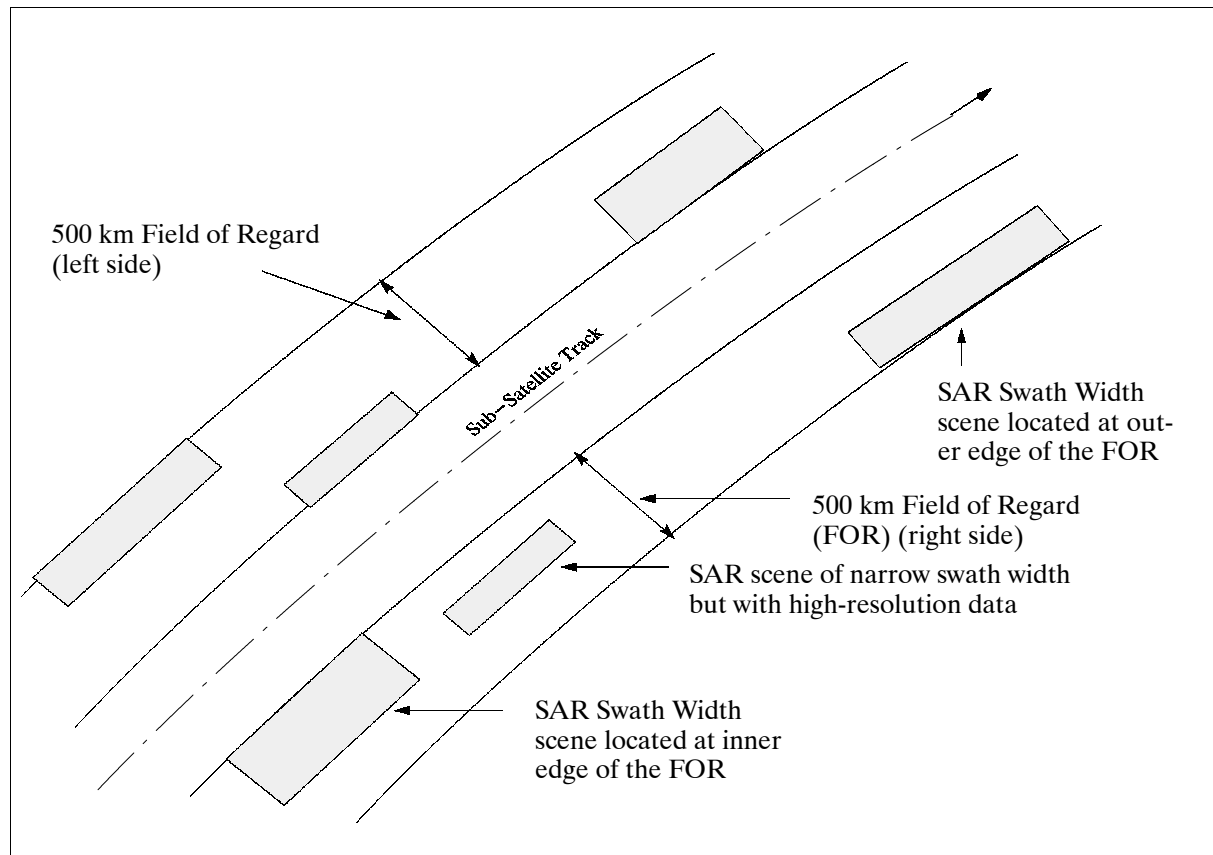

Figure 48: Observational coverage geometries of the SAR-10 instrument

Sensor complement:

SAR-10 (Synthetic Aperture Radar-10), designed and developed at NPO Vega. SAR-10 is an S-band instrument with a wavelength of 9.6 cm (or a frequency of 3.13 GHz). The overall SAR design concept employs a space-deployed parabolic dish antenna to save weight and to permit a cross-track pointing capability (a similar antenna has already been successfully tested on-board the MIR station). Unlike a phased-array antenna with a one-sided viewing capability from the spacecraft, the parabolic dish antenna design permits the observing equipment to be dynamically redirected in the cross-track direction. Thus, a Field of Regard (FOR) within the incidence-angle range of 20-55° on either side of the spacecraft may be observed. This concept is also employed on the US DoD Lacrosse satellite series.

Wavelength, (frequency)	9.6 cm, (3.13 GHz), S-band
Incidence angles	20-55° to either side of the spacecraft
Field of Regard (FOR)	500 km on either side (left or right) of the spacecraft
Swath width of imagery	20-150 km (medium swath), or 10-20 km (narrow swath, high resolution data)
Spatial resolution	5-22 m (medium swath) 1-5 m (narrow swath)
Length of a scene	Up to 4000 km
Parabolic dish antenna	6 m diameter
Antenna polarization (transmit/receive)	HH for medium swath, HH or VV for narrow swath
SNR (Signal-to-Noise Ratio)	>2
Instrument calibration	Performed in HF part of the equipment

Table 96: Main characteristics of the SAR-10 instrument

B.2 Diamant, OHB Bremen

Diamant is a cooperative low-cost minisatellite system with an end-user oriented infrastructure, designed and built a consortium of German (OHB-System, GAF) and Israeli (ELOP) companies. The overall objective of the commercial venture is to provide high-resolution imagery (spatial and spectral in combination with good radiometric sensitivity) with short revisit and delivery times to a user community. Applications of the image data are seen in particular in the fields of environmental and vegetation monitoring, hazard warning and damage assessment. Diamant has a direct relevance to the objectives of the ESA's "Living Planet Program" and is especially in line with the "Earth Explorer" research objectives. The final Diamant constellation will consist of three satellites. ^{511) 512) 513)}

Figure 49: Illustration of the Diamant spacecraft

511) A. Ginati, M. Fuchs, M. Kassebom, "Commercial Earth Observation with Small Satellites at OHB-System," Proceedings of the 13th AIAA/USU Conference on Small Satellites, Aug. 23-26, 1999, Logan UT, SSC99-IV-7

512) A. Ginati, M. Fuchs, M. Kassebom, "Earth Observation Program with Small Satellites at OHB-System," Acta Astronautica Vol. 46, No 2-6, 2000, pp. 297-306

513) <http://www.fuchs-gruppe.com/ohb-system/>

The Diamant satellite uses the UniSat (Universal Satellite Platform) bus of OHB-System, Bremen and NPO VNIIEM of Moscow, Russia. The S/C geometry is a boxlike structure of size: 71 cm x 71 cm x 91 cm. The overall S/C mass is <250 kg, power = 141 W (peak) 55 W orbital average. The S/C is three-axis stabilized providing a stability of <2 pixels/scene (or 3.2 arcsec) after 6 s; the target error is <10% of a 30 km swath this corresponds to 3 km or 0.26° (reaction wheels as actuators). A GPS receiver provides the S/C time reference and position determination. A body-pointing technique (slewing capability of the S/C) is employed for instrument pointing with a field of regard of $\pm 30^\circ$ in the along-track as well as in the cross-track direction. The angular slew rate is sufficient to perform both wide-area monoscopic and same-pass stereo imagery collections. The S/C design life is 3 years with a goal of five years.

A launch of Diamant-1 is planned for 2003/4 as a secondary payload (with a Cosmos launch vehicle).

Orbit: Sun-synchronous circular orbit, altitude = 670 km, inclination = 98.1°, equatorial nodal crossing at 11:30 AM on descending node, revisit time of 3 days above a latitude of $\pm 27^\circ$ (revisit time of 4 days above latitudes of $\pm 20^\circ$). The orbit decay is <35 km in five years.

Sensor complement:

MSRS (Multi-Spectral high Resolution System), built by ELOP (El-Op Electro-Optics Industries of Rehovot, Israel) in cooperation with OHB-System with some funding provided by the EC (European Commission).⁵¹⁴⁾ The overall objective is to demonstrate an advanced Earth observation system in a user-integrated approach (along with an end-user oriented infrastructure for commercial Earth observation). The MSRS imagery concept combines the qualities of high spatial resolution with high radiometric resolution using twelve finely defined multispectral bands in the VNIR (Visible Near-Infrared) spectral region.

Band No	Band center (nm)	Commercial applications	Science applications
1	415	Water quality mapping road detection, land cover, urban areas	Desert soils, biogenetic crusts, dissolved organic material
2	445	Real natural blue color for mass media, water quality, urban areas, landcover,	Low chlorophyll concentration, maximum chlorophyll-A absorption at 450 nm
3	490	Water monitoring, road detection, lithology and soils, crops and farming	Non-linear chlorophyll, medium chlorophyll concentration
4	510	Soils, landcover, surveying, water quality, coastal zones	Low suspended sediment, high pigment concentration
5	555	Real natural green color for mass media, landcover, crops and farming	Green peak of chlorophyll, null band of chlorophyll variation
6	645	Real natural red color for mass media, landcover, lithology and soils, forestry	Chlorophyll absorption, vegetation indices, high suspended sediment
7	670	Crops and farming, pest control, security	Max chlorophyll absorption, vegetation indices, 2nd peak of chlorophyll-A absorption
8	700	Vegetation general, nature conservation	Red edge of vegetation
9	740	Vegetation general, nature conservation	Red edge of vegetation
10	790	Vegetation general, nature conservation	Red edge of vegetation
11	865	Lithology and soils, crops and farming, forestry, landcover, nature conservation	Max. chlorophyll reflectance, vegetation indices, water vapor, atmospheric correction
12	905	Lithology and soils, nature conservation, wetlands, coastal waters	Max. chlorophyll reflectance, atmospheric correction

Table 97: Spectral bands of the MSRS instrument and data application scenarios

The MSRS instrument consists of the following elements: optical subsystem, detector subsystem, a data compression and storage unit, and an instrument control computer. MSRS

⁵¹⁴⁾ A. Ginati, B. Penné, A. Blasberger, P. Volk., "MSRS - Multi Spectral High Resolution System," IAF-1998-B3.10, 49th IAF Congress, Melbourne, Australia, Sept. 28 - Oct. 2, 1998

features the pushbroom imaging concept with twelve CCD detector channels (400 - 1000 nm) in a focal plane configuration; each channel is furnished with a separate interference filter for wavelength band definition and a TDI (Time Delay Integration) type detector array. The detector array for each channel has a size of 5200 pixels (cross-track direction) x 32 rows (used for TDI), thus offering a cumulative exposure concept to improve the SNR value for multispectral imaging. Three of such (5200 x 32 pixel) detector units are integrated on a single chip. Two of the detectors with two different spectral regions (6 spectral bands) are cemented to the exit surface of one BSGB (Beam-Splitter Glass Block). Two separate BSGBs are used to cover the spectral region of 12 bands. The spectral coverage is contiguous in the visible region (435 - 750 nm) with bandwidths of 10-50 nm, permitting good discrimination of image features.⁵¹⁵⁾

A spatial resolution of 5 m at nadir (IFOV = 0.075 mrad) is achieved for all channels of the imagery. The focal length of the catadioptric telescope (a modified Ritchey-Chretien instrument with an entrance pupil diameter of 250mm) is 1750 mm providing a FOV of 2.3° (26 km swath at an orbital altitude of 670 km). A body-pointing capability of ±30° in the cross-track and along-track directions is provided by the S/C, offering a short revisit period of 3 days for requested cross-track monitoring applications; an alternate service of this S/C agility is the provision of along-track stereo imagery.

Instrument mass, power, size	70 kg, 120 W peak, 60 cm x 58 cm x 58 cm
Spectral bands, range, spectral resolution	12, 400 - 1000 nm (VIS and VNIR), 10-50 nm
Spatial resolution	5 m (IFOV = 0.075 mrad)
TDI capability	4 TDI detectors with 3 channels each
Data quantization	10 bit/pixel
Source data rate	4 x 300 Mbit/s peak
Scene size	26 km x 40 km (nominal), up to 26 km x 400 km
Scene rate	Up to 140 scenes/day
On-board recorder capacity	210 Gbit

Table 98: Some instrument performance parameters of MSRS

On-board calibration uses the sun for direct calibration purposes. A small mirror, whose size controls the required attenuation level, reflects a defocused image of the sun onto the detectors via the MSRS telescope.

Data communication: The source imagery may be stored onto a 210 Gbit solid-state on-board recorder. Downlink communication in X-band (frequency = 8.2 GHz, modulation scheme = OQPSK) is provided at data rates of 100 Mbit/s (optionally at 320 Mbit/s). An online JPEG data compression scheme is employed to reduce the number of bits per pixel without compromising radiometric accuracy. The CCSDS protocols are used for all data communication.

The ground segment for the operational support of the Diamant mission consists of the following elements: Control Station, Data Archive & Distribution Center, and Data Receiving Stations (fixed and mobile). The services to the customer base consist of a number of data products (level 1 through level 5).

B.3 COSMO-SkyMed and Pléiades Programs

In 1996 the Italian Government provided initial funding for the realization of a national Earth observation program. In 1997 the general guidelines for the 1998-2002 Italian space plan were approved including the activities on Earth observation. The strategic element in this plan is the **COSMO-SkyMed** (Constellation of Small Satellites for Mediterranean ba-

⁵¹⁵⁾ Information provided by B. Penné of OHB System, Bremen

sin Observation) dual-use program of ASI (Agenzia Spaziale Italiana).⁵¹⁶⁾ The overall objective of this program is global Earth observation and the relevant data exploitation for the needs of the military community as well as for the civil (institutional, commercial) community.

Sample applications of COSMO-SkyMed data are seen the following fields:

- Defense and security applications: Surveillance, intelligence, mapping, damage assessment, vulnerability assessment, target detection/localization
- Risk management applications: Floods, droughts, landslides, volcanic/seismic, forest fire, industrial hazards, water pollution
- Other applications: Marine and coastal environments, agriculture, forestry, cartography, environment, geology and exploration, telecommunication, utilities and planning.

Since 1997 CNES (France) is studying the use of smaller satellites (a medium spacecraft size of about 500 kg instead of 3 tons as for the SPOT-5 S/C), resulting in the “3S” platform concept (Small Satellite System) standing for “Suite de Systeme du SPOT” or for “SPOT Successor System.” The focus is on cost reduction, technological innovation, user services, and performance upgrades for a new generation of satellites, referred to as **Pléiades**.^{517) 518) 519)}

On Jan. 29, 2001, an intergovernmental agreement (memorandum of understanding) was signed during the Turin meeting between Italy (Guiliano Amato) and France (Lionel Jospin). The objective of this agreement is the cooperation of France and Italy on a “dual high-resolution Earth observation system,” comprising a **two-satellite constellation in the optical region under the leadership of France**, and a **four-satellite constellation under Italian leadership in the microwave region of the spectrum (initially X-band SAR)**. The intent of this agreement is to provide a long-term perspective on a number of high-quality data products and services on the commercial market for a wide range of applications in the fields of cartography, agriculture, forestry, hydrology, and geological prospecting. The dual service concept is seen in the data requirements of the defense and civilian communities with an option of a daily revisit capability. The agreement calls for funding and development of the space segment by each country and a common sharing of the ground segment.^{520) 521)}

In this framework the Italian and French Governments started a cooperation with the goal of Earth observation for dual-use applications (military and civil) with SAR and optical instruments based on the on-going COSMO-SkyMed and Pléiades small satellite programs, respectively. This dual-use scenario calls for missions that offer advanced observation capabilities in several modes of operation, permitting to meet the objectives of the military and civil communities at the same time. The development of innovative and complementary instrumentation in the radar field (e.g., multi-mode and flexible-support SAR’s offering high-resolution data) and in the optical field (e. g., hyperspectral sensor with capabilities of variable spatial resolutions as well as high detection sensitivities in the visible and infrared spectral regions) are major objectives of the programs.

As of mid-2001, **COSMO-SkyMed** as well as **Pléiades** are proposed cooperative Public Private Partnership (PPP) initiatives between ASI and ESA and between CNES and ESA, respectively. Approval of the programs is expected by the European Council of Ministers in

519) In Greek mythology, Pléiades refers to the seven daughters of the Titan Atlas and the Oceanid Pleione: Maia, Electra, Taygete, Celaeno, Alcyone, Sterope, and Merope. They all fell in love with gods (except Merope, who loved a mortal) and were the mothers of gods. The Pléiades eventually formed a constellation.

520) “Earth Watch Program: COSMO-SkyMed Element,” ESA/PB-EO (2001) 55, May 18, 2001, with Annex: Draft Italian Earth Watch Program Proposal - ESA participation to COSMO-SkyMed Mission (Radar Component)

521) <http://www.alespazio.it/cosmo/skymed.htm>

Nov. 2001. Both programs are set within ESA's Earth Watch program and the European GMES (Global Monitoring for Environment and Security) initiative.

The COSMO-SkyMed / Pléiades space segment is based on a constellation of small satellites combined with a fast data reception capability. The provision of data on an operational basis (of continuity and quality) is essential for the system.

The constellation will be deployed in two orbital planes, one orbit plane for the SAR satellites and one orbit plane for the optical satellites. This permits a) the SAR satellites to collect the maximum solar radiation for S/C power demands in sun-synchronous dawn-dust orbits, and b) the optical satellites to operate under optimal illumination conditions in a sun-synchronous near noon orbit.

The COSMO-SkyMed / Pléiades ground segment provides all the infrastructures needed to support the mission in a dual-use scenario (functions/operations in terms of constellation control and global data management). The various elements are:

- CPCM (Centro Pianificazione e Controllo Missione - Mission Planning and Control Center). Coordination of on-board and ground activities, mission planning, and resource allocation.
- CCS (Centro Controllo Satelliti - Satellite Control Center). Provides the monitor and control function of the constellation including flight dynamics.
- TT&C stations. Primary service link between the space and ground segments (dedicated communications network).
- CREDO (Centro Ricezione ed Elaborazione Dati Operativi). CREDO operates X-band stations for high-rate data acquisition and provides data archiving and processing. To the user side there is a two-fold function:
 - As a civil support facility which handles civil user requests
 - As a military support facility to handle the military service needs.

B.3.1 COSMO-SkyMed

The COSMO-SkyMed space segment is composed of a constellation of four SAR satellites. The PRIMA [Piattaforma Riconfigurabile Italiana Multi-Applicativa (Reconfigurable Italian Platform for Multiple Applications)] bus of Alenia Spazio is employed. Alenia Spazio is also the prime contractor of the space segment (ASI funding). The S/C is three-axis stabilized, it consists of the main body (bus), two deployable solar arrays, and a SAR antenna. The bus provides all support functions like: AOCS, electrical power (power generation, storage and distribution), data handling, thermal control, RF communications, and on-orbit propulsion for orbit injection and maintenance. The platform mechanical configuration consists of two elements (boxes), namely a) SVM (Service Module) at the bottom of the bus which contains all bus subsystems including the propulsion module, and b) PLM (Payload Module) at the top, dedicated to the payload complement, the PDHT (Payload Data Handling and Transmission) subsystem, and the AOCS (Attitude and Orbit Control Subsystem) with star trackers gyros actuators. The bus structure material is CFRP (Carbon Fiber Reinforced Plastic) while SVM and PLM consist of aluminum alloys. The interfaces of the SAR antenna, star trackers and gyros are mounted on the CFRP structure for pointing precision and stability. The SAR antenna bore sight pointing with an incidence angle about 38° to the right side of the S/C ground track. AOCS provides an antenna steering capability of $\pm 2^\circ$ in yaw as well as for a re-pointing capability to the left side of the ground track.

Orbit: Circular sun-synchronous dawn-dusk orbit, nominal altitude = 619.6 km, inclination = 97.86° , with LTAN (Local Time of Ascending Node) at 6:00 AM, 14.8125 rev./day (or 14 13/16). All spacecraft of the SAR constellation will be positioned in the same orbital plane with a phasing outlined in Table 99. The nominal repeat cycle is 16 days; however, each single satellite will have a near revisit time of 5 days.

Figure 50: Illustration of the COSMO-SkyMed spacecraft

The phasing of the S/C in the orbit plane has been selected to achieve optimum performance in terms of accessibility and revisit time with respect to the number of satellites. Table 100 summarizes the achievable observation performance capabilities of the SAR satellites within the latitudinal coverage of $\pm 20^\circ - 60^\circ$.

Satellite number	True Anomaly
1	0°
2	$0^\circ, 180^\circ$
3	$0^\circ, 120^\circ, 240^\circ$
4	$0^\circ, 90^\circ, 180^\circ, 270^\circ$

Table 99: SAR satellite phasing scheme

Constellation	Right Looking		Left and Right Looking		Comment
	Nominal	Extended	Nominal	Extended	
1 satellite	37 to 64 h	25 to 44 h	18 to 35 h	12 to 23 h	Mean revisit time
	<252 h	<120 h	<156 h	<60 h	Max. revisit time
	38% (24 h)	55% (24 h)	67% (24 h)	85% (24 h)	Access % vs time
2 satellites	19 to 35 h	13 to 24 h	9 to 18 h	6 to 12 h	Mean revisit time
	<108 h	<60 h	<60 H	<36 h	Max. revisit time
	41% (12 h)	62% (12 h)	60% (12 h)	77% (12 h)	Access % vs time
	64% (24 h)	84% (24 h)	81% (24 h)	92% (24 h)	
3 satellites	13 to 24 h	9 to 16 h	6 to 12 h	4 to 8 h	Mean revisit time
	<60 h	<36 h	<36 h	<36 h	Max. revisit time
	62% (12 h)	88% (12 h)	84% (12 h)	98% (12 h)	Access % vs time
	84% (24 h)	98% (24 h)	96% (24 h)	99.97% (24 h)	
4 satellites	10 to 18 h	6 to 12 h	5 to 9 h	3 to 6 h	Mean revisit time
	<60 h	<24 h	<24 h	<12 h	Max. revisit time
	80% (12 h)	99% (12 h)	97% (12 h)	100% (12)	Access % vs time
	95% (24 h)	100% (24 h)	100% (24 h)		

Table 100: Accessibility parameters for the various constellation configurations

The phase B2 of COSMO-SkyMed project was completed in Dec. 2000. Launch/deployment of the constellation is planned to be in the time frame of late 2003 or early 2004.

Support Mode	Configuration	Comments
SAR observation side with respect to the nadir ground track	Right-side looking (nominal) Left-side looking for limited periods	Providing better performance of northern hemisphere coverage Use intended to satisfy ASAP priority requests
Duty cycle (estimated on a daily basis)	75 min of operation in Stripmap or ScanSAR 150 images in Spotlight mode	A duty cycle is needed to overcome the S/C power limitations
Max. imaging duty cycle (on an orbit basis)	10 min of continuous operations in Stripmap or ScanSAR 20 consecutive images in Spotlight mode	
Image acquisition management	On a 24 h basis	Capability of time-tagged commands for SAR-2000
PDHT max duty cycle	20% per orbit	
PDHT storage capacity PDHT storage strategy	256 Gbit a) Delete after output (nominal) b) Retain after output	
PDHT support modes	- Store only - Downlink only - Store and downlink - Pass through (near real time)	Both in right and left looking Only in right looking Only in right looking Only in right looking
PDHT downlink rates	- Downlink only - Store and downlink - Pass through (near real time)	2 separate links at 150 Mbit/s 1 link at 150 Mbit/s 1 link at 150 Mbit/s

Table 101: Overview of operational support modes

Note: It was not possible to receive any information from the COSMO project at Alenia Spazio although this was definitely promised in April 2001 with a due date of arrival on June 29, 2001, at the latest. On this date, however, I was simply informed that COSMO had just been classified concerning all information on technical parameters as well as on applications. Hence, a number of parameters could not be obtained such as: S/C mass and power, S/C dimensions, design life, instrument power, instrument frequency. Although the first constellation satellite SAR instruments (SAR-2000) are expected to observe in X-band (probably at 9.6 GHz with a wavelength of 3.1 cm), multi-mode scenarios (X-, C- L- and P-band) are planned for the future.

Sensor complement:

SAR-2000 (Synthetic Aperture Radar-2000) instrument, developed at Alenia Spazio. The objectives call for the following design features:

- Very large instantaneous bandwidth
- Electronic beam steering in range and azimuth
- Multi-polarization support
- Programmable PRF, pulse width and bandwidth
- Multiple imaging mode support
- On-board hardware calibration techniques
- On-board data compression processing techniques (both analog and digital)

The instrument is composed of two major elements: a phased array antenna subsystem (external equipment) and of the central electronics module (internal equipment). The central electronics module in turn consists of three parts:

- RFA (Radio Frequency Assembly). RFA has four units: XDU (X-band Driver Unit), XSU (X-band path Switch Unit), DCU (X-band Receiver), and FGU (Frequency Generation Unit).
- DESS (Digital Electronics Subsystem)
- CPSU (Central Power Supply Subsystem)

Operational modes with one polarization selectable among HH, VV, HV, or VH	
Spotlight (also referred to as "Frame")	Spatial resolution: ≤ 1 m Spot observation area: 10 km x 10 km
HIMAGE (Stripmap)	Spatial resolution: 3-15 m Swath width: 40 km
WideRegion (ScanSAR)	Spatial resolution: 30 m Swath width: 100 km
HugeRegion (ScanSAR)	Spatial resolution: 100 m Swath width: 200 km
Operational modes with two polarizations selectable among HH, VV, HV, or VH	
Ping Pong (Stripmap)	Spatial resolution: 15 m Swath width: 30 km km

Table 102: Some performance characteristics of the X-band SAR payload

The antenna subsystem is a large deployable planar phased array. It consists of 40 identical tiles arranged in five identical electrical configurations (5 electrical panels). Each tile consists of T/R (Transmit/Receive) modules. Within a tile there are all functions needed for beam forming and reception. Each tile is a self-consistent active antenna element including all functional support (thermal, RF, digital and power). The following operational acquisition modes are supported: Stripmap, ScanSAR, and Spotlight. The SAR data localization accuracy is 25 m without GCP (Ground Control Point).

Figure 51: Illustration of the SAR operational modes

The single orbital plane constellation offers a number of interferometric applications/features such as:

- A full interferometric accessibility (i.e. a double acquisition of all sites with the same incidence angle within the 16 day orbit repeat cycle)
- No degradation of the mean revisit time with respect to the performances achievable with the same number of satellites
- A fixed time period of one day between two interferometric acquisitions.

SAR product examples: Multidate basic products, stereo pairs for radargrammetry, interferograms (for DEM and DTM) or differential interferogram, coherence products, etc.

B.3.2 Pléiades

The Pléiades spacecraft structure is shown in Figure 52. The S/C is three-axis stabilized; attitude is sensed by star trackers (capable of finding attitude starting from a “lost-in-space” condition) and by fiber-optic gyros. The S/C permits a body-pointing capability with roll and pitch maneuvers, each up to 60° , within a period of 25 s. S/C power is provided by rigid AsGa solar arrays and by LI (Lithium-Ion) batteries. The total mass of the S/C is about 900 kg.⁵²²⁾
⁵²³⁾

A launch of Pléiades-1 is planned for the end of 2005, Pléiades-2 will follow a year later.

Orbit: Sun-synchronous phased orbits (180° phasing, 14 and 15/26 rev./day), altitude = 695 km, inclination = 98.2° , local equator crossing time on ascending node around 10:30. The two-satellite constellation in combination with agile cross-track pointing provides the capability of daily revisits.

RF communication: An X-band downlink provides a payload transmission rate of 600 Mbit/s in 4 channels, each of 150 Mbit/s capacity. All source data are compressed prior to on-board storage (mass memory of 600 Gbit).

Figure 52: Illustration of the Pléiades spacecraft

Sensor complement:

OHRI (Optical High-Resolution Imager). The objective is to provide high-resolution multispectral imagery with geo-location accuracy. The instrument employs a Korsch telescope with TMA (Three Mirror Anastigmatic) optics. The focal plane for the Pan band makes use of TDI (Time Delay Integration), the size of the detector array assembly is 5×6000 (30,000 pixels in cross-track). Five detector line arrays, each of 1,500 elements (7,500 pixels in cross-track), are utilized for the four MS channels.

⁵²²⁾ “Proposal for an Earth Watch Wide Field / Superspectral Element,” ESA/PB-EO (2001) 59, Annex-1, May 16, 2001

⁵²³⁾ The SPOT project management provided a set of viewgraphs in early June 2001. After my draft submission to the project, however, I did not receive any response (in spite of several reminders). In my experience, this disregard of small requested services seems to be a trademark of SPOT management.

Spectral bands	Pan, MS (RGB, NIR)
Spatial resolution	0.7 m for Pan, 2.8 m for MS bands
Swath width	21 km
FOR (Field of Regard)	60°
Coding	10 bit
Image location accuracy	1 m (with ground control points), 20 without GCP
Data compression	Wavelet compression algorithm with an average compression factor of 4
Source data rate	600 Mbit/s

Table 103: Characteristics of the OHRI instrument

The basic data products of Pléiades are level 0 and level 1 imagery (up to orthorectified imagery). Possible intermediate products are: Mosaicked imagery, DTM (Digital Terrain Model) extracted from stereo pairs.

The main application fields identified for the Pléiades program data fall into the following categories: Cartography, agriculture, forestry, hydrology, geological prospecting, dynamic geology and risk management.

Pléiades is a multi applications, multi sensor and multi partnership program. The first generation will only be furnished with an optical high-resolution imager. Wide-field, super-spectral, hyperspectral and thermal (TIR) system observation capabilities are options for future Pléiades implementations (with launches beyond 2006).

Sensor	Resolution (m)	Swath Width (km)	Nr. of Bands	Revisit Time (days)	Main applications
Wide Field	2-5	40-100	3-4	3-7	Cartography, geology, agriculture, forest, hydrology
Optical HR	<= 1	10-30	3-4	1-2	Cartography, risk, forest, geology
Superspectral	3-10	100-300	6-20	1-2	Agriculture, forest, geology
Hyperspectral	5-20	50-300	30-200	2-7	Geology
Thermal	1-40	100	TBD	<1	Forest fires, geology, ocean

Table 104: Optical system identification for possible user needs

B.4 EarthWatch (DigitalGlobe) Imaging Satellites

EarthWatch Inc. is changing its name to “DigitalGlobe Inc.” by Oct. 2001.

B.4.1 EarlyBird

EarlyBird is an imaging spacecraft designed, built and operated by EarthWatch Inc. of Longmont, CO, along with its major partners: Ball Aerospace Corporation, Boulder, CO; CTA Inc. of McLean, VA; Hitachi Ltd. of Tokyo, Japan; and Telespazio of Rome, Italy. The EarlyBird S/C is three-axis stabilized; the attitude is sensed by a star tracker, position knowledge by GPS; design life = 3 years, 5 years of on-board fuel; S/C mass = 310 kg; payload mass = 150 kg; power = 90 W; on-board storage capability of a 16 Gbit solid-state recorder. 524)

A launch of EarlyBird-1 took place on December 24, 1997 with a Start-1 launch vehicle from the Svobodny Cosmodrome in Eastern Russia (note: the Start-1 rocket is based on the SS20 and SS25 intercontinental ballistic missiles with proven launch performance). Earth-Watch controllers lost contact with the S/C on Dec. 28, 1997, stopping the commencement of operations.

Orbit: Sun-synchronous polar orbit, altitude = 470 km, inclination = 97.3°, period = 94 min, 10:30 AM equator crossing, descending node (1:30 PM equator crossing for the second

524) Information provided by D. B. Gerull, R. N. Herring, and B. Wientzen of EarthWatch, Longmont, CO.

satellite), repeat cycle = 20 days (max), revisit time = 1.5 - 2.5 days (with a two satellite configuration).

Figure 53: The EarlyBird S/C Model

Data: The downlink of imaging data is encrypted and provided in X-band at data rates of 25 Mbit/s to EarthWatch-owned ground receiving stations in the USA, Europe and Asia. The TT&C up- and downlinks are in UHF-band. The objective of EarthWatch is to become the first global supplier of commercial high-resolution imagery and related geographic information products by creating and maintaining a *Digital Globe™* product database (the master archive, a gateway, and the satellite control center are located in Longmont, CO). A number of customized service options are provided with product delivery times ranging from 30 minutes to 48 hours after acquisition.

Figure 54: The EBP and EBM optical design concept

Sensor complement:

EBP = EarlyBird Panchromatic, and **EBM** = EarlyBird Multispectral (built by Earth-Watch, same concept design as on Clark S/C, but with enhanced capabilities). The instrument provides high-resolution panchromatic and multispectral imagery simultaneously. A staring focal plane array detector technology (Kodak designed and built) is employed featuring a gimbaled mirror design (see Figure 54) with a 30° pointing capability from nadir into any direction. The fast steering mirror permits exposures of a single frame or of a matrix of images (point and shoot). The panchromatic image scene is always contained within the larger matrix of the multispectral image scene, in a fixed location. However, by taking a multispectral image and then moving the gimbal around to take additional multiple exposures, one can cover the area of the multispectral image with panchromatic images, or there is the ability to collect a panchromatic image in any desired location within a multispectral image. The cameras may also be used for stereo imaging by slewing the gimbal mirror fore and aft in the S/C flight direction. The on-board processor provides real-time radiometric/geometric calibration and image compression for all imaging data.

Parameter	Panchromatic camera (EBP))	Multispectral camera (EBM)
Spectral range(s)	0.45 - 0.80 μm	0.45-0.59, 0.61-0.68, 0.79-0.89 μm
Spatial resolution (at nadir)	3 m	15 m
Footprint (or scene)	3 km x 3 km per patch (4 patches exposed simultaneously) over a swath \sim 11.1 km	15 km x 15 km per patch (4 patches exposed simultaneously) over a swath \sim 55.5 km
Instrument (mirror) pointing	\pm 30° (along-track/across-track) providing a 560 km wide field of regard	
Pointing accuracy	6 m horizontal, 4 m vertical (relative)	
Stereo imaging	In along-track direction, maximum base/height ratio = 1	
Data quantization	8 bit	
Array size	4 10^6 pixel	4 10^6 pixel (x 3)
Data size/scene	4 MByte (uncompressed)	12 MByte (uncompressed)
Data volume	\sim 2000 patches (500 scenes) per orbit	

Table 105: Performance characteristics of the EarlyBird imagers

B.4.2 QuickBird-1

QuickBird-1 is a next-generation EarthWatch satellite, offering commercial imagery at 1 m (PAN) and at 4 m (MS) resolution. This high-resolution imaging capability requires a change in instrument technology from a staring array design to a pushbroom/large-telescope technique, resulting in a new spacecraft design. QuickBird-1 uses the BCP 2000 (Ball Commercial Platform 2000) satellite bus design.⁵²⁵⁾ It is 3-axis stabilized. The ADCS (Attitude Determination and Control subsystem) uses two star trackers, redundant IRUs, sun sensors and magnetometers for attitude sensing. Attitude control is provided by low-vibration reaction wheels (0.68 Nm, 20 Nms), three torque rods, and four hydrazine thrusters. Position knowledge is provided by redundant GPS receivers. The pointing accuracy is \pm 0.016° (3 sigma steady state in all three axes; the attitude pointing knowledge is \pm 0.0008° (3 sigma steady state in all three axes), geolocation knowledge <15 m (3 sigma) after ground processing. S/C design life of 5 years. S/C mass = 931 kg at launch. The BCP 2000 configuration uses a simple panel-post aluminum honeycomb structure. The total bus mass (wet) is 641 kg. Two solar panels (GaAs/Ge cells), each of 3.2 m² area and single axis drive, provide a S/C power of 1500 W. The NiH₂ battery provides energy of 40 Ah for ecliptic operations.

A launch of QuickBird-1 took place on Nov. 20, 2000 on a Cosmos-3M vehicle from Plesetsk, Russia. Unfortunately the launch ended in a failure. No contact could be established with the spacecraft.

525) “Ball Commercial Platform 2000 (BCP 2000),” Technical Description, Jan. 2000, provided by Tom Miers of BATC

Figure 55: Illustration of QuickBird configured with BGIS-2000

Orbit: Circular orbit (non-sun-synchronous), altitude = 600 km, inclination = 66°, the equator crossing time is variable, average revisit time = 1 to 5 days depending on latitude.

Sensor complement:

BGIS 2000 (Ball Global Imaging System 2000).⁵²⁶⁾ BGIS is a BATC-developed imager - the instrument-bus combination is called BGIS 2000. The bus itself is called BCP 2000. The camera instrument of BGIS-2000 is called **BHRC 60** (Ball High Resolution Camera 60). BHRC 60 consists of the following elements: Optical subsystem, FPU (Focal Plane Unit) and the DPU (Digital Processing Unit), with FPU and DPU designed and custom-built by Kodak (same, except for size, as that used on IKONOS). BHRC 60 has a design life of >5 years, achieved with a redundant architecture. Instrument mass = 380 kg, instrument power = 250 W silicon and 430 W for GaAs (orbital average).

- The optical subsystem, mounted on an optical bench (with sunshield and internal baffling to suppress stray light), is of Ball design (telescope aperture of 60 cm diameter, lightweight structure, focal length of 8.8 m, f/14.7, the telescope mass is 138 kg, telescope size: 115 cm x 141 cm x 195 cm), providing a FOV (Field of View) of 2.12°, obtained with an unobscured off-axis three-mirror-anastigmatic (TMA) optical form. A fourth mirror is used to fold the light bundle for compact telescope packaging. The enlarged FOV of the BHRC 60 instrument offers a ground swath of 15 km at 400 km orbital altitude or 34 km at 900 km altitude with a GSD varying between 0.5-1.5 m, respectively.
- The detector subsystem employs the pushbroom imaging technique. The CCD detector array features 27,568 pixels in the cross-track direction for the panchromatic band and 6892 pixels for each of the four multispectral bands. The spectral ranges of the multispectral BGIS bands correspond to the first four bands of the ETM+ instrument on Landsat-7, the PAN band is also identical to PAN on ETM+.
- The TDI (Time Delay Integration) concept is employed for PAN imagery. TDI levels of 10, 13, 18, 24, and 32 are available and selectable. The TDI arrays prevent exposure saturation while maximizing the SNR over a wide range of angles and Earth albedos.

⁵²⁶⁾ "Ball High Resolution Camera 60 (BHRC 60), Technical Description, Jan. 2000, provided by Tom Miers of BATC

Parameter	Panchromatic imagery	Multispectral imagery (4 bands)
Spectral range(s)	0.45 - 0.90 μm , grayscale	0.45-0.52, 0.52-0.60, 0.63-0.69, 0.76-0.90 μm
Spatial resolution, IFOV	1 m (GSD), 1.37 μrad	4 m (GSD), 5.47 μrad
Swath width, FOV	22 km (600 km altitude), 2.12°	
Camera	Pushbroom array (11 bits pixels)	Pushbroom arrays (11 bits x 4)
Detector array	27,000 pixels	6,700 pixels x 4
S/C body pointing capability	$\pm 30^\circ$ (along-track/across-track) providing a 704 km wide field of regard	
Pointing accuracy	<0.5 mrad absolute per axis (200 to 450 m)	
Geolocation of data	<15 m (3 sigma) after ground processing	
Pointing agility	Maneuver of 10° in 20 s, maneuver of 50° in 45 s	
Imaging modes	Snapshot: 22 km x 22 km Strip mode: 22 km x 200 km Mosaic patterns: Stereo: 20 km x 20 km typically; in along-track direction (single pass)	
Data quantization	11 bits	
Data size/ PAN scene	8 Gbit (uncompressed), 1.5 Gbit (compressed)	
Data volume	64 - 100 scenes per orbit	

Table 106: Performance parameters of the BGIS 2000 instrument on QuickBird-1

The instrument provides high-resolution panchromatic and multispectral imagery simultaneously. The pushbroom imager is rigidly aligned with the S/C axis, providing a nominal body-pointing capability of $\pm 30^\circ$ into the along-track and cross-track directions (45° max). The panchromatic and multispectral image scenes are coincident. BGIS 2000 may also be used for stereo imaging by slewing the S/C fore and aft. The on-board processor provides real-time radiometric/geometric calibration and image compression for all imaging data. The compression technique employed is ADPCM (Adaptive Differential Pulse Code Modulation) of Kodak.

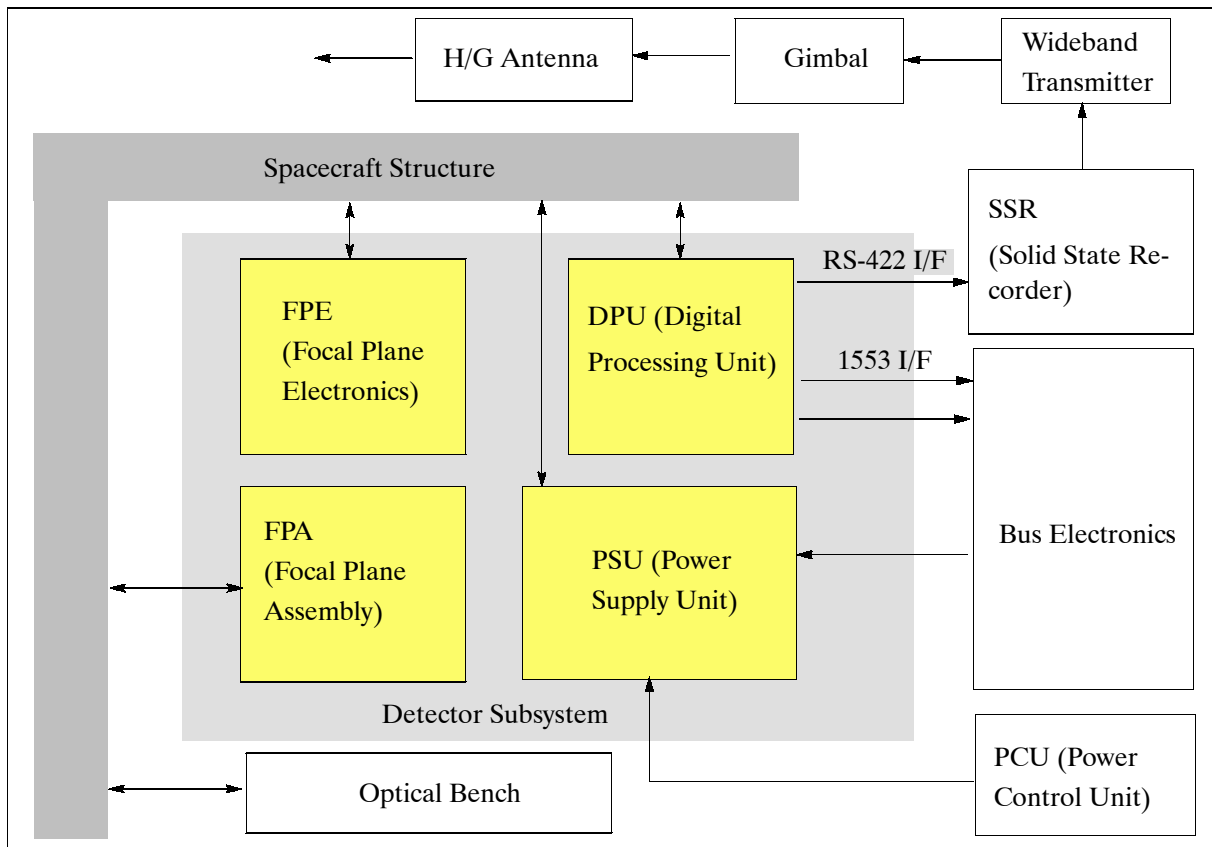

Figure 56: Functional block diagram of the BHRC 60 detector subsystem

Figure 57: Schematic illustration of the BHRC 60 instrument

S/C communications: An on-board image data storage capability of 137 Gbit is provided in solid-state memory. The downlink of all imaging data is provided in X-band at data rates of up to 320 Mbit/s to EarthWatch-owned ground receiving stations in the USA, Europe and Asia. The real-time X-band data channel is PCM/PSK/PM modulated, while the playback data channel is PCM/PM modulated. The TT&C functions are provided in S-band at data rates of 4-16 kbit/s in downlink and 2 kbit/s in uplink. The realtime narrow-band data is downlinked at these rates on the subcarrier, while the stored engineering data is downlinked on the carrier at a rate of 256 kbit/s.

B.4.3 QuickBird-2

QuickBird-2 is an almost identical follow-up optical imaging mission of QuickBird-1, owned and operated by EarthWatch Inc. of Longmont, CO. A higher ground resolution of the imagery is obtained with QuickBird-2 by selecting a lower orbital altitude, naturally at the expense of swath width. The S/C carries enough fuel to adjust the lower orbit more frequently (due to drag influences) over the operational lifetime of the mission. A launch of QuickBird-2 is scheduled for Oct. 2001 on a Delta-II vehicle from VAFB, CA. ^{527) 528)}

Orbit: Sun-synchronous circular orbit, altitude = 450 km, inclination = 98°, average revisit time of 1-3.5 days.

S/C pointing capability	Body-pointing S/C with $\pm 30^\circ$ nominal along-track and cross-track pointing capability, 45° maximum
S/C pointing accuracy	Standalone geolocation: 23 m Circular Error (CE), 17 m Linear Error (LE), 90% confidence
S/C autonomy	Autonomous Line-of-Site (LOS) pointing using GPS receivers and attitude sensors
S/C mass, size, design life	951 kg, 3 m in height, 5 years
On-board data storage	128 Gbit

Table 107: Performance features of QuickBird-2

⁵²⁷⁾ <http://www.digitalglobe.com/products/quickbird1.shtml>

⁵²⁸⁾ Information provided by Charles P. Herring of EarthWatch Inc., Longmont, CO

Parameter	Panchromatic imagery	Multispectral imagery
Spectral bands	Pan: 450-900 nm	450 to 520 nm (blue) 520 to 600 nm (green) 630 to 690 nm (red) 760 to 890 nm (VNIR)
Spatial resolution	0.61 m (GSD at nadir)	2.5 m (GSD at nadir)
Swath width (FOV)	17 km (450 km altitude), 2.12°

Table 108: Performance parameters of the BGIS 2000 instrument on QuickBird-2

B.5 EROS (Earth Remote Observation System), ImageSat International

EROS is a program of ISI (ImageSat International, N.V.), formerly WIS (West Indian Space) Ltd., Cayman Islands (a Netherlands Antilles-registered joint venture). ImageSat's ownership includes former WIS partners: Israel Aircraft Industries (IAI) of Tel-Aviv (owned by the Israeli government), Elbit Systems Ltd. of Haifa, CORE Software Technology (CST) Inc. of Pasadena, CA, and El-Op Electro-Optics Industries of Rehovot, Israel. The objective is to launch and operate a constellation of satellites under a license from the government of Israel, and to offer high-resolution imagery, collected by EROS satellites, on a commercial basis to a large customer base. Commercial spaceborne remote sensing technology, developed by IAI, was approved by the government of Israel in Oct. 1996. ⁵²⁹⁾

The first satellite, EROS-A, launched on Jan. 22, 1998 from the Yavne launch site in Israel, failed to reach orbit due to a Shavit launcher failure.

An enhanced EROS-A1 was launched on a Russian Start-1 launcher on Dec. 5, 2000 (Svobodny Cosmodrome). This is to be followed by EROS-A2 in 2001. The first EROS-B1 S/C is scheduled for launch in 2002. A constellation of six Eros-B satellites (B1 to B6) are planned to be operational by the year 2004. The operational constellation provides a global daily revisit for any point on Earth. ⁵³¹⁾

Note: In Feb. 2001, ISI changed plans in its launch sequence with the consequences that the launch of EROS-A2 was scratched in favor of a launch of EROS-B1. The B-series offers higher resolution imagery (<1 m versus 1.8 m for the A-series instrument). The decision to move directly to the B-series (with platform and instrument) results in a new launch date for EROS-B1 in 2003. In July 2001, ImageSat awarded a contract to IAI to build a new spacecraft. ⁵³²⁾

The EROS program offers a combination of services and products tailored to meet specific customer requirements and budgets: ⁵³³⁾

- Communication, computing and networking technology are designed to augment existing information sources including regional cartographic, aerial imagery, as well as commercially available information sources.
- Provision of low-cost imagery products to support applications in many fields.

⁵²⁹⁾ ISI is incorporated in the Netherlands Antilles and headquartered in Cyprus

Figure 58: The EROS-A S/C Model

B.5.1 EROS-A Spacecraft Series

EROS-A1 (of OFEQ-3 heritage)⁵³⁴ is an Israeli high-resolution commercial imaging satellite designed and built by IAI (Israeli Aircraft Industries). The S/C structure consists of low-mass composite material with passive thermal control, it is three-axis stabilized, attitude control and navigation is performed using horizon sensors, sun sensors, gyros and magnetometer, four reaction wheels and thrusters. The pointing accuracy is $<0.1^\circ$ in all three axes, attitude stabilization is <40 mrad/s, the jitter is <0.2 mrad. S/C mass = 250 kg (174 kg S/C bus, 36 kg of instrument mass and 30 kg of hydrazine), solar panel power (silicon array, fixed panels) = 450 W (EOL), plus 14 Ah NiCd batteries for eclipse operation, the bus power consumption is 100 W. S/C design life = 4 years.

Communications: Imagery is transmitted in X-band at a rate of 70 Mbit/s (RF downlink) to the ground receiving stations, using a 1.5 W transmitter and one of the two existing two-axis gimbaled directional antennas. The EROS satellites are monitored/operated in S-Band (TT&C) via a single ground control station (GCS), located at IAI/MBT in Israel (4 to 5 passes per day and per satellite are in station visibility). The S-band data rate is variable between 2.5 - 15 Kbit/s.

In addition there is a network of existing ground receiving stations (ImageSat has a ground segment infrastructure of at least ten stations), located around the world, for real-time image data acquisition.

Image data reception, processing (geocoding, value-added services), archiving and distribution is provided by CORE Software Technology (CST) of Pasadena, CA through CORE's online global network with the name of 'ImageNet'. Operational capabilities/services include such items as:

- SOP (Satellite Operating Partner). This service provides a dedicated regional satellite with local customer tasking. SOP receiving ground stations are able to plan, to generate and to transmit imaging commands to the satellite.
- PAS (Priority Access Satellite). The service provides priority tasking of EROS S/C on a global scale.

⁵³⁴) Note: OFEQ-1 was launched in September 1988, OFEQ-2 in April 1990; both had a lifetime of 6 months.

- AAD (Acquisition, Archiving and Dissemination). The service is intended for existing, experienced satellite imagery reception, archiving and distribution operations to support worldwide commercial imagery and derivative product sales.

Parameter	Value	Parameter	Value
Data transmission	Real-time downlink	Antenna gain	19 dBi
RF frequency	X-Band, 8200 GHz	Antenna polarization	RHCP
Modulation	QPSK	Ant. pointing accuracy	1.5°
Bit rate	70 Mbit/s	Nr. of channels	1 (+1 redundant)
Error correction code	Convolutional, R=4/5	Transmitted power	1.5 W (31.8 dBm)

Table 109: Performance characteristics of the EROS-A downlink

Orbit for EROS-A1: Circular sun-synchronous orbit, altitude = 480 km, inclination = 97.3°, period = 94.2 minutes, local time of descending node = 10:30 AM. The revisit capability of any point on Earth within a 15° cone is within seven days. A revisit period/satellite of any point at latitudes $> \pm 40^\circ$ is 2-7 days within a 30° cone, and only two days within a 45° cone.

Operational status of EROS-A1 as of June 2001: All subsystems are operating nominally.

Sensor:

PIC (Panchromatic Imaging Camera), built by El-Op Electro-Optics Industries Ltd. of Rehovot, Israel. PIC is a body-mounted instrument, featuring CCD pushbroom technology. PIC uses a Cassegrain telescope with an aperture of 30 cm in diameter and a focal length of 3.5 m. FOV = 1.5°. The CCD detector array provides 7000 pixels per line. The scan speed is 30 - 750 line/s, this corresponds to 18 to 1.3 ms of integration time, respectively. Asynchronous pushbroom scanning is provided for panchromatic imagery in the spectral range of 0.5 - 0.9 μm . The ground sampling distance (GSD) is 1.8 m, the swath width is 12.5 km (from a 480 km orbital altitude). The data is quantized at 12 bits (samples) and transmitted at 11 bits. SNR $< 2/2,048$ gray levels after quantization. Proper observations require sunlight conditions with a sun-over-the-horizon angle of $> 20^\circ$. Instrument mass = 36 kg (includes telemetry unit), power = 140 W (average).

Type of Scene	Scene Size	Max. Nr. of Scenes
Monostrips (30° inclination to ground track)	120 km x 12.5 km	5
Monostrips (43° inclination to ground track)	217 km x 12.5 km	3
Discrete scenes (nadir view along the ground track)	12.5 km x 12.5 km	28
Mosaics	25 km x 25 km	7
Stereo monostrips (nadir)	40 km x 12.5 km	5
Stereo scenes (24° fore and aft pointing)	12.5 km x 12.5 km	10
Stereo scenes (40° fore and aft pointing)	12.5 km x 12.5 km	7

Table 110: Observation options for image scenes of a satellite pass

A body-pointing technique is employed for instrument pointing (the entire S/C is pointed into the desired direction), permitting a field of regard of $\pm 45^\circ$ from nadir into any direction. The physical pointing of the S/C is provided by the four reaction wheels (the pointing acceleration is 0.4° s^{-2} with a maximum angular rate of $2.2^\circ/\text{s}$).

The non-availability of on-board source data storage permits only observations in real-time in view of a GRS (Ground Receiving Station). The following observation options (scenes) are possible within a single 10-minute pass:

B.5.2 EROS-B Spacecraft Series

The EROS-B series S/C structure is identical to that of EROS-A. The additional on-board fuel (up to 60 kg) is sufficient for S/C operations of up to 10 years. This increases the S/C

mass to about 350 kg. The S/C attitude is sensed and controlled as done with EROS-A1. In addition, there is a star sensor for the B satellites. The S/C design life is six years.

Orbit: Sun-synchronous circular orbit, altitude = 600 km, inclination = 97.8°, local time of descending node 10:45 AM.

Sensor:

PIC-2 (Panchromatic Imaging Camera-2). The EROS-B series imager instrument features CCD technology in combination with a TDI (Time Delay and Integration) scheme in its focal plane, a cumulative expose concept of each ground image line by a CCD detector array, to improve the SNR value (an important issue for high-resolution imaging). The instrument uses also a Cassegrain telescope with an aperture of 50 cm in diameter and a focal length of 5 m. FOV = 1.5°. The CCD detector array provides 9,666 pixels per line and a total of 96 lines. The scan speed is 3,050 lines/s (max) using VSU (Video Storage Unit) and 1,525 lines/s without VSU. Asynchronous pushbroom scanning is provided for panchromatic imagery in the spectral range of 0.5 - 0.9 μm . The ground sampling distance (GSD) is 0.82 m, the swath width is 16 km. The data is quantized at 8 bits (samples) and transmitted at 8 bits. SNR < 2/256 gray levels after quantization.

Type of Scene	Scene Size	Max. Scenes at 3,050 lines/s (scan rate)	Max. Scenes at 1,525 lines/s (scan rate)
Monostrips		4 of 305 km x 16 km or 5 of 246 km x 16 km	5 of 130 km x 16 km
Discrete scenes (computed along the ground track)	16 km x 16 km	40	30
Mosaics	32 km x 32 km	12	8
Stereo monostrips	160 km x 16 km	2	N/A
	68 km x 16 km	8	4
Stereo scenes	16 km x 16 km	20	10

Table 111: Observation options for image scenes of a B-satellite pass

Parameter	EROS-A1 and -A2	EROS-B1	EROS-B2 to B6
Orbit	Sun-synchronous, altitude = 480 km circular	Sun-synchronous, altitude = 600 km circular	Sun-synchronous, altitude = 600 km circular
Orbit repeat cycle	1 week	1 week	1 week
Equator crossing times	10:30, 10:30, 13:00, 13:30, and 14:00		
GSD	1.8 m	0.82 m	0.82 m
Swath width	12.5 km	16 km	16 km
Scanning	Asynchronous up to 750 lines/s	Asynchronous up to 3,050 lines/s	Synchronous and asynchronous up to 9000 lines/s
Sensor type	CCD	CCD/TDI, selectable: 1, 4, 8, 16, 32, 48, 96	CCD/TDI, selectable: 1, 4, 8, 16, 32, 48, 96
Spectral band	0.5 - 0.9 μm	0.5 - 0.9 μm	0.5 - 0.9 μm
Data quantization	12 bits (11 bits transmission)	8 bits	11 bits
Pointing accuracy	< 100 m	< 100 m	< 100 m
Pixel to pixel relative accuracy	< 100 m within 12.5 km x 12.5 km scene	< 50 m within a 16 km x 16 km scene	< 50 m within a 16 km x 16 km scene
Multispectral capability	No	No	Yes
Signal processing unit	No	No	Yes, loss-less compression of source data prior to transmission
Downlink data rate	70 Mbit/s	280 Mbit/s	280 Mbit/s
S/C mass	280 kg	<= 350 kg	

Table 112: Performance characteristics of EROS satellites

The imager instrument of the EROS-B series (B2 to B6) satellites can be operated in either asynchronous or in synchronous imaging mode. In synchronous mode, the S/C platform keeps a constant pointing angle toward the Earth's surface. In asynchronous mode, imaging by the detector array is performed in a "step-and-stare" fashion, i.e., by slewing the S/C platform in the along-track direction (this permits also stereo imaging).

The non-availability of on-board source data storage permits only observations in real-time in view of a GRS (Ground Receiving Station). The following observation options (scenes) are possible within a single 12-minute pass:

B.6 IKONOS (Space Imaging Inc., Thornton, CO)

Background: CRSS (Commercial Remote Sensing System) was a remote sensing imaging satellite project of Lockheed Martin that started in 1991.⁵³⁵⁾ In 1994 a new company was formed for this venture, namely Space Imaging Inc. (of Thornton, CO), with the following partners: Lockheed Martin (Sunnyvale, CA: space segment, satellite operations, and tasking of ground segment), Raytheon/E-Systems (Garland TX: communications, image processing and customer service center). Eastman Kodak Co. of Rochester, NY designed and built the digital camera/sensor. The overall objective is to offer commercial high-resolution (1 m GSD panchromatic and 4 m GSD multispectral) imagery with excellent location knowledge in near real-time and offline. In 1997 the CRSS satellite was renamed by Space Imaging to "IKONOS-1," supposedly a variant of the Greek word 'eikon' (icon), meaning "image."⁵³⁶⁾

Figure 59: The IKONOS S/C Model

B.6.1 IKONOS-1

IKONOS-1 is a 3-axis stabilized spacecraft, the attitude is measured by two star trackers and a sun sensor and controlled by four reaction wheels; location knowledge is provided by

⁵³⁵⁾ Information provided by S. Kilston, formerly of Lockheed Martin, Palo Alto, CA

⁵³⁶⁾ Note: Space Imaging acquired EOSAT (a joint venture of Lockheed Martin and Hughes Aircraft) in 1995. The new company was subsequently renamed into: Space Imaging EOSAT. Eventually, the became simply: Space Imaging

GPS; LM900 satellite bus system; design life = 7 years; S/C body size = 1.83 m x 1.57 m (hexagonal configuration); S/C mass = 728 kg; power = 1.5 kW.

Note: A launch of IKONOS-1 on LLV2 from VAFB was initially planned for December 1997. However, there were several launch delays, the last one to replace the laser ring gyro. Finally, IKONOS-1 was launched April 27, 1999 from VAFB aboard an Athena 2 launcher. Unfortunately, the rocket's nose cone failed to separate as planned at 4 minutes, 27 seconds into flight - resulting in a complete loss of the satellite. With the protective shroud still attached, the rocket's upper stage and satellite did not have enough speed to reach a stable orbit around Earth. The vehicle then reentered the atmosphere over the South Pacific Ocean.⁵³⁷⁾

B.6.2 IKONOS-2

IKONOS-2, identical to IKONOS-1 and built in parallel to IKONOS-1, was launched successfully on Sept. 24, 1999 from VAFB aboard an Athena 2 launcher of Lockheed Martin.

Orbit: Sun-synchronous near-polar circular orbit, altitude = 681 - 709 km, inclination = 98.1°, period = 98 min, repeat cycle = 14 days (max), revisit cycle = 1-3 days. Local equator crossing time is at 10:30 AM on descending node.

Sensor complement:

OSA (Optical Sensor Assembly), designed and custom-built by Kodak Co. of Rochester, NY (Space Imaging owns the design of OSA). The instrument features a Cassegrain-type telescope with a 70 cm diameter primary mirror, a 10 m focal length (folded optics design). OTA (Optical Telescope Assembly) captures imagery across a swath of 11-13 km, it uses five mirrors to reflect the imagery to the imaging sensor arrays at the back end of the telescope. Three of the mirrors are powered (curved), and are of TMA (Three Mirror Anastigmatic) design. Note: TMA refers to lenses that are able to form approximately point images of target (object) points. The other two mirrors are flat, and serve to 'fold' or bounce the imagery across the width of the telescope. Pushbroom detector technology (a large focal plane detector array, generation of 6500 lines/s of panchromatic image data) is employed. Simultaneous imaging in panchromatic and multispectral modes is provided. The pixel size on the detector array is 12 µm for the panchromatic (PAN), and 48 µm for the multispectral (MS) detectors. The MS bands correspond to those of TM on Landsat in the visible range of the spectrum. The instrument light level is governed by a 70 cm aperture and a choice of 10, 13, 18, 24, or 32 TDI (Time Delay and Integration) stages for panchromatic (gray-scale) imaging. The detector array offers a cumulative exposure concept for panchromatic imaging. On-board electronics provide low-loss data compression of the original 11-bit data using ADPCM (Adaptive Differential Pulse Code Modulation). - The OSA instrument design features lightweight materials and advanced manufacturing techniques. The mass of the primary mirror was reduced by cutting a honeycomb pattern into its core using abrasive waterjet technology, and fusing thin mirror plates to each face.

Optical telescope assembly	Assembly size: 1.524 m x 0.787 m (1 m ³ volume) Assembly mass without the focal plane unit: 109 kg Focal length / focal ratio: 10 m / f14.3 Primary mirror aperture diameter: 0.7 m
Imaging detectors & electronics	Focal plane unit, unit size: 25 cm x 23 cm x 23 cm Detector array: 13,500 pixels cross-track (PAN) Detector array: 3375 pixels cross-track (MS), pixel size: 48 x 48 µm
Digital processing unit	Unit size: 46 cm x 19 cm x 31 cm ADPCM data compression, compression rate of 4:25 : 1
Power supply unit	Unit size: 18 cm x 20 cm x 41 cm
Total instrument mass, power	171 kg, 350 W

Table 113: OSA instrument layout

A body-pointing technique with antenna gimbals and reaction wheels is employed for instrument pointing (the entire S/C is pointed into the desired direction), permitting a field of regard of $\pm 30^\circ$ into any direction. The angular slew rate is sufficient to perform both wide-area monoscopic and same-pass stereo collections. The location knowledge accuracy of the imagery is 2 m horizontal (relative) i.e. with ground control points, and 12 m (absolute), i.e. without the use of ground control points. Smooth scanning is provided with accurate gyros, low disturbance torques (smooth antenna gimbals and reaction wheels), and a rigid high-frequency structure of the satellite. Radiometric calibration provides relative and absolute corrections for detector channel responsivity differences.

The S/C may also be rotated about its imaging axis for proper (broadside) detector array orientation. This technique permits, for instance, the full-swath imaging of a particular feature of interest on the Earth's surface, such as a coastline, which traverses under some angle through the in-track direction.

Parameter	Value	Parameter	Value
Spectral range PAN	0.45 - 0.90 μm	Off-nadir pointing angle	$\pm 30^\circ$ in any direction
Spectral range MS (μm)	0.45-0.52, 0.52-0.60, 0.63-0.69, 0.76-0.90	Stereo capability	along-track
Spatial resolution	≤ 1 m PAN, ≤ 4 m MS	Swath width, scene	13 km, 13 km x 100 km
Pixel quantization	11 bit	Field of regard (FOR)	± 350 km at 1 m GSD

Table 114: Some performance parameters of the OSA instrument

Data: The downlink of all imaging data is in X-band at a rate of 320 Mbit/s to dedicated ground stations located around the world (on-board data recording capacity is 64 Gbit in solid-state memory). The TT&C function is provided in S-band (uplink of tasking and command data at 2 kbit/s, downlink of housekeeping data and metadata at 32 kbit/s).

Ground image data processing provides geocoding along with image compensation algorithms [misregistration, image motion, radiometric correction, MTF (modulation transfer function) compensation, etc.]. Space Imaging Inc. introduced a global archive (of digital imagery and services) under the trade name CARTERRA, which in turn is made up of regional archives, operated by regional partners. A great variety of image products and services are provided. Standard products are:

- Radiometrically corrected images
- Geometrically corrected images
- Orthorectified images and mosaics
- Digital terrain model (DTM) data
- Multispectral images

B.6.3 Kodak Model 1000 Camera System

As of July 1999, Kodak/C&GS (Commercial & Government Systems) is offering a “Model 1000™ camera system” of OSA camera heritage as an off-the-shelf product - at a 30% discount, deliverable within 24 months of order placement. This Model 1000 system design is owned by Kodak, containing some design changes with respect to OSA (reduced telescope aperture and instrument mass to fit onto minisatellites).^{538) 539) 540)}

The Model 1000 camera system consists of the following elements: OTU (Optical Telescope Unit), FPU (Focal Plane Unit), DPU (Digital Processing Unit), PSU (Power Supply Unit), and CU (Cabling Unit). The total mass of the system is <100 kg.

538) Information provided by Michael J. Richardson of Eastman Kodak Company, Rochester, NY
539) “Kodak Introduces 1-Meter-Resolution Remote Sensing Camera In An Off-The-Shelf, Fixed Price Configuration,” Kodak press release of July 19, 1999
540) T. Delaney, “Satellite Imagery in Land Development Applications,” EOM, Oct. 1999, pp. 47-48

- The OTU is an all-reflective three mirror anastigmatic design with two flat fold mirrors to decrease package volume. The optical components are made from high quality, low thermal expansion glass substrates. The metering and mounting structures are made from low thermal expansion materials to match the expansion properties of the glass components. OTU has a mass of 45 kg, the power consumption is 15 W.
- The FPU includes the PAN and MS detectors and A/D converters. Timing and command signals are received from the DPU, power is received from the PSU. The mass of FPU is 16 kg, power = 85 W.
- The DPU generates the timing for the sensor electronics via a master clock. DPU accepts S/C commands over a standard 1553 bus and routes the information to the FPU and PSU. The DPU compresses the 11 bit digitized image data to about 2.5 bits/pixel using the Kodak proprietary algorithms of ADPCM (Advanced Differential Pulse Code Modulation). The DPU can format data for interface with an on-board storage unit and data downlink. DPU mass = 14 kg, power = 130 W.
- The PSU filters, regulates and generates the unregulated S/C power to the DPU and PSU. Mass = 8 kg, power 75 W. There is full redundancy.
- The CU provides the cabling between the various electronic boxes. Mass = 5kg, power = 10W.

B.7 Infoterra/TerraSAR (Astrium, ESA)

As of June 2001, Infoterra/TerraSAR ⁵⁴¹) is a proposed cooperative Public-Private Partnership (PPP) program between TEC (TerraSAR Exploitation Company) and ESA (approval of the program is expected by the Council of Ministers in Nov. 2001). The Infoterra/TerraSAR initiative seeks to exploit the growing market for geo-information products and services through the establishment of a new global geo-information company, the TEC part of which is Infoterra (an Astrium company), founded on European partnerships. The TEC business concept is to service this market on a sustainable commercial basis primarily through the exploitation of Earth Observation (EO) information and to establish a viable share of the market through the introduction of new information products and services, optimized to satisfy the commercial and strategic needs of both private - and public - user communities. Many of these new products and services will be based on the exploitation of a spaceborne radar system, TerraSAR; a source of high-quality, reliable and secure data, superior to currently available data and specifically aimed to meet market needs.

TerraSAR is a space and ground system, which will consist of an initial deployment of two satellites (one X-band and one L-band). In the Infoterra business concept, TerraSAR is the key element to capturing a significant proportion of the existing market and, more importantly, to open new market opportunities from 2006 onwards when it becomes operational. To achieve operational advantage, Infoterra will employ TerraSAR whenever possible to provide data of the required quality. Infoterra will initially use current data sources to generate pilot products to provide early access to the market; these will be superseded by operational products as data from TerraSAR become available.

The Infoterra business concept and the technical concept of TerraSAR have evolved through feasibility and definition studies (initiated in 1997 and conducted in 1999/2000) led

⁵⁴¹) Infoterra is the generic name for different legal entities. As of early 2001 two companies have been founded: Infoterra GmbH, a subsidiary of Astrium GmbH, and Infoterra Ltd., a subsidiary of Astrium Ltd. Additional companies in other countries may be founded in the future. It is planned to combine all national Infoterra companies under an umbrella of an Infoterra Holding Company. Infoterra will be a shareholder within TEC.

by German and UK industry, namely Astrium, [the former industrial partners DSS (Dornier Satellitensysteme) and MMS (Matra Marconi Space, UK) together with NRSC (National Remote Sensing Center), are now all part of Astrium], and supported by government and expertise on the institutional side (DLR/BNSC).

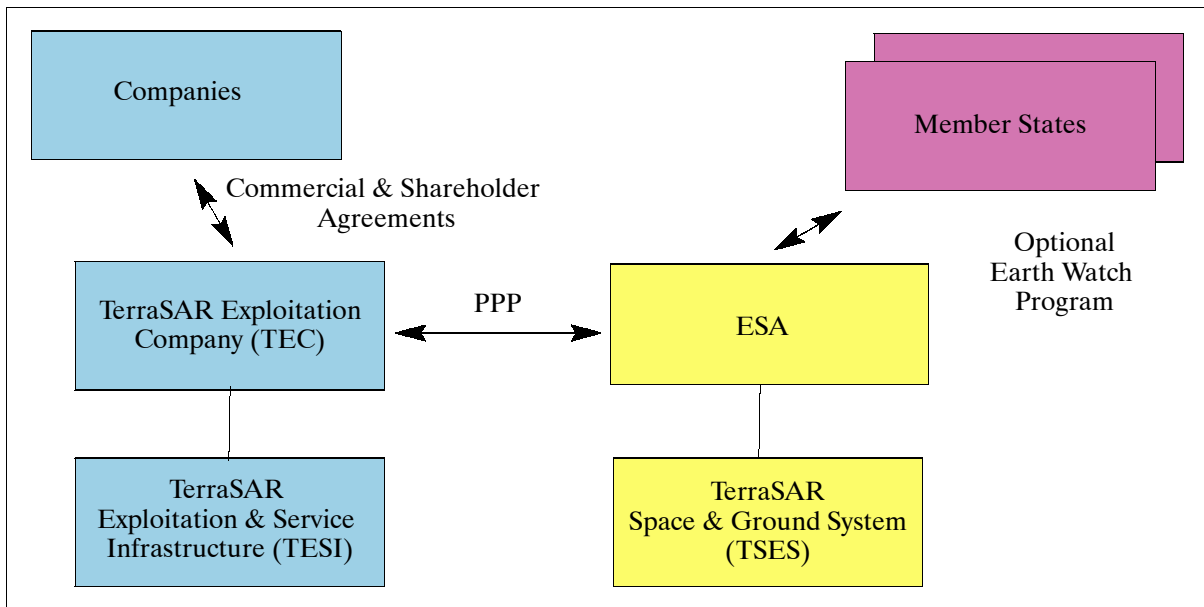

Figure 61: Overview of ESA - TEC partnership

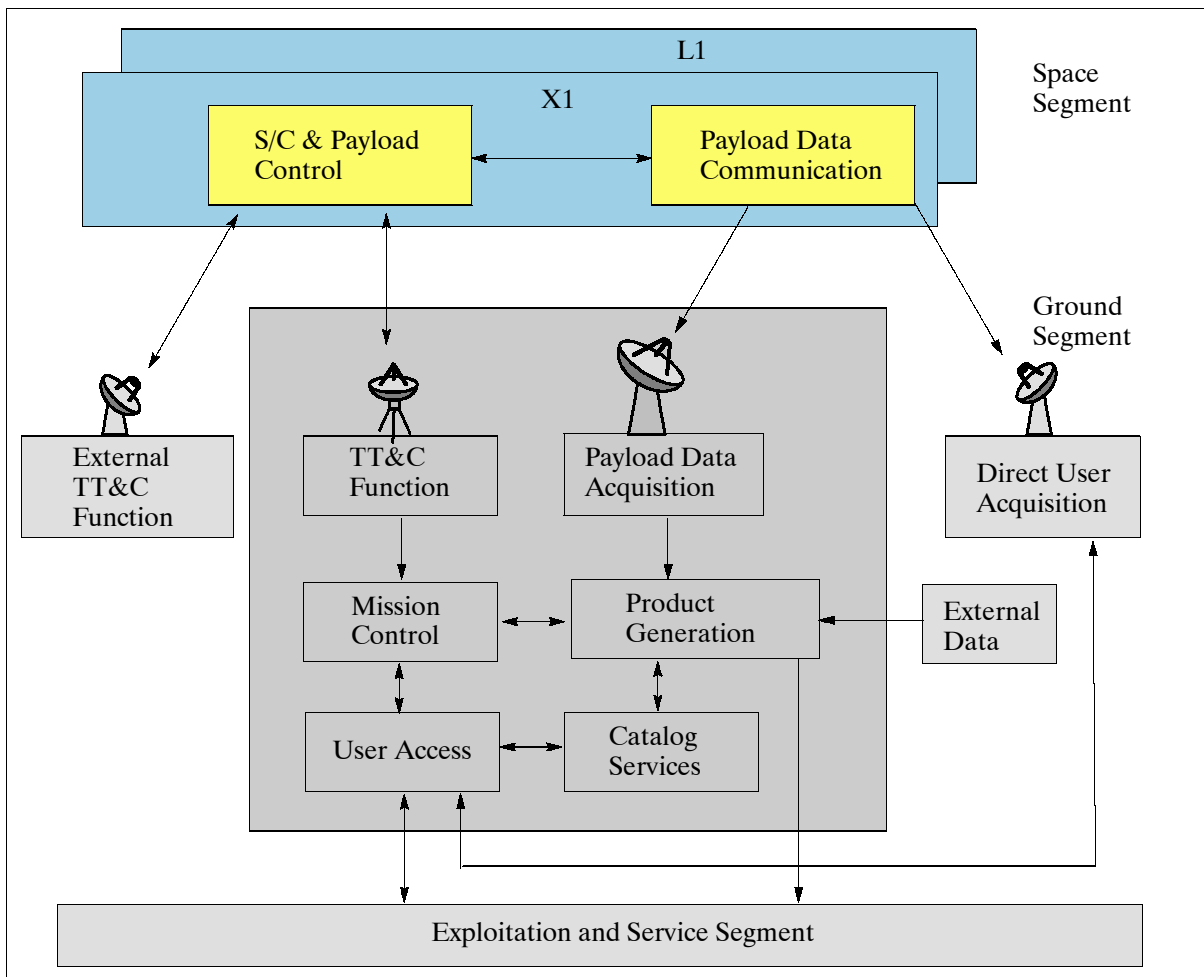

Figure 62: The system functional architecture of TerraSAR

The Infoterra/TerraSAR initiative is planned to become an integral part of the ESA Earth Watch Program. The TEC company started trading in January 2001. In the overall setup, Infoterra is the global service provider/distributor to the private and public customer base of geo-information services and SAR data products. These products may be applied to such fields as: agriculture, forestry, geology, cartography, and risk management.

The TerraSAR system has specifically been designed for land monitoring based on a dual frequency (L-band and X-band) SAR data source with multiple polarization capabilities. The X-band element will feature resolutions in the 1 m class for land mapping while the L-band, with its unique strengths for land monitoring, will enable discrimination of land cover types due to its penetrative ability, and with polarimetry enhancing both land cover classification and soil moisture retrieval.

The sensor system capabilities include stereo in X-band and repeat pass interferometry in L-band. Simultaneous dual frequency operation in combination with image sharpening will provide high resolution high quality thematic images. ^{542) 543) 544)}

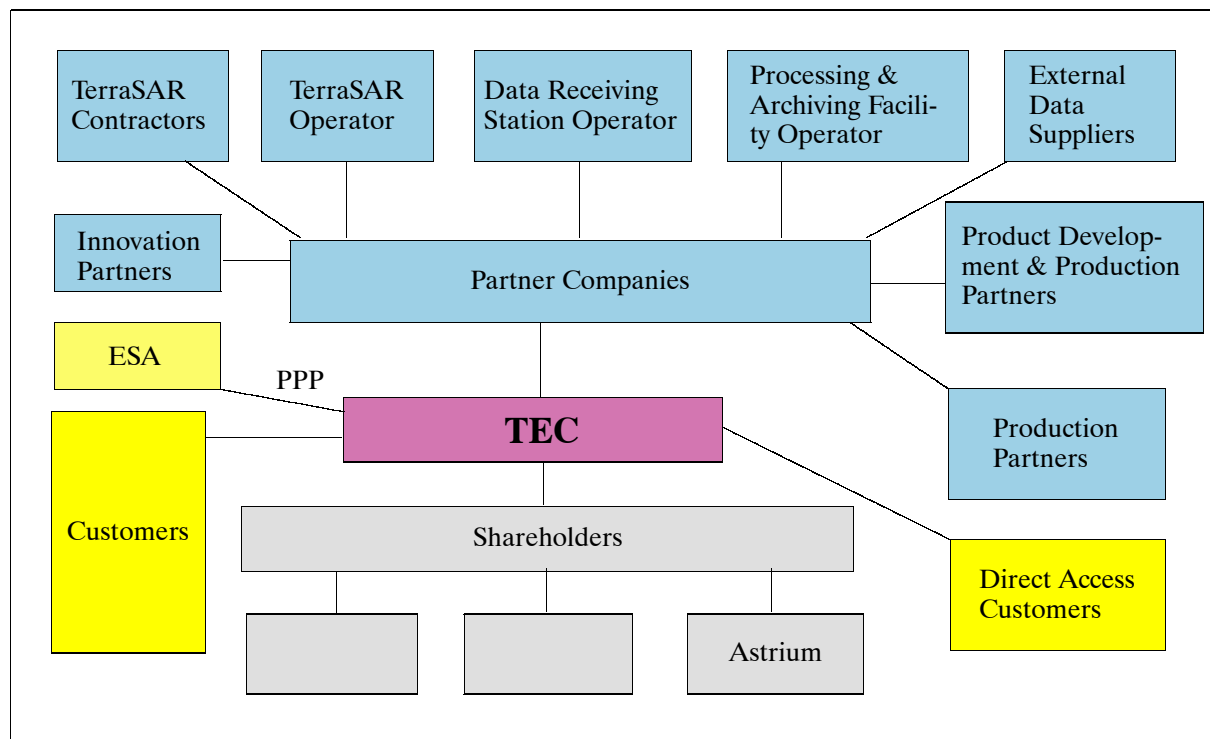

Figure 63: Infoterra & TerraSAR partnerships and opportunities

Based on the Infoterra business concept and the TerraSAR system definition, the fundamental objective of the Infoterra/TerraSAR initiative is to establish a self-sustaining geo-information business built on European strengths in SAR satellite technology, in SAR applications expertise and in the provision of services based on Earth observation data sources. The overall TerraSAR program represents a logical long-term continuation of European commitment comprising the development, launch and operations of SAR missions, as well as the needed infrastructure for the provision of a wide range of services. The first pair of satellites, TerraSAR-X1 and TerraSAR-L1, are planned to be launched in 2006, each with an operational life of five years (follow-up missions, i.e. TerraSAR-X2 and TerraSAR-L2, are planned beyond 2010). Both satellites will be launched into sun-synchronous dusk-dawn orbits with the same ground track and a spacing of 12 minutes, establishing a

so-called tandem mission. The nodal crossing time of X1 and L1 are shifted by ± 6.25 minutes to achieve the desired separation.

B.7.1 TerraSAR-X1 (X-band Satellite)

The TerraSAR X-band satellite (X1 is led by Astrium GmbH, Friedrichshafen, Germany) employs a mission-tailored Flexbus design with a total wet mass of approximately 1300 kg. The S/C structure features a central cylinder as the main load carrying element; it is of CFRP material with a diameter of 0.94 cm. The cross-sectional view of Figure 65 illustrates the mounting concept of radiator, solar array, and SAR antenna elements.⁵⁴⁵⁾ The outer shape of the spacecraft is mainly driven by the accommodation of the X-band SAR instrument and the geometrical limitations of the launcher fairing (PSLV of ISRO). The body-mounted solar array delivers an orbit average power of 875 W (EOL). The solar array is of size 7 m², the cells are of GaAs type with a size of 41 mm x 42 mm. The attitude control system is based on reaction wheels for fine-pointing, with magnetorquers for desaturation, and a propulsion system also capable of attitude control in order to achieve rapid rate damping during initial acquisition. Attitude measurement is performed with a GPS/Star Tracker system during nominal operation and a CESS (Coarse Earth and Sun Sensor) in safe mode situations, initial acquisition respectively (CESS is of CHAMP and GRACE heritage). A laser gyro and a magnetometer serve to support rate measurements in all mission phases. In fine pointing mode, a pointing accuracy of 30 arcsec is achieved. The S/C design life is 5 years of operation with a goal of 6.5 years (de-orbiting is planned at the end of the useful life time.). A launch of TerraSAR-1 is planned for 2006 - very probably on a PSLV launch vehicle from SHAR, India.

Orbit: Sun-synchronous circular dawn-dusk orbit (local time ascending node at 18:00 hours), altitude = 629 km, inclination = 98°, revisit period of 18 days with 3-4 days of sub-repeats. Global coverage within the latitudes $\pm 80^\circ$. - Spacecraft reentry (ESA requirement): At the end of its mission life the spacecraft orbit will be lowered to about 300 km (perigee) resulting eventually in enough air drag for a reentry (and a complete disintegration of the S/C in the atmosphere).

Figure 64: Illustration of the TerraSAR-X1 spacecraft

⁵⁴⁵⁾ Information provided by Sebastian Riegger of Astrium GmbH, Friedrichshafen

Figure 65: Cross-sectional view of the TerraSAR-X1 spacecraft

RF communications: A standard S-band TT&C System with 360° coverage in uplink and downlink (assuming switching) is used for satellite command reception and telemetry transmission. Generated payload (SAR) data are stored on-board in a Mass Memory Unit of 576 Gbit capacity prior to transmission via an X-band downlink at a data rate of 300 Mbit/s. The X-band downlink is encrypted. The on-board SAR raw data are compressed using the BAQ (Block Adaptive Quantization) algorithm, a standard SAR procedure. The compression factor is 2 (more efficient techniques can only be applied to processed SAR imagery). Both communication links are designed according to the ESA CCSDS Packet Telemetry Standard.

The Svalbard X/S-band station is considered the prime TT&C and payload acquisition station in the ground segment.

Sensor complement:

XSAR (X-band SAR instrument). XSAR is an active phased array X-band system providing high-resolution and multipolarization SAR imagery (H and V). The body-fixed SAR antenna has dimensions of 6.5 m (length) x 0.85 m (width) and 0.30 m in depth. The mass of XSAR is about 490 kg (370 kg of antenna mass and about 120 kg for instrument electronics accommodated within the service module). The antenna features 512 T/R (Transmit and Receive) modules each capable of operation in two polarizations. Beam steering is provided in azimuth ($\pm 0.6^\circ$) and elevation ($\pm 22^\circ$). The inherent flexibility due to amplitude and phase settings in the transmit/receive modules allows individual beam pattern pointing and shaping. This flexibility is mainly used in the elevation direction (cross-track) over the total range of incidence angles. A variable FOR (Field of Regard) is provided depending on support mode.

Legend to Table 116: NESZ= Noise Equivalent Sigma Nought. NESZ is that value of sigma nought of a uniform scene that produces a processor output signal to noise of unity. The value XXX is a swath length selectable up to 1600 km. The “access range” is the cross-track accessible (viewable) range on the ground provided by electronic beam steering. The instantaneous range of XSAR is e.g. only 40 km in stripmap mode and 100 km for ScanSAR mode.

Parameter/ Support Mode	Spotlight Mode 1	Spotlight Mode 2	StripMap Mode	ScanSAR Mode
Spatial resolution - Cross-track - Along-track	1.2 m (slant range) 1 m	1.2 m (slant range) 2 m	<3 m 3.2 m	15 m 15 m

XSAR (X-band SAR instrument)	Antenna: active phased array
	X-band center frequency of 9.6 GHz (3.1 cm), chirp bandwidth: 150 MHz
	Polarization: HH/VV/HV/VH (selectable or twin)
	Beam steering in azimuth ($\pm 0.6^\circ$) and elevation ($\pm 22^\circ$)
	512 T/R modules; PRF= 2.4 - 5.0 kHz
	Antenna dimensions: 650 cm x 85 cm x 30 cm (L x W x H)
	Body-fixed antenna: 370 kg antenna mass, 120 kg electronics
	Nominal radar duty cycle: 13% (20% max)
	Data quantization: 8 bit I, 8 bit Q
	Instrument power: 3.650 kW (for imaging)

TerraSAR-X1 spacecraft (Flexbus)	S/C wet mass: 1285 kg (bus=713 kg, payload=490 kg, propellant of 85 kg)
	S/C dimensions: 2.5 m (H) x 6.5 m (L) x 2.6 m (W)
	S/C 875 W of orbit average power (EOL); peak power=1.6 kW; energy storage of 40 Ah capacity (26 NiH cells)
	Power distribution: 55-83 V unregulated bus; converter to 28 V and converter to 115 V 30 kHz AC for XSAR front end
	S/C pointing control: 30 arcsec
	Communication: X-band of 300 Mbit/s payload data downlink with QPSK; S-band uplink of 4 kbit/s (2025-2110 MHz), BPSK modulation; S-band downlink of 32 kbit/s to 1 Mbit/s (2200-2400 MHz), BPSK modulation

Table 117: Overview of X1 spacecraft and instrument characteristics

B.7.2 TerraSAR-L1 (L-band Satellite)

The TerraSAR L-band satellite (L1 is led by Astrium Ltd. of Portsmouth, UK) uses a deployable Snapdragon platform design with a total wet mass of about 2600 kg. The L-band SAR antenna is large, at 11m x 2.5 m and presents formidable launcher accommodation problems if configured as a conventional deployable array. The Snapdragon platform of Astrium Ltd. elegantly avoids this problem by arranging the SAR array in two parts across the launcher fairing diameter, providing the deployment and deployed structure functions within the platform itself. In this way, a medium (Delta-2) class launcher can be selected, largely on a mass basis, rather than a large (Ariane V) class launcher on a stowed volume basis. Figure 68 illustrates the key deployment feature of the Snapdragon spacecraft, which is covered by European and US patents. ⁵⁴⁶⁾

S/C power is provided by solar arrays (GaAs) on each Snapdragon half totaling 1720 W (EOL). The arrays are fixed but could be made deployable (steerable array not required due to the dawn/dusk orbit) for an optimum solar radiation aspect. The S/C voltage is 33 V, the instrument operates at 50 V. Lithium Ion batteries are used: 42 Ah/33 V for the subsystems of the platform; 29 Ah/50 V for the leading side of the hingeline; and 21 Ah/50V on the trailing half. The S/C is three-axis stabilized. The attitude control system is based on a four-axis set of momentum wheels for fine-pointing, with magneto-torquers for desaturation. A propulsion system is only used for orbit control and end-of-life de-orbiting. Attitude and position measurement is performed with a star tracker system coupled with a solid-state inertial reference unit, a three axis magnetometer and GPS. A pointing accuracy of <1 arc-min is predicted, which is sufficient to achieve the L-SAR objectives. The S/C design life is 5 years of operation with a goal of 6.5 years (de-orbiting is planned at end of the useful life).

A launch of TerraSAR-L1 is planned for 2006. A Soyuz-Fregat ST, launched from the Baikonur Cosmodrome, is the current baseline launch vehicle.

Figure 67: Illustration of the TerraSAR-L1 S/C (shown without thermal blankets)

⁵⁴⁶⁾ Information provided by David M. Simpson of Astrium Ltd.

Figure 68: Separation deployment sequence of a Snapdragon spacecraft

Orbit: Sun-synchronous circular dawn-dusk orbit (local time ascending node at 18:00 hours), altitude = 629 km, inclination = 98° ; orbital period of about 97 minutes; revisit period of 18 days with 3-4 days of sub-repeats. Global coverage within the latitudes $\pm 80^\circ$. The TerraSAR-L1 spacecraft follows the same orbital track as the X1 spacecraft, which means that the two are displaced in crossing time by about 6.25 minutes. Otherwise the orbital parameters are identical.

At EOL, S/C reentry is initiated with thruster firings (using budgeted fuel) to obtain an elliptical orbit with a perigee of about 300 km or lower. This generates sufficient atmospheric drag to bring the S/C eventually into a reentry trajectory.

RF communication: A standard TT&C S-band system is used for spacecraft and payload services. Instrument data are stored on-board in a 384 Gbit (beginning of life) capacity recorder and downlinked in X-band at a rate of 300 Mbit/s with encryption via a uniform illumination hemispherical pattern antenna.

Sensor complement:

LSAR (L-band SAR instrument), designed and developed by Astrium Ltd., Portsmouth, UK. LSAR is an active phased array L-band system providing fine resolution and fully polarimetric imagery. The antenna is of size: 11 m x 2.5 m or 27.5 m². It is segmented into two rows and ten columns of tiles, where tiles are interchangeable units (of ASAR architecture heritage on Envisat). Each tile carries seven T/R modules, each of which feeds its own radiating sub-array of six elements. Discrete units on each tile service the T/R modules, providing power, control, and temperature compensation processing. Antenna beam steering in elevation (cross-track) is achieved with the use of 14 rows of T/R modules (each row has 10 T/R modules) with independent phase control. The instrument calibration scheme is implemented entirely within the T/R modules. Single, dual, and quad polarization is achieved.

Center frequency	1.2575 GHz (L-band) corresponding to a wavelength of 24 cm
Nr of sub-arrays	140 arranged as 20 panels with 7 sub-arrays per panel
Polarization	Horizontal (H) and Vertical (V) independently selectable for transmit, simultaneous on receive
Chirp bandwidth	55 MHz
Receive channel bandwidth (Rx)	27.5 MHz, 55 MHz selectable for adaptation to incidence angle
T/R module output power	46 dBm
Quantization of radar signal	8 bit for I and Q
SAR data compression	Online BAQ (Block Adaptive Quantization), 8:4, 8:3, 8:2 and 8:1 selectable
Data storage capacity	384 Gbit
Output data rate to X-band	300 Mbit/s encrypted and formatted (CCSDS) data, simultaneous to data input at max. rate

Table 118: Summary of LSAR instrument parameters

Parameter/ Support Mode	Quad StripMap	Dual StripMap	Low resolution L (Dual ScanSAR 200 km)	Low resolution XL (Dual ScanSAR 100 km)
Polarization	Alternating H&V on Tx; Co&cross pol on Rx	Single pol. on Tx; Co&cross pol on Rx	Single pol. on Tx; Co&cross pol on Rx	Single pol. on Rx Co&cross pol on Rx
Range resolution	9 m	9 m	30 m	30 m
Swath width	40 km	60 km	200 km	100 km
Sensitivity	-30 dB	-30 dB	-28 dB	-28 dB
DTAR	-17 dB	-17 dB	-17 dB	-17 dB
Field of Re- gard (FOR)	20° - 32°	20° - 45°	23° - 45°	20° - 45°

Table 119: Summary of instrument performance by support mode

Legend to Table 119:

- DTAR: Distributed Target Ambiguity Ratio (a combination of azimuth & range ambiguities)
- Dual StripMap: In conventional SAR operation the “transmit” pulse occurs on one polarization (e.g. H) while the “receive” echo signal is measured in both polarizations, H and V.
- Quad StripMap: The transmit pulses are alternatively H and V polarized. The receive function is in both polarizations, H and V simultaneously, thus providing polarimetric measurements (HH, HV, VV, VH), permitting the removal of the atmospheric Faraday rotation effect as well as enhanced land-use classification capabilities.
- Low resolution L: This mode provides a wide swath (L-band data only)
- Low resolution XL: This support mode offers almost co-temporal measurements (about 6 minutes apart) of the same location (target) by the L-band and X-band SAR satellite tandem. Individual swath widths are constrained by the narrowest of the two instruments, which is the XSAR; hence, a narrower total swath width is resulting (when both instruments are operating using same swaths/bandwidths etc..). Almost co-temporal data at two frequencies far apart in spectrum enables unique applications.

The LSAR subsystem ICE (Instrument Central Electronics) uses the existing “core radar” architecture (Note: core radar is the name of an Astrium product. The name comes from the idea that the same “core architecture” can be applied to various radar missions, not necessarily to SAR or to space for that matter.) as developed for Radarsat-2 and modified to L-band with the extended front-end subsystem control. A single transmit channel (without chirp switching) is employed with two receive channels. The core architecture uses a CAN (Controller Area Network) bus supplemented with timing strobes and SSB (Setting Selector Bus), allowing a relatively low-speed instrument control and monitoring bus when com-

bined with ASICs to the T/R modules. A MIL-STD-1553B bus interface is used from LSAR to the platform.

The LSAR instrument has a mass of 925 kg and a max. operating power consumption of 3.517 kW. This high power demand results in LSAR operation limitations to about 9.5 minutes (max)/orbit (in an period of about 97 minutes), or a maximum duty cycle of about 10%.

B.8 OrbView Satellite Series of ORBIMAGE

OrbView® is the name of an imaging satellite series of Orbital Image Corporation (ORBIMAGE) of Dulles, VA, an affiliate of Orbital Sciences Corporation (OSC). The objective of this commercial satellite series is to acquire affordable high-quality imagery of the Earth for a variety of customers that include local governments, telecommunication companies, architects, civil engineers, real estate managers, farmers and environmental monitoring agencies.

ORBIMAGE renamed its satellites in 1997, affecting S/C in development and in operational service. A renaming list is provided to avoid confusion depending on what references are cited of the available literature.

New S/C Name of ORBIMAGE as of 1997	Launch Date of S/C	Remarks/Sensors	Old S/C Name (given in literature)
OrbView-1	April 1, 1995	GPS/MET, OTD	Microlab-1
OrbView-2	August 1, 1997	SeaWiFS	SeaStar
OrbView-3	2002	commercial imaging PAN + MS	Not applicable
OrbView-4	Sept. 2001	commercial imaging PAN+MS+HS	OrbView-3

Figure 69: ORBIMAGE change of S/C naming

B.8.1 OrbView-1

OrbView-1 is an imaging satellite managed and operated by Orbital Imaging Corporation (ORBIMAGE) of Dulles, VA. ORBIMAGE and is a commercial provider of Earth imagery acquired from a family of imaging satellites that it owns and operates. The OrbView-1 satellite includes two sensor systems, OTD (Optical Transient Detector) a lightning imaging system, and GPS/MET (GPS/Meteorology), an atmospheric measurement system.

OrbView-1 was built and launched on April 3, 1995 by OSC. The mission design life is two years with a goal of four years. The primary payload of the OrbView-1 spacecraft is the OTD (Optical Transient Detector), a lightning instrument package provided by NASA/MSFC. The secondary payload on OrbView-1 is GPS/MET (GPS/Meteorology), an instrument provided by UCAR (University Consortium for Atmospheric Research, with collaboration by JPL, Stanford University, and U. of Arizona) which uses GPS signals to measure Earth atmospheric properties. Science data processing of OTD and GPS/MET is done at MSFC and UCAR, respectively. OrbView-1 mass = 69 kg, power = 42 W average, data rate = 2 Mbit/s (one OSC tracking station support). The S/C shape in orbit resembles a butterfly (a cylinder of 1 m diameter and 37 cm in height, whose covers open like the wings of a bird; the gravity gradient boom points toward the Earth's center).^{547) 548)}

Orbit: circular orbit, altitude = 785 km, inclination = 70°. The attitude control system is an active magnetic gravity-gradient system for nadir pointing within $\pm 5^\circ$ (1σ). The nominal pointing accuracy of OrbView-1 pointing knowledge is $\pm 2^\circ$ (1σ), depending on the model-

547) Information provided by Mark Pastrone of ORBIMAGE

548) Information provided by G. Moody and D. Finn of OSC, and by W. J. Koshak of NASA/MSFC

ing accuracy of the Earth's magnetic field. The short-term pointing stability is $0.10^\circ/\text{s}$. Yaw steering is used to maximize sun exposure of solar arrays.

Figure 70: The OrbView-1 S/C model

Operational status as of June 2001: OrbView-1 continues to operate nominally after six years in orbit. The satellite has far surpassed its original design life of three years.

Sensor complement:

OTD = Optical Transient Detector (NASA/MSFC instrument).⁵⁴⁹⁾ Objectives: observation of the global distribution of lightning, leading to the formation of a climatic database of the spatial and temporal distribution of thunderstorms and lightning. The goal is to better understand thunderstorm activity on a global scale. OTD is a staring imager for the detection of lightning over a large region of the Earth's surface with storm scale resolution; it marks the time of occurrence and location of the lightning and measures its radiant energy. Both intracloud and cloud-to-ground discharges can be detected during daytime and nighttime conditions. OTD images a scene much like a television camera; however, daytime detection of highly transient lightning sources against a bright cloud-top background makes actual data handling and processing much more involved than that required by a simple imager. The OTD instrument is actually the LIS engineering model of TRMM.

OTD is composed of six major subsystems: an imaging system, a focal plane assembly (including a CCD array detector, preamplifiers, and multiplexers), a Real-Time Event Processor (RTEP) and background remover, an event processor and formatter, power supply, and interface electronics. The imaging system is a simple telescope consisting of a beam expander, an interference filter, and reimaging optics. The filter is narrow band (8.4\AA) and is cen-

⁵⁴⁹⁾ <http://thunder.nsstc.nasa.gov/otd/>

tered about a prominent neutral oxygen emission triplet in the lightning spectrum to optimize SNR in the presence of a bright solar-lit cloud top.

OTD parameters: view direction: nadir; FOV = $80^\circ \times 80^\circ$; spatial resolution = 10 km; temporal resolution = 2 ms; wavelength = 777.4 nm; sensor mass = 2 kg; power = 3 W.

GPS/MET = GPS Meteorology (proof-of-concept system). Objective: global remote sensing of the atmosphere using the radio occultation measurement method. GPS/MET is a modified commercial high-precision GPS receiver (TurboRogue of Allen Osborne Associates, Westlake Village, CA) with the capability of simultaneously receiving GPS signals on L1 and L2 frequencies by tracking up to eight GPS satellites. The receiver can track both C/A and P codes and also implements a codeless carrier recovery technique. The accurate measurement in the change of carrier phase permits to determine the atmospheric refractive index as a function of altitude. Pressure and temperature profiles can then be derived using the gas law. All observables are sampled 50 times per second. A single low-gain antenna (a standard 'patch' on a ground plane) points roughly in the anti-velocity direction.^{550) 551) 552) 553)}

Figure 71: Observational geometries of the GPS/MET occultation measurements

High resolution atmospheric soundings can be retrieved when the radio path between the LEO GPS receiver and one GPS satellite traverses the Earth's atmosphere. When the path of the GPS signal begins to transect the mesopause at about 85 km altitude, it is sufficiently retarded so that a detectable delay in the order of 1 mm in the dual frequency carrier phase observations is obtained by the LEO GPS receiver. As the signal path descends through successively denser layers of the atmosphere, the delay increases to approximately 1 km at the Earth's surface. Thus the atmosphere creates a unique signal with over six orders of magnitude in dynamic range. A single LEO GPS receiver can observe about 200 such occultations per day. The key observables are atmospheric temperature and moisture distributions. GPS/MET measurement resolutions:

- Precision of phase measurements: order of 1 mm
- Velocity accuracy: 10^{-4} m/s
- Position accuracy: 1 m (vertical: < 1 km; horizontal: < 200 km)

GPS/MET temperature retrieval accuracies of better than 1K have been demonstrated in the altitude range of 10-30 km during the proof-of-concept phase of the mission with vertical resolution of better than 1 km.

B.8.2 OrbView-2 (renamed from SeaStar in 1997)

OrbView-2 is an imaging satellite managed and operated by Orbital Imaging Corporation (ORBIMAGE) of Dulles, VA. The OrbView-2 satellite includes the SeaWiFS imaging system, an 8-channel multispectral imaging instrument with a one kilometer spatial resolution.

Figure 72: The OrbView-2 S/C model

The S/C design is based on PegaStar, a multi-purpose bus of OSC. The platform combines functions common to both satellites and launch vehicles, including guidance and control, power, communications, and data systems. The S/C is three-axis stabilized (0.5° with 0.08° knowledge) using three orthogonal magnetic torque rods for roll and yaw control and two momentum wheels for pitch stabilization. Attitude is sensed with three 2-axis sun sensors, two scanning horizon sensors, and two 2-axis magnetometers. Redundant GPS receivers are used for orbit determination. The propulsion system consists of two subsystems, a reaction control system and a hydrazine propulsion system. Nominal design life = 5 years. S/C mass = 390 kg. A hydrazine propulsion system using four thrusters is used for orbit raising and orbit maintenance. Four deployed solar panels with zenith-facing cells and two body-mounted side-facing solar panels produce 165 W orbit-average power after 5 years. ^{554) 555)}

The OrbView-2 S/C was air-launched on August 1, 1997 by a Pegasus XL rocket (also of OSC) from Vandenberg AFB, CA. The OrbView-2 satellite operations as well as the commercial data processing and distribution functions are performed at ORBIMAGE. The

⁵⁵⁷⁾ <http://seawifs.gsfc.nasa.gov/SEAWIFS/SEASTAR/SPACECRAFT.html>

processing and distribution of data for research applications is handled by the SeaWiFS Project at NASA/GSFC.

Application: Ocean-color data, ocean biology and ecology, phytoplankton concentrations and growth, pollution, algae blooms, etc. The data may help scientists to understand the role of ocean plant life in the Earth's carbon cycle.

Orbit: Sun-synchronous polar orbit, altitude = 705 km, inclination = 98.2° , equator crossing time at local noon (descending node), successive orbit equatorial crossing longitude = -24.721° , period = 98.2 minutes, orbital repeat time = 16 days (233 orbits)

Operational status as of June 2001: OrbView-2 continues to perform exceedingly well on-orbit. For 2000, it achieved a 98.7% data availability rate and has achieved a 100% data availability rate for the first quarter of 2001. Because of its superb on-orbit performance, ORBIMAGE is developing plans for an extended mission beyond the original five-year mission which ends August 2002.

Sensor:

SeaWiFS (Sea-Viewing Wide Field-of-View Sensor) built by Raytheon SBRC of Goleta, CA.⁵⁵⁸⁾⁵⁵⁹⁾ Objective: measurement of reflected visible sunlight from the ocean surface for the derivation of ocean-color data. The SeaWiFS sensor may be regarded as a next generation instrument of CZCS (Nimbus-7 sensor which ceased operations in 1986, after an eight-year mission). The SeaWiFS instrument employs scanning mechanisms to drive an off-axis (afocal) folded-optics scanning telescope and a rotating half-angle mirror that is phase-synchronized with, and rotating at half the speed of, the folded telescope. The scanning telescope design minimizes the polarization sensitivity and, correspondingly, maximizes the radiometric fidelity of its ocean color measurements. The SeaWiFS scanning concept employs a 360° uni-directional cross-track rotating telescope scanner. A small counter-rotating flat scan mirror between the telescope and the focal planes eliminates image rotation which would otherwise occur as the telescope rotates. The absence of FOV rotation permits the use of a multichannel, time delay integration (TDI) processing in each of the eight spectral bands to achieve the required SNR. Incoming scene radiation is collected by the folded telescope and reflected onto the rotating half-angle mirror. The collected radiation is then relayed through dichroic beam splitters to separate the radiation into four wavelength intervals (each wavelength encompassing two of the eight SeaWiFS spectral bands). The radiation in the four separate wavelength intervals is directed by four corresponding aft-optics assemblies through two separate spectral bandpass filters that further separate the radiation into the eight required SeaWiFS spectral bands. The aft-optics also image each of the resultant bands of radiation onto four silicon detectors that are aligned in the scan direction. The detected signals are then amplified for TDI processing in the electronics module.

Radiometric accuracy	< 5% absolute each band
Calibration/stability monitor	solar diffuser, lunar view
Relative precision	< 1% linearity of signal output to radiance
Between-band precision	< 5% relative band/band over 50 - 90% of saturation
Polarization sensitivity	< 2% worst case, all scan and tilt angles
Dynamic range	15,000:1 using bilinear gain
Bright target recovery	< 10 samples
Location knowledge	0.5 km, at 1-sigma level for instrument

Table 120: SeaWiFS parameters

The off-axis telescope (with an aperture of 7.6 cm; f/2) rotates at six revolutions per second (or 360 rpm) in the cross-track direction (for HRPT format compatibility) to provide con-

tiguous scan coverage. Data quantization = 10 bit; spatial resolution = 1.6 mrad (1.13 km at nadir); an active scan angle of $\pm 58.3^\circ$ is used. A scanner tilt mechanism enables the entire sensor to be oriented in the along-track direction to $+20^\circ$, 0° , or -20° to avoid specular sun reflection (sun glint from the sea surface). Instrument mass = 45 kg; design life = 5 years.

Figure 73: Schematic illustration of the SeaWiFS sensor

Calibration: SeaWiFS uses short-period solar calibration (for a few orbits) and long-term lunar calibration (for a few months and longer). Solar calibration employs a solar radiation diffuser and an input port located in a fixed position outside of the 58.3° SeaWiFS scene-scan interval. Lunar calibration is accomplished by a S/C maneuver to view the moon during the nighttime portion of an orbit. Of particular importance to the postlaunch validation period are field measurements from MOBY (Marine Optical Buoy, see P.139) located off the coast of Lanai, Hawaii. ^{560) 561) 562)}

Data: ⁵⁶³⁾

On-board storage of sensor data is provided. With two dumps/day, this allows global observations at reduced spatial resolution to be recorded, and a limited amount (about 20 min/day) of high-resolution Local Area Coverage (LAC) data. The real-time LAC data stream is merged with S/C health and instrument telemetry at a rate of 665.4 kbit/s; this is transmitted at L-band with a frequency of 1702.56 MHz. To increase the coverage of LAC data, NASA encourages the operation of HRPT (High Resolution Picture Transmission) stations by the user community throughout the world. These HRPT stations can collect real

⁵⁶⁰⁾ G. Valenti, "Sea-viewing Wide Field-of-view Sensor," *The Earth Observer*, March/April 1998, Vol 10, pp. 20-22

⁵⁶¹⁾ Note: the reflected radiance is related to the concentration of chlorophyll and other plant pigments present, since chlorophyll is a green pigment and the color of the water changes from blue to green as the concentration of chlorophyll increases. If the concentration of chlorophyll is known, the amount of phytoplankton, or 'ocean color,' may be calculated.

8	845 - 885	Atmospheric aerosols	2.13	1.09	467

Table 122: SeaWiFS spectral performance summary

To protect the commercial interests of the builder and operator of the mission, ORBIMAGE, SeaWiFS real time LAC data are encrypted. All data users require a license from OSC (a decryptor is furnished with the license). Commercial data users pay a fee for their license, research licences are issued at no cost, but are subject to certain restrictions. Commercial stations requesting HRPT stations for research data use must obtain prior approval from NASA (SeaWiFS Project Office at GSFC).

Satellite transmitting power	5 Watt
HRPT L-band frequency	1702.56 MHz
Frequency stability	± 20 ppm
Modulation	Split-Phase
Modulation rate	0.6654 Mbit/s
Satellite transmitter antenna loss	2.0 dB
Satellite antenna gain	1.8 - 2.1 dBiC
EIRP	31 - 37 dBm
Slant range	2900 km
Free space loss	166.1 dB
Fading and rain margin	5 dB

B.8.3 OrbView-3

OrbView-3 is an imaging satellite owned and operated by Orbital Imaging Corporation (ORBIMAGE) of Dulles, VA, a commercial provider of Earth imagery acquired from a family of imaging satellites that it owns and operates. The S/C includes one imaging camera, the OrbView High Resolution Imaging System capable of collecting one meter resolution panchromatic and four meter resolution multispectral imagery.

The spacecraft of the OrbView-3 mission uses the flight-proven OSC bus design. The S/C body consists of a cylinder of about 1 m in diameter and 2.3 m in length. A solar panel is mounted to the “top side” of the cylinder. OrbView-3 is three-axis stabilized providing a real-time pointing accuracy of better than 100 arcseconds (knowledge). The post-processed pointing accuracy allows pixels to be located to within 12 m for certain product types. The ACS (Attitude Control Subsystem) employs Orbital-built gyroscope, star sensors, sun sensors, and a magnetometer for attitude sensing, and four reaction wheels (3 always active, one is a cold spare) and thrusters for all actuation functions. The S/C has the capability to perform body-pointing of $\pm 50^\circ$ into the in-track and cross-track directions thereby increasing the FOR (Field of Regard) for all observations. The S/C mass is about 300 kg, the design life is five years. ⁵⁶⁴⁾

Figure 74: OrbView-3 spacecraft

OrbView-3 is planned to be launched in 2002 on an OSC launch vehicle from VAFB.

Orbit: Circular sun-synchronous orbit, altitude = 470 km, inclination = 97.3°, equator crossing at 10:30 AM on a descending node. The revisit capability is 3 days (depending on latitude).

Data: On-board storage capability of 32 Gbit (the onboard storage is available for customers requiring imagery of regions where receiving stations are unavailable). Real-time down-link in X-band at 150 Mbit/s.

Sensor complement:

OHRIS (OrbView High Resolution Imaging System) of ORBIMAGE designed and built by Northrop Grumman, Baltimore, MD. The objective is to provide global high-resolution imagery (1 m panchromatic and 4 m multispectral) on a commercial basis. OHRIS is identical to the instrument flown on OrbView-4. OHRIS is an optoelectronic instrument based on a three-mirror anastigmatic telescope design. The nominal scene size of the imagery is 8 km x 8 km with a spatial resolution of 1 m (Pan) and 4 m (MS) at nadir. The source data is generated with 11-bit quantization and compressed to 2 bits/pixel.

⁵⁶⁴⁾ Information provided by Mark Pastrone of ORBIMAGE

Imaging Mode	Panchromatic	Multispectral (MS)
Spatial resolution	1 m	4 m
Imaging bands	1	4 MS
Spectral range	Pan: 450 - 900 nm	MS1: 450-520 nm MS2: 520-600 nm MS3: 625-695 nm MS4: 760-900 nm
Silicon detector size (linear array)	8000 pixels	2000 x 4

Table 124: OHRIS instrument parameters

Ground segment: The ORBIMAGE Operations Center (OOC) is located in Dulles, VA providing full-time service. The OOC generates the satellite tasking commands, which are uplinked to the OrbView satellites from two ground stations; one located in Point Barrow, Alaska and the other in Dulles, Virginia. These same ground stations receive and route the telemetry and imagery data downlinked from the satellite back to the OOC for processing and distribution. The imagery data routed to the OOC is processed, archived, and distributed to customers. In parallel, ORBIMAGE franchises these service tasks (data reception, archiving, product generation, distribution, requests for regional image acquisition scheduling, etc.) out to official regional distributors or to large-volume customers. ORBIMAGE offers several license options for its distributors and large-volume users with regard to their satellite tasking capabilities and priorities in their respective regions of coverage.

B.8.4 OrbView-4

OrbView-4 is a imaging minisatellite owned and operated by ORBIMAGE of Dulles, VA. The S/C includes two imaging instruments, OHRIS and OHIS (OrbView Hyperspectral Imaging System). The satellite is designed and built by Orbital Sciences Corporation.⁵⁶⁵⁾ The spacecraft structure (body) consists of a six-sided cylinder of 102 cm in diameter and 152 cm in length. Orbview-4 is three-axis stabilized; attitude is sensed by star trackers, sun sensors, a magnetometer, and a gyro; actuation is provided by four reaction wheels (3 are always active, one is a cold spare) and thrusters. The attitude system provides a real-time pointing accuracy of better than 100 arcseconds. The post-processed pointing accuracy allows pixels to be located to within 12 m for certain product types. An agile body-pointing technique, using reaction wheels, is employed for instrument pointing, i.e., the entire S/C is pointed into the desired direction, permitting a field of regard of $\pm 50^\circ$ into any direction. A GPS receiver provides orbit determination and all on-board timing services. Electrical power is provided by six solar panels, mounted in a star configuration on the cylinder base. In addition, NiH batteries serve as a power source for eclipse operations. The satellite mass is about 360 kg, the design life is five years. The satellite is planned to be launched on a Taurus vehicle in September 2001 along with QuikTOMS of NASA as a secondary payload from VAFB.⁵⁶⁶⁾

An on-board recorder of 32 Gbit capacity provides storage for non-contact periods. RF communications of the imagery is provided in X-band. The downlink data rates is 150 Mbit/s. Mission operations are provided by ORBIMAGE via its Dulles-based operations center and two uplink/downlink ground stations located in Point Barrow Alaska and Dulles, Virginia. Data distribution is provided by ORBIMAGE and its worldwide Regional Distributors.

Orbit: Sun-synchronous circular orbit, altitude = 470 km, inclination = 97.3° , equator crossing on descending node 10:30 AM. The large off-nadir slewing capability of Orbview-4 offers a worst-case revisit time of three days.

⁵⁶⁵⁾ Information provided by Mark Pastrone of ORBIMAGE

⁵⁶⁶⁾ W. Ferster, "Orbimage Restructuring Delays OrbView-4 Launch," Space News, Aug. 27, p. 3 and p. 27

Figure 75: Illustration of the OrbView-2 and -4 satellites

Sensor complement: Both instruments can be operated in parallel.

OHIS (OrbView Hyperspectral Imaging System). The objective is to demonstrate the utility of hyperspectral technology for the support of various applications. The instrument is a body-mounted optomechanical instrument (whiskbroom scanning imager), built by Northrop Grumman. The spectral range of the instrument is 0.4 - 2.5 μm . Up to 200 contiguous spectral bands can be defined within the spectral region. A typical scene size is 5 km (swath width) x 20 km (length) with a spatial resolution of 8 m (GSD) at nadir. The data quantization is at 12 bit. No data compression is employed.

Parameter	Detector Array Size	Type of Array	Band Spacing	Operating Temperature	Wavelength Range (μm)	Nr. of Bands
VNIR	40 x 640	Si	11.4 nm	257 K	0.45 - 0.905	40
NIR	80 x 640	HgCdTe	11.4 nm	257 K	0.83 - 1.74	80
SWIR	80 x 640	HgCdTe	11.4 nm	257 K	1.58 - 2.49	80

Table 125: Characteristics of the OHIS instrument

Note: OHIS had originally an additional MWIR band in the wavelength range 3.0 - 5.0 μm , with HgCdTe detectors (80 x 640), a band spacing of 25 nm, an operating temperature of 90 K, and 80 bands. This option was cancelled in 2000.

OHRIS (OrbView High Resolution Imaging System) of ORBIMAGE designed and built by Northrop Grumman. The instrument is identical to OHRIS flown on OrbView-3, the description is provided under OrbView-3.

B.9 RapidEye Satellite Constellation

RapidEye^{567) 568)} is a planned constellation of four minisatellites of RapidEye AG of Munich, Germany with the objective to provide high-resolution (6.5 m) multispectral imagery along with an operational GIS (Geographic Information System) service on a commercial basis. The overall objectives are to provide a range of Earth-observation products and services to a global user community. Typical fields of application and services are:

⁵⁶⁷⁾ M. Kruschke, W. Niemeyer, et al., "RapidEye - Satellite Based Geo-Information System," IAA 2nd International Symposium on Small Satellites for Earth Observation, Berlin, April 12-16, 1999, pp. 249-252

⁵⁶⁸⁾ Information provided by Manfred Kruschke of RapidEye

- Agriculture - crop monitoring and mapping, yield prediction
- Cartography - satellite based maps, ortho photos, DEM
- Other markets - disaster assessment, 3D-visualization
- Service spectrum at completion of constellation: Guaranteed daily revisit, global coverage, product delivery to the customer within 24 hours, possibility of dedicated programming, capability of direct transmission and imagery transfer within hours, global digital database of “ortho maps” of 1:25,000 scale and DEMs of 20 m x 20 m resolution. The service permits also the merging of multi-temporal imagery with information from other sources.

Figure 76: Schematic illustration of the RapidEye satellite

The satellites are being built by SSTL (Surrey, UK) as the prime contractor on its Minibus platform. The RapidEye spacecraft has a modified cylindrical barrel shape, with rectangular side facets, and two end panels. The launch vehicle attach fitting is mounted onto one of the end panels; two of the Earth-facing side facets contain the camera apertures and communications antennas. The solar panels are wrapped around the three zenith-facing facets of the structure to maximize the power generation of the S/C. The solar arrays are integrated on aluminium honeycomb substrates. They provide a power of up to 740 W when optimally illuminated. Three packs of NiCd batteries are used with a combined storage capacity of 21 Ah at 28 V. - The S/C structure is 877 mm in height, with additional height for the attach

fitting, and the solar panels, which are 1120 mm tall. The mounting frames are circular with a diameter of 500 mm. With the solar panels included, the cylinder (barrel) has a dimension of 560 mm in diameter.

Each S/C is three-axis stabilized. Attitude sensing is provided by star sensors and magnetometers, actuation is provided by reaction wheels and magnetorquers (for wheel momentum dumping). The spacecraft uses a redundant GPS receiver (model SRG-20 of SSTL) for orbit determination and on-board time provision. The attitude system operates nominally in three-axis reaction-wheel control mode and flies the S/C in a so-called barrel-roll configuration, with the cameras pointing towards nadir. A body-pointing capability in the roll axis of the spacecraft exists which permits a $\pm 30^\circ$ FOR (Field of Regard) for camera observations into any direction (however, the feature is planned to be used only in the cross-track direction). On-orbit geo-referencing of the imagery is provided using inputs of the autonomous navigation and attitude determination system. In post processing the images will be referenced to at least one pixel accuracy ($\pm 6.5\text{m}$). The wet mass of each S/C is 315 kg, the design life is seven years.

The RapidEye constellation is planned to be installed in two separate launches (two S/C each) on a Russian launch vehicle in 2003 and in 2004.

Orbit: Sun-synchronous orbit (all four satellites are evenly spaced in one orbital plane), altitude = 600 km (± 10 km), inclination = 98° , local equator crossing time at 12:00 hours (noon) on the ascending node. A regular full repeat coverage is provided in 3-4 days depending on latitude, a revisit time of one day can be obtained with body-pointing techniques.

The on-board storage capacity of data is 126 Gbit. RF communication of imagery is provided in X-band (8.25-8.40 GHz) while TT&C communications are in S-band. The X-band downlink has a data rate of 150 Mbit/s.

Sensor complement:

REIS (RapidEye Earth Imaging System), designed and developed by Sira Electro-Optics Ltd of Chislehurst, Kent, UK. REIS is a multispectral pushbroom instrument, providing a swath width of 158 km with continuous observation coverage of up to 1500 km in length. The spatial resolution (GSD) of the imagery is 6.5 m. REIS is a camera with a dual optical-system design resulting in a dual-swath observation, each swath is of width 79 km with a slight overlapping configuration.

The telescope is of catadioptric design with a focal length of 74 cm. The instrument employs a linear silicon CCD detector array of size 6 x 12288 for each focal plane. The instrument mass is 62 kg, power = 73 W (orbit average).

The source data of REIS are compressed in real-time (lossless or lossy compression) prior to on-board storage and/or downlink transmission. In addition, a capability is provided to perform on-board pixel binning (2 x 2 or 3 x 3 pixels) prior to data compression.

Band Number	Band Name	Spectral Coverage (nm)
1	Blue	440-510
2	Green	520-590
3	Red	630-685
4	Red edge	690-730
5	NIR 1	760-900
6	Pan	550-850

Table 126: Spectral parameters of REIS

Figure 77: Schematic illustration of the REIS instrument

Part C Data Collection (Messaging) Systems

C.1 ARGOS (Data Collection System)

ARGOS is a joint program of CNES, NASA and NOAA, started in 1974 for the purpose of long-term continued global satellite data collection services (in particular environmental data) from fixed and mobile platforms located anywhere in the world. The ARGOS system package has been flown on all TIROS-N family satellite since 1978 (see chapter G.15.4). The space segment comprises two NOAA satellites in simultaneous orbit.

The ARGOS system exploitation, i.e. the data collection and distribution function and user interface, is a service provided commercially by CLS (Collecte Localisation Satellites), a CNES daughter in Toulouse, France, and by Service Argos of Landover MD, USA (a CLS subsidiary). Service to the user community has been continuously provided since fall 1978.

Orbit: the ARGOS payload on NOAA satellites is in sun-synchronous polar orbit, altitude = 830 - 870 km, inclination = 98 - 99°, period = 102 minutes (approximately 14 orbits/day). The circle of visibility (or the footprint) is 5000 km in diameter at 5° elevation, which is identical with the swath width.

ARGOS Space Segment:

Each ARGOS payload is equipped with a DCLS (Data Collection and Location System), also referred to simply as DCS, which receives all transmissions from the platforms in view during a pass. Functionally a DCLS is comprised of the following subsystems:

- housekeeping equipment, power supply and DCLS command interface
- receive assembly (receiver and search unit, both with full redundancy)
- signal processing assembly (four identical Data Recovery Units (DRUs, eight DRUs are planned for the next ARGOS series), and command unit, telemetry encoder, and buffer memory). All data are tape recorded on board the spacecraft.

ARGOS Ground Segment:

A set of user platforms, fixed or mobile, deployed at sea, on land, or in the air. All platforms reporting to the ARGOS system must carry a certified PTT (Platform Transmitter Terminal) package for satellite uplink communication. Each PTT outputs a short message (of 0.36 to 0.92 seconds duration, or of 32 bits to 256 bits maximum length) modulating a carrier frequency. Message transmission intervals range from 90 - 300 s, depending on the application.

The ground segment of the service provider consists of two NOAA/NESDIS CDA (Command and Data Acquisition) stations, one at Wallops Island VA, the other at Fairbanks, AK. In addition there is a downlink station at CMS (Centre de Météorologie Spatiale) Lannion, France. All these stations also provide real-time data during the pass. ARGOS provides two GPCs (Global Processing Centers), one in Landover, MD, the other in Toulouse, France. Each GPC receives data from all platforms but processes only the data that belong to “its” users. Both centers will, however, immediately process all data in case of necessity, thereby ensuring full redundancy.

Communication Concept:

Collection Uplink: ARGOS provides a total of four (eight in next series) parallel receiving channels for data collection, each at a rate of 400 bit/s. Each PTT in the ground segment transmits encoded messages at regular intervals (fixed platforms at 200 - 300 seconds, drifting or mobile platforms in the order of 90 - 150 seconds).

Note: the search unit is a spectrum analyzer that scans a 24 kHz band centered at 401.650 MHz. The next series of DCLS will have 80 kHz of bandwidth (100 kHz allocated, two safe-

guard bands of 10 kHz at each end). Time tagging and frequency measurements are made by the DRUs and processed on the ground for location determination.

Downlink: The data received by the ARGOS DCLS is multiplexed on-board by the TIP processor and transmitted to the ground via three paths:

- Real-time: the TIP output (8.32 kbit/s, see Figure 216) directly modulates a VHF beacon which transmits continuously.
- Real-time: the TIP output is multiplexed on-board the satellite with HRPT data and transmitted in S-band
- Delayed Transfer: the TIP output is also recorded by a tape recorder, and each time the satellite passes over one of the ground stations, the recorded data is dumped via S-band telemetry.

The ARGOS communication capability is limited to the function of data collection from the PTTs. The concept does not offer a remote configuration control capability of the data collection platforms in the ground segment.

Access Method: The on-board DCLS receiver picks up messages from the transmitting platforms in its area of visibility. The receiving system can discriminate between message arrival times and between frequency shift due to the Doppler effect. Up to four (eight in next series) messages may be processed simultaneously.

The ARGOS access scheme employs 'pure (i.e. unslotted) ALOHA.' Messages from the PTTs are received on-board on a random access basis. The ARGOS Doppler system provides a position fix for drifter (or mobile) platforms. This setup requires between three and five successful transmissions, which must occur within one pass (footprint).

Within an average footprint of 10 minute duration, each platform in the ground segment usually has a number of attempts to make contact with the DCLS in the space segment.

- Fixed platforms: the number of transmission attempts of fixed platforms is three at a repetition rate of 200 seconds (average = 3).
- Drifting (mobile) platforms: the repetition rate is 90 - 150 seconds, hence the maximum number of transmission attempts possible within a footprint is 5 - 6 (average = 5). [About 80% of the possible position fixes are actually achieved by the system; 20% are rejected during ground processing for various reasons, mainly geometrical configuration: number of messages, pass duration, distance to the track, etc., according to CLS ARGOS].

The nature of random access very much degrades data collection performance by the space segment. The scheme of pure ALOHA permits under normalized offered channel traffic a maximum channel throughput rate of 18%. Any two signals overlapping in time and frequency may interfere, with the loss of both. The principal parameter that affects the performance of the ARGOS data relay system is "interference": it occurs when the demand for service exceeds the system's capability. The result is loss of data from system 'blockage'. The maximum number of platforms that a single ARGOS DCLS can actually service within a footprint is in the order of 650. In this number, there is a certain mix of fixed (collection service only) platforms and drifting (collection and location services) platforms, a further assumption is a certain message length.^{569),570)}

The probability of good message reception is 67% with a traffic density of 2.6 Erlang, and 8.3 Erlang for the next improved DCLS series which is scheduled to be launched starting in 1998 with NOAA-K.

The total number of platforms registered as active in the ARGOS system globally is around 4000, out of which around 2300 are transmitting every day. The remaining platforms trans-

⁵⁶⁹⁾ Note: the figure of 650 serviceable platforms in a footprint was provided by 'CLS ARGOS' of Toulouse

⁵⁷⁰⁾ "A Definition Study of an Advanced Data Collection and Location System (ADCLS)," prepared for GSFC by ECOSYSTEMS International Inc., January 1986

mit once every two or three days, or less. This information was provided by CLS ARGOS (6/1993), the service provider of the system.

C.2 FAISAT (Final Analysis Inc. Satellite)

FAISAT-1⁵⁷¹⁾ is a store-and-forward/data-collection/communication minisatellite of Final Analysis Inc. (FAI) of Greenbelt, MD, which was launched as a secondary payload from Russia (Plesetsk) on a Cosmos launch vehicle on January 24, 1995. FAISAT-1 is an experimental version of the satellites in a constellation of 26 LEO satellites planned by FAI within the next years. The objective of the FAISAT program is to provide a short digital messaging service (< 512 bytes per transmission) to customers around the globe. The capability of this two-way messaging service includes a range of support options and applications, such as: tracking, electronic mail, paging, environmental monitoring of autonomous remote ground stations (collection of ground truth), location determination, and distress signaling. Most other applications are anticipated to evolve as the system potential becomes obvious to the user community.

The FAISAT-1 S/C has the shape of an octagonal cylinder of 45 cm diameter and 90 cm in length. Spacecraft stabilization is provided by a gravity boom and magnetic torquers providing an attitude accuracy of 5° in yaw and 1° in the pitch direction. The outside of the S/C cylinder is covered with solar cells, S/C mass = 114.5 kg. In addition to its own subsystems, FAISAT-1 carries the SSTT (Small Satellite Thermal Technology) secondary payload, an Air Force Flight Experiment of the Phillips Laboratory. The SSTT is a two-phase capillary-pumped loop thermal device which is being developed to provide thermal control for future space missions. Communication parameters are:

- Transmitter power: 10 W, 20 W selectable
- UHF downlink frequency: synthesized 387 - 407 MHz in 50 kHz steps; FCC experimental licence range: 400.595 - 400.645 MHz; Air Force allocation: 399.8375 MHz with a 38 kHz bandwidth
- VHF uplink frequency: synthesized 131-151 MHz in 10 kHz steps; FCC experimental license range: 148.65-148.75 MHz and 149.25-149.35 MHz; Air Force allocation: 141.775 MHz with a 25 kHz bandwidth
- Modulation methods:
 - CPFSK (Continuous Phase Frequency Shift Keying) @ 4800 bit/s
 - GMSK (Gaussian Minimum Shift Keying) @ 9600 bit/s
- Data storage capacity: 7.5 MByte

Orbit: Polar near-circular orbit, apogee = 1041 km, perigee = 988 km, inclination = 82.9°, period = 105 minutes.

FAISAT-1 contains a synthesized receiver capable of tuning from 131-151 MHz in 10 kHz steps. The experimental license granted to FAI allows for uplink operation in two 100 kHz wideband segments. With the on-board receiver scanning these segments in 10 kHz steps, each segment has nine potential channels (148.66, 148.67, 148.68, 148.69, 149.70, 140.71, 148.72, 148.73, and 148.74 MHz for segment 1).

The FAISAT ground segment consists of the Master Ground Station (MGS) and the Remote Terminals (RTs). The MGS provides the command and control functions of the satellite and the downlink data collection center. The RTs collect data from the monitoring instruments and transmit it to the satellite for store-and-forwarding. The access scheme for the monitoring task in the ground segment uses a modified TDMA technique.

- The satellite emits a beacon to signal the RTs in its footprint (polling scheme). The message includes the RTs ID code, transmission time and transmission frequency

⁵⁷¹⁾ Information provided by J. T. Skladany of Final Analysis Inc., Greenbelt, MD

- The RTs in the ground segment power up their transmitters upon receiving the ID code and set the transmitter to the assigned frequency
- The satellite RT receivers collect data from 50 RTs polled in series
- The satellite continues taking data in 10-second cycles until it is out of range. Data retransmission requests occur if the RT's transmission data is corrupted. In such cases the RT will be requested to retransmit 10 seconds later
- The RT powers down to stand-by mode after a transmission sequence is successfully completed.

An RT must have a synthesized transceiver and some intelligence provided by a simple microprocessor. A future extension of satellite communication capability is the provision of a transponder mode used for those cases when sender and receiver of a message are in the same footprint, or for the purpose of sending messages from one RT to another. The maximum footprint of FAISAT communication is 5650 km in diameter, assuming an orbit altitude of 1000 km and a 5° elevation angle. With a typical orbital pass of 10 minutes across such a footprint, and a polling scheme chosen to interrogate 50 RTs in 10 second intervals, this amounts to 3000 RTs per footprint for each satellite in the FAISAT constellation of 26 satellites.

FAISAT-1 was not able to establish satisfactory remote terminal demonstrations and communication links. It was eventually switched off in May 1996 when it was decided that different frequency bands were to be used for the constellation.

The FAISAT experimental messaging S/C, **FAISAT-2V**, was launched on Sept. 24, 1997 on a Cosmos-3M launch vehicle from Plesetsk. An on-board GPS receiver is part of the FAISAT-2V payload (and planned for all successive launches). VITA of Arlington, VA is leasing communications capacity on FAISAT-2V.

C.3 LLMS (Little LEO Messaging System)

LLMS is a demonstration store-and-forward messaging payload of ESA, flown on the Russian satellite RESURS-O-N4 (launch July 10, 1998), with the overall objective to provide a simple and low-cost communication access scheme (e-mail, etc.) on a commercial basis to organizations with personnel in remote locations; an additional service objective is data collection from environmental platforms in the ground segment. The global e-mail service function of LLMS is referred to as **IRIS** (International Retrieval of Information via Satellite). An IRIS subscriber needs a small, relatively inexpensive satellite terminal (about half the size of a portable PC) to communicate with his platform via IRIS. ^{572) 573) 574) 575)}

Background: The LLMS/IRIS program, an initiative of Belgium's space industry, is mainly financed by the Federal Office for Scientific, Technical and Cultural Affairs (OSTC) of Belgium, with a contribution from its German counterpart (DLR). The development of this advanced telecommunication platform (a turnkey demonstrator system) has been carried out within the context of an ESA development initiative, under SAIT-Systems S. A. of Brussels as the prime contractor. Other industrial participants in the program are: OHB-System of Bremen, Germany, Alcatel Bell of Belgium, the SEMA Group SAE of Spain, and Warberry Communications, UK. LLMS/IRIS is the first Little-LEO communications system using spread-spectrum modulation in the service links to and from the S/C as well as on-

board demodulation techniques. SAIT Systems has also a contract from ESA to operate LLMS/IRIS for a period of three years.⁵⁷⁶⁾

Orbit: Sun-synchronous polar orbit, altitude = 830 km, inclination = 98°, period = 101.3 min.

LLMS/IRIS payload and ground segment elements:

The payload consists of four redundant and interconnected units: OBC (On-Board Computer), TT&C, the RF unit and the SS (Spread Spectrum) unit with CDMA modem and UHF transceiver. The payload is planned to be available eventually in two polar orbiting S/C for reasons of redundancy. In the overall configuration, messaging is uploaded during contact periods from the HUB (or gateway) station in the ground segment via satellite to its destination and vice versa (remote subscriber terminal at the one end and fixed user at the other end). Each HUB station pass enables the exchange of all data collected by the satellite (and by the HUB station) since the last contact by store-and-forward techniques. The HUB station, located at the high-latitude site of Svalbard (78° N), Spitzbergen, Norway, for reasons of frequent satellite contact times (visibility of each S/C orbit), is connected via public network to the user community. A dedicated TT&C station provides in addition operations control of the payload(s). The message storage and retrieval functions of OBC are handled by an adaption of a transputer-based architecture already flown on BREMSAT-1 and on SAFIR-1/2 satellites. The total mass of the attached LLMS/IRIS payload is 67 kg, its power consumption is 72 W, of which 44 W is for the communication payload (RF+SS).

LLMS/IRIS Communication Concept:

LLMS/IRIS is employing a data transmission scheme referred to as SSMA (Spread Spectrum Multiple Access) in the UHF frequency band (uplink at 388 MHz, downlink at 400.6 MHz), permitting shared operations for customer services from remote user terminals. SSMA is used in both directions (uplink and downlink) offering such advantages as: a) interference-tolerant transmission, b) use of anti-jamming features, c) the random access scheme provides very good channel discrimination for multiple access, and d) it permits the measurement of propagation time between payload and user terminal (in combination with the Doppler estimation this measurement enables the system to localize the user terminal). The chip-based timing resolution of the spread-spectrum downlink is 0.2 µs. Localization accuracies projected: a) <3 km for coarse and b) <1 km for fine localization.

The communication payload can be put into one of two different communication modes:

- Service link: The service link is used for communication between the user terminal and the payload (or vice versa).
- Feeder link. The feeder link serves as high-rate communication link between the payload and the HUB station.

Parameter	Service downlink	Service uplink	Feeder downlink	Feeder Uplink
F-chip (MHz)	0.538	1.077	0.538	1.077
L (chips)	128	512	32	64
Efficiency (bit/symbol)	2	1	6	6
Byte/slot	134	134	345	345
Symbol rate (s/s)	4207	2103	16,827	16,827
Brute bit rate (bit/s)	8,414	2103	100,962	100,962
Net bit rate (bit/s)	4,709	1,177	71,112	71,112
Slot duration (ms)	127.4	509.7	27.3	27.3
Modulation scheme	O-QPN	B-PN	O-QPN	B-PN

Table 127: Modulation parameters employed on the different link modes

⁵⁷⁶⁾ P. B. de Selding, "Belgium Firm Seeks Investors for IRIS E-Mail Venture," Space News, Sept. 28 - Oct. 4, '98, p. 22

A user terminal (fixed or mobile) design resorts to custom (ASIC) integration to process the spread-spectrum signals used by LLMS/IRIS. Typical terminal characteristics are:

- Standard RS-232 interfaces (one RS-232 opto isolated)
- Antenna: 1/4 wave groundplane or drooped-dipole
- Batteries: 6 x UM-3; standby: autonomy for 100 hrs, and continuous receive for 5 hrs
- Transmit power of <3 W
- Terminal size: 200 mm x 150 mm x 50 mm; mass < 1 kg.

C.4 Orbcomm Satellite System

Orbcomm is a family of store-and-forward communication microsattellites designed and built by OSC and operated by Orbcomm (Orbital Communications Corporation) of Dulles, VA, USA (project financing by OSC, Telglobe Inc. of Canada, and Technology Resources Industries Berhad of Malaysia). The objective is the provision of global two-way (store-and-forward) messaging services between any two users (subscribers) in the ground segment. The capability of this two-way messaging service includes a range of applications, such as: tracking, paging services, e-mail interconnection, remote data collection, location determination, and emergency alerts. The initial deployment configuration consists of two satellites, Orbcomm FM1 and FM2, which were launched April 3, 1995 on a Pegasus launch vehicle.^{577) 578)}

Figure 78: The Orbcomm S/C model (deployed configuration)

Orbit of FM1 and FM2: Polar circular orbit, altitude = 785 km, inclination = 70°, period = 100 minutes.

Orbcomm is licensed to operate up to 36 satellites. The space segment has a total of up to 35 satellites in four inclined orbital planes (eight satellites per plane, and three spares) provid-

⁵⁷⁷⁾ Information provided by M. Deckett of Orbcomm, Dulles, VA

⁵⁷⁸⁾ http://www.orbcomm.com/our_technology/satellites.htm

ing near-overlapping footprint coverage of the world - resulting in near-continuous communications capability.

Spacecraft parameters: The Orbcomm family uses the OSC bus design (a cylinder of 1 m diameter and 17 cm height with deployed solar panels in orbit, resembling a butterfly); the S/C is stabilized with a nadir-pointing gravity boom and magnetic torquers (1σ nadir pointing is within $\pm 5^\circ$); S/C mass = 42 kg; power = 70 W; S/C expected life = 4-5 years; on-board data storage is into solid-state memory, up to 2 MByte. The antenna FOV is 120° providing a footprint of 5000 km in diameter (5° elevation limit). FM1 and FM2 are flying GPS receivers (Trimble TANS II) with the objective to demonstrate real-time on-board orbit determination.⁵⁷⁹⁾

Communication parameters of the S/C:

- Data rates: 2400 bps inbound (from ST to NCC), 4800 bps outbound (from NCC to ST)
- Frequencies: 148.00-150.05 MHz (VHF) data uplink; 137.00-138.00 MHz (VHF) TT&C up/downlink and 400.05-400.15 MHz (UHF) data downlink
- The access scheme between a subscriber terminal (ST) and the satellite is by FDMA (Frequency Division Multiple Access). Other links are either continuous or by TDMA.
- Number of parallel communication channels: 18
- Addressing: X.400 (CCITT 1988) standard
- Message size: 6-250 bytes typical length (no maximum length limit)
- Each packet contains overhead information and error detection bits

Spacecraft	Launch	Comments
FM1, FM2	April 3, 1995	Experimental S/C, altitude 785 km, inclination = 70°
FM5 to FM12 (8 S/C)	Dec. 23, 1997, Wallops	Orbit altitude of 810 km, inclination = 45°

FM30 to FM36 (7 S/C)	Dec. 4, 1999,	

Table 128: Orbcomm satellite constellation

Meanwhile, operational experience with FM1 and FM2 attitude control has led to an augmented ACS (Attitude Control System) design which includes substantially improved attitude determination and control relative to the experimental S/C, FM1 and FM1. A vertically oriented reaction wheel (0.63 kg) has been added providing improved torque inputs. In addition, residual magnetic dipole states in the attitude estimator algorithms were added. The resulting pointing accuracy of the S/C is more than doubled.⁵⁸⁰⁾

Communication/messaging concept:

The Orbcomm ground system has a prevailing star architecture where a Network Control Center (NCC) functions as a central base station monitoring and controlling the network of a geographical region (like the USA, or Europe). Each NCC uses several unattended Gateway Earth Stations (GES) which relay messages between the satellites and the NCC in both directions. [A GES consists of two independent tracking antennas (HPA/LNA units), each enclosed in a radome, and auxiliary equipment]. The number and location of the GESs in any network are chosen to achieve the needed availability for a given region in the network. The USA network covers initially (1995) the contiguous 48 states, it consists of four GESs located in the states of New York, Georgia, Arizona and Washington, controlled and monitored by the NCC at Orbcomm, VA. The NCCs control only the communication of their networks. In addition, there is one Satellite Control Center, collocated with the USA NCC,

579) D. A. Steffy, "Orbcomm Satellites Launch and Initial Flight Operations," Proceedings of the AIAA/USU Conference on Small Satellites, Sept. 16-19, 1996, Logan, UT
580) M. R. Krebs, "A New Attitude Control Mechanism for LEO Satellites," Proceedings of the AIAA/USU Conference on Small Satellites, Sept. 16-19, 1996, Logan, UT

which monitors and controls the bus subsystems (power, attitude, thermal household, etc.) of all Orbcomm satellites.

Orbcomm satellites do not communicate with each other (i.e., there are no intersatellite links). Each GES tracks one of the satellites whenever it is in view; during this period (a pass may be up to 15 minutes long) there is continuous two-way communication between them. If more than one satellite is visible to a GES, then the controlling NCC decides which satellite should be tracked. There may also be an occasion when more than one GES is tracking the same satellite. This happens when the satellite can be seen by GESs located in different networks (and controlled by different NCCs). In this case, the uplinks from the GESs to the satellite are operated in TDMA mode; the downlink is continuous and received by all NCCs.

Remote stations in the ground segment are referred to as STs (Subscriber Terminals); they are always in listening mode. STs scan through a list of frequencies used by the satellites for downlink transmissions. Each satellite has a specific frequency for this purpose, and transmits continually. When an ST receives one of these signals at some threshold level, and determines that the satellite is in communication with the NCC controlling the territory in which the ST is located, it stops scanning and stays on that channel until the signal level drops below the threshold, whereupon it starts scanning again. There are 18 such channels, allocated to the satellites such that co-frequency satellites are never close to each other.

If an outbound message is addressed to a fixed ST, then the NCC knows which satellite to use. If the ST is mobile, then the system must know (or be told) which network it can be in, and a search routine is followed. The extent of the search, including the number of retries, depends on the contractual agreement with the customer. The Orbcomm facilities are used only for communications between an ST and the NCC of the region in which the ST is located. Communications between the NCC and the base station use the public switched network or other non-Orbcomm link.

The probability that at any given moment an ST can see a satellite that is also in contact with a GES is termed the availability. Availability varies with latitude and with the position of the ST relative to the GESs in the network. The orbits have been selected to maximize availability in the temperate latitudes. With a 26-satellite constellation, availability varies from about 70% in the equatorial zone to about 95% in the temperate zone. It is about 12% at the polar caps. - The number of STs that can be served by a network depends on the usage statistics and the acceptable queuing delays. About 250,000 STs can be served by each satellite (depending on the types of the STs).

The following types of data collection and messaging services are provided:

Data communication service: This service refers to the periodic or discrete collection of digital data from remote stations (STs) in the ground segment that are known to the system. In environmental monitoring this may mean the collection of ground truth data from a buoy network or from other sensors (meteorological stations, balloons, etc.) distributed throughout the world. For a utility company, it may mean the reading of meters of their customers. - All of these 'passive' sensors or meters (STs) must have an intelligent interface (communicator) as well as a small memory for storage capability. The space segment communicates with a remote station via a standard RS 232 dataport (using X.400 addressing and other standard protocols); data may be communicated in both ways (depending on need), inbound to configure the remote station, outbound to collect data from the remote station.

One application is position determination of a remote station or any other remote subscriber unit. The objective is to track objects. In the field of science this may apply to Lagrangian experiments (drifting buoys in the ocean or balloons in the atmosphere). In the commercial world, tracking may involve locating stolen or other vehicles (ships, barges, trucks, planes, etc.).

Further applications are in the field of emergency alerts and confirmation (distress signaling by people in remote areas, alarms due to an intrusion into protected property, simple limit sensing of a particular device, etc.). In all cases an alarm message is initiated by a remote communicator and transmitted periodically through the system until confirmation of receipt is provided.

Messaging service: A personal two-way messaging service combines the functions of the data communications service into one package. A message can be sent by a user to a remote subscriber communicator through any personal computer using standard communication protocols (X.400, X.25, dial-up). The user (A) simply connects to the NCC and sends a message using a computer keyboard. The NCC routes and relays the message via the appropriate satellite to the remote subscriber (B). This messaging service supports any type of paging throughout the world.

C.5 SAFIR (Satellite For Information Relay)

SAFIR (SATellite For Information Relay) is a commercially operated data collection system (DCS) developed and built by OHB-System GmbH of Bremen, Germany, and sponsored in part by DARA. The system is intended to offer data collection and positioning services on a global scale for an international user community. SAFIR systems operations are intended to be provided by OHB-Teledata (an associated company).⁵⁸¹⁾

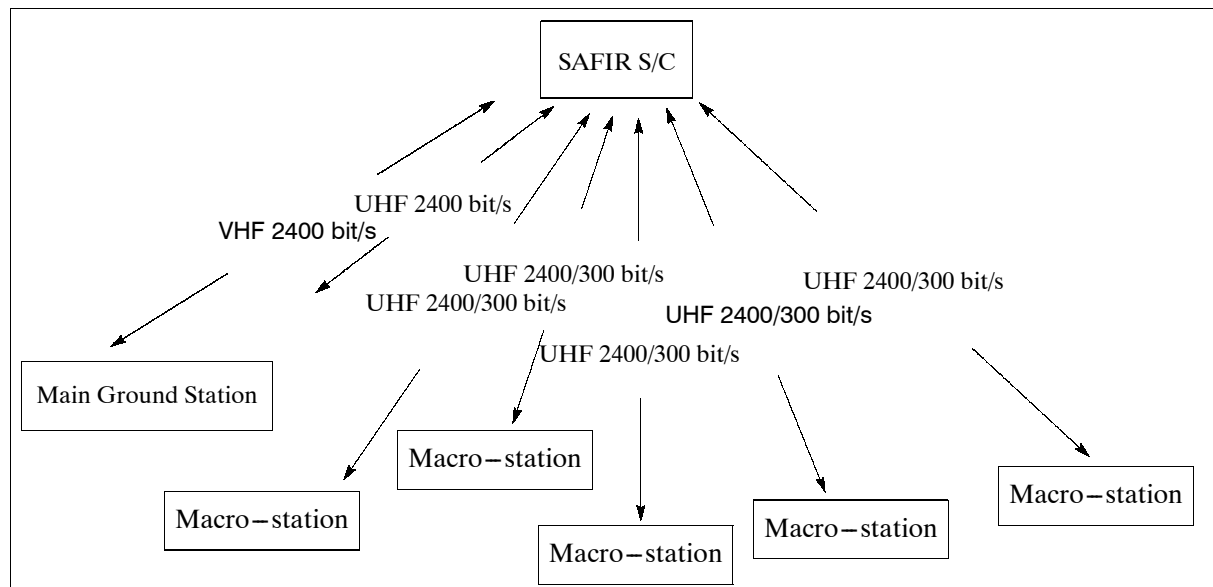

Figure 79: Concept overview of the SAFIR system

C.5.1 SAFIR-1

The space segment of SAFIR consists in phase 1 (1994-95) of an independent and autonomous SAFIR payload on the Russian RESURS-O1-3 spacecraft (referred to as SAFIR-R), launched November 4, 1994, for technological verification of the system concept. The nominal life of SAFIR-1 is 5 years. Phase 2 considers an autonomous polar-orbiting microsatellite, called SAFIR-2.

Operational status: As of 2001 SAFIR is fully operational with over 100 customers.

The SAFIR-1 satellite consists of a baseplate with several electronic units which is attached to RESURS-O1-3. SAFIR is equipped with an electronic box containing two on-board

⁵⁸¹⁾ Brochures and documentation provided by OHB-System

computers, two data storage units (5 MByte), and two TM/TC transmitter/receiver units for redundancy plus antennas, a GPS receiver, and a clock. The satellite is capable of measuring the frequency difference of any ground station based on the Doppler effect which serves in turn as input into the on-board computer in the form of integrated Doppler counts.

The ground segment consists of a main ground station at OHB-Teledata (for central scheduling of all customer traffic, distribution of all customer data, and for satellite control), and small portable ground stations that collect the data at customer-selected sites.

Orbit: (SAFIR-1) polar orbit, perigee = 663 km, apogee = 691 km, inclination = 98° , period = 98 minutes.

User Ground Stations:

The data collection concept considers macro-stations (in the order of 0.5 kg), which provide a storage capacity of 190 kByte for user data; they can collect and store data from their own monitoring instruments or from the satellite. Macro-stations may be able to transmit their data at 300 bit/s or 2400 bit/s to the satellite, depending on communication requirements. A standard macro-station consists of a CPU board, a HF board, and an interface board. The I/F board provides the following external interfaces: RS 232, digital input channels, and digital output channels. The macro-station may optionally be equipped with a GPS receiver board (for position monitoring), a battery pack, and a telephone modem.

The ground concept consists of a number remote macro-stations as well as a 'home station' for each user. The home station consists of a macro-station with a PC interface, a battery pack, and a loading unit.

Each ground station knows the next nominally scheduled contact time. In case of failure (no nominal contact between the ground station and SAFIR) the ground station uses the next possible contact time that is known in advance and stored in its memory. A minimum power level of 5 W EIRP is required at the ground station to communicate with the satellite. A ground station may be configured go into a 'sleep mode' during noncontact periods (in order to save power; in this case only real-time measurements at contact time are possible); it goes back into listening mode according to a calculated schedule. It is also possible to configure a station to remain in operational (listening) mode and to record measurements during noncontact periods if called for by the requirements.

Communication Concept:

The principal task of the satellite is scheduled data collection when in view of user ground stations, intermediate on-board storage of the data, and relay of the data to the main ground station (store-and-forward mode with the use of a mailbox). The bidirectional communication principle also permits data transmission from the main ground station or from the user home station via SAFIR to individual user ground stations (for configuration control, to reprogram the remote station, etc.). Users are normally equipped with a home station which permit communication with their remote stations in store-and-forward or relay mode, depending on visibility conditions within the satellite link.

SAFIR operates with two communication frequencies:

- VHF-band (137.175 MHz) link between the satellite and the main ground station at a transmission rate of 2.4 kbit/s.
- UHF-band (401.00 MHz uplink, and 400.75 MHz downlink) between the ground stations and the satellite, and also between the main ground station and the satellite, at transmission rates of 300 or 2400 bit/s, respectively.

The digital transmission of messages between the satellite and the ground stations is based on an HDLC protocol for error-free communication (error-free in the sense that the SAFIR communication concept provides either correct data or no data). The protocol permits

any system user to select an individual message length for a ground station. The transfer frame length depends on the total amount of user data. Shorter messages are transmitted with short frames. The maximum frame length is 1 kByte.

Access Method:

SAFIR-1 is equipped with one receive and one transmit channel for servicing the user ground segment. Each ground station has a scheduled time slot within the time of visibility in which there is communication with SAFIR. A communication link is established by addressing the user station by its individual identification number. The addressed user station must respond to this addressing prior to message transfer. The link is closed by SAFIR after the data transfer is completed. The overall efficiency of this access method is affected by synchronization delays and the error rate of the channel. The access method of SAFIR-1 is TDMA.

With an average contact time of 6 seconds per remote link (5 seconds of data transfer on the average plus 1 second of synchronization time) SAFIR is capable of servicing up to 100 remote stations within a 10 minute circle of view (of 5000 km diameter). A Doppler location service requires three to six consecutive contacts for each remote station (depending on accuracy requirements), which amounts to a SAFIR serviceability of 34 or 17 moving stations, respectively, within a circle of view (instead of the 100 normal stations).

The swath of SAFIR provides the following coverage conditions (changing with latitude):

- 3 times of daily coverage at equatorial latitudes (min)
- 4 times of daily coverage at 40-45° latitudes (min)
- 5 times of daily coverage at 50° latitude (min)
- > 10 times of daily coverage in polar regions

Communication between Main Ground Station and Satellite		Communication between Macro-station and Satellite	
Frequency	137.175 - 137.275 MHz	Frequency uplink	401.00 - 401.10 MHz
Modulation	BPSK, $\Phi = 0, 180^\circ$	Frequency downlink	400.75 - 400.85 MHz
Transmission rate	2400 bit/s	Modulation	FSK, $\Delta f = 9$ kHz
Coding	Manchester code	Transmission rate	300/2400 selectable
On-board computer		Coding	Manchester code
SAFIR-1 mass		Transputer-based multiprocessor	
SAFIR-1 stabilization		38.5 kg	
SAFIR-1 power consumption		provided by RESURS-01-3	
		20 W average, 80 W maximum	

Table 129: Some SAFIR specification parameters

C.5.2 SAFIR-2

SAFIR-2 is an advanced and follow-up satellite (commercially operated little LEO store-and-forward communication system of the Fuchs Group, built by OHB-System, and operated by OHB-Teledata, Bremen, Germany) to continue and enhance the services provided by SAFIR-1.^{582) 583)} The overall objective is to provide communication/data collection services for logistical (tracking), environmental (monitoring) and industrial (meter reading) applications. The SAFIR-2 microsatellite is of cubical structure (0.5 m x 0.5 m x 0.5 m) with four surface-mounted solar panels, providing power (average/peak) of 20/50 W. In addition, NiH₂ batteries of 4 Ah capacity provide power during eclipse the phase of the orbit. Total S/C mass of 65 kg. The S/C is passively stabilized with a 6 m gravity-gradient boom and by an active control loop consisting of magnetic coils in three dimensions, two magnetometers, and a horizon sensor. A pointing accuracy of $\pm 10^\circ$ is provided. The S./C undergoes a very

582) B. Brünjes, F. Ellmers, M. Fuchs, et al., "SAFIR-2 Small Commercial Telecommunication Satellite," Proceedings of the 49th IAF Congress in Melbourne, Australia, Sept. 28 - Oct. 2, 1998

583) OHB company brochure of SAFIR-2 provided by F. Ellmers

slow spin rate of about seven revolutions in one orbit. Two OBC (T800 CPU transputer) operate in master/slave configuration. A total of four MByte on-board user data storage is provided.

The S/C was launched as a secondary payload on a Zenit-2 vehicle (along with the primary payload of RESURS-O1-4 of Russia, Thai-Phutt of Thailand, the Israeli TechSat/Gurwin-II, WESTPAC of Australia, and Chilean FASat-Bravo) from the Baikonur Cosmodrome on July 10, 1998. Status as of June 2001: SAFIR-2 is fully operational.

Orbit: Sun-synchronous polar orbit, altitude = 830 km, inclination = 98°, period = 101.3 min.

Communication Concept:

SAFIR-2 uses a combined UHF/VHF Earth-pointed antenna system (5 or 10 W transmit power). The UHF/A (analog) assembly is dedicated to user communication and redundant satellite operation, while the UHF/D (digital) assembly is dedicated to mass user communication. The modulation of all VHF and UHF/A telemetry is in FSK with Manchester encoding and RH circular polarization. Selectable data rates of 300, 600, 1200, 2400, or 4800 bit/s are provided for the various services. The modulation of UHF/D data is in BPSK for uplink and FSK for downlink transmission with data rates of 3200 bit/s (200 bit/s per station, up to 16 stations simultaneously). The newly developed FHT (Frequency Hopping Telemetry) access technology is implemented for UHF/D mobile user stations in parallel to the TDMA access scheme in order to permit 16 user stations to transmit their data within the same time slot in the same frequency channel. The SAFIR-2 system has the capacity of collecting 10.000 telegrams/day and per 50 kHz bandwidth from a single defined coverage area (communication footprint). Forward error correction (FEC) is implemented on all transmissions. Bidirectional semi-duplex operation is possible within each of the telemetry assemblies.

The ground segment includes one HUB station in Bremen to operate the satellite and three types of user ground terminals: 1) user home stations, 2) 1-channel user mobile stations, and 3) 16-channel user mobile stations based on advanced DSP (Digital Signal Processing) technology.

- Service A provides a direct global bidirectional point-to-point user communication (arbitrary data files) in store-and-forward fashion between any user home stations. Connection of all user home stations in the network by a single S/C.
- Service B provides global unidirectional transmission in store-and-forward fashion of position telegrams and short messages to the S/C from 16-channel user mobile stations (moving assets like trucks, containers, etc.). The position telegrams include asset ID, time and GPS position. The telegrams are received by the HUB station and distributed to the customer.

Service type	Frequency allocation	Communication service
Bidirectional between user stations (Service A)	400 MHz downlink, 401 MHz uplink, UHF	Between S/C and HUB, user home station and 1-channel user mobile stations
Unidirectional from moving assets to user stations (Service B)	400 MHz downlink, 400.00 MHz uplink, UHF	Between 16-channel user mobile stations and the S/C. Transmission of position telegrams and short messages to the S/C.
Bidirectional S/C operations	137 MHz, VHF band	Between S/C and HUB

Table 130: Frequency allocations for service types

C.6 SCD-1 (Satélite de Coleta de Dados)

SCD-1 is Brazil's first experimental Data Collection Satellite, a portion of MECB (Missão Espacial Completa Brasileira). INPE's responsibility in MECB was the space segment and

associated ground segment of the program [six satellites were planned within this program: four for environmental data collection (SCD-1, SCD-2, SCD-2A and SCD-3) and two for remote sensing of the Earth (SSR1 and SSR2)]. The Brazilian Space Activities Program has been reorganized in 2000, now, the satellites are part of the Application Satellites Program.

A DCP network in Brazil is equipped with sensors suitable for the fields of meteorology, hydrology, oceanography and atmospheric chemistry. Spin-stabilized S/C; mass = 115 kg; power = 90 W; design life = 1 year (projected life is now 2.5 years). Launch of SCD-1: Feb. 9, 1993 from NASA's Kennedy Space Center by OSC of Fairfax VA (Pegasus launch vehicle). SCD-1 is performing nominally. ^{584) 585)}

The shape of SCD-1 is an octagonal prism, 80 cm tall, whose base fits into a 1 m diameter circle. The outer surface of the S/C is covered with solar cells. S-band TT&C communication is provided by a TM/TC subsystem for housekeeping telemetry transmission, telecommand and ranging (S/C mission control functions). On-board storage capability for TT&C data.

Orbit: Near-circular orbit; altitude = 750 km; inclination = 25°; period = 98.8 minutes.

The SCD-1 satellite is a real-time repeater of environmental data gathered on the ground by automatic data collection platforms (DCPs) providing random access service for DCPs. The real-time repeater concept implies that there is no on-board processing and storage capability but simply a relay function of data by the satellite. Data reception on the ground is at a single station in Cuiabá, Brazil every time SCD-1 comes into view. This concept permits a data collection capability from all sites in Brazil and well beyond (coverage region of 3000 km radius). It is estimated that the system setup is capable of servicing up to 1000 DCPs randomly located in the coverage area with a probability of 85% of acquiring the data of any DCP at least once per day. The DCP data received by the Cuiabá station are processed by the MCC in Cachoeira Paulista and subsequently stored in a database for user access.

The random access method employed by SCD-1 for data collection is similar to and compatible with the ARGOS system. This means:

- Access scheme is pure (i.e. unslotted) ALOHA, without a return channel
- Message format, data rates, and transmission frequencies are ARGOS compatible (message length of 32-256 bits, 400 bit/s uplink rate, 401.650 MHz and 401.620 MHz uplink frequencies).
- Brazilian DCPs in the ground segment can also be serviced by other satellites carrying ARGOS.

As of 2001 there are 400 DCPs operational in Brazil; others are in the phase of installation or are being planned for the future (including those from other South American countries).

Note with regard to the SCD-1 access scheme: ⁵⁸⁶⁾

SCD-1 uses a "random time-division multiple access" scheme which is similar to "unslotted ALOHA." However, SCD-1 and also ARGOS access are simpler than ALOHA due to the lack of a return channel from the satellite to the DCP. This means in fact loss of data due to interference (interference occurs when the demand for service exceeds the system's capability; the result is loss of data from system 'blockage'). However, the system works satisfactorily in spite of this disadvantage for the following reasons:

- interference is mitigated by Doppler shifts, which tends to spread the DCP transmissions
- the system operates at a low input rate (400 bit/s) so that a data packet has at least a probability of 80-90% of getting through without interference

⁵⁸⁴⁾ INPE brochure 'SCD-1 Data Collection Satellite,' and fax information from Prof. P. M. Fagundes, Rio de Janeiro

⁵⁸⁵⁾ "SCD-1 Satellite Description," and "The Brazilian Data Collecting System," papers provided by C. E. Santana of INPE, May/June 1992

⁵⁸⁶⁾ Information provided by C. E. Santana and by J. Kono of INPE

- there is a lot of redundancy in the data of consecutive transmissions from the same DCP, so that successful reception of one out of two or even three transmissions is still satisfactory
- there is no catastrophic effect for subsequent communications if some data are lost.

C.6.1 SCD-2

The launch of SCD-2 took place Oct. 23, 1998 on a Pegasus launcher (with OSC's L-1011 Stargazer aircraft) from Cape Canaveral, FL. The launch site of SCD-2 was at 29.0° N and 78.3° W. SCD-2 is a follow-on satellite with the same objectives as SCD-1, but with improved data collection performances, due to modifications in the antenna- and attitude control subsystems. SCD-2 has a mass of 117 kg and power of 110 W. SCD-2 is performing nominally as of 2001.

Orbit of SCD-2: perigee = 743 km, apogee = 768 km, inclination = 25.0°.

The SCD-3 satellite will carry, along with the same payload as SCD-1, another data collection payload, capable of supporting advanced DCPs (the intent is the transmission of longer messages from the DCPs). SCD-3 will be in an equatorial orbit, collecting data from the Amazon region with a revisit period of two hours. The launch of SCD-3 is planned for 2006.

C.7 TEMISAT (Telespazio MicroSatellite)

TEMISAT^{587),588),589)} is a data collection and distribution satellite for environmental monitoring of autonomous ground stations. The satellite and a portion of the corresponding ground segment are owned and operated by Telespazio of Rome, Italy; it was built by Kayser Threde of Munich, Germany. TEMISAT-1 was launched (piggyback on Meteor-2-24) on August 31, 1993 on a Russian Cyclone launcher from Plesetsk. The spacecraft is essentially a cube of 0.35 m side length with a mass of about 40 kg, and passive magnetic field stabilization, power = 62 W, expected lifetime = 5 years.

A second microsatellite (TEMISAT-2) was built together with the TEMISAT-1. As of the end of 1995 TEMISAT-2 is still in storage; however, it is going to be launched to increase in-orbit service capacity.

Application: worldwide commercial data collection, in particular for the science community in remote areas.

Orbit: Polar circular orbit, altitude = 950 km, inclination = 82.5°, period = 112 minutes.

The ground segment consists of a Mission Control Center (MCC, a major task being central scheduling and configuration control of all customer traffic), a number of User Control Stations (UCS, for those users who operate under their own control a sizable number of remote terminals), Remote Terminals (RTs, which control the monitoring instrument(s), receive and store data from the monitoring instrument(s), and function as communication nodes with the satellite), and finally the monitoring instruments themselves.

The TEMISAT polar orbit provides about a 10-12 minute contact period for all the monitoring platforms in the instantaneous area of visibility, or the footprint, of its orbit. TEMISAT is constantly polling the ground segment for possible customers (RTs, UCSs, or MCC) to initiate communication opportunities. It is foreseen that all the platforms with their RTs in this footprint will have a chance to communicate their data to the satellite in due time.

All instrument location knowledge is provided with a built-in GPS receiver in the monitoring instrument configuration (this applies to moving instrumentation in the ground seg-

⁵⁸⁷⁾ "Telespazio Readies Temisat Satellite for Summer Launch," Space News, April 19-25, p. 24

⁵⁸⁹⁾ "Blackbird: A Family of Microsatellites for Communications and Remote Sensing," Kayser Threde brochure

ment such as drifting buoys, or other moving objects). The GPS concept offers position accuracy of about 30-100 m.

Communication Concept: TEMISAT covers the VHF and UHF frequency spectrum allocated by WARC 92 for micro satellite LEO communication applications. A total of eight parallel receiving channels and two simultaneous transmitting channels are provided for the monitoring task of the ground segment. With this capability TEMISAT operates as an intelligent communications node in orbit with two different operational support modes:

- Transparent regenerative transponder mode (data relay function when data sender and receiver are in the same coverage area of the satellite)
In this mode, data from the receiving channels (eg., from the ground segment platforms) are decoded, forward corrected, then again recoded and formatted for retransmission to the ground in real time (either to the MCC or to the UCS, or to both).
- Store-and-forward mode (operational function when data sender and receiver are in different coverage areas of the satellite)
The received data are decoded, forward corrected, and stored on board (total storage capability of 30 MByte RAM) until the intended receiving station is in satellite visibility. Then the specific data file is recoded, formatted, and transmitted to the ground.

Data can generally be collected by the MCC and provided/distributed to the user community via electronic interface.

Table 131: Summary of TEMISAT specification

Access Methods: TEMISAT uses a TDMA/SCPC (Time Division Multiplexing Access/Single Channel per Carrier) access scheme for the monitoring task of the ground segment. TDMA/SCPC is centrally controlled by MCC (computer scheduling of customer traffic up to four times per day), which avoids data collision in the uplink and maximizes the channel throughput rate.

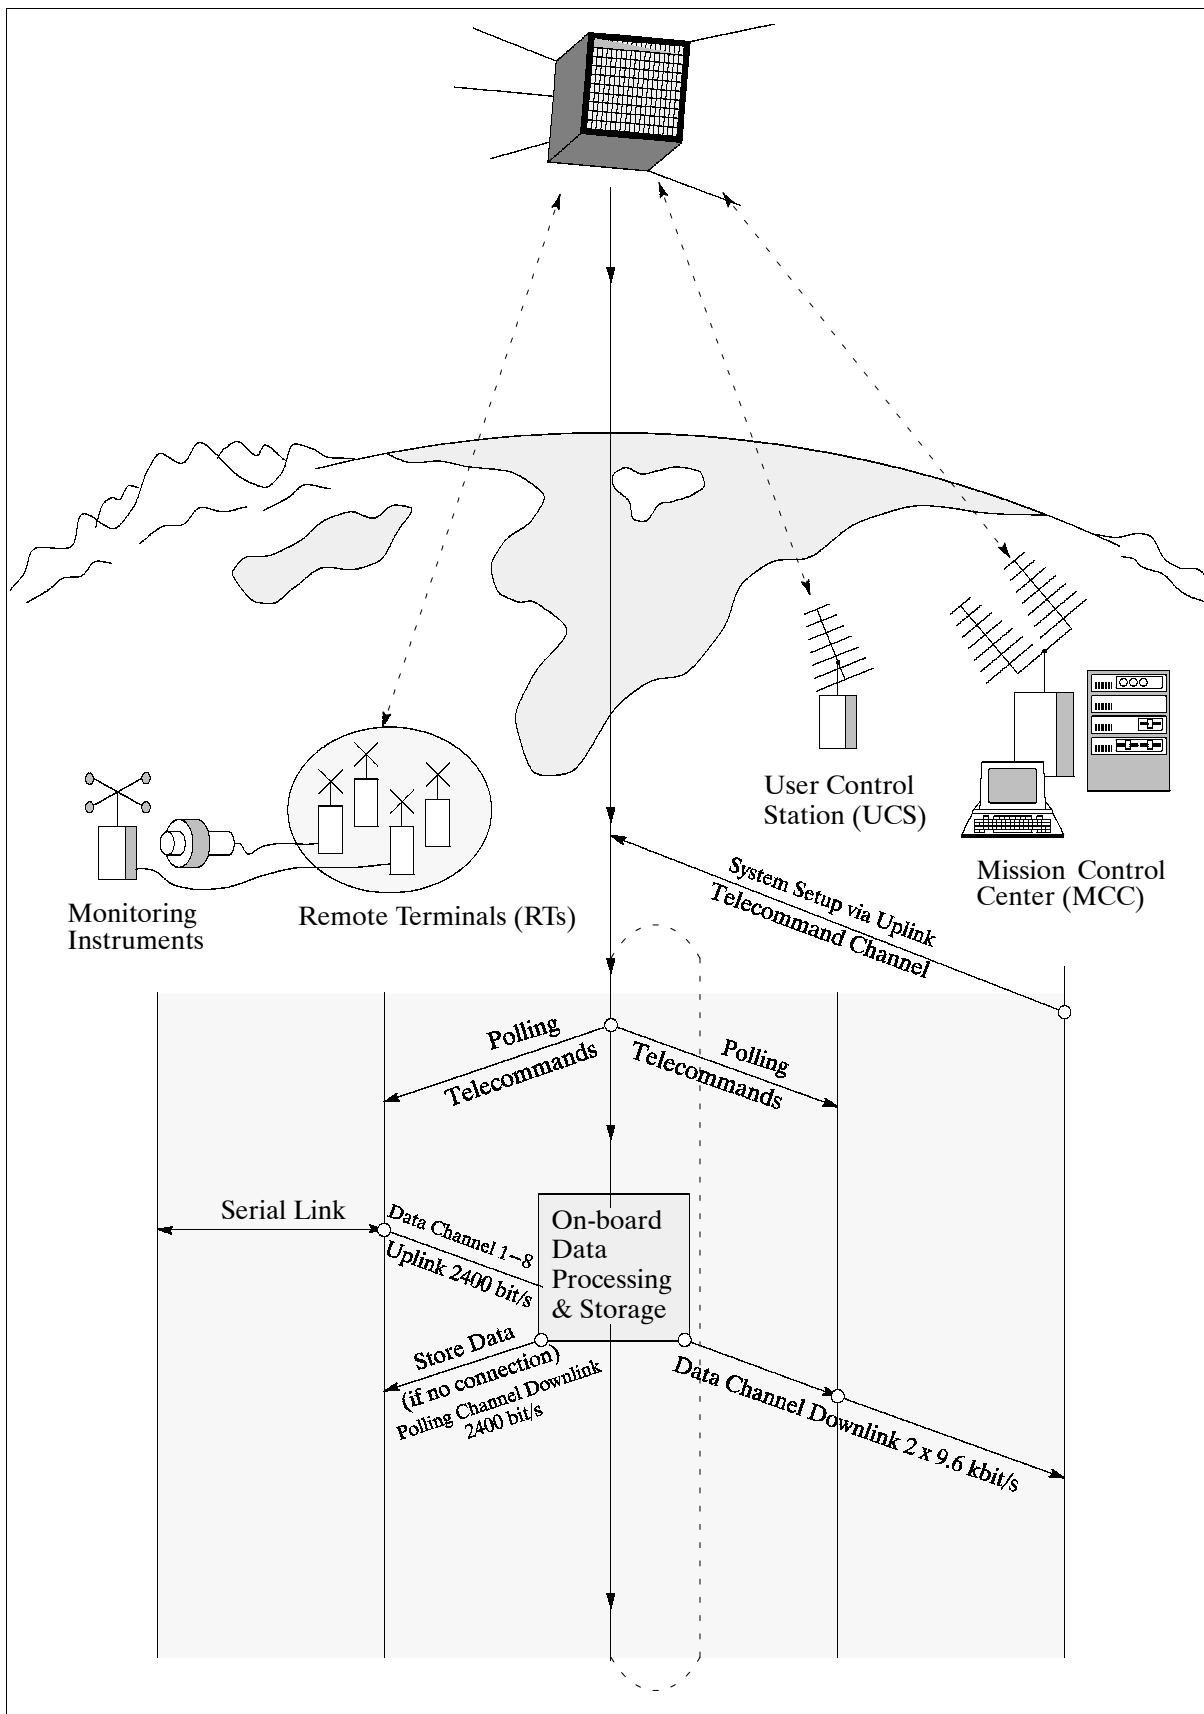

Figure 80: Scenario/Communication logic of the TEMISAT Data Collection System

The TDMA/SCPC access scheme permits a data rate of 1200 bit/s (2400 bit/s viterbi-encoded) for every one of the eight channels. The MCC has configuration control over the channel assignment and time slot allocation for each customer.

VHF Uplink Frequencies (MHz)	UHF Uplink Frequencies (MHz)	VHF Downlink Frequencies (MHz)
149.6625	402.3375	137.645
149.6875	402.3625	137.670
149.7125	402.3875	137.695
149.7375	402.4125	137.720
149.7625	402.5875	137.745
149.7875	402.6125	
149.8125	402.6375	
149.8375	402.6625	
149.8625		
149.8875		

Table 132: Operational frequencies of TEMISAT (allocated by WARC)

Note: The TDMA/SCPC access scheme allows a system throughput capacity of over 80% which is practically independent of the number of simultaneous users (30 or 300); on the other hand, the access scheme of ARGOS is ‘unslotted ALOHA,’ which permits under 0.5 normalized offered channel traffic a channel throughput rate of about 18% (max).

All RTs in the ground segment are always in listening mode, ready to establish contact with the TEMISAT polling channels at the scheduled time slot. If an average contact time of 5 seconds per RT is considered, in which the communication link (about 200 ms of sync time) is established and the data transmitted (uplinked), then TEMISAT is capable of servicing up to 960 RTs within a 600 second period with eight parallel channels [10 minute pass period over any ground point in the TEMISAT swath width of 5000 km (10° elevation above the horizon)].

The wide swath of TEMISAT visibility provides the following coverage conditions:

- 3 times of daily coverage at equatorial latitudes (min)
- 4 times of daily coverage at $40\text{-}45^\circ$ latitudes (min)
- 5 times of daily coverage at 50° latitude (min)
- > 10 times of daily coverage in polar regions

TEMISAT recognizes every remote terminal (RT) in the ground segment by its unique address in the message header. The message length for an uplink transmission can be variable, depending on the individual RT requirements. With an available net data rate of 1200 bit/s and an actual transmission time of four seconds in a contact, this amounts to 600 bytes of data in a single transmission. All user data is packetized with 600 bits per packet (2 packets per second in the transmission link). Users have the freedom to insert data into the frame according to their specific requirements (this may be sensor data along with a time stamp plus GPS data, there may be super- or subcommutations, etc.). A transmission can consist of some real-time data and some stored data. In general every RT stores its collected sensor data and provides it for the next available uplink opportunity. Data can be sent twice (i.e. on the next possible pass) in case of an unsuccessful transmission connection.

The concept and technology of TEMISAT operation represent a new dimension - in fact a new generation - in data collection services for the user community. This applies in particular to the introduction of the following features:

- Selection of the most efficient access scheme technology (TDMA/SCPC)
- The availability of sufficient data rates for the data collection function along with eight communication channels for instantaneous parallel service assignments
- The bidirectional store-and-forward communication concept, which offers a remote control capability for every remote sensing instrument to the user (or to the MCC on user request).
- Provision of real-time/stored data transmission which offers full-time (round-the-clock) coverage (as compared to spot coverage) of the measured parameters.

- The inclusion of position data into every packet, if needed. There are no constraints of several contacts per RT within the same footprint for Doppler position fixing (as is the case for ARGOS PTTs).

C.8 Store-and-Forward (S&F) Systems

Automatic S&F data collection of ground truth from satellites has grown over the years from the first operation of the ARGOS system (on polar orbiting satellites) in the seventies to an Armada of systems and services (institutional and commercial) in the mid-nineties. The following table serves as an overview; descriptions of the different systems are provided in the text.⁵⁹⁰⁾

System Designation (Service Provider)	Satellite/Platform	Orbit	Service offered	Start of Operation, (Description in text)
ADEOS II DCS	ADEOS II	LEO	environmental monitoring	2002, (D.2)
ARGOS (CLS Argos)	NOAA-POES series		environmental monitoring, emergency signalling	1978, (C.1, G.15.4)
CBERS DCS	CBERS	LEO	environmental monitoring	1999, (D.7)
FAISAT (FAISAT)	FAISAT series	LEO	commercial DCS	1995, (C.2)
FedSat (Australia)	FedSat (ADAM)	LEO	environmental monitoring	2002, (M.9)
GMS (JMA)	GMS series	GEO	environmental monitoring	1985, (F.3.1)
GOES DCS(NOAA)	NOAA-GOES series	GEO	environmental monitoring	1974, (F.4.1)
GOMS DCS (Planeta)	GOMS series	GEO	environmental monitoring	1995, (F.5) no info available
INSAT DCS (ISRO)	INSAT series	GEO	environmental monitoring	1981 (F.6)
KAISTSAT DCS	KAISTSAT-4	LEO	environmental monitoring	2002 (D.19.3)
LLMS/IRIS (ESA)	LLMS	LEO	two-way messaging	1998 (C.3)
Meteosat DCS (Eumetsat)	Meteosat series	GEO	environmental monitoring	1977, (F.7.1, F.7.2)
MetOp DCS-2 (Eumetsat)	MetOp series	LEO	environmental monitoring	2005, (G.2.1)
MTSAT (JMA)	MTSAT-1R (JCAB)	GEO	environmental monitoring	2003, (F.9.1.3)
OKEAN Kondor (Planeta, NSAU)	OKEAN, SICH series	LEO	environmental monitoring	(D.26.2) no info available
Orbcomm (Orbcomm)	FM series	LEO	commercial DCS, two-way messaging	1995, (C.4)
SAC-C (CONAE)	SAC-C	LEO	environmental monitoring	2000, (D.34)
SAFIR (OHF)	SAFIR series	LEO	commercial DCS	1994, (C.5)
SCD1 (INPE)	SCD series	LEO	environmental monitoring	1993, (C.6)
UoSAT/SSTL	UoSAT	LEO	S&F, messaging	1984, (D.40)
TEMISAT (Telespazio)	TEMISAT	LEO	commercial DCS	1993, (C.7)

Table 133: Survey of data collection/S&F data communication systems and services

The capabilities of S&F systems have grown with the general developments in the satellite communications industry. Many commercial entries into this nonvoice communication market view the data collection part of environmental monitoring only as an additional source of income; their interest is mainly in global two-way data messaging services for a variety of applications to a large customer base. The provision of operational commercial (private) networks with their own space segments (constellations of microsatellites, also referred to as ‘little LEO systems’) and ground segments may be regarded as ‘emerging and experimental’ in early 1996; however, the real potential of this service market is considered promising. There are several projects on the drawing boards; others are in various phases of completion. However, the future may mean licensing problems for the little LEO system services from ITU (WARC-95 did not allocate sufficient bandwidth for these services).

Part D Earth Observation/Monitoring Missions

D.1 ADEOS (Advanced Earth Observing Satellite)

ADEOS = Advanced Earth Observing Satellite. Japanese (NASDA) satellite mission.⁵⁹¹⁾ Objective: Global observation of land, ocean and atmospheric processes (ocean color and sea surface temperature). In addition, communication experiments are planned for the study (feasibility) of interorbit links, called IOCS (Inter-Orbital Communication Subsystem). Launch with H-II launch vehicle from Tanegashima Space Center, Japan, on August 17, 1996⁵⁹²⁾

Figure 81: The ADEOS S/C model

Satellite mass = 3560 kg at lift-off, payload mass = 1300 kg, power = 4.5 kW, size: 4 m x 4.5 m. The AOCS employs a three-axis strap-down attitude detection system and a zero-momentum attitude control system, attitude error $< 0.3^\circ$, attitude stability $< 0.003^\circ/\text{s}$. Mission design life=3 years. The IOCS transmits observation data via ETS-VI (Engineering Test Satellite-VI) and COMETS (Communications and Broadcast Engineering Test Satellite).^{593) 594) 595)}

Orbit: Sun-synchronous sub-recurrent polar orbit; apogee = 804.6 km; perigee = 789.0 km; orbital period = 100.8 min, 10:30 AM local sun orbit (descending node). Ground repeat cycle=41 days (subcycle = 3 days), inclination = 98.625° .

ADEOS S/C operations are terminated: ADEOS operated nominally for some period, but then suffered several malfunctions and stopped functioning June 30, 1997 after an apparent loss of power (solar panel failure).

⁵⁹¹⁾ NASDA handout at the CEOS WGD-10 Meeting in Annapolis MD, April 16-19, 1991

⁵⁹²⁾ In Japan the ADEOS satellite is also referred to as 'MIDORI', meaning 'green'.

Sensor complement:

OCTS = Ocean Color and Temperature Scanner (mechanical scanning radiometer, NASDA core sensor). Objectives: Ocean color and sea surface temperature measurements (ocean primary productivity, interaction between the ocean and the atmosphere and environmental studies). OCTS offers 12 measurement bands from 0.402 - 12.5 μm . Swath width = 1400 km; $\pm 20^\circ$ along-track tilting. Spatial resolution: approx. 700 m. Operation requirements: global observation of the Earth during daytime (TIR channel during night if required).

Band Number	Spectral Band (μm)	Bandwidth (μm)	Radiance ($\text{W/m}^2/\text{sr}/\mu\text{m}$)	SNR
1	0.402 - 0.422	0.020	145	450
2	0.433 - 0.453	0.020	150	500
3	0.480 - 0.500	0.020	130	500
4	0.511 - 0.529	0.018	120	500
5	0.555 - 0.575	0.020	90	500
6	0.660 - 0.680	0.020	60	500
7	0.745 - 0.785	0.040	40	500
8	0.845 - 0.885	0.040	20	450
			NEDT	
9	3.55 - 3.88	0.33	0.15K	
10	8.25 - 8.80	0.55	0.15K	
11	10.3 - 11.4	1.1	0.15K	
12	11.4 - 12.7	1.3	0.20K	
	IFOV	0.85 mrad (~ 700 m)	Quantization	10 bit/pixel
	Scanning angle	$\sim \pm 40^\circ$ (1400 km)	Tilting angle	$-20^\circ, 0^\circ, +20^\circ$
	Polarization sensitivity	Band 1 $\leq 5\%$ Band 2-8 $\leq 2\%$	Calibration VIS/NIR IR	Solar, internal lights, deep space, blackbody

Table 134: Definition of OCTS parameters

The OCTS sensor consists of a scanning radiometer with an optical system, a detector module and an electrical unit. OCTS employs a catoptric optical system and a mechanical rotating scanning method with a mirror (due to wide spectral coverage). OCTS can be tilted about the along-track axis to prevent sea surface sun glitter. The IR detectors are cooled to 100 K by a large radiant cooler facing deep space. Calibration: solar and internal lamp for VNIR, deep space and black body for IR.

AVNIR = Advanced Visible and Near-Infrared Radiometer (NASDA core sensor). Electronic scanning radiometer. Objective: Land and coastal zone observations, measurement of reflected sunlight from the Earth's surface. Scanning method: electronic (CCD). Spectral range: 5 bands from 0.42 - 0.89 μm (multispectral bands: 0.42-0.50, 0.52-0.60, 0.61-0.69 and 0.76-0.89 μm , panchromatic band (visible): 1 band 0.52-0.69 μm). Spatial resolution: multispectral bands: ~ 16 m (IFOV = $20\mu\text{rad}$), panchromatic band: about 8 m (IFOV = $10\mu\text{rad}$). Swath width = 80 km (FOV = 5.7°). Observation requirements: regional observation according to user requests; simultaneous multispectral and panchromatic operation.

The AVNIR instrument has the capability to tilt the observation field by $\pm 40^\circ$ about the across-track axis. The 0.42-0.50 μm band is useful for coastal zones and lakes. The scanning radiometer unit uses a catadioptric Schmidt optical system to reduce aberration in a wide field of view. Calibration of sensor using solar light and internal lamps. The radiometric absolute accuracy is $\pm 10\%$, the on-board calibration accuracy = $\pm 5\%$. The large linear array CCDs offer 5,000 and 10,000 detector elements for high spatial resolution. Instrument mass = 250 kg, power = 300W.

Figure 82: The observation concept of the OCTS instrument

Figure 83: The observation geometries of the AVNIR instrument

NSCAT = NASA Scatterometer (NASA/JPL sensor).⁵⁹⁶ Objective: Measurement of surface wind speeds and directions over the global oceans, coverage every two days under all weather and cloud conditions. NSCAT is a microwave radar instrument (a fan-beam Doppler scatterometer), using an array of six antennas that radiate microwave pulses at a frequency of 13.995 GHz across broad regions of the Earth's surface. An array of six, 3 m

⁵⁹⁶ F. M. Naderi, M. H. Freilich, D. G. Long, "Spaceborne Radar Measurement of Wind Velocity Over the Ocean - An Overview of the NSCAT Scatterometer System," Proceedings of IEEE, Vol. 79, No. 6, June 1991, pp. 850-866

long antennas scan two swaths of 600 km width each, one band to each side of the flight path, separated by a gap of 330 km at nadir. Wind speed accuracy = 2 m/s (rms), direction accuracy = 20° (rms), resolution = 50 km; antenna polarization: 6 V, 2 H; antenna beam width=25° (3 dB broad beam) =0.42° (3 dB narrow beam); instrument mass=300 kg; power=275 W; data rate=2.9 kbit/s; peak transmit power=110 W; pulse width=5 ms; PRF=62 Hz. Operation requirements: continuous operation for global observation of the oceans (about 190,000 wind measurements/day). Note: NSCAT is an upgraded version of the Radar Scatterometer (SASS) on SEASAT (see D.35).

NSCAT transmits microwave pulses and receives a backscattered echo from the ocean surface. Changes in wind velocity cause changes in ocean surface roughness, modifying the radar cross section of the ocean and the magnitude of the backscattered power. Multiple collocated measurements acquired from several directions can thus be used to solve for wind speed and direction simultaneously.

Wind velocity	2 m/s 10%	3 - 20 m/s 20 - 30 m/s
Wind direction	20° (rms)	3 - 30 m/s
Spatial resolution	25 km 50 km	σ_0 cells wind cells
Location accuracy	25 km (rms) 10 km (rms)	absolute relative
Coverage	90% of ice-free ocean surface every two days	
Instrument mass	300 kg	
Instrument power	275 W	

Table 135: NSCAT instrument parameters

TOMS = Total Ozone Mapping Spectrometer (NASA/GSFC sensor). Objective: Observation of total ozone changes, evaluation of changes in UV radiation and the observation of sulfur dioxide. Measurement wavelengths: 308.6, 312.5, 317.5, 322.3, 331.2 and 360 nm with 1 nm bandpass. Swath width: 2795 km. IFOV= 50 km at nadir; cross-track scan = 111° (37 3° steps). Operation requirements: global observation of illuminated part. TOMS mass=34 kg, power=24 W, data rate=700 bit/s.

TOMS measures the albedo of the Earth's atmosphere at six narrow spectral bands in the near-ultraviolet region. The albedo is measured by comparing the radiance of the Earth with the radiance of a calibrated on-band diffuser plate. Total ozone is derived from the differential albedo in three pairs of spectral bands, which are selected to function at all latitudes and solar illumination conditions.

POLDER = Polarization and Directionality of the Earth's Reflectances (passive optical imaging radiometer, CNES sensor as passenger instrument on ADEOS).^{597) 598)} Objectives: Observation of bidirectionality and polarization of the solar radiation reflected by the atmosphere: tropospheric aerosols (inversion of the physical properties); ocean color (accurate determination of sea surface reflectances); land surfaces (determination of surface BRDF and improvement in the correction of the surface bidirectional and atmospheric effects on vegetation indices); Earth radiation budget (determination of cloud BRDF and classification of clouds according to their bidirectional properties).

- a) measurement of polarized reflectance in VIS/NIR
- b) observation of the Earth's target reflectance from 12 directions during a single S/C pass
- c) operation in two dynamic modes for high SNR and wide dynamic range

⁵⁹⁷⁾ P. Y. Deschamps, F. M. Bréon, et al., "The POLDER mission: Instrument characteristics and scientific objectives," IEEE Transactions on Geoscience and Remote Sensing, Vol. 32, 1994, pp. 598-615

⁵⁹⁸⁾ P. Y. Deschamps, M. Herman, A. Podaire, M. Leroy, M Laporte, P. Vermande, "A Spatial Instrument for the Observation of Polarization and Directionality of Earth Reflectances: POLDER," IGARSS '90 Conference Proceedings, Washington, D. C.

Six of POLDER's eight frequencies are optimized for observing atmospheric aerosols, clouds, ocean color, and land surfaces. The other two frequencies are centered on the H₂O and O₂ absorption bands for retrieving atmospheric water vapor amount and cloud top height, respectively.

Measurement channels: 15 channels (three channels for each polarized band) Swath width = 1440 km x 2200 (across-track) km, ground spatial resolution of 7 km x 6 km at nadir. Data rate: 0.882 Mbit/s, 12 bit quantization. Operation requirements: global observation of the Earth with more than 15° of solar elevation, simultaneous operation with OCTS.

POLDER is a pushbroom, wide-field-of-view, multi-band imaging radiometer/polarimeter. Multi-angle viewing is achieved by the along-track migration of the S/C of a quasi-square footprint. The optical detection unit of the POLDER consists of a telecentric lens, a rotating wheel supporting filters and polarizers, and a matrix CCD sensor (242 x 548 photoelements, the pixels are binned one by two, resulting in 242 x 274 sensitive areas). The instrument has a focal length of 3.57 mm, f/4.6, FOV = ±43° along-track, FOV = ±51° across-track, FOV = ±57° diagonal. Instrument mass = 33 kg, power = 42 W.

Wavelength nm (FWHM)	Bandwidth (nm)	Polarization	Dynamic Range (Normalized Radiance) High Low		Main Measurement Objective

Table 136: Spectral characteristics of POLDER

IMG = Interferometric Monitor for Greenhouse Gases, [MITI sensor developed by JAROS, this is a nadir-looking Fourier transform infrared spectrometer (FTIR)]; Objectives: Observation of detailed spectra of IR radiation of the Earth's surface and the atmosphere, mapping greenhouse gases on a global scale (CO₂, CH₄, N₂O). Continuous measurements of the infrared spectrum in the range from 3.3 - 14.0 μm with a very fine spectral resolution of 0.1 cm⁻¹ (apodized) absolute accuracy of measurement = < 1 K, stability of measurement < 0.1K, IFOV = 10 mrad (~ 64 km² footprint); vertical resolution about 2-6 km depending on species; interferogram scan time ≤ 10 s. Operation requirements: full time operation for 3 days out of 13 days. A mechanical cryogenic coolant system is used to regulate the temperature of the quantum detectors. An image motion compensation mirror is used to compensate for the satellite orbital motion. Measurements are made in 20 km swaths at 8 km resolution.

Spectral range (in 3 bands)	600 - 3030 cm ⁻¹ (3.3 - 16.7 μm)
Band 1	2335 - 3030 cm ⁻¹ (3.3-4.3 μm)
Band 2	2000 - 2326 cm ⁻¹ (4.3 - 5.0 μm)
Band 3	600 - 2000 cm ⁻¹ (5.0 - 16.7 μm)
Nr. of samples	Band 1: 1.6 x 10 ⁵ ; band 2 & 3: 1.0 x 10 ⁵
Spectral resolution	<0.15 cm ⁻¹ (band 3); <0.25 cm ⁻¹ (band 2)
Measurement stability	<0.43 K (band 3); <1.59 K (band 2), < 1.58 K (band 1)
Data rate	882 kbit/s
Instrument mass, power	130 kg , 150 W
Instrument size	1150 mm x 930 mm x 650 mm

Table 137: Some characteristics of the IMG instrument

IMG is a Michelson-type Fourier Transform Spectrometer (FTS) with two mirrors and a beam splitter. The incident radiation is divided by the beam splitter into two paths. One mirror is moved so that the two paths produce an interference pattern when recombined. The signal measured by the detector, the interferogram, can be Fourier-transformed to obtain the incident spectrum. The diameter of the entrance aperture is 10 cm. The moving mirror is suspended on magnetic bearings and scans a 10 cm long path in 10 seconds.⁵⁹⁹⁾

ILAS = Improved Limb Atmospheric Spectrometer (sensor of the Environment Agency of Japan, EA), heritage of LAS on Ohzora (EXOS-C).^{600), 601), 602)} Objectives: Measurement of atmospheric trace gases and the pressure and temperature profiles by the solar occultation technique (vertical profiles of O₃, NO₂, aerosols, H₂O, CFC11, CH₄, N₂O). ILAS has two grating spectrometers, one is used for the IR-band trace gases, the other measures aerosols, air temperature and pressure in the VIS-band. The ILAS occultation measurements are performed only at high latitudes in both hemispheres (due to orbit characteristics). ILAS keeps looking at the sun during sunrise and sunset, it measures the sequence of spectral intensity changes in the solar light which pass through the various tangent heights of the atmosphere. Since atmospheric trace gases have their own characteristic absorption spectra, the concentration of gases can be derived from these absorption measurements.

Spectrometer	2 grating spectrometers (VIS and IR) with linear array detectors
Spectral coverage	44 infrared channels in the range from 6.21-11.77 μm (850-1610 cm^{-1}) and 1024 visible channels in the range of 0.753 - 0.784 μm
Telescope	Cassegrain, 12 cm diameter
Sun tracker	Pointing mirror: 18 x 18 cm; sun edge sensor: 512 element array
I FOV (at tangent height)	IR channels: 2 km (vertical) x 13 km (horizontal) VIS channels: 2 km (vertical) x 2 km (horizontal)
Observation parameters	O ₃ , HNO ₃ , NO ₂ , N ₂ O, H ₂ O, CFC-11, CH ₄ , aerosols, pressure, air temp.
Observation region	Latitudinal zones 56° - 70° N and 63° - 88° S
Data rate	517 kbit/s, sampling rate at 12 Hz
Instrument operation	10 minutes per occultation (limb observations)
ILAS mass, power, size	130 kg, 78 W, 800 x 1630 x 550 mm

Table 138: ILAS instrument parameters

RIS = Retroreflector in Space (JEA sensor).⁶⁰³⁾ RIS is a single element corner-cube reflector for Earth-satellite-Earth laser long-path absorption measurements of atmospheric trace gases. RIS has a hollow reflector structure with an effective diameter of 0.5 m. A spherical mirror with a very small curvature is used for one of the three mirrors forming the corner cube, in order to optimize the ground pattern of the beam reflected by RIS.⁶⁰⁴⁾ Instrument mass=43 kg.

Objective: Used for laser long-path absorption measurements of atmospheric trace species and to support two color laser ranging experiments. Measurements of ozone (O₃), CFC12, HNO₃, methane (CH₄), CO, and other gases by the laser beam absorption technique. Wavelength range: 0.4 - 14 μm . - In the RIS experiments a laser beam is transmitted from a SLR ground station, reflected by RIS, and received back at the ground station. The absorption of the intervening atmosphere is measured in the round-trip optical path (measure-

ment of absorption spectra by the Doppler shift of the reflected beam). The column contents and vertical profiles of atmospheric trace gases are obtained from the measured spectra. The RIS experiments are performed when ADEOS passes over the ground stations in Japan. The ground stations use two single-longitudinal-mode TEA-CO₂ lasers for the spectroscopic measurements.

Figure 84: Schematic configuration of the RIS corner retroreflector

ADEOS carries in addition TEDA (Technical Engineering Data Acquisition Equipment) to measure the space environment surrounding the S/C. TEDA monitors radiation absorption, memory malfunction, static charge voltage, and contamination, and analyzes heavy ions.

Data rates of ADEOS:

ADEOS provides on-board recording (MDR=Mission Data Recorder (three instruments) and LMDR = Low Speed Mission Data Recorder).

Observation data rates: AVNIR (M): 60 Mbit/s, AVNIR (P): 60 Mbit/s, OCTS: 3.0 Mbit/s. Polder: 0.882 Mbit/s. IMG: 0.9 Mbit/s. ILAS: 0.517 Mbit/s. NSCAT: 2.9 kbit/s. TOMS: 0.7 kbit/s.

Data links: Uplink frequency (S-band) = 2.0 GHz (CMD and ranging), downlink frequency = 2.2 GHz (TLM and ranging), command bit rate = 500 bit/s.

Science data transmission: 3 X-band links (8.15, 8.25, 8.35 GHz) with QPSK modulation. IOCS frequencies = S-band (low rate mission data), Ka-band (120 Mbit/s max).

D.2 ADEOS-II (Advanced Earth Observing Satellite-II)

A Japanese (NASDA) mission planned for launch in Feb. 2002 with a mission life of three years minimum [(five years goal), FedSat of Australia is a secondary payload on the mission].⁶⁰⁵⁾ As a successor mission to ADEOS, the objectives of ADEOS-II are to acquire data contributing for international global change research (carbon cycle and the water and energy cycle), as well as for applications in such fields as meteorology and fishery. ADEOS-II is the Japanese contribution in the framework of the International Earth Observation System (IEOS). Other parts of IEOS are EOS (USA), and the ENVISAT and MetOp programs of ESA and EUMETSAT respectively. The ADEOS-II mission is dedicated to the following programs: WCRP/GEWEX & CLIVER, IGBP and GCOS.

⁶⁰⁵⁾ "Monitoring the Earth Environment from Space," NASDA Bulletin

Figure 85: Illustration of the ADEOS-II spacecraft model

The ADEOS-II S/C employs the general design of ADEOS to reduce costs. Dimension of main S/C body: approximately 6 m x 4 m x 4 m. S/C mass = 3700 kg, payload mass = 1300 kg, power = 5 kW (EOL), launch vehicle = H-IIA rocket, launch site = TNSC (Tanegashima Space Center). Attitude and Orbit Control: The Attitude and Orbit Control Subsystem (AOCS) employs a three-axis strap down attitude detection system and zero momentum attitude control system achieving an attitude pointing error of less than 0.3° .

Communication: Mission data are downlinked in X-band to ground receiving stations. S-band is used for TT&C support. In addition there is communication via DRTS (Data Relay and Test Satellite) in Ka-band for mission data and S-band for TT&C data.

Orbit: Sun-synchronous subrecurrent orbit, altitude = 802.9 km, inclination = 98.62° , period = 101 minutes, recurrent period = 4 days, local time = 10:30 AM ± 15 minutes.

Sensor complement:

AMSR = Advanced Microwave Scanning Radiometer (passive NASDA core sensor) of MSR heritage on MOS-1 and -1B satellites. Objectives: measurement of sea surface temperature (SST), soil water content, sea wind speed, water equivalent of snow cover, precipitation intensity, sea ice distribution, precipitable water, etc. Microwave emission from the atmosphere, ocean, sea ice, and land are measured at multiple frequencies. From this information a number of geophysical data related to the Earth environment, such as water vapor content, water content of clouds, water equivalent of the snow cover, etc. are measured.⁶⁰⁶⁾ AMSR has a high-temperature calibration source (about 340 K) and a small reflector to acquire the radiant temperature of deep space (about 2.7 K). Each feed horn, from 6.9-89 GHz sees the calibration sources once per scan period. The total power receiver technique is employed for radiometric sensitivity. The antenna scans conically the Earth's surface at an incidence angle of 55° (a scan drive motor rotates the antenna, rotating mass is nearly 200 kg, momentum and torque compensation is achieved with momentum wheels).

⁶⁰⁶⁾ M. Nakajima, Y. Ito, H. Maejima, Y. Kojima, "The Development of AMSR and GLI for ADEOS-II," presented at the 45th Congress of the International Astronautical Federation, October 9-14, 1994, Jerusalem, Israel

Center frequencies, (GHz)	6.925	10.65	18.7	23.8	36.5	89.0	50.2	53.8
Bandwidth, (MHz)	350	100	200	400	1000	3000	200	400
Radiometric resolution	0.34 K	0.7 K	0.7 K	0.6 K	0.7 K	1.2 K	1.8 K	1.6 K
Spatial resolution (km)	50		25		15	5	10	
Antenna	offset parabolic, aperture diameter = 2 m, conical scan at 55° incid. angle							
Polarization	H/V (horizontal and vertical)						H (vertical)	
Antenna scan rate	40 rpm							
Cross-polarization	less than -20 dB							
Swath width	1600 km							
Dynamic range	2.7 K to 340 K							
Absolute accuracy	1 K (1 sigma)							
A/D quantization	12 bit	10 bit						
Data rate	130 kbit/s (CCSDS format, 14 channels of data acquisition)							
Instrument mass, power	320 kg, 400 W							

Table 139: AMSR parameter requirements

GLI = Global Imager (NASDA core sensor) of OCTS heritage on ADEOS. Objectives: Biological and physical processes, stratospheric ozone. GLI is for studying and monitoring the carbon cycle in the ocean, principally as to biological processes. Multispectral observations from the near UV to the near IR reflected solar radiation from the Earth's surface including land, ocean and clouds. Determination of chlorophyll pigment, phycobilin and dissolved organic matter (DOM) in the ocean; classification of phytoplankton according to their pigment. Measurement of sea surface temperature (SST), cloud distribution, land coverage, vegetation index, etc.

Spectral bands	
Visible and near infrared (VNIR)	23 bands (380 - 830 nm), 18 channels with 10 nm bandwidth
Short wavelength infrared (SWIR)	6 bands (1050 - 2215 nm)
Middle and thermal IR (MWIR, TIR)	7 bands (3.715 - 11.95 μ m) channels 0.33-1.0 μ m bandwidth
IFOV	1.25 mrad (or 1 km at nadir) for 28 bands 0.3125 mrad (or 250 m at nadir) for 6 bands
FOV	$\pm 43^\circ$ (swath = 1600 km)
A/D quantization	12 bit
Polarization sensitivity	< 2%
Registration among total bands	< 0.2 pixels
Data rate	4 Mbit/s (for 1 km resolution), 16 Mbit/s (250 m resolution)
Tilt angle	+ 20°, 0°, -20°
GLI scan mirror shape, size mass reflectance	Material: beryllium, surface coated with silver and SiO ₂ Elliptic flat mirror with both faces (600 mm x 260 mm) 2 kg (mirror), 0.8 kg (axis) Over 90% (370 - 400 nm) Over 95% (400 - 550 nm) Over 90% (550 nm - 14 μ m)
Instrument mass, power	450 kg, 400 W

Table 140: GLI parameter specification

GLI is an imaging spectrometer featuring a cross-track mirror and an off-axis parabolic mirror as the collecting optics and focal planes in which the detectors are arrayed in the along-track direction with spectral interference (dichroic) filters. The scan mirror rotates at 16.7 Hz. GLI can tilt the scan mirror $\pm 20^\circ$ from nadir in order to avoid sun glitter. GLI has five focal planes, two for VNIR, two for SWIR, and one for MWIR/TIR. Two VNIR focal planes have detector arrays for 13 and 10 bands respectively. Two SWIR focal planes have detector arrays for 4 and 2 bands, while the MWIR/TIR regions have one focal plane with a detector array for 7 bands. One SWIR and the MWIR/TIR focal planes are cooled to 220 K and 80 K by a multistage Peltier element and Stirling cycle mechanical cooler, respectively. The VNIR detector material is Si, the SWIR is InGaAs, the MWIR/TIR material is CMT. -

GLI employs piecewise linear method with cascade amplification for signal processing on four bands in order to meet requirements for automatic observation of objects with large radiance differences (ocean color and land vegetation) exhibiting a wide dynamic range. 607)

SeaWinds = NASA Scatterometer II (PI: M. Freilich, NASA/JPL - old designation: NSCAT II). Objective: to acquire accurate, high-resolution, global measurements of sea-surface wind vectors in 1 to 2 day repeat cycles. Applications: studies of tropospheric dynamics and air-sea interaction processes, including air-sea momentum transfer. Improvement of weather forecasts near coastlines by using wind data in numerical weather- and wave-prediction models. SeaWinds consists of three major parts: SAS (SeaWinds Antenna Subsystem), SES (SeaWinds Electronics Subsystem), and CDS (Command and Data Subsystem). The instrument is an active microwave radar (a scanning pencil-beam scatterometer) with dual-beam, 40° and 46° look angle from nadir, conical scan 1 m diameter reflector (dish) antenna, operating in Ku-band at 13.402 GHz (110 W pulse at 189 Hz PRF). Measurement of wind speeds between 3-20 m/s to an accuracy of 2 m/s, wind vector directions to an accuracy of 20°. The dish antenna is rotated about the satellite nadir axis at 18 rpm. Data is collected in a continuous 1800 km swath, centered about nadir. Spatial resolution = 50 km; IFOV = ±52° from nadir; mass = 200 kg; power = 220 W; duty cycle = 100%; average data rate = 40 kbit/s; thermal operating range is 5-40°C; pointing knowledge to 500 arcseconds. - SeaWinds data products consist of global multi-azimuth normalized radar cross section measurements and 50-km-resolution ocean vector wind maps. 608) 609)

ILAS-II = Improved Limb Atmospheric Spectrometer-II, the sensor is [funded by MOE (Ministry of the Environment)] of ILAS heritage on ADEOS. The spectrometer uses gratings for solar occultation measurements of polar stratospheric ozone, atmospheric trace gases (O₃, HNO₃, NO₂, N₂O, CH₄, H₂O, CFC-11, CFC-12, ClONO₂, etc.), aerosols, temperature and pressure. ILAS-II is used to monitor and study changes in the stratosphere which are triggered by emissions of CFC gases. 610) 611)

Spectrometer	4 grating spectrometers (VIS and IR)	
Spectral coverage	Band 1	44 IR channels from 6.21-11.76 μm (850-1610 cm ⁻¹) with 0.1296 μm interval
	Band 2	22 IR channels from 3.0 - 5.7 μm (1754-3330 cm ⁻¹)
	Band 3	22 IR channels from 12.78-12.85 μm (778.2-782.4 cm ⁻¹) with 0.2 cm ⁻¹ resol.
	VIS	1024 channels from 0.753 - 0.784 μm with 0.1 nm FWHM resolution
Telescope	Cassegrain, 13 cm diameter	
Sun tracker	pointing mirror: 20 (az.) x 17 (el.) cm; sun edge sensor, 8 arcsec resolution per pixel	
IFOV (at tangent height)	IR channels: 1 km (vertical) x 13 km (horizontal) (Band 1 and Band 2) 1 km (vertical) x 21.7 km (horizontal) (Band 3) VIS channels: 1 km (vertical) x 2 km (horizontal)	
Observation parameters	O ₃ , HNO ₃ , NO ₂ , N ₂ O, CH ₄ , H ₂ O, CFC-11, CFC-12, ClONO ₂ , aerosols, pressure and temperature	
Observation region	Latitudinal zones 56° - 70° N and 63° - 88° S	
Data rate	453.7 kbit/s, sampling rate at 10 Hz, CCSDS packeting	
Instrument operation	12 minutes per occultation (limb observations)	
ILAS mass, power, size	< 138 kg, < 120 W, 950 mm x 1670 mm x 600 mm

611) Y. Sasano, et al., "ILAS-II Instrument and Data Processing System for Stratospheric Ozone Layer Monitoring", Proceedings of SPIE, Vol.4150, pp.106-114, 2001

The instrument consists of the following elements: a two-axis gimbal mirror which is controlled to track the radiometer center of the sun, a 13 cm diameter Cassegrain telescope, beam splitters, and reflective transfer optics, three IR spectrometers, a VIS spectrometer, a sun-edge sensor, and signal processing units. The band 1 and 2 spectrometers employ a Czerny-Turner type spectrograph design with a plane grating in 30 gr./mm for band 1; the detector material for both bands is PbTiO₃. The band 3 spectrometer employs an echelle grating with 23.2 gr./mm. The VIS spectrometer uses a holographic concave grating (f/8.0, f=400 mm, 1800 lines/mm) with a 1024 pixel MOS photo diode array detector. The VIS spectrometer is self-calibrating using the information on the solar Fraunhofer lines. Instrument spectral coverage: 3-12.85 μ m and 753-784 nm, spatial coverage = 10 - 60 km, vertical resolution = 1 km, observation accuracy = 5% (1% for ozone). The prime contractor for ILAS-II is MEI (Matsushita Electric Industrial Co. Ltd.).⁶¹²⁾

POLDER (Polarization and Directionality of the Earth's Reflectances), passive optical imaging radiometer of CNES.

Receiving Frequency	401.65 MHz \pm 0.0405 MHz
Receiving Signal Bit Rate	400bit/s
Receiving Signal Modulation Mode	PCM(Bi phi -L)/PM
Receiving Signal Bit Error	below 1×10^{-5}
Transmitting Frequency	465.9875 MHz
Transmitting Power	over 5 W
Transmitting Signal Bit Rate	200 bit/s
Transmitting Signal Modulation Mode	PCM(Bi-L)/PM
UHF Antenna	Formed broad beam pattern
G/T	over -36.6 dBk
EIRP	over 27.1 dBm

Table 142: Some DCS characteristics

DCS = Data Collection System (NASDA/CNES joint development). The DCS offers worldwide capabilities for location and environmental data collection for fixed and moving platforms. The downlink frequency = 460-470 MHz with a data rate of 200 bit/s is added to the existing ARGOS. The received frequency of the DCP (Data Collection Platform)= 401.65 MHz, the data rate of the DCP=400 bit/s. Total DCS instrument mass = 76 kg, power consumption = 60 W.

D.3 ALOS (Advanced Land Observing Satellite)

ALOS is a Japanese Earth-observation satellite, developed by NASDA, manufactured by NEC, Toshiba, and Mitsubishi Electric Corp. The objectives call for an optical and microwave sensor payload who's high-resolution data may be used for such applications as cartographic mapping, environmental and hazard monitoring (within 48 hours). The intent is to provide the user community with data of sufficient resolution to be able to generate 1:25,000 scale maps. This in turn requires observational data of 2.5 m horizontal resolution for the determination of land conditions, and a 3-5 m vertical accuracy for contour mapping. Multispectral data with 10 m horizontal resolution is needed for the classification of land cover (vegetation, forests, etc.). Short-term hazard monitoring (within 24 hours on average) will be accommodated by the use of pointing mechanisms. Particular application features of the ALOS mission are:

- The mapping of land areas (without the need for ground control points)
- The monitoring of disasters (as a complement to the capabilities of other spacecraft)

⁶¹²⁾ <http://www.ilas2.nies.go.jp/>

Figure 86: Illustration of the ALOS S/C model

The S/C structure consists of CFRP (Carbon Fiber Reinforced Plastic) trusses and aluminum fittings. The approximate S/C dimensions in the stowed configuration are: 6.4 m x 3.4 m x 4.3 m (x, y, z); the in-orbit configuration dimensions are: 8.9 m x 27.4 m x 6.2 m (x, y, z, where x is in the velocity direction and z is toward nadir). The ALOS S/C requires in particular precise attitude and position determination to minimize image quality degradation. This is provided by star trackers, carrier phase tracking of a GPS receiver, and by an IRU (Inertial Reference Unit). The actuators used are: reaction wheels, magnetic torque rods and hydrazine thrusters. A short-term attitude stability of $\pm 0.00002^\circ/0.37$ ms (3 sigma) is provided; the long-term stability is $\pm 0.0002^\circ/5$ s (3 sigma). The pointing accuracy knowledge is $\pm 0.0002^\circ$, and the spacecraft position accuracy knowledge is ± 1.0 m. The dual-frequency carrier-phase tracking GPS receiver of Toshiba Corp. is used for orbit determination. The S/C mass is 4000 kg (at lift-off), the largest satellite ever for Japan. Its 22 m long solar array generates power of 7 kW (EOL). The design life is 3 years with a goal of 5 years. ^{613) 614)}

A launch of ALOS is planned for mid-2003 by a Japanese H-IIA rocket from Tanegashima Space Center, Japan. ^{615) 616)}

Orbit: Sun-synchronous near-recursive circular orbit, altitude = 692 km, inclination = 98.16° , repeat cycle = 46 days (with a sub-cycle of 2 days), local time at descending node 10:30 AM (± 15 min).

Communication: The primary data transmission link is via DRTS (Data Relay and Test Satellite of Japan) in Ka-band for mission data at 240 Mbit/s, and S-band for TT&C data. In addition there is an X-band downlink for maximum data rates of 120 Mbit/s. This is considered a backup only for AVNIR-2 data. A further Ka-band downlink at 120 Mbit/s is considered via the Artemis relay satellite of ESA. - ALOS is equipped with a solid-state recorder with a capacity of 768 Gbit using 64 Mbit DRAM technology. The storage capacity is suffi-

cient for a 50 minute recording of a 240 Mbit/s data stream. The data rate capabilities of the recorder are: 360 Mbit/s for recording and 240 Mbit/s for readout of playback data.

Sensor complement:

PRISM (Panchromatic Remote-sensing Instrument for Stereo Mapping). The objective is to obtain high-resolution stereo data (pixel size of 2.5 m) for cartographic applications (extraction of highly accurate digital elevation models, etc.). The instrument is a “three-line sensor” with three independent catoptric systems for nadir, forward and backward-looking to achieve along-track stereoscopy. Each of the three telescope employs a three mirror type optics design (30 cm aperture diameter and 2 m focal length) and several CCD detectors for pushbroom scanning. Eight silicon CCDs (5000 pixels each) are physically aligned at each telescope’s focal plane. Of the 40,000 pixels per telescope, 14,000 pixels are electronically selected and transferred to the ground station. Thus, a triplet image consists of three (fore, nadir aft-looking) 14,000 pixels/line. - The nadir-looking telescope provides a swath of 70 km width (28,000 pixels per band), each of the fore and aft-looking telescopes provides a swath of 35 km (14,000 pixels per band). The fore and aft telescopes are inclined by $\pm 24^\circ$ from nadir to realize a base to height/ratio of one at an orbital altitude of 692 km.

Figure 87: Illustration of the PRISM instrument and imaging configuration

Parameter	Panchromatic Sensor
Spectral band (panchromatic)	0.52-0.77 μm (nadir, forward, backward)
SNR, MTF	>70, >0.2
IFOV	2.5 m (3.57 μrad)
Swath width	35 km (triplet stereo observations), 70 km for nadir observations)
Gimbal angle	$\pm 1.5^\circ$ (cross-track)
Data quantization	7 bits
Data rate	1 Gbit/s of raw data, a lossy (DCT and Huffman coding) data compression technique reduces the actual downlink data rate of PRISM to either 240 Mbit/s (1/4 reduction) or to 120 Mbit/s (1/8 reduction)

Table 143: PRISM parameters

The PRISM optics are mounted on a rigid optical bench which is thermally controlled within $\pm 3^\circ\text{C}$ to minimize distortions in the optics system.

Calibration: PRISM has electrical calibration sources on-board. They are used to estimate gain and offset of the amplifiers. For absolute and relative radiometric calibration, PRISM uses AVNIR-2 data. AVNIR-2 is calibrated using internal calibration lamps.

Note: PRISM is now a separate sensor with stereo capability what used to be the Panchromatic Sensor of AVNIR-2.

AVNIR-2 (Advanced Visible and Near-Infrared Radiometer - 2), a NASDA instrument of AVNIR heritage, built by Mitsubishi Electric Corporation. Objective: provision of high-resolution (10 m) multispectral data. The instrument optics are of “folding Schmidt” type. The telescope aperture is 24 cm in diameter, it has a focal length of about 800 mm. AVNIR-2 features a pointing capability of $\pm 44^\circ$ in the across-track direction, thereby providing a wide field of regard for disaster monitoring. The silicon CCD detector arrays have 7000 pixels per line. Applications: monitoring of regional environment (land coverage and land-use maps, etc.). A quasi-lossless data compression technique of DPCM (Differential Pulse Code Modulation) with Huffman coding is employed for a source data reduction from 160 Mbit/s to 120 Mbit/s.

Calibration: AVNIR-2 uses two on-board calibration lamps which are used for absolute and relative calibration sequences. In addition, internal electrical calibration is provided.

Parameter	Multispectral Sensor
Spectral bands (4)	
Band 1	0.42-0.50 μm
Band 2	0.52-0.60 μm
Band 3	0.61-0.69 μm
Band 4	0.76-0.89 μm
SNR	>200
IFOV (spatial resolution)	10 m (at nadir, 14.3 μrad)
Swath width	70 km
Gimbal angle	$\pm 44^\circ$ (cross-track)
MTF (Modulation Transfer Function)	Band 1-3 $\Rightarrow >0.25$; band 4 $\Rightarrow >0.20$
Data rate	about 160 Mbit/s of raw data, a quasi-lossless (DPCM) data compression technique reduces the actual downlink data rate of AVNIR-2 to 120 Mbit/s (3/4 reduction)

Table 144: Some characteristics of the AVNIR-2 instrument

PALSAR (Phased Array L-band Synthetic Aperture Radar), developed jointly by NASDA and JAROS (Japan Resources Observation System Organization), heritage of SAR on JERS-1. PALSAR is a side-looking phased array L-band instrument with a pointing capability from 8 to 60° of incidence angle. The antenna is of size: 8.9 m (length, along-track direction) and 3.1 m in width. An array of 80 transmitting/receiving modules is mounted behind the antenna panels. PALSAR features a ScanSAR mode (employing the active phased array technique) permitting extended observation coverage of at least 250 km swath width. The instrument performance parameters for high-resolution mode at a standard incidence angle of 39° are: 10 m spatial resolution, 70 km swath width, and -23 dB NE sigma-zero.

Parameter	High-resolution Mode		ScanSAR Mode	Polarimetry
Center frequency	1270 MHz (L-band)			
Bandwidth	30 MHz			
Polarization	HH or VV	HH/HV or VV/VH	HH or VV	HH/HV + VV/VH
Spatial resolution (range)	7.0-44.3 m	14.0-88.6 m	≤ 100 m	24.1-88.6 m
Number of looks		2	8	
Swath width	40 - 70 km		250-350 km	30 km
Incidence angle	8° - 60°		18° - 43°	8° - 30°

Parameter	High-resolution Mode	ScanSAR Mode	Polarimetry
Data quantization	3/5	5	3/5
Data rate	120 Mbit/s / 240 Mbit/s		240 Mbit/s

Table 145: Parameters of the PALSAR instrument

The ALOS instruments are capable to observe the surface of the entire world within the following limits:

- Any place within two days
- Around the equator: about 60% of the area within one day
- At latitudes of 35°: about 70% of the area within one day
- At latitudes larger than 55°: any place every day (provided there is no cloud cover for the optical instruments).

Daytime observation modes: PRISM (fore, nadir & aft) and AVNIR-2 simultaneously

Nighttime observation modes: PALSAR (Note: AVNIR-2 and PALSAR are able to operate simultaneously).

Data policy:

The significance of ALOS is its ability to provide global coverage of land observation and to transmit this huge amount of data acquired. NASDA seeks to implement the ALOS Data Node concept for processing and utilizing ALOS data through international cooperation. The Data Node consists of one representative organization in each region and cooperative organizations including the data distributors. All the ALOS data is downlinked to NASDA's Earth Observation Center (EOC) via a data relay satellite. NASDA will transfer the regional level-0 data it has obtained to the ALOS Data Node. The ALOS Data Node is responsible for providing regional level-1 data upon request from data users, including NASDA, throughout the ALOS mission life. The current plan is to divide the entire world into four regions: Asia, Europe and Africa, North and South America, and Australia and Oceania. The Data Nodes would serve both as a regional ALOS data center and a scientific research center.⁶¹⁷⁾

The main concept of the ALOS data policy should be that each Data Node would be allowed to handle their regional data according to its own data policy. International talks on this concept are about to produce an agreed inter-Node distribution policy defining an interface where the respective regional policies will meet. The whole mechanism will be a combination of de-centralized research and non-research data distribution. A private consortium may be established for promoting commercial data use.

At a multilateral level, nations have not been able to reach a coherent, effectively functioning data policy despite decades of lengthy discussions. If this Data Node concept is successfully implemented, it may demonstrate an effective model of a program-oriented approach to an integrated, disseminated data policy.

D.4 ALMAZ Program

Background: The ALMAZ (=“diamond”) Earth Resources Satellite program of the former Soviet Union did not start with the launch of ALMAZ-1 in March 1991. At NPO Machinostroyenia in Reutov near Moscow, S/C of the ALMAZ series have been developed for more than 25 years. The program is based on the technical experience gained at NPO Machinostroyenia when developing manned and automatic space stations - the Salyut Space Stations of the 60's and 70's were a very essential part of the ALMAZ program. The former

⁶¹⁷⁾ Information provided by the NASDA ALOS team (Naoto Matsuura) during the review process of my ALOS draft

USSR needed an all-weather remote sensing capability based on SAR technology, due to the cloud coverage conditions predominant in the northern latitudes of its land mass. Even today (1993), ALMAZ automatic (i.e. unmanned) spacecraft are actually of the type 'Salyut space station' - a proven technology - such a S/C can even be visited by a crew in case of serious problems.

Some of the ALMAZ program objectives:

- Development of a series of automatic space stations on the basis of a universal ALMAZ platform
- Development of a sensor complement with upgrading capability in sensor performance characteristics with regard to spatial resolution, coverage, spectral characteristics, etc. Increase in the number of instruments and the number of solvable tasks with every mission.
- Development of a data system on-board and on-ground and a corresponding infrastructure to cope with the vast volumes of data.
- Provision of an all-weather remote sensing capability to support the following tasks:
 - Prospecting for natural resources for many sectors of the national economy
 - Collecting of remote sensing data for ecological analysis and applications
 - Observing natural catastrophes/disasters of immediate interest.

D.4.1 COSMOS-1870 (also Kosmos-1870)

This mission is regarded as the first USSR radar mission (ALMAZ prototype mission). The S/C was launched on July 25, 1987 with a Proton vehicle from the Baikonur Cosmodrome launch facility; the COSMOS-1870 mission ended July 30, 1989.

Orbit: altitude = 275 km, inclination = 73°, orbital period = 92 minutes

Spacecraft mass = 18550 kg, payload mass = 1950 kg, design life = 2 years, attitude precision = 15-20', stabilization precision = 4-6'.

Sensor:

- **SAR** = Synthetic Aperture Radar (S-band; freq. = 3.125 GHz, instrument built by NPO Vega, Moscow). Wavelength = 9.6 cm, spatial resolution = 20-25 m, swath width = 20 km.

The S/C carried two SAR instruments, one on each side for surveying. The S/C had the capability to roll about its axis, thereby extending the pointing range of the SAR antennas in the cross-track direction to 250 km field of regard (swath width is nearly constant at 20 km). The S/C had three tons of fuel on board permitting many roll maneuvers for this type of operational support.

Data: On-board recording capability and subsequent stored data dump during passes over ground stations, or real-time data transmission. Data transmission rate: 90 Mbit/s.

D.4.2 ALMAZ-1

ALMAZ-1⁶¹⁸⁾,⁶¹⁹⁾,⁶²⁰⁾,⁶²¹⁾,⁶²²⁾,⁶²³⁾ was launched on March 31, 1991 (Proton booster from the Baikonur Cosmodrome launch facility, ALMAZ S/C designer and builder: NPO Machinostroyenia, Reutov, Moscow Region), the operational phase started in May 1991. End of mission: Oct. 17, 1992 (controlled descent into the Pacific ocean due to lack of fuel).

622) "Sowjetisches Weltraumauge sammelt Ströme digitaler Daten," VDI Nachrichten, 21. Dez., 1990, Seite 20

The ALMAZ-1 S/C has a total mass of 18550 kg, and a payload mass of 3420 kg. Attitude precision = 15-20', stabilization precision = 4-6'. The stabilization precision during the SAR operation is 1 arcmin.

ALMAZ-1 is considered an important operational satellite (after SEASAT in 1978, SIR-A in 1981, SIR-B in 1984 and Cosmos-1870 in 1987) with a radar sensor for Earth observation. The Soviet space agency Glavkosmos has contractual agreements (Western marketing rights for Almaz data) with Almaz Corp., a subsidiary of the Houston-based Space Commerce Corp. (SCC). The Radar data of ALMAZ are complementary to the SPOT and Landsat data. ALMAZ-1 data are also considered to be in direct competition with ERS-1 and JERS-1 data.

Figure 88: The Almaz-1 S/C model and its SAR sensor's observation geometry

Application: oceanology (study of the distribution and dynamics of currents and hydro-spheric fronts, the spatial structure of wave formations and turbulence, the evaluation of surface winds and hurricanes, the topography of the ocean floor and its effects on wave patterns at the surface, the identification of oil spills and other forms of pollution, the state of the ice cover and its seasonal variations, boundaries of water exchange of rivers with the ocean, etc.); geology (structure of geological formations (such as folds, valleys and fractures) and the nature of volcanic activity, survey of mineral deposits, etc.); cartography and

geophysics (topographical maps, climatic changes (such as ice thawing and desertification)); agriculture and forestry (large scale evaluation of agricultural lands and crops, over-all volume of the biomass in a region, soil moisture conditions, etc.); statistics, ecology, etc.

Orbit: Inclination = 72.7°; altitude = 270-380 km, Orbital period = 92 Minutes;

Sensor complement:

- **SAR** = Synthetic Aperture Radar (S-band; freq. = 3.125 GHz, wavelength = 9.6 cm, built by NPO Vega).
 - Resolution = 10-15 m (depending on range and azimuth).
 - SAR images can be taken from each side of the satellite; the swath width of each SAR is 40 km within a field of regard (FOR) of 350 km (obtained by rolling the S/C)
 - Observation (incidence) angles: 30-60°
 - Radiometric resolution: 2-3 dB
- **UHF Radiometer.** Wavelengths of 0.8 cm, 5 cm, 11 μm, 12 μm, and 13.7 μm (or 37.5 GHz, 6 GHz, 2.72 THz, 2.5 THz, and 2.19 THz, respectively); swath width = 10-30 km, FOR = 500 km; temperature resolution = 0.1 - 0.3 K, spatial resolution = 5km. Objective: compilation of an Earth surface temperature map.

Data: Ground station in Moscow Region. The ALMAZ-1 schedule calls for a transmission of 60 images (=scenes per day). A scene = 40 km x 300 km. Data rate: 10 Mbit/s. Operational modes: on-board data recording and subsequent transmission via relay satellite to a DRP (Data Reception Point).

D.5 BADR-B

BADR-B, a follow-up of the Pakistani BADR-A microsatellite, in collaboration with European industry and science institutes. SIL (Space Innovations Limited) of Newbury, UK provided the satellite bus, the spacecraft integration was performed by SUPARCO (Pakistan Space and Upper Atmosphere Research Commission), demonstrating the use of relatively inexpensive microsatellite missions in the field of space technology transfer. Prime objectives of the Badr-B mission are: ⁶²⁴⁾ ⁶²⁵⁾

- Commencement of an indigenous development capability of low-cost satellites and creation of a needed infrastructure for future development in this field
- Acquisition of know-how in all fields of satellite and instrument design/development.

Background: BADR-A, a microsatellite of 52 kg (an experimental digital communications satellite built by SSTL of Surrey, UK), was launched July 16, 1990 as a secondary payload on a Chinese booster (Long March 2) from Xichang, China, into an elliptical orbit (perigee of 208 km, apogee of 988 km, inclination of 28.5°). The S/C operated until Aug. 21, 1990; it ceased functioning due to an on-board subsystem failure.

BADR-B is a gravity-gradient stabilized small Earth Observation satellite (the S/C is spin-stabilized prior to boom deployment). The S/C bus structure is polyhedral in shape fabricated from aluminum alloy (T6061). The bus has a size of 51 cm x 51 cm x 46.5 cm. Most subsystems are mounted onto a central shelf, which is attached to a thrust tube; its base contains a strong-ring, forming part of the separation system. The boom has a length of 6 m, it is mounted within the thrust tube and deploys through the strong-ring. The Earth-pointing face of the S/C accommodates the communication antennas (VHF, UHF, and S-band), the magnetometer, and the CCD camera. S/C power is provided with GaAs solar panels mounted on the external surface of the S/C bus. Attitude sensing is provided by a pair of two-axis digi-

⁶²⁵⁾ <http://www.sil.com/PROJECTS.htm>

tal sun sensors and by a three-axis fluxgate magnetometer. Actuation is achieved by a pair of magnetorquer rods and by the gravity-gradient boom (4 kg of tip mass). The satellite mass is 70 kg, and produces 25W of average power.

RF communications: S-band telemetry and telecommand, VHF/UHF store-and-forward operations.

S-band uplink freq.	2061.976 MHz	UHF uplink frequency	449.850 MHz
Subcarrier modulation	PSK	Subcarrier modulation	FSK
Carrier modulation	PM	Carrier modulation	FM
Data rate	4 kbit/s max.	Data rate	1.2 kbit/s
Line coding	SP-L	Line coding	NRZ-L
S-band downlink	2239.250 MHz	VHF downlink	143.625 MHz
Subcarrier modulation	None	Subcarrier modulation	FSK
Carrier modulation	BPSK	Carrier modulation	FM
Data rate	150 kbit/s max	Data rate	1.2 kbit/s
Line coding	SP-L	Line coding	NRZ-L
S-band beacon	2250 MHz on +17 dBm carrier		

Table 146: Overview of communication parameters

BADR-B will be launched on a Zenit-2 launch vehicle from Baikonur as a secondary payload in 2001. The prime payload on this flight is METEOR-3M-1 of Russia; other secondary payloads are: Compass of IZMIRAN, Moscow, Maroc-Tubsat of Morocco, and REFLECTOR (Russian/US microsatellite).

Orbit: Sun-synchronous polar orbit, altitude = 830 km, inclination = 98.85°, period = 102 minutes.

Sensor complement:

EIC (Earth Imaging Camera), developed at RAL. EIC utilizes a wide-angle CCD array camera with an instrument mass of 2.5 kg. The camera operates at visible wavelengths and uses a large format CCD to achieve 250 m x 250 m resolution on the ground with a field of view of $\pm 8.5^\circ$ (equivalent to 194 x 144 km on the ground). The challenge in designing and building this instrument has been the need to maintain performance with restrictions on the available space, mass, power and schedule. Snapshot imagery can be provided from any part of the globe, stored on-board and later transmitted to the ground.⁶²⁶⁾

CDE (Compact Dosimeter Experiment). The objective is to measure ionizing radiation levels encountered in polar orbits. The total accumulated dose is measured with miniature RadFET (Radiation-sensitive Field Effect Transistor) sensors based on pMOS technology, installed at various spacecraft locations (total of 8 RadFETs).

S&FE (Store & Forward Experiment). The objective is to provide point-to-point communications for 5-7 users. It consists of a UHF/VHF communications system linked to the on-board computer. The system permits uplinking of encoded information along with recipient address. The information is downlinked when the S/C is in reach of the recipient user location.

Battery End-of-Charge Detector. The objective is to monitor the battery charge status. The technique employed is to monitor the temperature of the battery. It detects a small rise in temperature at the end of the battery charge sequence and acts for overcharge protection.

Figure 89: Illustration of the camera head and the compact electronics control unit

D.6 Bhaskara

In 1975, ISRO (Indian Space Research Organization) started the design and development of two experimental Earth observation satellites, Bhaskara-I (launch June 7, 1979), and Bhaskara-II (launch Nov. 20, 1981). The objective of the program was to develop an initial capability of satellite/instrument building, to gain hands-on experience in satellite operations, and to develop a capability/infrastructure for data reception, processing, evaluation and interpretation on practical remote sensing applications (oceanography, atmosphere, etc.).^{627) 628)}

The Bhaskara satellites were spin-stabilized [heritage and design of the first Indian satellite, *Aryabhata*,⁶²⁹⁾ launch April 19, 1975, orbital altitude of 400 km, inclination of 50.7°, mass = 360 kg, Aryabhata was instrumented to explore the Earth's ionosphere, measure neutrons and gamma rays from the sun, and perform investigations in x-ray astronomy], generated 47 W of power from silicon solar panels, and used NiCd batteries for orbital eclipse periods. The S/C spin axis was maintained at right angles to the orbital plane. The S/C structure was a quasi-spherical polyhedron, 1.59 m in diameter and a height of 1.19 m. The mass of each S/C was 444 kg, the design life was one year. The attitude control system employed cold gas jets in combination with a nutation damper and magnetic bias coils. The Bhaskara satellites were launched on a Vostok vehicle from the Kapustin Yar Cosmodrome (provided by the USSR) within the Intercosmos program.

S/C Communication: VHF antenna; low bit rate telemetry at 224 bit/s in PCM/FM/PM modulation; high bit rate at 91.4 kbit/s in PCM/PSK modulation. Telecommand in PCM/FSK/AM modulation. Data reception at SAC and at SHAR (Sriharikota, East coast launch facility of ISRO), mission control and operations from SAC (Space Applications Center, Ahmedabad). The Bhaskara-I satellite was formally turned off in March 1981.

Orbit: Near circular orbit, altitude = 557 km (572 km for Bhaskara-II), inclination = 50.7°, period = 95.2 minutes.

⁶²⁷⁾ Information provided by George Joseph of ISRO

⁶²⁸⁾ "Bhaskara - Satellite for Earth Observations," ISRO publication, June 1979

⁶²⁹⁾ Aryabhata (476-550) and Bhaskara (1114-1185) were two ancient mathematicians and astronomers of India. Aryabhata is the earliest Hindu mathematician whose work and history are available to modern scholars. He was one of the first known to use algebra. Bhaskara ("The Learned") was the leading mathematician of the 12th century, who wrote the first work with full and systematic use of the decimal number system.

Sensor complement:

Vidicon TV Camera, PI: George Joseph. Objective: Collection of Earth surface imagery for use in geology, forestry and land use. The two camera assembly was of RBV type, providing framing imagery with a slow scan vidicon coupled to an image intensifier (exposure is achieved by electronically gating the intensifier). The optical axis of the camera was normal to the spin axis of the S/C, providing a 'look' along the local vertical once every spin. Focal length of the imaging lens = 18.46 mm, FOV = 49.37°, f/1.9. Spectral channels: 0.54 - 0.66 µm (camera-1) and 0.75 - 0.85 µm (camera-2). An image frame had the size of 341 km x 341 km for an orbital altitude of 525 km (typical overlap of imagery about 10%), the spatial resolution was about 1 km. The instrument provided commandable exposure control (1, 1.5 or 2 ms). Power = 225 W, mass = 44 kg.

SAMIR (Satellite Microwave Radiometer), developed at ISRO/SAC, PI: P. N. Calla.⁶³⁰⁾ A nadir-pointing three-channel Dicke-type passive radiometer with the objective to measure atmospheric water vapor (liquid content), surface rain and wind (ocean surface studies). Frequencies at 19, 22, and 37 GHz. Ground resolutions (footprint) were 125 km for the 19-GHz channel, 150 km for the 22-GHz channel, and 230 km for the 37-GHz channel. Swath widths were 300 km and 230 km.

In addition, the following experiments (secondary payloads) were conducted on the Bhas-kara platform: Heat Pipe Experiment, Solar Cell Experiment, X-Ray Sky Monitor Experiment (objectives: investigations on transient X-ray sources and on the long term variability of steady X-ray sources in the energy range of 2 to 10 keV), Thermal Control Coating Experiment, and a DCS (Data Collection System) experiment (downlink frequency at 136.43 MHz, uplink frequency at 402.5 MHz) for data collection from remote platforms in India.

D.7 CBERS (China/Brazil - Earth Resources Satellite)

CBERS is a cooperative program between the People's Republic of China, PRC (CAST) and Brazil (INPE), it was started in 1988 to establish a complete remote sensing system (space and ground segment) to supply both countries with multispectral remotely sensed imagery. Prior to the international cooperative program of CBERS, there existed already a Chinese program, referred to as **Zi Yuan** or simply **ZY**, meaning **resource** in Chinese. The satellite (ZY-1) of this program came to be known as CBERS-1.^{631) 632) 633) 634) 635) 636)}

D.7.1 CBERS-1

The first satellite, CBERS-1, was launched Oct. 14, 1999 (along with SACI-1 as a piggyback payload) by a Chinese launch vehicle (CZ-4 series) from the Taiyuan launch site in China's Shangxi province.

The CBERS-1&2 S/C is composed of two modules. The payload module houses the optical and electronic systems used for Earth observation and for data collecting. The service module incorporates the equipment that ensures the power supply, the control, the telecommunications and all other functions needed for the satellite operation. The main S/C character-

630) In the Sanskrit language, SAMIR means "breeze"

istics are: three-axis stabilized, satellite mass = 1450 kg, power = 1100 W (solar), in addition there are two NiCd batteries with 30 Ah of energy. S/C body dimensions: 1.8 m x 2.0 m x 2.2, the solar array has a size of 6.3 m x 2.6 m. The hydrazine propulsion system has 16 thrusters of 1 N and 2 thrusters of 20 N each. The nominal design life is 2 years.

Figure 90: The CBERS/Ziyuan-1 spacecraft model

Orbit: Sun-synchronous orbit; altitude = 778 km; inclination = 98.5°; nodal period = 100.26 min; mean local solar time at descending node=10:30 AM; revisit period=26 days.

Objectives: Observation and monitoring of the Earth's resources and environment with a multi-sensor imaging payload providing different spatial resolutions.

Sensor complement: CBERS features a multisensor payload with imaging sensors of different spatial resolutions and collection frequencies.

Parameter	Band	Wavelength	Radiance (W/m ² sr)		SNR (dB)	
			Maximum	Minimum	Maximum	Minimum
MS band	B1	0.42-0.52 μm	28.7	4.6	48	32
	B2	0.52-0.59 μm	30.1	3.7	50	31
	B3	0.63-0.69 μm	25.9	2.4	48	26
	B4	0.77-0.89 μm	35.6	2.7	52	29
PAN band	B5	0.51-0.73 μm	55.6	9.0	53	37

Table 147: Spectral parameters of HRCC

HRCC (High Resolution CCD Camera), prime sensor on CBERS, developed and built by the Beijing Institute of Space Machines and Electricity and sponsored by CAST (Chinese Academy of Space Technology).⁶³⁷⁾ The multispectral instrument consists of the following main subsystems: optical, beam-splitting, detection, and an electronics unit; the auxiliary subsystems are: the side-looking reflector, relative calibration mechanism, focusing device, and a thermal control subsystem. Telescope focal length=520 mm (all refracting lens system); aperture=f/4; spatial resolution = 19.5 m (at nadir); IFOV=25 μrad; FOV = 8.4°; temporal resolution=26 days (nadir view), off-nadir view (pointable side-looking capability of ±32°, providing an increased observation frequency for a given region - any phenomenon or event detected by WFI may be zoomed by HRCC) minimum time lag of 3 days;

⁶³⁷⁾ D. Lin, S. Cui, "CCD Camera for CBERS," Proceedings of the Asian Conference on Remote Sensing, Hongkong, Nov. 1999, pp. 285-288

swath width = 113 km; objective: high resolution imaging. The pushbroom detector subsystem uses a Fairchild detector array (CCD-143A) with a pixel size of $13\ \mu\text{m} \times 13\ \mu\text{m}$. There are a total of five bands with 5812 pixels per band. Calibration: a tungsten filament lamp of known spatial profile provides illumination of the CCD arrays. Absolute calibration is made using a ground test site.

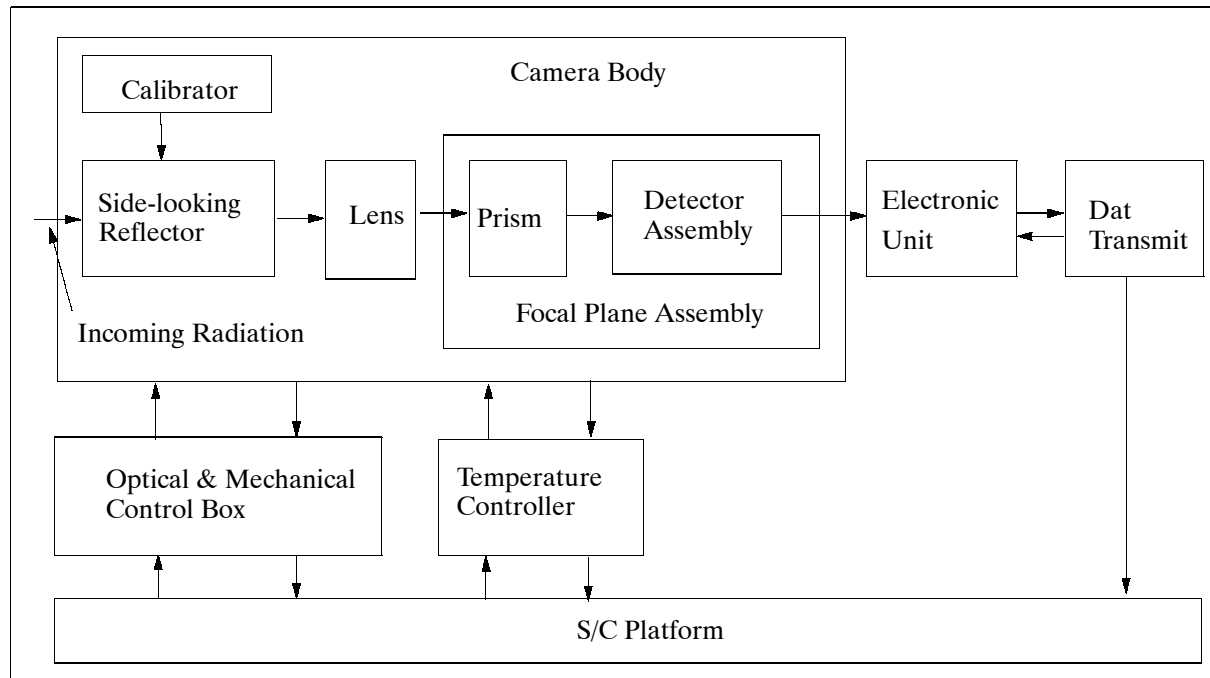

Figure 91: Block diagram of HRCC

IRMSS (Infrared Multispectral Scanner), developed and built by the Beijing Institute of Space Machines and Electricity and sponsored by CAST.⁶³⁸⁾ The instrument is an optomechanical system, consisting of a main module [scan mirror, primary optics (Ritchey Chretien telescope), prime focal plane assembly, relay optics, detectors, etc.], an electronic unit, an on-board calibration assembly, a radiative cooler, and a thermal control unit. The telescope has an aperture diameter of 250 mm and a focal length of 1 m for the Pan and SWIR bands, and 0.5 m for the TIR (Thermal Infrared) band. The telescope mirrors are made of fused silica and held by an invar structure. There are four spectral bands: 0.50-1.1 μm (panchromatic), 1.55-1.75 μm (SWIR), 2.08-2.35 μm (SWIR), 10.40-12.50 μm (TIR); spatial resolution: = 78 m for (0.5 - 2.35 μm ranges), 156 m for the TIR band; temporal resolution = 26 days; swath width = 120 km; IFOV=0.1 mrad (0.2 mrad for TIR band); FOV = 8.78°; objective: medium resolution imaging (complementary information to HRCC). The data rate of IRMSS is 6 Mbit/s.

The linear scan mirror performs cross-track scanning at a scan rate of 5.39 Hz and a scan angle of $\pm 2.5^\circ$. Each of the four bands employs an eight-element staggered detector array in the along-track direction. For the TIR band, four of the eight detectors are spares. The Pan band detectors use silicon photodiodes, photovoltaic HgCdTe detectors are used for the SWIR bands, while the TIR band utilizes photoconductive HgCdTe detectors. The detector size is 0.1 mm x 0.1 mm for all bands.

The radiation from the prime focal mirror is divided into three parts by relay optics. IRMSS features three focal plane assemblies (Pan, SWIR and TIR). The Pan band is in the warm FPA while the SWIR and TIR bands are located in the cooled FPAs with temperatures of 148 K and 101 K, respectively. Active and passive thermal control methods are employed.

⁶³⁸⁾ W. Huaiyi, M. Wenpo, "The IRMSS for CBERS," Proceedings of the Asian Conference on Remote Sensing, Hongkong, Nov. 1999, pp. 902-905

The on-board calibration system is used to correct the output changes of the scanner in flight. It includes an internal calibrator (lamp and blackbody) and a solar calibrator. The calibration precision is 3% for both, the band-to-band and the channel-to-channel calibration. The absolute calibration accuracy is <10%. Internal calibration occurs at every return stroke of the scan mirror, sun calibration is performed occasionally on ground command.

While IRMSS employs the same principles as the MSS and TM instruments on the Landsat series, it differs in many ways in the implementation approach such as in the three-level FPAs, the SWIR detectors, the relay optics, and the calibration system.

Parameter	HRCC	IRMSS	WFI
Spectral bands (μm)	0.51 - 0.73 (PAN) 0.45 - 0.52 0.52 - 0.59 0.63 - 0.69 0.77 - 0.89	0.50 - 1.10 (PAN) 1.55 - 1.75 (SWIR) 2.08 - 2.35 (SWIR) 10.4 - 12.5 (TIR)	0.63 - 0.69 0.76 - 0.90
Spatial resolution	20 m	80 m (PAN & SWIR) 160 m (TIR)	260 m
Swath width (FOV)	113 km (8.32°)	120 km (8.78°)	885 km (60°)
Temporal resolution	26 days	26 days	3-5 days
Cross-track pointing	±32°		
Data rate	2 x 53 Mbit/s	6.13 Mbit/s	1.1 Mbit/s
Carrier frequency (X-band)	8.103 and 8.321 GHz	8.216 GHz	8.203 GHz
EIRP	43 dBm	39.2 dBm	31.8 dBm
Modulation	QPSK	BPSK	QPSK
Tracking beam frequency	8.196 GHz	8.196 GHz	8.196 GHz

Table 148: Overview of CBERS imaging instruments

WFI = Wide-Field Imager (INPE). WFI is also a complementary sensor to HRCC. It consists of an electro-optics module (optics, spectral filters, CCD detectors, and radiometric calibration device), a signal processor and a modulator. Spectral bands: 0.63-0.69 μm, 0.77-0.89 μm; spatial resolution = 260 m (3456 pixels per line); temporal resolution = 3-5 days; swath width = 885 km (FOV = 60°); data quantization = 8 bit; data rate = 1.1 Mbit/s; objective: acquisition of low-resolution wide-swath imaging (WFI provides a synoptic view). Note: The WFI instrument experienced a malfunction in May 2000, after seven months of service.

In addition to the imaging payload, the satellite carries a Data Collection System (DCS) for environmental monitoring; a Space Environment Monitor (SEM), and an experimental High Density Tape Recorder (HDTR) to record imagery on-board. Each DCP (Data Collection Platform) in the ground segment transmits randomly short digital data messages at a fixed rate (in UHF band). The DCS retransmits these messages in UHF and S bands to Earth. The DCS concept is similar to that of SCD-1 (see C.6).

DCS system access type	Random
Uplink carrier frequency, EIRP	401.635 MHz ±30 kHz (UHF), 33 dBm
Downlink carrier frequencies	2267.52 MHz (S-band); EIRP = 20 dBm 462.5 MHz (UHF-band); EIRP = 35 dBm

Table 149: The DCS parameters

SEM = Space Environment Monitor. Objective: detection of high-energy radiation. The CAST instrument consists of the following subsystems: PRD (Particle Radiation Detector), APD (Aurora Particle Detector), CRED (CMOS-IC Radiation Effect Detector), SDM (SEM Data Memory) and a 4.8 kHz subcarrier modulator.

Data: X-band downlink transmission of all science data in four channels, two for HRCC (8103 and 8321 MHz) at data rates of 2 x 53 Mbit/s, one for IRMSS (8216.84 MHz) at a data

rate of 6.13 Mbit/s, and one for WFI data (8203.35 MHz) at a data rate of 1.1 Mbit/s. The modulation is QPSK for HRCC and WFI data streams and BPSK for IRMSS. The TT&C subsystem uses S-band and UHF-band data transmission.

Both countries, China and Brazil, plan widespread use of CBERS image data in their countries and offer the data also to other nations.

D.7.2 CBERS-2

CBERS-2 is planned to be launched in Dec. 2001 from the Taiyuan launch site in China. The spacecraft carries the identical payload as CBERS-1. The intend is to provide continuity of observations.

Orbit: Sun-synchronous orbit; altitude = 778 km; inclination = 98.5°; nodal period = 100.26 minutes; mean local solar time at descending node = 10:30 AM

D.7.3 CBERS-3 & 4

The planned cooperative CBERS 3&4 program of CAST and INPE employs enhanced versions of spacecraft and instruments. The specification of the project is still under discussion, but the new satellites CBERS 3&4 will be compatible with CBERS 1&2. The planned launch date for CBERS-3 is 2004.⁶³⁹⁾

Orbit: Sun-synchronous orbit; altitude = 778 km; inclination = 98.5°; nodal period = 100.26 minutes; mean local solar time at descending node = 10:30 AM

Sensor complement:

PANCAM (Panchromatic Camera). The objective is to provide imagery for cartographic applications. The instrument features a spectral range of 0.51-0.73 μm with a ground resolution of 5 m and a swath width of 60 km. In addition, an instrument cross-pointing capability is provided to extend the FOR (Field of Regard) of the instrument.

MUXCAM (Multispectral Camera) of CAST and of HRCC heritage. The spectral coverage is identical to HRCC with the Pan band eliminated. The ground resolution is 20 m with a swath width of 120 km. The additional instrument feature is a cross-pointing capability.

Parameter	MUXCAM	PANCAM	IRCAM	WFI
Spectral bands (μm)	0.45-0.52 Blue 0.52-0.59 Green 0.63-0.69 Red 0.77-0.89 VNIR	0.51-0.73	0.80-1.10 NIR 1.55-1.75 SWIR 2.08-2.35 SWIR 10.40-12.50 TIR	0.52-0.59 Green 0.63-0.69 Red 0.77-0.89 VNIR
Spatial resolution (m)	20	5	20/40/40/80 (TIR)	160
Swath width (km)	120	60	120	890
Revisit capability (days)	4	5		
Normal revisit time (days)	26	1-26	26	5
Data quantization (bits)	8	8	8	8
Data rate (Mbit/s)	64	140	26	6

Table 150: Basic characteristics of the CBERS-3 & 4 instruments

IRCAM (Infrared Camera) of CAST of IRMSS heritage. Three of the four bands are identical to those of IRMSS (0.80-1.10; 1.55-1.75; 2.08-2.35; 10.4-12.5) μm. The spatial resolution is halved with regard to IRMSS.

WFI = Wide-Field Imager (INPE). WFI features three spectral bands (0.52-0.59; 0.63-0.69; 0.77-0.89) μm, with ground resolution of 160 m and ground swath of 890 km.

⁶³⁹⁾ Information provided by Luiz A. Bueno of INPE

D.8 CORONA

Declassification of all imagery, acquired by three early US military/CIA reconnaissance programs (CORONA, ARGON, and LANYARD), was announced by the US government (Vice President Al Gore) on February 24, 1995. CORONA is the program name of the first and most extensive operational DoD satellite photo-reconnaissance series, managed jointly by the USAF and by the CIA, during the observation period 1960 - 1972. ⁶⁴⁰⁾ ⁶⁴¹⁾

Camera system	KH-1	KH-2	KH-3	KH-4	KH-4A	KH-4B
Camera manufacturer	Fairchild Camera Co.		Itek Corporation			
Period of operation	1959 - 1960	1960 - 1961	1961 - 1962	1962 - 1963	1963 - 1969	1967 - 1972
Total missions	10	10	6	26	52	17
Successful missions (usable photography)	1	4	4	21	49	16
Mission designations	9000 series				1000 series	1100 series
Mission series life	1 day	2-3 days	1-4 days	6-7 days	4-15 days	19 days
Orbit (average values)						
Perigee	190 km	250 km	215 km	210 km		
Apogee	820 km	700 km	230 km	410 km		
Inclination	80°	81.5° - 83°	81° - 82°	81° - 83°		

Table 151: Overview of the operational CORONA reconnaissance program

The industry team of the CORONA program included: Lockheed Missiles & Space Co. (S/C integrator), Itek with Fairchild Camera & Instrument Corporation (camera system), General Electric (recovery capsule), and Kodak (film material).

CORONA's first successful mission on Aug. 18, 1960 [Discoverer-14 (mission 9009) on a Thor launch vehicle from VAFB, on-orbit mass = 850 kg] opened a new era in spaceborne reconnaissance (successful air recovery of the first photo reconnaissance product, stowed away in a reentry capsule, on Aug. 19, 1960). This film product became the first object in history to be recovered in mid-air by an aircraft (USAF C-119). The cassette contained observations stored on film material of about 1000 m in length.

The total coverage of Earth surface imagery acquired by the CORONA program amounts to nearly 2 billion km² (95% abroad and 5% of domestic US coverage) of high-resolution data, collected over a 12 year period. After declassification in 1995, it represents a significant amount of imagery to the civil community. ⁶⁴²⁾ ⁶⁴³⁾

Sensor complement:

The users of the imagery referred to the reconnaissance satellites and their imagery by the KH (KeyHole) designators that were assigned to the camera systems.

The quality of CORONA's imagery improved significantly over the life of the program from KH-1 to KH-4B. The resolution of the KH-4 systems could be enlarged routinely by a factor of 20, for the KH-4A and -B systems, enlargement up to a factor of 40 was possible. Starting with KH-3 missions, a secondary sensor system in the form of horizon, stellar and/or index cameras, was installed in parallel. The imagery acquired of the horizon camera was used to determine the attitude of the major imaging camera system. The imagery of the star camera was used for accurate determination of pitch, roll, and yaw angles during operational cycles. The index (or terrain) camera acquired correlative imagery used for proper position of the prime imagery.

KH-1 and KH-2 camera systems. These were panchromatic nadir-looking reciprocating film cameras, providing a 70° scan (FOV) in the cross-track direction. The KH-1 camera provided constant-velocity image motion compensation, while for the KH-2 camera, image motion compensation was variable throughout the orbit.

KH-3 cameras. There were five design changes. 1) the structural design was modified to avoid the negative impact of thermal differentials, 2) the camera controls were made more reliable, 3) the method of metering film and achieving/maintaining camera focus was improved, 4) the scan arm design was improved, and 5) a faster lens system was used, which in turn permitted the use of slower, finer grain film.

KH-4 stereo camera system. The KH-4 system consisted of two KH-3 cameras on a common mount, one aft-looking at 15°, the other forward-looking at 15° from nadir, providing a 30° view angle for stereo photography. The cameras were mounted back-to-back and scanned the target region in opposite directions.

KH-4A and KH-4B camera systems. The KH-4A system featured increased film load with a second film recovery bucket - thereby offering improved coverage of imaging targets. The KH-4B camera, a further improvement over KH-4A, could accommodate a variety of film types and operate more effectively under varying exposure conditions.

Camera system (data user designation)	KH-1	KH-2	KH-3	KH-4	KH-4A	KH-4B
Camera model (engineering designation)	C	C'	C'''	Mural	J or J-1	J-3
Imaging capability	mono	mono	mono	stereo	stereo	stereo

D.9 ENVISAT (Environmental Satellite)

The ENVISAT program of ESA is a renamed successor program to the original POEM (Polar Orbit Earth-Observation Missions) utilizing the Polar Platform (PPF). ⁶⁴⁴⁾ ⁶⁴⁵⁾ ⁶⁴⁶⁾ ⁶⁴⁷⁾ ⁶⁴⁸⁾ ⁶⁴⁹⁾

Background: Originally, two parallel and staggered mission series were proposed in the POEM program. The first series was planned with a Morning Orbit (M), the second series

with an (After) Noon Orbit (N). The objectives of the M-series were dedicated studies in meteorology/atmosphere/ocean/ice/environment, while the N-Series was considered for the study of land resources/atmosphere/environment. This scenario was followed in 1991 by the POEM-1 mission (a single satellite mission) which fulfilled both environmental and meteorological mission objectives.

The updated POEM program of 1992/93 considers a split scenario of two dedicated mission series called **ENVISAT** (Environmental Satellite) and **MetOp** (Meteorology Operational Programme). The key element of the split scenario is the transfer of the meteorological instrument package onto a separate platform with a morning orbit devoted primarily to operational meteorology and climate monitoring. This allows the ENVISAT mission to focus on environmental issues that are more research-oriented with a package of essentially pre-operational instruments.

of the services provided to the worldwide operational meteorological community. Contribution to the understanding of the structure and dynamics of the Earth's crust and interior. Major disciplines covered: meteorology, climatology, environment, atmospheric chemistry, vegetation, hydrology, land use, ocean and ice processes.

Spacecraft: 653) 654) 655)

Configuration: The ENVISAT satellite comprises the PPF bus and the payload complement. The PPF itself comprises: a) the service module (SM) providing the main satellite support functions, and b) the payload module (PLM), providing accommodation and supporting subsystems (data handling, power, communications) to the payload complement.

The SM is derived from the SPOT Mk-II bus design. The PPF is being developed and integrated by MMS, Bristol, UK as the prime contractor.

The payload module features externally mounted antennas (of ASAR and RA-2) and the following instruments (MERIS, MIPAS, GOMOS optical assembly, SCIAMACHY, MWR and DORIS) on a payload carrier. In addition there is a payload equipment bay which houses internally-mounted instruments (ASAR, RA-2, GOMOS) and subsystems like instrument control and data handling as well as X-band and Ka-band communications. The industrial team for the ENVISAT payload is being led by DASA/DSS.

Orbit: Near-circular sun-synchronous orbit; altitude = 800 km; descending node at 10 AM local time, inclination = 98.55° , orbit period = 100.6 minutes, repeat cycle = 35 days, same ground track as ERS-2.

The launch of ENVISAT is projected for Nov. 2001 on an Ariane-5 launch vehicle, nominal lifetime of 5 years (including 6 months' commissioning phase). Spacecraft operations are being conducted at ESA/ESOC, the payload center is at ESA/ESRIN.

Parameter	Description
S/C dimensions	Launch configuration: 10.5 m length; 4.57 m envelope diameter In-orbit configuration: 26 m x 10 m x 5 m
S/C stabilization	Three-axis stabilized, attitude pointing: $<0.1^\circ$ (3 sigma); attitude measurement: $<0.03^\circ$ (3 sigma)
S/C mass	8140 kg including 319 kg of hydrazine
Payload mass	2150 kg (instruments and interfacing hardware)
S/C power	6.5 kW (EOL) with single sided solar arrays, size of solar panel: 5 m x 14 m Eclipse power provided by eight 40 Ah NiCd batteries
Payload power	1.9 kW sunlight and eclipse average (peak = 4.1 kW)
On-board data storage	Three tape recorders of 30 Gbit each, a LBR (Low Bit Rate) recording rate capability of 4.6 Mbit/s and a replay rate of 50 Mbit/s. One solid-state recorder of 60 Gbit, for LBR as well as ASAR high rate and MERIS full resolution
Payload data transmission	2 Ka-band channels each at 50/100 Mbit/s via DRS (Artemis) for payload data 2 X-band channels each at 50/100 Mbit/s (direct transmission to ground)
RF links	S-band direct to/from ground via DRS for TT&C Ka-band to ground via DRS for payload data X-band direct to ground for payload data
RF link operation	Half link operation uses BPSK modulation, full link operation with QPSK
Command & Control	2 kbit/s uplink and 4.096 kbit/s downlink in S-band

Table 153: Overview of ENVISAT spacecraft parameters

Data transmission:

The satellite is capable of providing simultaneous operation of X-band and Ka-band channels.

653) J. Louet, "The Envisat Mission and System," ESA Bulletin No 106, June 2001, pp. 11-25

654) P. A. Dubock, F. Spoto, J. Simpson, D. Spencer, E. Schutte, H. Sonntag, "The Envisat Satellite and its Integration," ESA Bulletin, No 106, June 2001, pp. 26-45

655) "ENVISAT: Mission and System Summary," ESA brochure, March 1998

- Global mission data (low rate) = 4.6 Mbit/s - ‘global mission’ involves the operation of all low data instrument modes, whenever observation conditions permit, with on-board data recording. Nominal operation involves one tape dump per orbit at 50 Mbit/s.
- Regional mission data (the term ‘regional mission’ implies real-time data acquisition via DRS or via X-band ground stations.). This includes:
 - ASAR data in its imaging modes with a real-time dedicated channel at 100 Mbit/s
 - MERIS full resolution data multiplexed with low rate instrument data. This includes half of a 50 Mbit/s channel. The other half of the channel is used for tape recorder dump. In the absence of a dump, this channel is operated at half rate (BPSK modulation at 50 Mbit/s versus QPSK for 100 Mbit/s).

Sensor operations strategy:

Continuous operations around the orbit of GOMOS, MIPAS, SCIAMACHY, AATSR, RA-2, MWR, and DORIS. On-board recording of all the above mentioned low-rate instrument data outside the visibility range of ESA X-band stations. ^{656) 657)}

ASAR can be operated in high rate mode up to 30 minutes per orbit, including 10 minutes in the eclipse phase. MERIS can be operated only out of eclipse and when the sun zenith angle at the subsatellite point is less than 80° (this corresponds to about 43% of the orbit).

Sensor complement:

1) Instruments provided by ESA

- MERIS (Medium Resolution Imaging Spectrometer)
- MIPAS (Michelson Interferometer for Passive Atmospheric Sounding)
- RA-2 (Radar Altimeter-2, a Laser Retro-Reflector (LRR) is included)
- MWR (Microwave Radiometer)
- ASAR (Advanced SAR)
- GOMOS (Global Ozone Monitoring by Occultation of Stars), chemistry and dynamics of upper atmosphere

2) Announcement of Opportunity (AO) Instruments

- SCIAMACHY (Scanning Imaging Absorption Spectrometer for Atmospheric Cartography, provided by Germany and The Netherlands)
- AATSR (Advanced Along Track Scanning Radiometer, provided by the UK and Australia), see also ATSR (ERS-1, -2)
- DORIS (see E.21.1) provided by France

MERIS = Medium Resolution Imaging Spectrometer, built by Alcatel Space Industries, France (formerly Aerospatiale). ^{658) 659) 660)} MERIS is a passive optical pushbroom wide-field instrument (CCD technology) intended to measure reflected radiation the Earth’s surface, the ocean, and from clouds with high spectral resolution (high radiometric resolution in the VIS range). MERIS features individual gain settings to optimize the dynamic range of each of its fifteen bands (ability to reprogram the position and width of the spectral bands in flight).

MERIS objectives/applications:

- Ocean: monitoring marine biophysical and biochemical parameters (chlorophyll, gelbstoff concentrations, suspended particles). Mapping of sea pollution, coastal erosions, sea ice.
- Atmosphere: monitoring cloud distribution, cloud altitude, water vapor column content, aerosols
- Land: monitoring vegetation/biomass, inland water, agriculture/forestry. Mapping snow and ice, vegetation stress and calamities (fires) ⁶⁶¹⁾

Spectral characteristics:	
Spectral range	0.39 - 1.04 μm (VNIR)
Spectral sampling interval	1.25 nm
Spectral bandwidth	1.25 - 25 nm (programmable)
Registration between bands	< 0.1 pixel (FR)
Band transmission capability	15 bands programmable in position and width
Band center knowledge	< 1 nm
Radiometric characteristics:	
Polarization sensitivity	< 0.5% over the full spectral range
Radiometric accuracy	< 2% in reflectance (relative to the sun irradiance)
Spectral band/band accuracy	< 0.05%
Pixel to pixel accuracy	< NEDL = Noise Equivalent Detected Radiance at top of atmosphere with input signal Locean (upwelling radiance from ocean surface)
Dynamic range	up to albedo 1.0 (in appropriate spectral bands)
Spatial resolutions:	
Open ocean observation	1040 m x 1200 m at nadir (reduced resolution: RR)
Land and coastal zones	260 m x 300 m at nadir (full resolution: FR)
Integration time/frame	about 44 ms
TFOV, swath width	$\pm 34.2^\circ$ or about 1150 km, providing global coverage every 3 days.
Operational modes:	
Full resolution: FR (300 m)	Data rate = 24.0 Mbit/s (no on-board recording is considered), duty cycle of about 43%
Reduced resolution (RR)	Data rate = 1.6 Mbit/s, full coverage duty cycle (1.2 km resolution)
Data localization accuracy	< 2 km without use of landmarks
Instrument mass, power, size	200 kg, 175 W (average), 1.8 m x 0.9 m x 1.0 m

Table 154: MERIS instrument performance parameters

The MERIS instrument is a programmable, high-spectral resolution imaging spectrometer measuring in the spectral region of 390 - 1040 nm. The total swath is covered by five identical modules (cameras) each having a 14° FOV, with 0.4° overlap between adjacent cameras (1150 km total swath, with a FOV of 68.5°). The cameras are arranged in a fan-shaped configuration and view the Earth through five depolarizing windows with a common depointing prism. An image is formed at the entrance slit of a grating imaging spectrometer, which disperses the image spectrum on an area array CCD detector matrix (576 lines x 780 columns, the element size is $22.5 \mu\text{m} \times 22.5 \mu\text{m}$). The CCDs (thinned backside illuminated) are operated in frame-transfer mode. The CCDs are coupled to a Peltier cooler to keep the temperature at -22°C . A five-channel VEU (Video Electronic Unit) performs 12 bit A/D conversion of the video signals provided by the five CCDs (each CCD has 740 useful pixels per line and 576 lines). After onboard digital conversion, the data is corrected in real-time with the calibration coefficients to produce raw image data in 15 spectral bands. ^{662) 663)}

The MERIS optics subsystem consists of an external window, a folding mirror, an off-axis catadioptric-ground imager, and a spectrometer of concentric design. The windows are used to scramble the incident polarized radiation thereby making the instrument less sensitive to polarization changes. The dispersive element of the spectrometer is a low-groove-density holographic grating.

⁶⁶¹⁾ M. Morel, J. L. Bézy, F. Montagner, A. Morel, J. Fischer, "Envisat's Medium-Resolution Imaging Spectrometer," ESA Bulletin, No. 76, November 1993, pp. 40-46

⁶⁶²⁾ G. Levrini, E. Attema, "The Commissioning Phase and the Calibration/Validation Activities," ESA Bulletin, No 106, June 2001, pp. 109-117

⁶⁶³⁾ G. Levrini, E. Attema, "The Envisat Calibration and Validation Approach," ESA Earth Observation Quarterly, No 67, Oct. 2000, pp. 9-16

Instrument calibration is performed at the orbital south pole, where the calibration flat-plate diffuser is illuminated by the sun by rotating a calibration mechanism (the reference for absolute calibration is based on an assumed solar irradiance at the time of calibration). Four in-flight calibration sequences are defined:

- Dark calibration, During calibration the signal is recorded with the Earth and sun aperture closed to provide, in the case of radiometric calibration, a uniform (spectrally and spatially) radiance source, and in the case of spectrometric calibration, a radiance source with a spectral signature.
- Radiometric gain calibration (a white diffuser plate, sun illuminated, is inserted at the cross-over point of the five cameras FOVs). The diffuser provides a reflectance standard across the entire spectral range and FOV.
- Diffuser ageing characterization (exposure to the sun for 1 hr during the mission life)
- Wavelength referencing (another diffuser is used with known absorption peaks)

MERIS operation: The MERIS instrument can only observe out of eclipse and when the sun zenith angle at the subsatellite point is below 80°. The instrument can be operated either in “averaging” or in “direct and averaging” observation modes. In averaging mode, the data are spatially averaged on-board to produce an additional but separate data stream at 1200 m resolution, referred to as RSR (Reduced Spatial Resolution). When in direct and averaging mode, the instrument delivers, in addition to the RSR data, FSR (Full Spatial Resolution) data at 300 m resolution in the same 15 spectral bands. FSR data is available for up to 20 minutes per orbit.

Band No.	Band center (nm)	Bandwidth (nm)	Application
1	412.5	10	Yellow substance and turbidity
2	442.5	10	Chlorophyll absorption maximum
3	490	10	Chlorophyll and other pigments
4	510	10	Turbidity, suspended sediment and red tides
5	560	10	Chlorophyll, suspended sediment
6	620	10	Suspended sediment
7	665	10	Chlorophyll absorption
8	681.25	7.5	Chlorophyll fluorescence, red edge
9	705	10	Aerosol, red edge transition
10	753.75	7.5	Oxygen absorption reference band, vegetation
11	760	2.5	O ₂ absorption R-branch

variety of relevant trace gases (over 20), including the complete family of nitrogen-oxygen compounds and several CFCs, especially in the stratosphere and in cloud-free regions in the upper troposphere. In 1989 ESA selected MIPAS as an 'ESA developed instrument' for the POEM/ENVISAT program. The MIPAS satellite instrument development (by DASA/DSS) results from a long heritage of airborne MIPAS instruments (see P.129).

Major MIPAS objectives:

- Chemistry of the stratosphere: O_3 (global and polar), NO , NO_2 , HNO_3 , HNO_4 , N_2O_5 , $ClONO_2$, COF_2 , $HOCl$.
- Climate research: (global distribution of relevant parameters and clouds) eg., O_3 , CH_4 , H_2O , N_2O , CFCs, (F11, F12, F22, CCl_4 , CF_4), CO , OCS , aerosols and clouds.
- Transport processes (tropospheric-stratospheric exchange): O_3 , CH_4 , N_2O , C_2H_2 , C_2H_6 , SF_6 .
- Upper tropospheric chemistry: NO , CO , CH_4 , O_3 , HNO_3 .

MIPAS makes measurements in either of two pointing regimes: rearwards within a 35° -wide range (anti-flight direction), and sideways within a 30° -wide range on the anti-sun side. The rearward viewing geometry is the prime measurement mode of MIPAS. The sideways observation mode is intended to cover special events (volcanic eruptions, etc.). As a result of the limb viewing geometry, the distance between the instrument and the tangent point of the target area is between 3000 and 3300 km, depending on the tangent height.

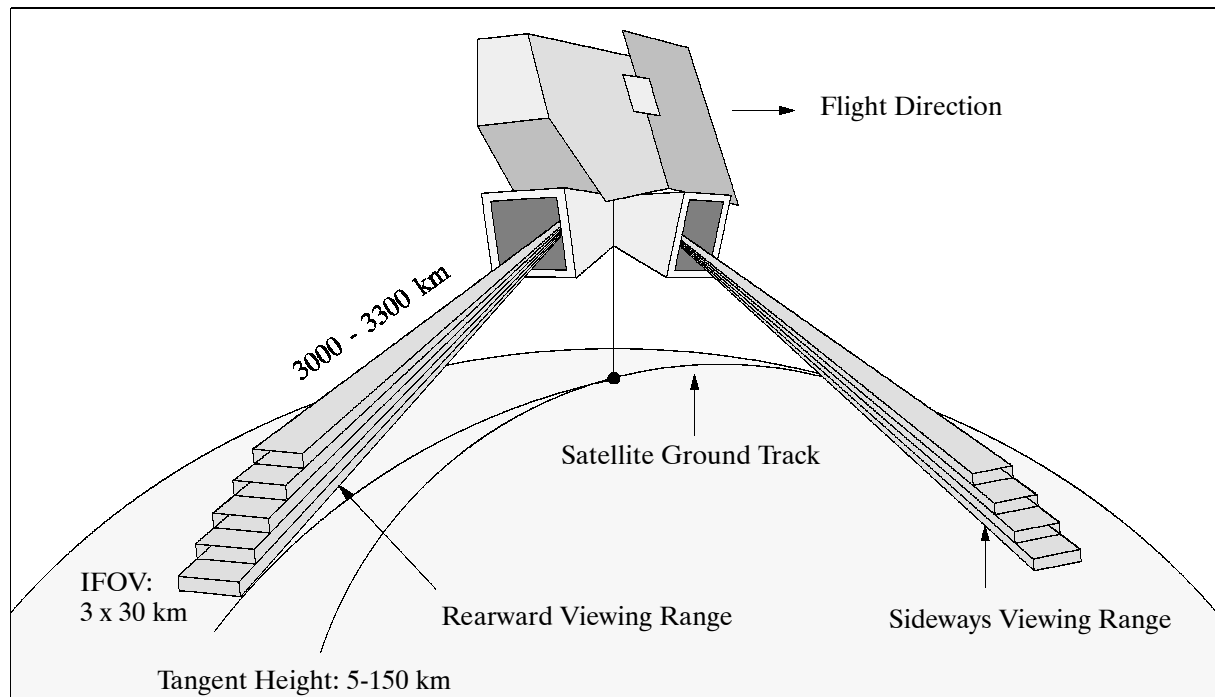

Figure 93: The MIPAS limb-observation geometry from a satellite

MIPAS instrument:

MIPAS measures a series of spectra from different tangent heights. The spectrometer transforms the spectra into a modulated signal, the interferogram, where many IR bands are present simultaneously. The spectrometer output consists of such interferograms for each observed scene. One basic elevation scan sequence comprises 16 high-resolution spectra (or up to 75 spectra with reduced spectral resolution) and takes 75 seconds. A typical elevation scan starts at about 50 km tangent height and descends in 3 km steps to 8 km (any limb heights from 150 km downwards in 5 km steps can be performed). Instrument pointing accuracy is of utmost importance to measure at a predetermined limb height with a standard deviation below 600 m. This in turn requires a S/C pointing knowledge of $>0.01^\circ$ (1 sigma) to nadir.

The MIPAS instrument has a total mass of 327 kg and a power consumption of 210 W. It consists of the following basic modules:

- Optics module: with front-end optics (comprising the azimuth and elevation scan units and a receiving telescope), Michelson interferometer, focal plane subsystem, calibration blackbody, and reference laser.
- Electronics module: with signal processing subsystem, instrument control unit, and Stirling cooler, on a common carrier plate.

Observation geometry IFOV	3 x 30 km (height x width) - 3 km height correspond to a 0.05° viewing angle
Elevation scan range	5 - 150 km above the Earth horizon (tangential height)
Azimuth scan range (with respect to flight direction)	between 160°-195° (rearwards), and 80°-110° (sideways)
Spectral coverage	
Spectral range	685 - 2410 cm ⁻¹ (14.6 - 4.15 μm)
Spectral resolution (unapodized)	0.035 cm ⁻¹
Spectral resolution submodes	selectable in range from 0.035 - 0.35 cm ⁻¹
Radiometric parameters	
Radiometric sensitivity (NESR)	50 (at 685 cm ⁻¹) - 4.2 (at 2410 cm ⁻¹) nW/(cm ² sr cm ⁻¹)
Absolute radiometric accuracy	2% (at 14.6 μm) - 5% (at 4.15 μm) of input radiance with an offset of 2 NESR
Measurement duration	
Time per spectrum	4.5 s (full spectral resolution); 1.0 s (1/10 spectral resolution)
Time per elevation scan	75 s (500 km ground trace)
Spectra per elevation scan	16 (full spectral resolution); 75 (1/10 spectral resolution)
In-orbit lifetime	4 years
Instrument operation	continuously over full orbit
Data rate	533 kbit/s; raw data mode = 8 Mbit/s
Mass, power	320 kg, 210 W
Detector operating temperature	65-75 K

Table 156: Summary of MIPAS performance parameters

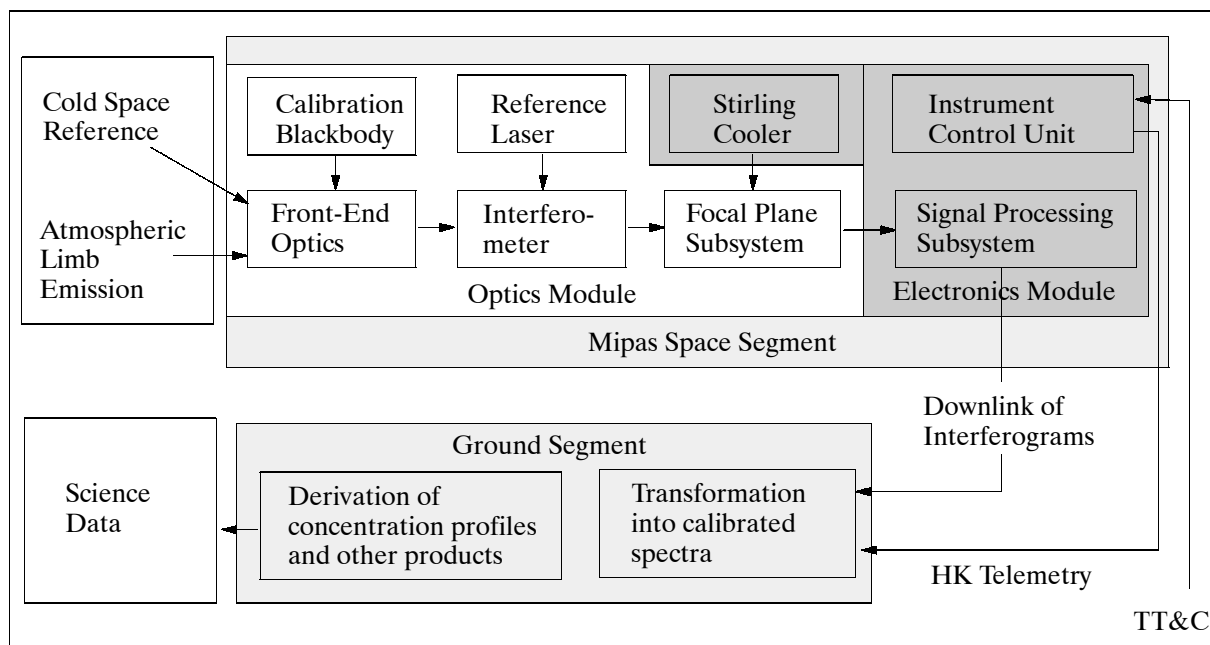

Figure 94: Schematic of MIPAS instrument elements and data flow

From the telescope, the radiation is directed to the interferometer. The input signals are divided at the beamsplitter inside the interferometer and directed to cube corners moving at a constant velocity of 25 mm/s along a path of 100 mm. This permits a spectrum to be recorded in 4s. Depending on the optical path difference in the two interferometer arms, the recombined signal is an intensity-modulated interferogram. [The Michelson interferome-

ter provides an unapodized spectral resolution of better than 0.035 cm^{-1} throughout the spectral range. This is necessary to resolve the lines in the spectrum and to reduce the interference of overlapping spectral features. With this high spectral resolution, MIPAS provides a total of about 60,000 independent spectral samples in each spectrum.] - The output signal (interferogram) enters the focal-plane subsystem where beam size matching, beam splitting and optical filtering is performed. After optical filtering the input spectrum is separated into eight narrow spectral bands for detection by eight HgCdTe detectors operating at about 70 K for maximum sensitivity. The detectors are of photoconductive type in the spectral region from about 7-14.6 μm , and of photovoltaic type in the region 4-7 μm . The detectors are cooled by a pair of synchronized Stirling cycle coolers. The detector output is filtered and compressed in the signal processing subsystem, which outputs the interferograms and ancillary data for ground processing.

The calibration blackbody is mounted in the azimuth scan unit, it is used for the in-flight calibration of the instrument responsivity. MIPAS performs regular in-orbit calibration sequences.

- Radiometric offset calibration: This is done every two to four scans and prior to every elevation scan sequence to correct for the instrument self-emission
- Gain calibration: This occurs about once a week, applying a two-point calibration method, where radiances from deep space and an internal blackbody are observed in sequence.
- Line of sight calibration (used for inflight determination of the line-of-sight pointing direction): Performed every week. This is based on star observations crossing the instrument FOV and subsequent correlation of actual and predicted time of star crossing.
- Spectral calibration: Performed every two scans. The calibration parameters are retrieved from subsets of the atmospheric limb measurements, so that the routine scene data acquisition is not interrupted.
- Instrument line shape calibration is performed once a week. This involves retrieval from subsets of the routine scene data.

ASAR (Advanced SAR). ^{669) 670) 671) 672) 673)} ASAR, of AMI heritage heritage flown on ERS-1/2 (built by MMS, UK, now Astrium Ltd.), measures the radar backscatter of the Earth's surface at C-band with a choice of five polarization modes: VV, HH, VV/HH, HV/HH, or VH/VV. The ASAR instrument comprises two major functional groups, the Antenna Subassembly (ASA), and the Central Electronics Subassembly (CESA). The antenna array contains 20 tiles (each 1 m x 0.65 m in size) with 16 transmit/receive (Tx/Rx) modules each. The transmit pulse characteristics are: the output is a linear FM up-chirp pulse centered at 124 MHz of the IF carrier. In the RF subsystem the pulse is up-converted to the RF frequency (5.331 GHz) and amplified. The signal is then passed to the Tx/Rx modules in the tile subsystem. - In general, the use of digital technologies for signal generation and processing is implemented. These permit chirp versatility in terms of pulse duration and bandwidth required for the operational modes and various swaths of the instrument. On reflection, AMI of ERS-1/2 used SAW devices for analog chirp generation.

The ASAR active antenna is a phased array of size 1.3 m x 10 m with distributed Tx/Rx modules arranged across the antenna, such that by adjusting individual module phase and gain, the transmit and receive beams may be steered and configured (independent control of the phase and amplitude of the transmitted radiators from different regions of the antenna sur-

face). Use of GaAs MMIC (Monolithic Microwave Integrated Circuit) technology, based on field effect transistors, for amplifiers, switches, attenuators, and phase shifters. ASAR also provides independent weighting of the received signal to each of these regions. This offers great flexibility in the generation and control of the radar beam, giving the ASAR instrument the capability to operate in a number of different modes (37 different and mutually exclusive high-rate operating modes). These modes use two principal methods of taking measurements; the ASAR instrument may operate as a conventional stripmap SAR or as a ScanSAR.

ASAR stripmap modes (Image and Wave):

When operating as a stripmap SAR, the phased array antenna gives ASAR the flexibility to select an imaging swath by changing the beam incidence angle and the elevation beam-width. In addition, the appropriate PRF required to ensure acceptable ambiguity performance and to suppress unwanted nadir returns is selected.

- **Image mode:** ASAR operates as an imaging radar collecting data in one of seven predetermined but relatively narrow swaths (up to 100 km within a viewing area of about 485 km) with high spatial resolution (30 m). The image mode provides continuous coverage over a single swath that can be pointed anywhere with 15-45° incidence angles. The transmit and receive polarization may be either HH or VV.
- **Wave mode:** imaging of small areas of 5 km x 5 km (referred to as vignettes) in frequent intervals over along-track distances of 100 km on ocean surfaces. Measurement of the change in radar backscatter from the sea surface due to ocean surface waves. The wave mode uses the same swaths and polarizations as image mode. The intermittent operation provides a low data rate, such that the data can be stored on board the satellite, rather than being downlinked immediately to a ground station.

Operating Mode ----> Parameter	Image Mode	Wide Swath Mode	Alternating/ Cross Polariz.	Wave Mode	Global Monitoring
Polarization	VV or HH	VV or HH	VV/HH, HH/HV or VV/VH	VV or HH	VV or HH
Spatial resolution (along-track and across-track)	28 m x 28 m	150 m x 150 m	29 m x 30 m	28 m x 30 m	950 m x 980 m
Radiometric resolution	1.5 dB	1.5-1.7 dB	2.5 dB	1.5 dB	1.4 dB
Swath width	up to 100 km 7 subswaths	400 km 5 subswaths	up to 100 km 7 subswaths	5 km vignette 7 subswaths	> =400 km 5 subswaths
Ambiguity ratio (point) along-track across-track	26-30 dB 32-46 dB	22-29 dB 26-34 dB	19-28 dB 26-41 dB	27-30 dB 31-46 dB	27-29 dB 25-32 dB
Ambiguity ratio (distrib.) along-track across-track	23-25 dB 17-39 dB	20-25 dB 17-31 dB	18-25 dB 17-39 dB	23-25 dB 21-48 dB	25-28 dB 17-31 dB
Radiometric stability	0.32-0.40 dB	0.32-0.42 dB	0.50-0.55 dB	0.55-0.60 dB	0.46-0.53 dB
Noise equivalent sigma zero	-22 to -22 dB	-21 to -26 dB	-19 to -22 dB	-20 to -22 dB	-32 to -35 dB
Incidence angle range	15-45°		15-45°	15-45°	
Center frequency	5.331 GHz (C-band)				
PRF	1650 to 2100 Hz				
Chirp bandwidth	up to 16 MHz				
Antenna size	10 m x 1.3 m (consisting of five 1.3 m x 2 m panels)				
Operation (duty cycle)	up to 30 min/orbit			rest of orbit	
Data rate	up to 100 Mbit/s			0.9 Mbit/s	
Power	1365 W	1200 W	1395 W	647 W	713 W
Instrument mass	832 kg				

Table 157: ASAR instrument parameters

ASAR ScanSAR modes (Alternating polarization, Wide swath, and Global monitoring)
The ScanSAR principle achieves swath widening by the use of an antenna beam which is

electronically steerable in elevation. Radar images can then be synthesized by scanning the incidence angle and sequentially synthesizing images for the different beam positions. The area imaged from each particular beam forms a sub-swath. The principle of the ScanSAR is to share the radar operation time between two or more separate sub-swaths in such a way as to obtain full image coverage of each. The system transmits pulses to and receives echoes from a sub-swath for a period long enough to synthesize a radar image of the area within the beam footprint at the required resolution. It then switches beams to illuminate a different sub-swath and continues in this manner until the full wide swath is covered. At this point the system returns to the original sub-swath and the scanning cycle is repeated.

- **Alternating polarization mode:** provides a choice of HH or VV or cross-polarized imaging of the same scene by interleaving looks with each polarization along track within the synthetic aperture. The mode employs a modified ScanSAR technique. Instead of scanning between different elevation sub-swaths, the alternating polarization mode (co-polar) scans between two polarizations, HH and VV, within a single swath (which is preselected, as for image and wave modes).
- **Wide swath mode:** continuous image coverage over a swath width of 405 km (or more), divided into five subswaths ranging from 60 to 100 km in width; the spatial resolution is 150 m.
- **Global monitoring mode:** provides continuous along-track sampling across a 405 km swath. Allows ASAR to be operated in a reduced spatial resolution mode of 1000 m (with a corresponding reduced data rate for on-board recording). Global monitoring of features such as ice or snow coverage, deforestation, desertification or humidity.

Figure 95: ASAR observation geometries (simplified)

Application: The main objective of ASAR is to provide information on: ocean waves, sea ice extent and motion, snow and ice extent, surface topography, land surface properties, Earth's biomass (especially deforestation in equatorial zones), surface soil moisture and wetland extent. Important applications by ASAR to the global mission include: ⁶⁷⁴⁾

- Measuring sea-state conditions at various scales
- Mapping ice-sheet characteristics and dynamics
- Mapping sea-ice distribution and dynamics
- Detecting large-scale vegetation changes
- Monitoring natural and man-made pollution over the oceans.

Some ASAR applications for the regional mission are in the following areas:

⁶⁷⁴⁾ E. Attema, Y-L. Desnos, G. Duchossois, "Synthetic Aperture Radar in Europe: ERS, Envisat, and Beyond," JHU/APL Technical Digest, Vol. 21, No. 1, 2000, pp. 155- 161

- Offshore operations in sea ice
- Snow and ice mapping
- Coastal protection and pollution monitoring
- Ship traffic monitoring
- Agriculture and forest monitoring
- Soil moisture monitoring
- Geological exploration, topographic mapping
- Predicting, tracking and responding to natural hazards

Compared with AMI of ERS-1/2, a single-channel fixed-geometry instrument, ASAR represents a step forward in system flexibility and the science value of the data sets. The new features of ASAR are:

- A digital chirp generator and an improved linear dynamic range
- Flexible swath positioning offers the choice among several image swath positions at various distances from the sub-satellite track, i.e. with different incidence angles
- The dual polarization capability offers simultaneous operation at H, V, and cross-polarization combinations
- Wide-swath coverage offers a 405 km swath with 150 m or 1 km resolution imagery
- The enhanced wave-mode acquires imageries at 100 km intervals in along-track
- An extended duty cycle (operating time) is available at high resolution (30 min of operation, 10 min eclipse)
- Global SAR coverage is possible by using a solid-state on-board recorder and a data relay satellite (ARTEMIS).

RA-2 (Radar Altimeter-2, extended capability of ERS-1/2). RA-2 is a nadir-pointing pulse-limited radar altimeter which transmits frequency-modulated (chirp) pulses. Alenia Spazio SpA of Rome, Italy is the prime contractor for the ESA instrument. Frequencies: 13.575 GHz (Ku-band) and a second frequency at 3.2 GHz (S-band) for the measurement and correction of ionospheric delays. Adaptable width/resolution windows (measurements over ice surfaces), autonomous resolution control. ^{675) 676) 677) 678) 679)}

The main objectives of RA-2 are high-precision measurements of distance (time delay) from the satellite to the Earth surface (topography) and the measurement of the power and the shape of the radar echoes from ocean, ice and land. Ground processing of the radar echo power and shape data enables the determination of wind speed and significant wave height in the observed target area (supporting studies of ocean circulation, bathymetry, gravity anomalies, and marine geoid characteristics). Sea ice monitoring is possible through frequent temporal coverages.

RA-2 transmits radio frequency pulses and measures the run time of the echoes. A model-free tracker in the on-board signal processor keeps the radar echoes within the sampling window. Adaptive height resolution operation is implemented by selecting the bandwidth of the transmitted pulses. As a result, measurements over ocean surfaces are carried out with improved accuracy. Internal calibration measurements are performed periodically in parallel to the tracking functions. For this the transmit pulse is coupled into the receiver by means of a calibration coupler. Echo samples are processed on ground to account for correction and calibration data.

In parallel to the nominal collection of echo waveforms, which are collected on-board at 19 kHz rate, RA-2 has also the capability (on ground command) to record streams of non-aver-

aged “individual” waveforms. The feature is used to study the physics of the backscattering process.

Altitude	764 - 824 km range with an accuracy of <4.5 cm
Backscatter coefficient	-10 dB to +50 dB with an accuracy of <0.4 dB (bias)
Wave height	0.5 m to 20 m with an accuracy of <5% or 0.25 m
Measurement datation	±100 µs with respect to UTC
Operating center frequencies	13.575 GHz (Ku-band), and 3.2 GHz (S-band)
Chirp bandwidths	320, 80, 20 MHz CW (Ku-band), 160 MHz (S-band)
Pulse repetition frequency (PRF)	1795.33 Hz (Ku-band), 448.83 Hz (S-band) interleaved operation
Pulse length	20 µs
Peak transmission power	60 W (Ku-band), 60 W (S-band)
Antenna diameter	1.5 m
Antenna beamwidth	1.33° (Ku-band), 5.25° (S-band)
IF center frequency	6.4 MHz
A/D conversion	8 bit
Instrument operation	continuously over full orbit
FFT resolution	128 complex points (samples) at 16 bit
Antenna diameter, beamwidth	1.2 m, 1.84° (Ku-band), 6.2° (S-band)
Total mass, power, data rate	110 kg, 161 W, 100 kbit/s

Table 158: RA-2 instrument parameters

LRR (Laser Retro Reflector), built by Alcatel Space Industries, France. LRR is mounted on the nadir panel close to the RA-2 antenna to support satellite laser ranging and RA-2 altitude measurement calibration. The LRR is a passive device which is used as a reflector by groundbased satellite laser ranging (SLR) stations. The operating principle is to measure the round-trip run time of laser pulses reflected from an array of corner cubes at the satellite. The corner cubes are designed to reflect the incident laser beam back directly, keeping the reflected beam parallel to the incident beam within a few arcseconds. The corner cubes of LRR work at two specified wavelengths: $\lambda = 694$ nm and $\lambda = 532$ nm. Laser ranging to LRR is possible for view angles of 360° in azimuth and 60° elevation around the perpendicular to the satellite’s Zs Earth panel. The total mass of LRR is 2 kg.

GOMOS = Global Ozone Monitoring by Occultation of Stars (built by MMS, France). GOMOS is a UV/Visible/Near-infrared limb viewing grating spectrometer, operating in a star occultation mode. 680) 681) 682) 683) 684) 685) 686) GOMOS relies on the self-calibrating occultation method (which minimizes the impact of instrument degradation). GOMOS introduces a new measurement principle: using stars rather than the sun or the moon as light sources (occultation measurement method), it achieves permanent, homogeneous global coverage through the measurement of 25 to 40 stars per orbit. The optical configuration, based on two grating spectrometers (range: 250 - 950 nm), permits the measurement of stratospheric profiles of O₃, H₂O, NO₂, NO₃, aerosols and temperatures with a 1.7 km vertical resolution.

Objectives: High accuracy (altitude-resolved) and global long-term monitoring of stratospheric and mesospheric ozone. Global survey of related stratospheric trace gases (NO₂,

Linearity	0.5%	<0.33%	<0.34%	N/A
Spectral stability	0.04 nm	0.007 nm	0.008 nm	N/A
Altitude range	20 - 100 km			
Vertical resolution	1.7 km			
Operation	continuously over full orbit			

Table 159: GOMOS characteristics

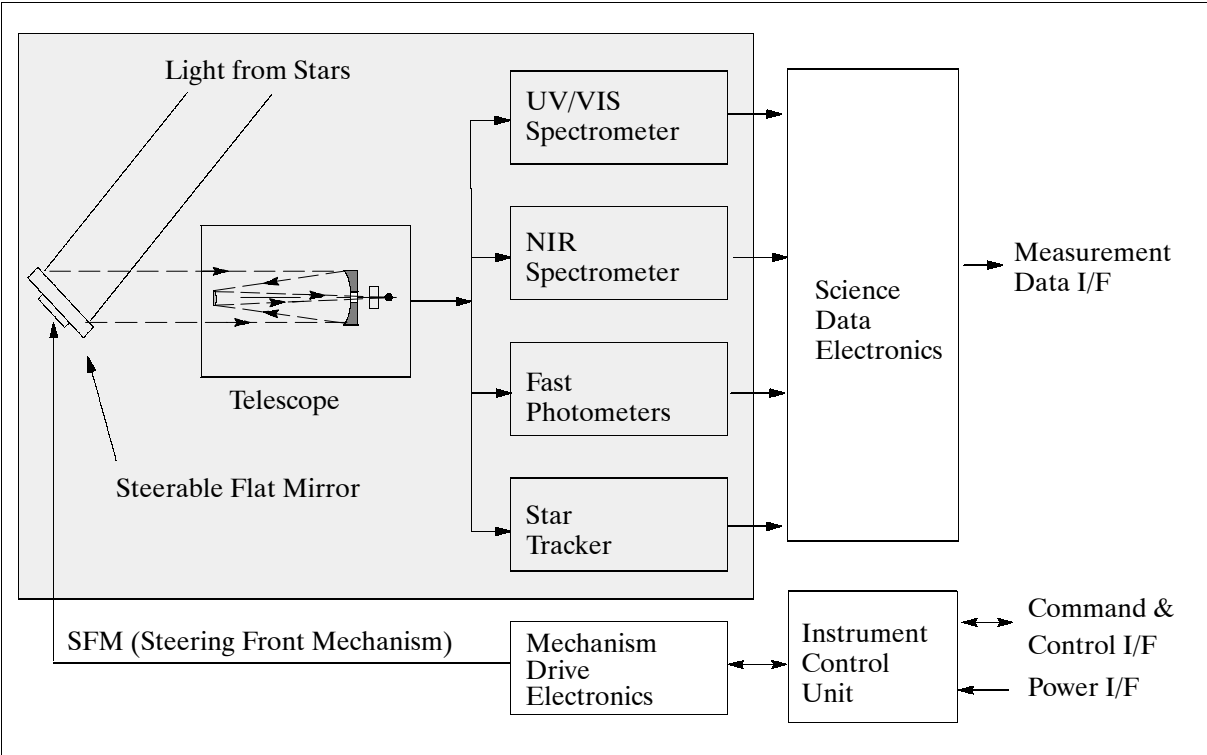

Figure 96: Functional block diagram of GOMOS

GOMOS instrument: The instrument’s optical design (all-reflective system) is based on a single telescope concept: a Cassegrain telescope simultaneously feeding a UV/VIS medium-resolution spectrometer, NIR high resolution spectrometers, two photometers (monitoring the input signal scintillation) and two (redundant) star trackers. The photometer measurements allow to correct the spectral data from the high-frequency component introduced by the atmospheric scintillations. The telescope, the optics, all sensors and their associated front-end electronics are mounted on a thermally controlled CFRP optical bench. By using a steerable flat mirror (30 cm x 40 cm) in front of the telescope, GOMOS is able to acquire and track stars down to a magnitude of 5 over a very large angular range (Figure 96). The two-stage Steering Front Mechanism (SFM) is used to point the line of sight towards the selected star and to track it with very high accuracy as it sets through the atmosphere. SFM has an angular steering range of 100° in azimuth and 8° in elevation, and a pointing accuracy of some 20 μrad at a bandwidth of 5 Hz (a typical scan is 50 s in duration). During the occultation phase, SFM is operated over a reduced FOV (8° in azimuth and 6° in elevation) to provide fine centering of the star image within the spectrometer entrance slit.

The SFM relies on a combination of linear motors and flexible joints for its operation. The accurate tracking function is performed via a digital closed control loop using star tracker information read at 1000 Hz sampling rate. 687) 688)

A special frame-transfer CCD has been developed for the spectrometers to meet the needs of the GOMOS mission. A thinned, backside-illuminated, anti-reflection coated CCD (2 x 143 lines and 1353 columns with 20 x 27 µm pixels), operating in MPP (Multi Pin Phase) mode, serves as primary detector array. A total of eight CCDs are used (two for the UV/VIS, two for the NIR, two for the fast photometers, and two for the star trackers). - The entire spacecraft and external GOMOS instrumentation (optomechanical assembly: OMA) is covered by an optomechanical cover responsible for protecting the instrument from light coming from a different direction other than the defined angular range, and for ensuring a stable, defined thermal environment.

Figure 97: Illustration of some ENVISAT instruments

Requirements	Typical GOMOS Performance	Design Driver for
Nr. of occultations/orbit (45 on average)	about 820.000 occultations during 4 year mission	Lifetime of pointing mechanism
Wide angular coverage	-11° to +91° with respect to flight direction	Large FOV of pointing mechanism
Altitude resolution/accuracy	1.7 km/30 m, pointing stability better than 40 µrad	High angular pointing accuracy (pointing servo electronics)
Spectral resolution of spectrometer (FWHM)	0.72 / 0.89 nm UV/VIS, min/max 0.12/0.14 nm in NIR, min/max	High-transmission optics, high detector sensitivity in the UV
Photometer frame rate	1 kHz in the spectral range: 466-528 nm and 644-705 nm	Fast, high-sensitivity detectors

Table 160: GOMOS instrument performances and major technical challenges

687) J. Langen, “Envisat’s Contribution to Atmospheric Chemistry Studies,” Proceedings of IGARSS’99, Hamburg, Vol. III, June 28-July 2, 1999, pp. 1497-1499
688) J. Bertaux, “Vertical Profiles of Ozone from Envisat Space Platform with GOMOS Instrument,” Proceedings of IGARSS’99, Hamburg, Vol. III, June 28-July 2, 1999, pp. 1616-1618

The occultation-mode operation of GOMOS involves pointing the instrument (telescope) toward preselected stars, acquiring and then tracking them with high accuracy. GOMOS observes stars whose lines-of-sight are tangential to the Earth's limb. For each individual star, the spectrum measured outside the atmosphere is compared to the spectrum seen through the atmosphere as the star sinks below the horizon. The difference reveals the presence of ozone and other trace gases. - The instrument has three additional calibration modes to meet the stringent pointing requirements; these are:

- A linearity monitoring mode, allowing calibration for possible nonlinearity of the sensor chains within the large dynamic range.
- A spatial-spread monitoring mode, allowing optimization of position of the CCD read-out regions with respect to that of the stellar spectrum.
- A uniformity monitoring mode, allowing measurement of the sensitivity difference between the various CCD pixels of a spectral sampling interval.

Some GOMOS instrument parameters: Telescope: 30 cm x 20 cm rectangular aperture, FOV: 0.6°, Cassegrain design based on aspherical primary and secondary mirrors; cooled 2-D CCD array; 2-axis stabilized platform; star tracker: $\pm 0.3^\circ$ FOV; total mass: 163 kg; power: 146 W; data rate: 222 kbit/s; data quantization: 12 bits.

MWR = Microwave Radiometer (of ERS-1/2 heritage, built by Alenia Spazio, Italy). A nadir-viewing, two-channel Dicke-type radiometer (passive sensor) operating at 23.8 (K-band) and 36.5 (Ka-band) GHz. The main objectives of MWR is the measurement of atmospheric humidity as supplementary information for tropospheric path correction of the RA-2 signal, which is influenced by the integrated atmospheric water content and by liquid water. In addition, MWR measurements are useful for the determination of surface emissivity and soil moisture of land, for surface energy budget estimations, investigations to support atmospheric studies, and for ice characterization.⁶⁸⁹⁾

Some instrument parameters: FOV = 20 km diameter at nadir; bandwidth = 650 MHz; dynamic range = 3 K - 330 K; absolute radiometric accuracy <3 K, radiometric sensitivity <0.4 K; operation of instrument: continuously over full orbit, data rate = 16.7 kbit/s, instrument mass = 24 kg, power = 18 W. The microwave radiation is received by an offset feed parabolic reflector antenna (fully integrated into the instrument structure), routed through a Dicke switch assembly to a down converter which translates the K- and Ka-band signals to a suitable IF range. The antenna subsystem includes a 60 cm reflector with a focal length of 350 mm and an offset-angle of 47°. Two feeds are used such that the 23.8 GHz channel is pointing in the forward direction and the 36.5 GHz channel in the aft direction, both beams with a footprint of about 20 km (1.5° beam). These frequencies are separately routed into the RF front-end where a two-point calibration scheme is adopted, namely with hot and cold references. MWR is controlled by a common MWR-DORIS instrument control unit. MWR has independent thermal-control elements (heaters and thermostats) to give its electronic circuits optimum performance. - Retrieval of antenna and brightness temperature values from measurement data is accomplished by ground processing. This includes ground calibration data, antenna characteristics and in orbit characterization data.

AATSR = Advanced Along Track Scanning Radiometer, built by the prime contractor Astrium Ltd., UK, and funded by DETR (UK Department of the Environment, Transport and the Regions), DISR (Australian Department of Industry, Science and Resources), and by NERC (UK Natural Environment Research Council). Under DETR's agreements with the Commonwealth of Australia, DISR have provided certain instrument components via contracts with Australian industry, and CSIRO (Commonwealth Science and Industrial Research Organization) of Canberra have been the interface for science issues. Technical support on data processing is provided by RAL (Rutherford Appleton Laboratory) of Chilton, UK.

⁶⁸⁹⁾ J. Guijarro, A. Auriol, et al., "MWR and DORIS - Supporting Envisat's Radar Altimetry Mission," ESA Bulletin, No 104, Nov. 2000, pp. 41-46

AASTR is an imaging radiometer operating in four infrared channels (1.6, 3.7, 10.8, and 12.0 μm) and with three visible/reflected channels (0.55, 0.66, 0.87 μm). AATSR retains the full capability of ATSR (of ERS-1,2).⁶⁹⁰⁾

Objectives of AATSR: a) Continuation of precise measurement of Sea Surface Temperature (SST) started with ATSR-1 and ATSR-2; b) To provide high-quality imagery of TOA (Top-of-Atmosphere) brightness temperature at 1 km resolution covering all parts of the globe except the polar regions, c) To enable scientific studies of ocean dynamics, land surface properties and the properties of clouds.

Channel	Center wavelength	Bandwidth	Primary application
0.55 μm	0.555 μm	20 nm	Chlorophyll
0.66 μm	0.659 μm	20 nm	Vegetation index
0.87 μm	0.865 μm	20 nm	Vegetation index
1.6 μm	1.61 μm	300 nm	Cloud clearing
3.7 μm	3.70 μm	300 nm	SST
11 μm	10.85 μm	1000 nm	SST
12 μm	12.00 μm	1000 nm	SST
Spatial resolution		1 km x 1 km	
Radiometric resolution		0.1 K	
Data quantization		12 bit	
SST accuracy		better than 0.3 K	
Swath width		500 km	
Instrument operation		Continuously over full orbit	
Data rate, instrument mass, power		625 kbit/s, 101 kg, 100 W	

Table 161: AASTR instrument parameters

Figure 98: Illustration of the AATSR instrument

AATSR consists of the following elements: the IR/VIS radiometer, the electronics unit (providing the signal processing function, the scan mirror drive control and temperature sensor conditioning), the blackbody electronics unit (provides control of the blackbody

⁶⁹⁰⁾ J.-P. Huot, H. Tait, M. Rast, S. Delwart, J.-L. Bézy, G. Levrini, “The Optical Imaging Instruments and their Applications: AATSR and MERIS,” ESA Bulletin, No 106, June 2001, pp. 56-66

heaters and collects temperature sensor data), the cooler control unit (provide the control function for the Stirling-cycle coolers), the DEU (Digital Electronics Unit) for instrument control and data formatting functions, and the instrument harness.⁶⁹¹⁾

The VIS/IR radiometer includes an inclined plane scan mirror which is rotated continuously in front of a reflecting telescope to provide a conical scan. The scan axis projects downwards (nadir) and ahead in the along-track direction (about 47°), achieving scanning across the satellite track in two regions: 1) close to the nadir, and 2) at an angle to the sea surface normal looking along the track (47°). The two-angle viewing technique provides improved atmospheric corrections. The focal plane assembly (FPA) is equipped with the detectors, one per channel, converting the radiation to electrical signals. A pair of Stirling cycle coolers keep the detector temperature at 80 K. Two blackbody infrared calibration targets, controlled by the blackbody electronics unit and a diffuse reflector visible calibration target, are viewed between the nadir and along-track scans.

SSTs are derived using the 11 and 12 μm channels for day time data, and the 11, 12 and 3.7 μm channels for night time data. In addition, the two VIS channels centered at 0.67 and 0.87 μm provide measurements of the vegetation index in the same way as AVHRR. An additional channel at 0.55 μm is provided, to indicate, from chlorophyll content, the growth stage and health of vegetation.

The Level 1B product (calibrated and geolocated BT/reflectance) is provided at 1km x 1km resolution at nadir. The Level 2 product containing SST and land parameters is available at 1 km x 1km resolution for regional studies, or spatially averaged over 10 arc min and 30 arc min or 17 km and 50 km cells for global measurements.

Figure 99: Typical AATSR viewing geometries

SCIAMACHY = Scanning Imaging Absorption Spectrometer for Atmospheric Cartography [a cooperative project funded by DLR/NIVR; PIs: J. P. Burrows, University of Bremen;

⁶⁹¹⁾ D. Llewellyn-Jones, M. C. Edwards, C. T. Mutlow, A. R. Birks, I. J. Barton, H. Tait, "AATSR: Global-Change and Surface Temperature Measurements from Envisat," ESA Bulletin, 105, Feb. 2001, pp. 11-21

H. van Dop, University of Utrecht; built by DASA/DSS (electrical assembly) and Fokker Space, TNO and SRON (optical assembly and radiant cooler)]. SCIAMACHY is a passive spectrometer (of GOME heritage) for the measurement of trace gases in the troposphere and stratosphere, operating by differential optical absorption spectroscopy (DOAS) of solar and lunar radiation in the spectral region between 240 nm and 2400 nm. Parallel application of DOAS and BUV (Backscatter UV) measuring techniques. Viewing in three different modes: occultation (sun/moon), nadir, and limb scattering. Data rate: 400 kbit/s for nadir and limb observations; 1.867 Mbit/s for sun occultations.

SCIAMACHY observation objectives:

- Global measurement (abundance and distribution) of trace gases in the troposphere and stratosphere.
- Measurement of aerosol, cloud altitudes and spectral reflection of the surface.
- Troposphere: O₃, O₂, O₄, NO₂, N₂O, CO, CO₂, CH₄ and H₂O. Under special conditions also: HCHO, SO₂ and NO₃
- Stratosphere: O₃, O₂, NO, NO₂, NO₃, N₂O, CO, CO₂, CH₄, H₂O, and BrO. Observation of the NO column above 40 km. Under ozone hole conditions measurement of OClO and ClO in the lower stratosphere are possible.

Spectral Band	Spectral Range (nm)	Spectral Resolution	Detector Operating Temperature	Measured Constituents
1	240-314	0.24 nm	200 K	O ₃ , NO, (ClO)
2	309-405	0.26 nm	200 K	O ₃ , O ₄ , BrO, NO ₂ , HCHO, SO ₂
3	394-620	0.44 nm	200 K	O ₂ , O ₃ , O ₄ , OClO, NO ₂ , NO ₃
4	604-805	0.48 nm	200 K	O ₂ , O ₄ , NO ₃ , H ₂ O
5	785-1050	0.54 nm	200 K	
6	1000-1750	1.48 nm	200 K	O ₄ , H ₂ O
7	1940-2040	0.22 nm	135 K	CO ₂ , H ₂ O
8	2265-2380	0.26 nm	135 K	CO, CH ₄ , N ₂ O, H ₂ O
PMD 1-7	310 - 2380	67 to 137 (channel dependent)		

Table 162: Spectral parameters of SCIAMACHY

The instrument consists of the following systems: optical assembly [scanner module (elevation and azimuth scanners), telescope (off-axis parabolic mirror), spectrometer (grating for each band), detector modules (photodiode array detectors), thermal hardware (cooling of telescope)]; SCIAMACHY Radiant Cooler [radiator, thermal busses]; electronic assembly [power, mechanism and thermal control unit; science data processing unit; instrument control unit; and the digital bus unit]. Instrument mass = 198 kg; power = 122 W. Instrument operation: continuously over the full orbit. IFOV=0.045° x 1.8°. ⁶⁹²⁾

a) Limb-scanning mode (into the flight direction). Objective: vertical distribution of trace gases and aerosols. In this mode the instrument is scanning across-track with a swath width of ±500 km with respect to the subsatellite track.. Scan layers of 3 km vertical thickness (and 100 km pixel width) are measured up to an altitude of 100 km.

b) Nadir-viewing mode. Objective: global distribution and abundance of trace gases, aerosols, cloud cover (observation at least once within three days); swath width = 1000 km; scan period=4 s in forward and 1 s in backward motion; pixel size at nadir (resolution) = 32 km along-track x 16 km across-track.

c) Solar and lunar occultation modes (measurements during each orbit). Objective: high-resolution absorption spectroscopy (DOAS). IFOV = 0.07° (azimuth) x 0.014° (elevation).

⁶⁹²⁾ A. P. H. Goede, H. Schrijver, "SCIAMACHY: An Atmospheric Chemistry Instrument on ENVISAT," Proceedings of IGARSS'99, Hamburg, Vol. III, June28-July 2, 1999, pp. 1609-1611

The sun or moon are either tracked or a vertical scan over the complete sun/moon surface is performed. The obtained spectra can then be compared with suitable calibration spectra to yield the differential absorption of the atmosphere.

In the optical assembly the radiation from the atmosphere is fed by the scanner (consisting of an azimuth and an elevation scanner) into the telescope which directs it onto the entrance slit of the spectrometer. The spectrometer contains a pre-disperser which separates the radiation into three bands, followed by a series of dichroic mirrors which further divide the radiation into eight bands. Each band features a grating to diffract the radiation into a high-resolution spectrum which is then focused onto the detectors (each band has its own 1024 pixel detector array). The pre-disperser also serves as a Brewster window to separate polarized light, a portion of which is sensed by the PMD (Polarization Measurement Device). The PMD output is later used to correct for the polarization effects.

Calibration: In order to guarantee long-term stability of the scientific measurements, SCIAMACHY can perform many different calibration measurements. The calibration system includes internal calibration lamps; SCIAMACHY is radiometrically calibrated for backscattered UV measurements by direct observation of the sun and the full moon (occasionally). Direct measurements of the sun are also used to obtain the background solar source function for the DOAS measurements. Calibrations can in principle be made every orbit.

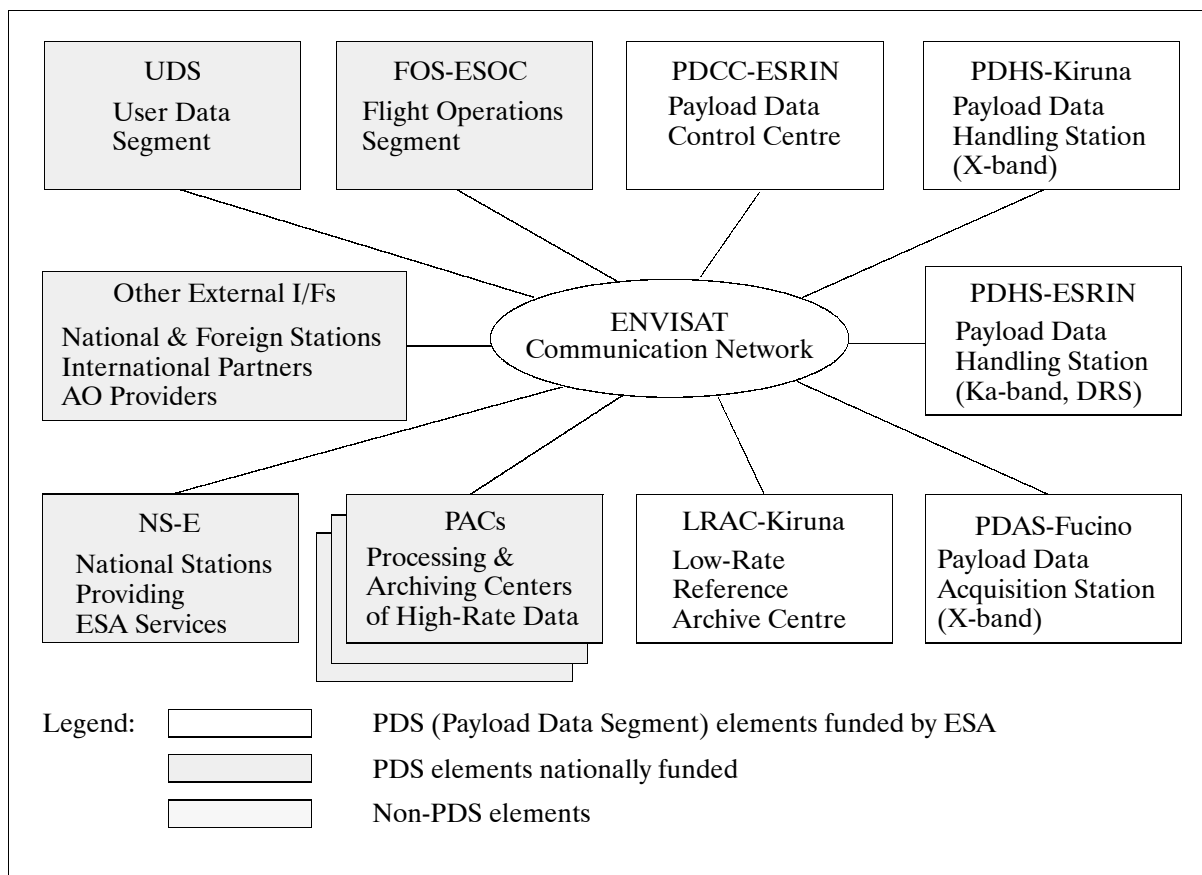

Figure 101: The ENVISAT ground segment concept

D.10 EO-1 (Earth Observing-1)

EO-1 is a technology mission. See description under M.6.

D.11 EOS (Earth Observing System)

EOS is the centerpiece of NASA's Earth Science Enterprise (ESE). It consists of a science component and a data system supporting a coordinated series of polar-orbiting and low inclination satellites for long-term global observations of the land surface, biosphere, solid Earth, atmosphere, and oceans.^{693) 694) 695) 696)}

Background: The EOS program is a NASA initiative of the US Global Change Research Program (USGCRP). Planning for EOS began in the early 1980s, and an AO (Announcement of Opportunity) for the selection of instruments and science teams was issued in 1988. Early in 1990 NASA announced the selection of 30 instruments to be developed for EOS. Major budget constraints imposed by the US Congress forced the EOS program into a restructuring process in the time frame of 1991-92. In addition a rescoping of the EOS program occurred in 1992 leading to just half of the 1990 budget allocation (the HIRIS sensor was eliminated). The instruments adopted as part of the restructured/rescoped EOS program were chosen to address the key scientific issues associated with global climate change. This action reduced the required instruments to 17 that needed to fly by the year 2002 (six

were deferred and seven instruments were deselected from the original 30). Furthermore, a shift occurred in the conceptual design of the EOS satellite platforms from “large observatories” to intermediate and smaller spacecraft that may be launched by smaller and existing launch vehicles. The EOS program experienced a further rebaselining process in 1994, due to a budget reduction of about 9%. This resulted in the cancellation of the combined EOS Radar and Laser Altimeter Mission (but rephasing the latter as two separate missions), deferring the development of some sensors and spreading the launch of missions by increasing the basic re-flight periods of missions from 5 to 6 years, and flying some EOS instruments on missions of partner space agencies (NASDA, RKA, CNES, ESA) in a framework of international cooperation. The EOS program includes instruments provided by international partners (ASTER, MOPITT, HSB, OMI) as well as an instrument developed by a joint US/UK partnership (HIRDLS).

The overall goal of the EOS program is to determine the extent, causes, and regional consequences of global climate change. The following science and policy priorities are defined for EOS observations (established by the EOS investigators working group and in coordination with the national and international Earth science community):

- **Water and Energy Cycles:** Cloud formation, dissipation, and radiative properties which influence the response of the atmosphere to greenhouse forcing, large-scale hydrology, evaporation
- **Oceans:** Exchange of energy, water, and chemicals between the ocean and atmosphere, and between the upper layers of the ocean and the deep ocean (including sea ice and formation of bottom water)
- **Chemistry of the Troposphere and Lower Stratosphere:** Links to the hydrologic cycle and ecosystems, transformations of greenhouse gases in the atmosphere, and interactions including climate change
- **Land-Surface Hydrology and Ecosystem Processes:** Improved estimates of runoff over the land surface and into the oceans. Sources and sinks of greenhouse gases. Exchange of moisture and energy between the land surface and the atmosphere. Changes in land cover
- **Glaciers and Polar Ice Sheets:** Predictions of sea level and global water balance
- **Chemistry of the Middle and Upper Stratosphere:** Chemical reactions, solar-atmosphere relations, and sources and sinks of radiatively important gases
- **Solid Earth:** Volcanoes and their role in climate change.

EOS Satellites

The original EOS mission elements (AM S/C series, PM S/C series, Chemistry S/C series) was redefined again in 1999. The EOS program space segment elements are now: Landsat-7, QuikSCAT, Terra, ACRIMSAT, Aqua, Aura and ICESat (see also Table 179 in D.12).

Parameter	Terra (EOS/AM-1) S/C	Aqua (EOS/PM-1 S/C)
Downlink center frequency	8212.5 MHz	8160 MHz
EIRP	14 W	27.2 W
Bandwidth	26 MHz	15 MHz
Data modulation	OQPSK	SQPSK
Data format	NRZ-L	NRZ-L
I/Q power ratio (nominal)	1:1	1:1
Operational duty cycle	100%	100%
Antenna coverage from nadir	$\pm 64^\circ$	$\pm 64^\circ$
Antenna polarization	RHCP	RHCP
Data rate	13 Mbit/s	15 Mbit/s
Data protocol standard	CCSDS	CCSDS
Instrument data provided	MODIS	MODIS, AIRS, AMSU-A, CERES, HSB, AMSR-E

Table 163: Specification of Direct Broadcast (DB) service of Terra and Aqua satellites

EOS policy includes providing Direct Broadcast (DB) service to the user community; this applies to real-time MODIS data from the Terra spacecraft, as well as to the entire real-time data stream of the Aqua satellite. These data may be received by anyone with the appropriate receiving station, without charge. The broadcast data are transmitted in X-band. A 3 m antenna dish (minimum) should be sufficient for X-band data reception.

D.11.1 Terra Mission (EOS/AM-1)

Terra⁶⁹⁷ is a joint Earth observing mission within NASA's ESE (Earth Science Enterprise) program between the United States, Japan, and Canada. The US provided the spacecraft, the launch, and three instruments developed by NASA (CERES, MISR, MODIS). Japan provided ASTER and Canada MOPITT.

Figure 102: Illustration of the Terra spacecraft

The objective of the mission is to obtain information about the physical and radiative properties of clouds (ASTER, CERES, MISR, MODIS); air-land and air-sea exchanges of energy, carbon, and water (ASTER, MISR, MODIS); measurements of trace gases (MOPITT); and volcanology (ASTER, MISR, MODIS). The science objectives are:

- To provide the first global and seasonal measurements of the Earth system, including such critical functions as biological productivity of the land and oceans, snow and ice, surface temperature, clouds, water vapor, and land cover;
- To improve the ability to detect human impacts on the Earth system and climate, identify the “fingerprint” of human activity on climate, and predict climate change by using the new global observations in climate models;
- To help develop technologies for disaster prediction, characterization, and risk reduction from wildfires, volcanoes, floods, and droughts
- To start long-term monitoring of global climate change and environmental change.

Terra consists of a spacecraft bus built by Lockheed Martin Missiles and Space, Valley Forge, PA. It is three-axis stabilized with a bus size of 6.8 m (length) x 3.5 m (diameter) and a total launch mass of 5,190 kg. The total payload mass is 1155 kg. The average power of the satellite is 2.53 kW provided by a GaAs solar array. The design life is six years. The average

⁶⁹⁷) The EOS/AM-1 satellite was renamed by NASA to “Terra” in Feb. 1999

data rate of the payload is 18.545 Mbit/s (109 Mbit/s peak); on-board recorders for data collection of one orbit. Mission operations are performed at GSFC.

RF communications: ⁶⁹⁸⁾ The primary Terra telemetry data transmissions are via TDRSS (Tracking & Data Relay Satellite System). Command and engineering telemetry data are transmitted in S-band. The science data recorded onboard are transmitted via Ku-band at 150 Mbit/s. The nominal mode of operation is to acquire two 12 minute TDRSS contacts per orbit. During each TDRSS contact, both S-band and Ku-band transmission is being used.

Besides Ku-band and S-band communication, Terra is also capable of downlinking science data via X-band. The X-band communication can be operated in three different modes, Direct Broadcast (DB), Direct Downlink (DDL) and Direct Playback (DP). DB and DDL is used to directly transmit real-time MODIS and ASTER science data respectively to users. The Direct Access System (DAS) provides a backup option for direct transmission in X-band. DAS supports transmission of data to ground stations of qualified EOS users around the world. These users fall into three categories:

- EOS team participants and interdisciplinary scientists
- International meteorological and environmental agencies
- International partners who require data from their EOS instruments

The launch of Terra took place on Dec. 18, 1999 from the VAFB, CA, on an Atlas-Centaur IAS rocket.

Orbit: Sun-synchronous circular orbit, altitude = 705 km, inclination = 98.5°, period = 99 minutes (16 orbits per day, 233 orbit repeat cycles). The descending nodal crossing is at 10:30 AM.

Sensor complement: (ASTER, CERES (2), MISR, MODIS, MOPITT)

ASTER (Advanced Spaceborne Thermal Emission and Reflection Radiometer), a Japanese instrument sponsored by MITI (cooperative project with NASA). The ASTER team leaders are Hiroji Tsu of ERSDAC (Japan) and Anne B. Kahle of JPL. ASTER management is provided by JAROS (Japan Resources Observation System Organization). A Joint US/Japan Science Team is responsible for instrument design, calibration, and validation. Previous instrument name: ITIR (Intermediate Thermal Infrared Radiometer). Objective: Provision of high-resolution and multispectral imagery of the Earth's surface and clouds for a better understanding of the physical processes that affect climate change. Applications: studies of the surface energy balance (surface brightness temperature), plant evaporation, vegetation and soil characteristics, hydrologic cycle, volcanic processes, etc. ⁶⁹⁹⁾ ⁷⁰⁰⁾

The ASTER instrument consists of three separate instrument subsystems; each subsystem operates in a different spectral region, has its own telescope(s), and is built by a different Japanese company. The subsystems are in the VNIR (Visible Near Infrared), SWIR (Shortwave Infrared) and TIR (Thermal Infrared) spectral regions. ASTER is pointable in the cross-track direction such that any point on the globe may be observed at least once within 16 days in all 14 bands and once every 5 days in the VNIR bands. The absolute temperature accuracy is 3K in the 200-240 K range, 2K in the 240-270 K range, and 2 k in the 340-370 K range for TIR bands. Instrument mass=421 kg; power=463 W average, 646 W peak; data rate = 8.3 Mbit/s average and 89.2 Mbit/s peak; thermal control by 80 K Stirling cycle coolers, heaters, cold plate/capillary pumped loop, and radiators; pointing accuracy: for control = 1 km on ground (all axes), knowledge= 342 m on ground (per axis), stability=2 pixels for 60 seconds.

Table 166: Spectral range comparison of ASTER and TM (on Landsat)

The VNIR subsystem, built by NEC Corporation, is a reflecting-refracting improved Schmidt design. VNIR features two telescopes, one nadir-looking with a three-spectral-band detector, and the other backward-looking with a single-band detector. The backward-

looking telescope provides a second view of the target area in band 3B for stereo observations. Cross-track pointing is accomplished by rotating the entire telescope assembly. Band separation is through a combination of dichroic elements and interference filters that allow all three bands to view the same ground area simultaneously. Calibration of the nadir-pointing detectors is performed with two halogen lamps.

The SWIR subsystem, built by MELCO (Mitsubishi Electric Company), uses a nadir-pointing aspheric refracting telescope. Cross-track pointing is accomplished by a pointing mirror. The size of the detector/filter combination requires a wide spacing of the detectors, causing in turn a parallax error of about 0.5 pixels per 900 m of elevation. This error is correctable if elevation data (DEM) are available. Two halogen lamps are used for calibration. The maximum data rate is 23 Mbit/s.

Figure 103: Illustration of the ASTER subsystems

CERES (Clouds and the Earth's Radiant Energy System), PI: B. Barkstrom, NASA/LaRC, built by TRW. Objective: Long-term measurement of the Earth's radiation budget and atmospheric radiation from the top of the atmosphere to the surface; provision of an accurate and self-consistent cloud and radiation database (input to WCRP international programs like TOGA, WOCE, and GEWEX). Retrieval of cloud parameters in terms of measured areal coverage, altitude, liquid water content, and shortwave and longwave optical depths. Specific science objectives are: ⁷⁰¹⁾

- For climate change analysis, provide a continuation of the ERBE record of radiative fluxes at the top of the atmosphere (TOA), analyzed using the same algorithms that produced the ERBE data.
- Double the accuracy of estimates of radiative fluxes at TOA and the Earth's surface.
- Provide the first long-term global estimates of the radiative fluxes within the Earth's atmosphere.
- Provide cloud property estimates that are consistent with the radiative fluxes from surface to TOA.

The CERES instrument assembly (of ERBE heritage) consists of a pair of broadband scanning radiometers (two identical instruments), one instrument operates in the cross-track mode for complete spatial coverage from limb to limb; the other one operates in a rotating scan plane (biaxial scanning) mode to provide angular sampling. The cross-track radiometer measurements are a continuation of the ERBS mission. The biaxially scanning radiometer provides angular flux information to improve model accuracy. A single cross-track CERES instrument is flown on TRMM, while the dual scanner instrument flies on Terra (EOS/AM-1) and Aqua (EOS/PM-1).

Instrument parameters (2 scanners): mass = 90 kg , power = 103 W (average), data rate = 20 kbit/s, duty cycle = 100%, thermal control by heaters and radiators, pointing knowledge

⁷⁰¹⁾ NASA/LaRC CERES brochure, NP-1999-04-069-GSFC

= 180 arcsec. CERES measures longwave and shortwave infrared radiation using thermistor bolometers to determine the Earth’s radiation budget. There are three channels in each radiometer:

- Total radiance in the spectral range of 0.35 - 505 μm . Measurement accuracy of 0.5%.
- Shortwave: 0.3 - 55 μm . Measurement of reflected sunlight to an accuracy of 1%.
- Longwave: 85 - 125 μm . Measurement of Earth-emitted radiation to an accuracy of 0.3%.

Limb-to-limb scanning with a nadir IFOV (Instantaneous Field of View) of 14 mrad, FOV = $\pm 78^\circ$ cross-track, 360° azimuth. Spatial resolution = 20 km at nadir.

Figure 104: Schematic illustration of some EOS instruments

MISR (Multi-angle Imaging SpectroRadiometer), PI: D. J. Diner, NASA/JPL. Objective: provision of multiple-angle continuous sunlight coverage of the Earth with high spatial resolution (multidirectional observations of each scene within a time scale of minutes). MISR uses nine CCD cameras to observe the Earth at nine discrete viewing angles: one at nadir, plus eight other symmetrical views at 26.1°, 45.6°, 60.0°, and 70.5° forward and aft of nadir. Images at each angle are obtained in four spectral bands centered at 0.446, 0.558, 0.672, and 0.866 μm . Each of the 36 instrument data channels (i.e. four spectral bands for each of the nine cameras) is individually commandable to provide ground sampling of 275 m, 550 m, or 1100 m. The swath is 360 km; multi-angle coverage (repeat cycle) of the entire Earth in nine days at the equator, and in two days at higher latitudes.

Camera	View angle	Boresight angle	Swath offset angle	Effective focal length
Df	70.3° forward	57.88°	-2.62°	123.67 mm
Cf	60.2° forward	51.30°	-2.22°	95.34 mm
Bf	45.7° forward	40.10°	-1.71°	73.03 mm
Af	26.2° forward	23.34°	-1.06°	58.90 mm
An	0.1° nadir	-0.04°	0.04°	58.94 mm
Aa	26.2° aftward	-23.35°	1.09°	59.03 mm
Ba	45.7° aftward	-40.06°	1.76°	73.00 mm
Ca	60.2° aftward	-51.31°	2.24°	95.33 mm
Da	70.6° aftward	-58.03°	2.69°	123.66 mm

Table 167: MISR as-built camera pointing specifications

Application: MISR provides global maps of planetary and surface albedo (brightness temperature), and aerosols and vegetation properties. Monitoring of global and regional trends

in radiatively important optical properties (eg., opacity, single scattering albedo, and scattering phase function) of natural and anthropogenic aerosols. ⁷⁰²⁾

Parameter	Description
Mission life	6 years
Global coverage time	Every 9 days, with repeat coverage between 2-9 days depending on latitude
Cross-track swath width	360 km common overlap of all 9 cameras, FOV = $\pm 60^\circ$ along-track and $\pm 15^\circ$ cross-track.
Nine CCD cameras	Named An, Af, Aa, Bf, Ba, Cf, Ca, Df, and Da where fore, nadir, and aft viewing cameras have names ending with letters f, n, a respectively and four camera designs are named A, B, C, D with increasing viewing angle respectively
View angles at Earth surface	0° , 26.1° , 45.6° , 60.0° , and 70.5°
Spectral coverage	Four bands centered at 0.446, 0.558, 0.672, and 0.866 μm (blue, green, red, and NIR)
Spatial resolution	275 m, 550 m, or 1.1 km, selectable in-flight
Detectors	CCDs, each camera with 4 independent line arrays (one per filter), 1504 active pixels per line
Radiometric accuracy	3% at maximum signal
Detector temperature	$-5 \pm 0.1^\circ\text{C}$ (cooled by thermo-electric cooler) of focal plane
Structure temperature	5°C
Instrument mass, power	149 kg, 131 W peak and 83 W average
Instrument size	0.9 m x 0.9 m x 1.3 m
Data rate	3.3 Mbit/s average, 9.0 Mbit/s peak

Table 168: MISR instrument specification

Figure 105: Illustration of the MISR observing concept from Terra

MISR images are acquired in two observing modes: global and local. The global mode provides continuous planet-wide observations, with most channels operating at moderate reso-

⁷⁰²⁾ <http://www-misr.jpl.nasa.gov/>

lution; some selected channels operate at the highest resolution for cloud screening and classification, image navigation, and stereo-photogrammetry. The local mode provides data at the highest resolution in all spectral bands and all cameras for selected 300 km x 300 km regions. In addition to data products providing radiometrically calibrated and geo-rectified images, global mode data will be used to generate two standard (level 2) science products: TOA (Top-of-Atmosphere)/Cloud Product and the Aerosol/Surface Product.

MISR on-orbit radiometric calibration is performed bi-monthly, using deployable white Spectralon panels to reflect diffuse sunlight into the cameras, and a set of photodiodes to measure the reflected radiance. Additionally, vicarious calibrations using field and Air-MISR data are done on six-month intervals. Geometric calibration of the cameras is done using ground control points.

MODIS (Moderate-Resolution Imaging Spectroradiometer), Science team leader: V. Salomonson, NASA/GSFC; prime contractor is Raytheon SBRs; MODIS algorithm development by an international team of scientists from USA, UK, Australia, and France; there are four discipline groups: Atmosphere, Land, Oceans, and Calibration. 703) 704) 705)

The instrument is flown on the Terra and Aqua satellites (prime instrument). Objective: to measure biological and physical processes on a global basis on time scales of 1 to 2 days. MODIS is an optomechanical imaging spectroradiometer, consisting of a cross-track scan mirror (continuously rotating double-sided scan mirror assembly) and collecting optics, and a set of linear detector arrays with spectral interference filters located in four focal planes. The optical arrangement provides imagery in 36 discrete bands between 0.4 and 14.5 μm (21 bands within 0.4-3.0 μm range, 15 bands within 3-14.5 μm range). The spectral bands provide a spatial resolution of 250 m, 500 m, or 1 km at nadir. MODIS heritage: AVHRR (POES), HIRS (POES), TM (Landsat), CZCS (Nimbus-7). In fact, the MODIS instrument is considered to be a next-generation AVHRR instrument, having 36 bands (AVHRR/3 has 6) and a spatial resolution of 250 m (AVHRR has 1 km).

Figure 106: MODIS instrument illustration

A high-performance passive radiative cooler provides cooling to 83 K for the infrared bands on two HgCdTe FPAs (Focal Plane Assemblies). A new photodiode-silicon readout technology for the VNIR range provides unsurpassed quantum efficiency and low-noise readout with a very good dynamic range.

Table 169: MODIS spectral performance parameters

MODIS polarization sensitivity < 2% for the visible range out to 2.2 μm ; the performance goal for SNR (Signal-to-Noise Ratio) and NEAT (Noise-Equivalent Temperature Difference) values is 30-40% better than the required values in Table 169.; absolute irradiance accuracy of 5% for < 3 μm and 1% for > 3 μm ; absolute temperature accuracy of 0.2 K for oceans and 1 K for land; daylight reflection and day/night emission spectral imaging; swath width of 2330 km at 110° FOV; scan rate = 20.3 rpm across track; instrument mass = 250 kg; duty cycle = 100%; power = 225 W (average); data rate = 6.2 Mbit/s (average), 10.6 Mbit/s (peak daytime), 3.2 Mbit/s (night); quantization = 12 bit. Instrument IFOV (spatial resolution) = 250 m (bands 1-2), = 500 m (bands 3-7), = 1000 m (bands 8-36).

MODIS provides global coverage every 1 to 2 days. It provides specific global survey data, which includes the following (some standard data products):

- Cloud mask: at 250 m and 1 km resolution by day and at night
- Aerosol concentration and optical properties: at 5 km resolution over oceans and 10 km over land during the day
- Cloud properties: characterized by optical thickness, effective particle radius, cloud droplet phase, cloud-top altitude, cloud-top temperature
- Vegetation and land-surface cover, conditions, and productivity, defined as:
 - Vegetation indices corrected for atmospheric effects, soil, polarization, and directional effects

- Surface reflectance
- Land-cover type with identification and detection of change
- Net primary productivity, leaf-area index, and intercepted photosynthetically active radiation
- Snow and sea-ice cover and reflectance
- Surface temperature with 1 km resolution, day and night, with absolute accuracy goals of 0.3-0.5°C for oceans and 1°C for land surfaces.
- Ocean color: defined as ocean-leaving spectral radiance within 5% from 415-653 nm, based on adequate atmospheric correction from NIR sensor channels
- Concentration of chlorophyll-a within 35% from 0.05 to 50 mg/m³ for case 1 waters
- Chlorophyll fluorescence within 50% at surface water concentrations of 0.5 mg/m³ of chlorophyll-a.

Parameter	Value	Parameter	Value
Instrument type	Opto-mechanical design (whiskbroom scanner)	Data rate	10.6 Mbit/s (peak daytime), 6.1 Mbit/s (orbital average)
Scan rate	20.3 rpm	Data quantization	12 bit
Telescope	17.8 cm diameter off-axis, afocal (collimated) with intermediate field stop	Spatial resolution	250 m (bands 1-2) 500 m (bands 3-7) 1000 m (bands 8-36)
Size	1.0 m x 1.6 m x 1.0 m	Swath width, FOV	2330 km, 110°
Mass	229 kg	Swath length/scan	10 km (along track)
Power	162.5 W	Design life	6 years

Table 170: Some specification parameters of the MODIS instrument

MODIS on-board calibration employs various techniques for comprehensive verification of spectral, radiometric and spatial measurements. They include:⁷⁰⁶⁾

- Spectroradiometric Calibration Assembly (SRCA)
 - Spectral calibration of reflective channel bandpasses
 - Verification of spectral band registration
 - DC restoration on every scan using a direct view of space
 - Lunar calibration via the space-view port as well as periodic rotations of the S/C to enable full scans across the moon through the active scan aperture
- Blackbody calibration of thermal bands on every scan (a v-groove blackbody)
- Solar Diffuser (SD) reference
- Solar Diffuser Stability Monitor (SDSM)

MOPITT (Measurement of Pollution in the Troposphere), PI: J. Drummond, University of Toronto, Canadian sensor supported by CSA, built by COMDEC.^{707) 708) 709)} MOPITT is the first satellite sensor to use gas correlation spectroscopy. The instrument measures emitted and reflected infrared radiance in the atmospheric column. Analysis of these data permit retrieval of tropospheric CO profiles and total column CH₄. Objective: study of how these gases interact with the surface, ocean, and biomass systems (distribution, transport, sources and sinks). Measurements are performed on the principle of correlation spectroscopy utilizing both pressure-modulated and length-modulated gas cells, with detectors at 2.3, 2.4, and 4.7 µm. Vertical profile of CO (carbon monoxide) and total column of CH₄ (methane) are to be measured; CO concentration in 4 km layers with an accuracy of 10%; CH₄ column abundance accuracy is 1%. Swath width = 616 km, spatial resolution = 22 x 22 km; instrument mass = 182 kg; power = 243 W; duty cycle = 100%; data rate = 25 kbit/s; thermal control by an 80 K Stirling cycle cooler, capillary-pumped cold plate and passive radiation; thermal operating range = 25° C (instrument) and 100 K (detectors).

⁷⁰⁶⁾ Information provided by C. Schueler and J. Thunen of Hughes SBRC (now Raytheon SBRS)

⁷⁰⁷⁾ MOPITT brochure of CSA/NASA

⁷⁰⁸⁾ [http://www.science.sp-agency.ca/J1-MOPITT\(Eng\).htm](http://www.science.sp-agency.ca/J1-MOPITT(Eng).htm)

⁷⁰⁹⁾ <http://www.atmosp.physics.utoronto.ca/MOPITT/home.html>

MOPITT is designed as a scanning instrument. IFOV = $1.8^\circ \times 1.8^\circ$ (22 km x 22 km at nadir). The instrument scan line consists of 29 pixels, each at 1.8° increments. The maximum scan angle is 26.1° off-axis which is equivalent to a swath width of 640 km. - MOPITT data products include gridded retrievals of CH_4 with a horizontal resolution of 22 km and a precision of 1%. Gridded CO soundings are retrieved with 10% accuracy in three vertical layers between 0 and 15 km. Three-dimensional maps to model global tropospheric chemistry.

D.11.2 Aqua Mission (EOS/PM-1)

The focus of the Aqua mission objective is the multi-disciplinary study of the Earth's inter-related processes (atmosphere, oceans, and land surface) and their relationship to Earth system changes. The data sets of Aqua provide information on cloud formation, precipitation, and radiative properties, air-sea fluxes of energy, carbon, and moisture (AIRS, AMSU, AMSR-E, HSB, CERES, MODIS); and sea ice extent (MODIS). A launch of Aqua is planned for Dec. 2001 with a Delta-2 7920-10L vehicle from VAFB.

The Aqua ⁷¹⁰⁾ (EOS/PM-1) S/C is based on TRW's modular, standardized AB1200 bus design with common subsystems. The satellite dimensions are: 2.68 m x 2.47 m x 6.49 m (stowed) and 4.81 m x 16.70 m x 8.04 m (deployed). Aqua is three-axis stabilized, with a total mass of 2,934 kg at launch, S/C mass of 1,750 kg, payload mass = 1,082 kg, propellant mass = 102 kg; power = 4.86 kW (EOL). Propulsion: hydrazine blow-down system; 4 pairs of thrusters. The spacecraft mass is 6.468 kg, the design life is six years.

Figure 107: Illustration of the Aqua satellite

Communication: X-band. S-band (TDRSS and Deep Space Network/Ground Network compatible).

⁷¹⁰⁾ Note: NASA renamed the EOS/PM-1 satellite to Aqua on Oct. 18, 1999

Orbit: Sun-synchronous circular orbit, altitude = 705 km (nominal), inclination = 98.2°, local equator crossing at 13:30 (1:30 PM) on ascending node, period = 98.8 minutes.

Sensor complement: (AIRS, AMSU, AMSU-E, CERES, HSB, MODIS). The descriptions of CERES and MODIS can be found under Terra.

AIRS (Atmospheric Infrared Sounder), NASA/JPL instrument, PI: M. T. Chahine; prime contractor is LMIRIS (Lockheed Martin Infrared Instrument Systems), Lexington, MA. AIRS, along with AMSU and HSB, is of HIRS and MSU heritage flown on the NOAA POES series. Objective: High-spectral-resolution measurement of global temperature/humidity profiles in the atmosphere. Measurement of the Earth’s upwelling infrared radiances in the spectral range of 3.74 - 15.4 μm , simultaneously at 2378 frequencies (bands). A limited number of visible wavelength channels are also present.⁷¹¹⁾

The AIRS instrument consists of an array grating spectrometer that provides coverage in the infrared region (spectral range of 3.74 - 15.4 μm) with a spectral resolution of 1200 ($\lambda/\Delta\lambda$). The high spectral resolution permits the separation of unwanted spectral emissions and, in particular, provides spectrally clean “super windows,” ideal for surface observations. - This is supplemented by a VNIR photometer of four bands in the range between 0.4 and 1.0 μm . The VNIR channels are used to discriminate between low-level clouds and different terrain and surface covers, including snow and ice. The AIRS infrared bands have an IFOV of 1.1° and FOV = $\pm 49^\circ$ scanning capability perpendicular to the spacecraft ground track (swath width = 1650 km, 13.5 km horizontal resolution in nadir, 1 km vertical). It takes 22.41 ms for each footprint of 1.1° in diameter (or 13.5 km). Each IR scan produces 90 footprints across the flight track and takes 2.67 s. The VNIR channels have a footprint of 0.185° or about 2.3 km on the ground, nine VNIR footprints are within a 40 km swath. The VNIR photometer is boresighted to the spectrometer to allow simultaneous VNIR observations.

The IR detectors array (HgCdTe) is positioned at the focal plane, it is cooled to 60K by redundant Stirling cycle cryocoolers. The IR spectrometer is also cooled to 150 K by a two-stage radiative cooler. The VNIR photometer uses optical filters to define the four spectral bands. It operates at ambient temperatures (293-300 K). Inflight calibration is performed during each scan period. In addition, AIRS uses four independent cold-space views.

Spectral coverage	3.74 - 15.4 μm for the array grating spectrometer (IR bands) 0.4 - 1.0 μm for photometer (4 VNIR bands)
Spectral resolution	1200 ($\lambda/\Delta\lambda$) array grating spectrometer, 2378 bands
Spatial resolution	13.5 km horizontal at nadir for IR bands (IFOV = 1.1°), 1 km vertical resol. 2.3 km x 2.3 km for VNIR bands (IFOV = 0.185°)
Swath width	1650 km (FOV = $\pm 49.5^\circ$) for IR bands 40 km for VNIR bands
Instrument mass, power	140 kg, 224 W
Date rate, duty cycle	1.42 Mbit/s, 100%

Table 171: Overview of some AIRS parameters

Thermal control by redundant 60 K Stirling cycle coolers, heater, mini thermal bus, two-stage radiator; thermal operating range = 20-25 °C.

The major data products derived from AIRS are atmospheric temperature profiles, humidity profiles (from channels in the 6.3 μm water vapor band and the 11 μm windows, sensitive to the water vapor continuum), and land skin surface temperature.

AIRS has been selected to fly on the Aqua (EOS/PM-1) satellite with two operational microwave sounders: NOAA’s AMSU and Brazil’s HSB (Humidity Sounder Brazil). Together, the three sensors constitute the advanced operational sounding system on future NOAA missions.

⁷¹¹⁾ <http://www-airs.jpl.nasa.gov/>

AMSU/HSB (Advanced Microwave Sounding Unit (NOAA Instrument)/ (Humidity Sounder for Brazil), provided by INPE. Both instruments operate in conjunction. AMSU was designed and developed by Aerojet of Azusa, CA (a GenCorp company). AMSU primarily provides temperature soundings, whereas HSB provides humidity soundings. AMSU is a 15-channel microwave radiometer. AMSU and HSB have a total of 19 channels, 15 are assigned to AMSU, each having a 3.3° beamwidth, and four are assigned to HSB, each having a beamwidth of 1.1°. AMSU comprises two separate units: AMSU-A-1 (channels 3-15), and AMSU-A-2 (channels 1 and 2). Channels 3 - 14 use the 50 to 60 GHz oxygen band to provide data for vertical temperature profiles up to 50 km. The “window” channels (1, 2, and 15) provide data to enhance the temperature sounding by correcting for surface emissivity, atmospheric liquid water, and total precipitable water. HSB channels 17 - 20 use the 183.3 GHz water vapor absorption line to provide data for the humidity profile.

AMSU-A1 measures temperature profiles from the surface up to 50 km in 15 channels. Temperature resolution: 0.25 - 1.2 K. The AMSU-A1 instrument has two 15 cm diameter antennas (reflectors with momentum compensation), each with a 3.3° nominal IFOV at the half power points or FWHM (Full width Half maximum). Each antenna provides a cross-track scan of $\pm 49.5^\circ$ from nadir with a total of 30 Earth views (scan positions) per scan line. The total scan period is eight seconds. The footprint (resolution) at nadir is 40 km. The swath width is approximately 1650 km. Internal calibration is performed with internal warm loads and cold space.

AMSU-A-2 has a single 28 cm diameter antenna (reflector without momentum compensation) with a 3.3° nominal IFOV. All other instrument/observation parameters are the same as those of AMSU-A1.

AMSU parameters: mass = 100 kg; power = 125 W; data rate = 3.2 kbit/s; thermal control by heater, central thermal bus, radiator; thermal operating range = 0-20° C.

Sensor	Channel	Center Frequency (GHz)	Bandwidth (MHz)	Sensitivity NEAT (K)
AMSU-A2 (2 channels)	1	23.8	280	0.3
	2	31.4	180	0.3

	19	183.31 \pm 3.00	2000	1.0
	20	183.31 \pm 7.00	4000	1.2

Table 172: Spectral parameters of the AMSU-A and HSB instruments

HSB (Humidity Sounder for Brazil). An INPE-provided instrument of AMSU-B heritage [built by MMS of Bristol, UK (now Astrium Ltd) with participation of Equatorial Sistemas of Brazil], and sponsored by AEB (Brazilian Space Agency).⁷¹²⁾ HSB is a microwave radiometer which the objective to measure atmospheric radiation, to obtain atmospheric water vapor profile measurements and to detect precipitation under clouds with 13.5 km horizontal nadir resolution (humidity profiles for weather forecasting). HSB is a four-channel self-calibrating instrument (passive sounder) providing a humidity profiling capability in the

⁷¹²⁾ <http://www.dss.inpe.br/programas/hsb/ingl/index.html>

frequency range of 150 - 190 GHz, spanning the height from surface to about 42 km. The measured signals are also sensitive to a) liquid water in clouds (cloud liquid water content) and b) graupel and large water droplets in precipitating clouds (qualitative estimate of precipitation rate). HSB scans in the cross-track direction at a rate of 2.67 seconds in continuous mode. The instrument features a momentum-compensated scan mirror system. HSB is operated in combination with AMSU-A, they have a total of 19 channels: 15 are assigned to AMSU-A, each having a 3.3° beamwidth, and four assigned to HSB, each having a 1.1° beamwidth. The HSB receiver channels are configured to operate in DSB (Double Sideband). ⁷¹³⁾

Nr. of channels	4 (total), Ch 17 at 150 GHz, Ch 18: 183.31 ±1 GHz, Ch. 19: 183.31 ±3 GHz, and Ch 20: 183.31 ±7 GHz
Swath width, scan period	1650 km, 2.67 s
FOV	±49.5° cross track from nadir (+90° to -49.5° for calibration)
IFOV (spatial resolution)	1.1° (13.5 km at nadir)
Instrument pointing	Control = 3600 arcseconds, knowledge = 360 arcseconds, stability = 74 arcseconds/s
Thermal control, operating range	Radiator, 13 - 35°C
Instrument power	80 W average, 154 W peak
Instrument mass, size, data rate	50.5 kg, 73 cm x 69 cm x 47 cm, 4.2 kbit/s
Temperature accuracy (data profile)	1.0 - 1.2 K, coverage (twice daily) of land and ocean surfaces, resolution of 50 km (horiz.) and 1 km (vertical), up to 100 mb
Humidity accuracy (data profile)	20%, global coverage (twice daily), res. = 50 km, 1 km (vertical)
Radiance accuracy (data profile)	1-1.2 K, global coverage (twice daily), res. = 15 km (average)

Table 173: Specification of the HSB instrument

AMSR-E (Advanced Microwave Scanning Radiometer-EOS), a NASDA/NASA cooperative instrument, of AMSR heritage, built by Mitsubishi Electronics Corporation (PIs: A. Shibata, R. W. Spencer). The objective is the measurement of geophysical parameters such as: cloud properties, radiative energy flux, precipitation, land surface wetness, sea ice, snow cover, sea surface temperature (SST), and sea surface wind fields. AMSR-E is a modified design of AMSR on ADEOS-II (Japan). AMSR-E is a twelve channel, six frequency total power passive microwave radiometer system. It measures brightness temperatures at 6.925, 10.65, 18.7, 23.8, 36.5, and 89.0 GHz. Vertically and horizontally polarized measurements are taken at all channels. ⁷¹⁴⁾

Center frequency (GHz)	6.925	10.65	18.7	23.8	36.5	89.0
Bandwidth (MHz)	350	100	200	400	1000	3000
Sensitivity (K)	0.3	0.6	0.6	0.6	0.6	1.1

Beamwidth (°)	2.2	1.4	0.8	0.9	0.4	0.18

Table 174: Performance parameters of AMSR-E

AMSR-E consists of an offset parabolic reflector 1.6 m in diameter, fed by an array of six feedhorns. The reflector and feedhorn arrays are mounted on a drum which contains the radiometers, digital data subsystem, mechanical scanning subsystem, and power subsystem. The reflector/feed/drum assembly is rotated about the axis of the drum by a coaxially mounted bearing and power transfer assembly. All data, commands, timing and telemetry signals, and power pass through the assembly on slip ring connectors to the rotating assembly. The AMSR-E instrument has a mass of 324 kg, power = 350 W, a duty cycle of 100%, and an average data rate of 87.4 kbit/s.

⁷¹³⁾ Information provided by Janio Kono of INPE, Sao José dos Campos, Brazil

⁷¹⁴⁾ <http://www.ghecc.msfc.nasa.gov/AMSR/>

Figure 108: Illustration of the AMSR-E instrument

The AMSR-E instrument rotates continuously about an axis parallel to the local spacecraft vertical at 40 rpm. At an altitude of 705 km, it measures the upwelling scene brightness temperatures over an angular sector of $\pm 61^\circ$ about the subsatellite track, resulting in a swath width of 1445 km. During a period of 1.5 seconds the S/C subsatellite point travels 10 km. Even though the IFOV for each channel is different, active scene measurements are recorded at equal intervals of 10 km (5 km for the 89 GHz channels) along the scan. The half cone angle at which the reflector is fixed is 47.4° which results in an Earth incidence angle of 55.0° .

The AMSR-E instrument rotates continuously about an axis parallel to the local spacecraft vertical at 40 rpm. The half cone angle at which the reflector is fixed is 47.4° which results in an Earth incidence angle of 55.0° .

Instrument calibration. The radiometer calibration accuracy budget, exclusive of antenna pattern correction effects, is composed of three major contributors: warm load reference error, cold load reference error, radiometer electronics nonlinearities and errors.

D.11.3 Aura Mission (EOS/Chem-1)

Aura ⁷¹⁵⁾ is the chemistry mission of NASA with the overall objective to study the chemistry and dynamics of Earth's atmosphere from the ground through the mesosphere. The goal is to monitor the complex interactions of atmospheric constituents from both natural sources, such as biological activity and volcanoes, and man-made sources, such as biomass burning, are contributing to global change and effect the creation and depletion of ozone. The Aura mission will provide global surveys of several atmospheric constituents which can be classi-

⁷¹⁵⁾ Note: The EOS/Chem-1 mission was renamed in 2000 to Aura.

fied into anthropogenic sources (CFC types), radicals (e.g., ClO, NO, OH), reservoirs (e.g., HNO, HCl), and tracers (e.g., N₂O, CO₂, H₂O). Temperature, geopotential heights, and aerosol fields will also be mapped. A launch of Aura on a Delta-2 7920 vehicle from VAFB is planned for 2003.

The Aura spacecraft, like Aqua, is based on TRW's modular, standardized AB1200 bus design with common subsystems. The S/C dimensions are: 2.68 m x 2.34 m x 6.85 m (stowed) and 4.71 m x 17.03 m x 6.85 m (deployed). Aqua is three-axis stabilized, with a total mass of 2,967 kg at launch, S/C mass of 1,767 kg, payload mass = 1,200 kg. The S/C design life is six years. RF communications are in S-band.

Orbit: Sun-synchronous circular orbit, altitude = 705 km, inclination = 98.7°, with a local equator crossing time of 13.45 (1:45 PM) on the ascending node.

Figure 109: Illustration of the Aura spacecraft

Sensor complement: (HIRDLS, MLS, OMI, and TES)

HIRDLS (High-Resolution Dynamics Limb Sounder), a joint instrument between the University of Colorado at Boulder and Oxford University, Oxford, UK. PIs: J. Gille of the University of Colorado and J. Barnett, Oxford University; prime contractors are Lockheed Martin and Astrium Ltd., UK. - Spectral range: 6 - 18 μ m. The instrument is selected to fly on Aura. HIRDLS observes global distributions of temperature and trace gas concentrations of O₃, H₂O, CH₄, N₂O, HNO₃, NO₂, N₂O₅, CFC₁₁, CFC₁₂, ClONO₂, and aerosols in the upper troposphere, stratosphere, and mesosphere plus water vapor, aerosol, and cloud tops. The swath width is 2000-3000 km (typically six profiles across swath). Complete Earth coverage (including polar night) can be obtained in 12 hours. High horizontal resolution is obtained with a commandable azimuth scan which, in conjunction with a rapid elevation

scan, provides profiles up to 3,000 km apart in an across-track swath. Spatial resolution: standard profile spacing is 500 x 500 km horizontally (equivalent to 5° longitude x 5° latitude) x 1 km vertically; averaging volume for each data sample 1 km vertical x 10 km across x 300 km along line-of-sight.⁷¹⁶⁾

HIRDLS is an infrared limb-scanning radiometer designed to sound the upper troposphere, stratosphere, and mesosphere. HIRDLS performs limb scans in the vertical at multiple azimuth angles, measuring infrared emissions in 21 channels (temperature distribution) ranging from 6.12 - 17.76 μm . Four channels measure the emission of CO₂. Taking advantage of the known mixing ratio of CO₂, the transmittance is calculated, and the equation of radiative transfer is inverted to determine the vertical distribution of the Planck black body function, from which the temperature is derived as a function of pressure. Winds and potential vorticity are determined from spatial variations of the height of geopotential surfaces.

Data rate = 65 kbit/s; mass = 220 kg; duty cycle = 100%; power = 220 W(average), 239 W (peak); instrument size: 154.5 cm x 113.5 cm x 130 cm; FOV(scan range): elevation from 22.1° to 27.3° below horizontal, azimuth: -21° (sun side) to +43° (anti-sun side). Detector IFOV: 1 km vertical x 10 km (2.5°) horizontal. The instrument has 21 photoconductive HgCdTe detectors cooled to 65 K; each detector has a separate bandpass interference filter. Thermal control by paired Stirling cycle coolers, heaters, sun baffle, radiator panel; the thermal operating range is 20-30° C.

MLS (Microwave Limb Sounder), of UARS MLS heritage, PI: J. W. Waters, NASA/JPL. MLS is selected to fly on the Aura mission. The instrument measures thermal emissions from the atmospheric limb in submillimeter and millimeter wavelength spectral bands and is intended for studies of the following processes and parameters:⁷¹⁷⁾

- Chemistry of the lower stratosphere and upper troposphere. Measurement of lower stratospheric temperature and concentrations of: H₂O, O₃, ClO, BrO, HCl, OH, HO₂, HNO₃, and HCN, and N₂O. Measurement of upper tropospheric H₂O and O₃ (radiative forcing on climate change).
- Chemistry of the middle and upper stratosphere. Monitoring of ozone chemistry by measuring radicals, reservoirs, and source gases in chemical cycles which destroy ozone
- The effects of volcanoes on global change. MLS measures SO₂ and other gases in volcanic plumes.

Measurements are performed continuously, at all times of day and night, altitude range from the upper troposphere to the lower thermosphere. The vertical scan is chosen to emphasize the lower stratosphere and upper troposphere. Complete latitude coverage is obtained each orbit. Pressure (from O₂ lines) and height (from a gyroscope measuring small changes in the FOV direction) are measured to provide accurate vertical information for the composition measurements.

Measurement approach: passive limb sounder; thermal emission spectra collected by offset Cassegrain scanning antenna system; Limb scan = 0 - 120 km; spatial resolution = 3 x 300 km horizontal x 1.2 km vertical. MLS contains heterodyne radiometers in five spectral bands.

FOV: boresight 60-70° relative to nadir; IFOV = $\pm 2.5^\circ$ (half-cone, along-track); spatial resolution: measurements are performed along the suborbital track; the resolution varies for different bands, at 640 GHz the spatial resolution is: 1.5 km vertical x 3 km cross-track x 300 km along-track at the limb tangent point; a typical resolution is: 3 km vertical x 5 km cross-track x 500 km along-track. Spectral bands at millimeter and submillimeter wavelengths. Instrument mass = 430 kg, power = 530 W; duty cycle = 100%; data rate = 100 kbit/s; thermal control via radiators and louvers to space as well as heaters; thermal operating range is 10-35°C.

⁷¹⁶⁾ <http://aura.gsfc.nasa.gov/hirdls/>

⁷¹⁷⁾ <http://aura.gsfc.nasa.gov/mls/>

Spectral band center	Measurement objective
118 GHz	Primarily for temperature and pressure
190 GHz	Primarily for H ₂ O, HNO ₃ , and continuity with UARS MLS measurements
240 GHz	Primarily for O ₃ and CO
640 GHz	Primarily for N ₂ O, HCl, ClO, HOCl, BrO, HO ₂ , and SO ₂
2.5 THz	Primarily for OH

Table 175: MLS instrument frequency bands

OMI (Ozone Monitoring Instrument), ^{718) 719) 720)} the instrument is a contribution of NIVR (Netherlands Institute for Air and Space Development) of Delft in collaboration with FMI (Finnish Meteorological Institute), Helsinki, Finland, to the EOS Aura mission. The PI is Pieter Levelt of KNMI; co-PIs are: Gilbert W. Leppelmeier of FMI and Ernest Hilsenrath of NASA/GSFC. OMI is of GOME heritage, flown on ERS-2, as well as of SCIAMACHY and GOMOS heritage, flown on Envisat. The overall objective is to monitor ozone and other trace gases (continuation of the TOMS measurement series) and to monitor tropospheric pollutants worldwide. The OMI measurements are highly synergistic with the HIRDLS and MLS instruments on the Aura platform. The OMI observations provide the following capabilities and features:

- Mapping of ozone columns at 13 km x 24 km and profiles at 36 km x 48 km (continuation of TOMS and GOME ozone column data records and the ozone profile records of SBUV and GOME)
- Measurement of key air quality components: NO₂, SO₂, BrO, OClO, and aerosol (continuation of GOME measurements)
- Distinguish between aerosol types, such as smoke, dust, and sulfates
- Measurement of cloud pressure and coverage
- Mapping of the global distribution and trends in UV-B radiation
- A combination of processing algorithms is employed including TOMS version 7, DOAS (Differential Optical Absorption Spectroscopy), Hyperspectral BUV retrievals and forward modeling to extract the various OMI data products
- Near real-time production of ozone and other trace gases.

OMI is a wide-angle, non-scanning and nadir-viewing instrument measuring the solar back-scattered irradiance with a swath width of 2600 km. The telescope has a FOV of 114°. The instrument is designed as a compact UV/VIS imaging spectrograph, using two array CCDs for simultaneous spatial and spectral registration (hyperspectral imaging in push-broom mode). The instrument has two channels measuring in the spectral range of 270-500 nm. The Earth is viewed in 1500 bands in the along-track direction providing daily global coverage. OMI employs a polarization scrambler to depolarize the incoming radiance. The radiation is then focussed by the secondary telescope mirror. A dichroic element separates the radiation into a UV and a VIS channel. The UV channel is split again into two subchannels UV1 (270-314 nm) and UV2 (306-380 nm). In the UV1 subchannel, the spatial sampling distance per pixel is a factor two larger than in the UV2 subchannel. The idea is to increase the ratio between the useful signal and the dark current signal, hence, to increase SNR in UV1. The resulting IFOV values of a pixel in the cross-track direction are 6 km for UV1 and 3 km for UV2 and VIS. The corresponding spatial resolution is twice as good as the sampling distances. Groups of 4 or 8 CCD detector pixels are binned in the cross-track direction. The basic detector exposure time is 0.4 s, corresponding to an along-track distance of 2.7 km. In OMI, five subsequent CCD images are electronically co-added, resulting in a

720) E. Laan, J. de Vries, P. Levelt, P. Stammes, H. Saari, J. Lundell, A. Maelkki, et al., "Ozone Monitoring in the Next Millennium with the OMI Instrument," Proc. IAF Congress, Oct. 2-6, 2000, Rio de Janeiro, IAF-99-B.2.09

FOV of 13 km in the along-track direction. In addition, one column (wavelength) of each CCD data is downlinked without co-adding (monitoring of clouds, ground albedo). The pixel binning and image co-adding techniques are used to increase SNR and to reduce the data rate.

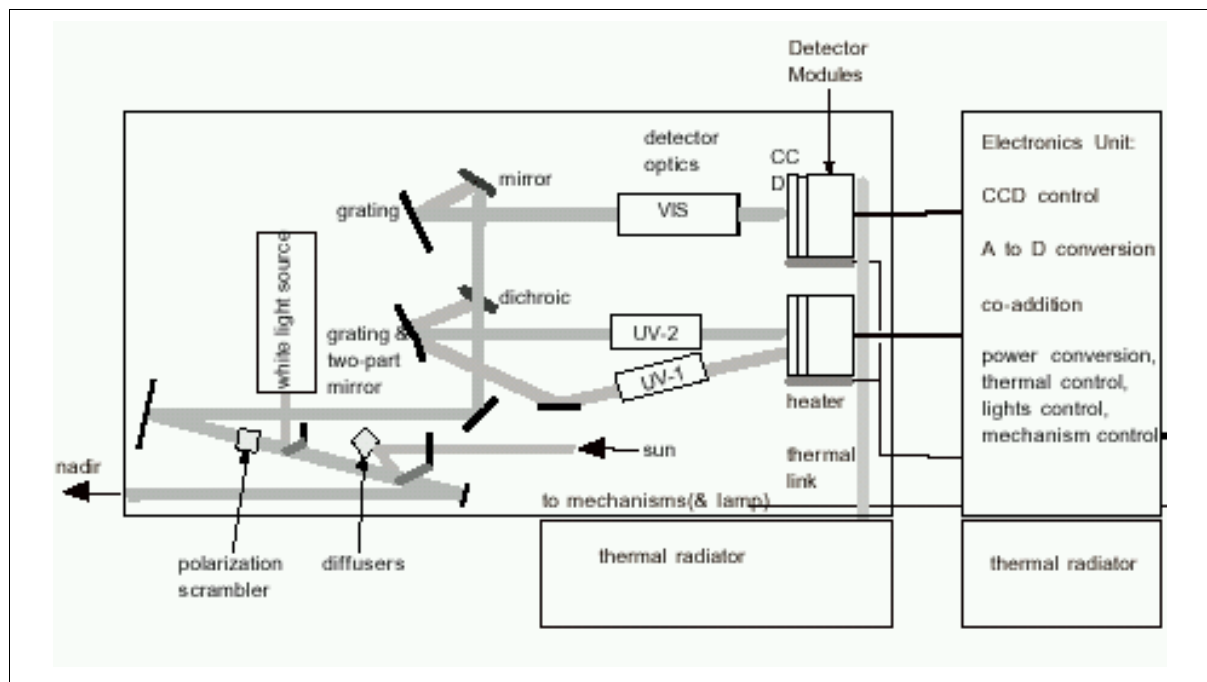

Figure 110: Conceptual design of the OMI instrument

Visible band; two UV bands	UV1: 270-314 nm, UV-2: 306-380 nm, VIS: 350-500 nm
Spectral resolution	0.42 - 0.65 nm FWHM (Full width Half Maximum)
Spectral sampling	1.3 - 3 for FWHM
Telescope FOV	114° (providing a surface swath width of 2600 km)
IFOV (spatial resolution)	13 km x 24 km; or 36 km x 48 km (depending on the product) Two zoom modes: 13 km x 13 km (detection of urban pollution)
Detector	CCD pushbroom with 780 x 576 (spectral x spatial) pixels
Instrument mass, power, data rate	65 kg, 66 W, 0.8 Mbit/s (average)
Instrument size	50 cm x 40 cm x 35 cm
Duty cycle	60 minutes on the daylight side of the orbit

Table 176: OMI instrument parameters

The CCD detector arrays are of the back-illuminated and frame-transfer type, each with 576 x 780 pixels in the image section and the same amount in the storage or readout section. The frame transfer layout allows simultaneous exposure and readout of the previous exposure. This in turn permits fair pixel readout rates (130 kHz) and good data integrity. There are two zoom modes, besides the global observation mode, for regional studies with a spatial resolution of 13 km x 13 km. In one zoom mode, the swath width is reduced to 725 km; in the other zoom mode, the spectrum is reduced to 306 - 432 nm. Cloud coverage information is retrieved with a high spatial resolution, independent of the operational mode.

Instrument calibration: Daily measurements of the sun are taken with a set of reflective diffusers for absolute radiometric calibration. Relative radiometric calibration is performed using a WLS (White Light Source) and two LEDs per spectral (sub-) channel. The two LEDs fairly uniformly illuminate the CCD's. Spectral calibration is being performed using Fraunhofer features in the sun and nadir spectra. This is supported by a dedicated spectral correction algorithm in the level 0-1 b software. Dark signal calibration is performed at the dark side of the orbit using long-exposure time dark measurements. Straylight is always

monitored at dedicated rows at the side of the images; there are also covered CCD pixels measuring dark current and, at the top and bottom of the image, exposure smear.

TES (Tropospheric Emission Spectrometer), PI: R. Beer, NASA/JPL. ⁷²¹⁾

The instrument is selected to fly on the Aura mission. Heritage: ATMOS (ATLAS), and AES. TES is a high-resolution infrared imaging Fourier transform spectrometer with spectral coverage from 3.2 - 15.4 μm . TES has the capability to make both limb and nadir observations. Limb mode: height resolution = 2.3 km, height coverage = 0 - 34 km. In the nadir modes, TES has a spatial resolution of 0.53 km x 5.3 km with a swath of 5.3 km x 8.5 km. TES is a pointable instrument; it can access any target within 45° of the local vertical, or produce regional transects up to 885 km in length without any gaps in coverage. TES employs both, the natural thermal emission of the surface and atmosphere, and reflected sunlight, thereby providing day and night coverage anywhere on the globe.

Observations from TES will further understanding of long-term variations in the quantity, distribution, and mixing of minor gases in the troposphere, including sources, sinks, troposphere-stratosphere exchange, and the resulting effects on climate and the biosphere. TES will provide 3-D global maps of tropospheric ozone (primary objective) and its photochemical precursors (chemical species involved in ozone formation and destruction). Other objectives:

- Simultaneous measurements of NO_y , CO , O_3 , and H_2O , determination of the global distribution of OH.
- Measurements of SO_2 and NO_y as precursors to the strong acids H_2SO_4 and HNO_3
- Measurements of gradients of many tropospheric species
- Determination of long-term trends in radiatively active minor constituents in the lower atmosphere.

The following key features are part of the TES instrument design:

- Back-to-back cube corner reflectors to provide the change in optical path difference
- Use of KBr (potassium bromide) material for the beam splitter-recombiner and the compensator
- Only one of two input ports for actual atmospheric measurements. The other input views an internal, grooved, clod reference target
- A diode-pumped solid-state Nd:YAG laser for interferogram sampling control
- Cassegrain telescopes for condensing and collimating wherever possible to minimize the number of transmissive elements in the system.
- A passive space-viewing radiator to maintain the interferometer and optics at 180 K.
- A two-axis gimballed pointing mirror operating at ambient temperature to permit observation of the full field of regard (a 45° cone about nadir plus the trailing limb).
- Two independent focal plane assemblies maintained at 65 K with active pulse-tube coolers.

The TES instrument operates in a step-and stare configuration when in downlooking mode. At the limb the instrument points to a constant tangent height. Thus, the footprint is smeared along the line-of-sight by about 110 km during the 16 s limb scan (this is comparable to the effective size of the footprint itself). Hence, atmospheric inhomogeneity in the atmosphere becomes an issue; it must be dealt with in data processing (usually through a simplified form of tomography).

The routine operating procedure for TES is to make continual sets of nadir and limb observations (plus calibrations) on a one-day on, one-day off cycle. During the off-days, extensive calibrations and spectral product observations are made.

⁷²¹⁾ R. Beer, T. A. Glavich, D. M. Rider, "Tropospheric emission spectrometer for the Earth Observing System's Aura satellite," *Applied Optics*, Vol. 40, No 15, May 20, 2001, pp. 2356-2367

Parameter	Specification	Comments
Spectrometer type	Connes-type four-port FTS (Fourier Transform Spectrometer)	Both limb and nadir viewing capability essential
Spectral sampling distance	Interchangeably 0.0592 cm^{-1} down-looking and 0.0148 cm^{-1} at the limb	Unapodized
Optical path difference	Interchangeably $\pm 8.45\text{ cm}^{-1}$ down-looking and $\pm 33.8\text{ cm}$ at the limb	Double-sided interferograms
Overall spectral coverage	$650\text{-}3050\text{ cm}^{-1}$ ($3.2\text{-}15.4\text{ }\mu\text{m}$)	Continuous, but with multiple sub-ranges typically $200\text{-}300\text{ cm}^{-1}$ wide
Individual detector array coverage	1A, $1900\text{-}3050\text{ cm}^{-1}$ 1B, $820\text{-}150\text{ cm}^{-1}$ 2A, $1100\text{-}1950\text{ cm}^{-1}$ 2B, $650\text{-}900\text{ cm}^{-1}$	All MCT photo voltaic (PV) detectors at 65 K.
Array configuration	1 x 16	All four arrays optically conjugated
Aperture diameter	5 cm	Unit magnification system
System étendue (per pixel)	$9.45 \times 10^{-5}\text{ cm}^2\text{ sr}$	Not allowing for small central obscuration from the Cassegrain secondaries
Modulation index	>0.7 ; $650\text{-}3050\text{ cm}^{-1}$	>0.5 at $1.06\text{ }\mu\text{m}$ (control laser)
Spectral accuracy	$\pm 0.00025\text{ cm}^{-1}$	After correction for finite FOV, off-axis effects, Doppler shifts, etc.
Channeling	$<10\%$ peak to peak; $<1\%$ after calibration	All planar transmissive elements wedged
Spatial resolution	$0.5\text{ km} \times 0.5\text{ km}$ at nadir $2.3\text{ km} \times 2.3\text{ km}$ at limb	IFOV IFOV
Spatial coverage	$5.3\text{ km} \times 8.5\text{ km}$ at nadir $37\text{ km} \times 23\text{ km}$ at limb	
Pointing accuracy	$75\text{ }\mu\text{rad}$ pitch, $750\text{ }\mu\text{rad}$ yaw, $1100\text{ }\mu\text{rad}$ roll	Peak-to-peak values
Field of regard	45° cone about nadir plus trailing limb	Also views internal calibration sources
Scan (integration) time	4 s nadir and calibration, 16 s limb	Constant-speed scan, 4.2 cm/s (optical path difference rate)
Max stare time at nadir	208 s	40 downlooking scans
Transect coverage	885 km maximum	
Interferogram dynamic range	$\leq 16\text{ bit}$	Plus four switchable gain steps
Radiometric accuracy	$\leq 1\text{ K}$, $650\text{-}2500\text{ cm}^{-1}$	Internal, adjustable, hot blackbody plus cold space
Pixel-to-pixel cross talk	$<10\%$	Includes diffraction, aberrations, carrier diffusion, etc.
Spectral SNR	As much as 600:1, 30:1 min requirement	Depends on spectral region and target. General goal is to be source photon shot-noise limited
Instrument lifetime	5 year on orbit	Plus 2 years before launch
Size	$1.0\text{ m} \times 1.3\text{ m} \times 1.4\text{ m}$	Earth shade stowed
Power	334 W (average, 361 W (peak))	
Instrument mass	385 kg	
Instrument data rate	4.5 Mbit/s (average), 6.2 Mbit/s (peak)	Science only

Table 177: TES performance characteristics

D.12 ESE (Earth Science Enterprise)

ESE, formerly called MTPE (Mission to Planet Earth), is a NASA-initiated but US-wide framework, concept and strategy of spaceborne, airborne, and ground-based measurement/observation systems, which began in the 1980s. It represents in a sense the US ‘Earth Observation Program’, and is as such a contribution to the U.S. Global Change Research Program (USGCRP) and to related international efforts to better understand Earth and how humans may be affecting it. Aside from NASA, other US agencies are participating in

and contributing to ESE and to USGCRP such as NOAA (DOC), USGS (DOI), NSF/NCAR, DOE, USDA, EPA, DoD, a number of US universities, and others (by designing and/or operating satellites, providing facilities, participating in numerous campaigns, building instruments, maintaining archives, analyzing data, etc.). The ESE framework is in fact so vast and complex that it also has a considerable international component. ^{722) 723) 724) 725)}

The goal of ESE is to advance our understanding of the entire Earth system and its interactions. The ESE science objectives address the physical, chemical, and biological phenomena that govern the dynamic Earth system. The emphasis of ESE process research is on the following Earth system topics:

- Hydrologic processes that govern the interactions of land and ocean surfaces with the atmosphere through the transport of heat, moisture, and momentum
- Biogeochemical processes which contribute to the formation, dissipation, and transport of trace gases and aerosols, and their global distributions.
- Atmospheric processes which control the formation, dissipation, and distribution of clouds and aerosols and their interaction with solar radiation
- Ecological processes which are affected by and/or will affect global change, and their response to such changes through adaptation
- Geophysical processes which have shaped or continue to modify the surface of the Earth through tectonics, volcanism, and the melting of glaciers and sea ice.

ESE is regarded as a long-term program consisting of spaceborne, airborne, and ground-based measurement systems, of the corresponding infrastructure and operational services (of data processing and distribution centers, archives, communication, etc.), and of the elements of data analysis and interpretation. Phase 1 of ESE is considered the time frame from 1990 to 1998, consisting of ongoing Earth observation missions. Phase 2 of ESE starts with the launch of the first EOS (Earth Observing System) satellite in 1999 (Terra). The EOS program is regarded as the principal element of ESE, providing systematic and continuous observations from low Earth orbit for a minimum time period of 15 years.

NASA Missions/Sensors	Mission Objectives
ERBS (operational)	Earth radiation budget, aerosol, and ozone data from 57° inclination orbit
UARS (operational)	Stratospheric and mesospheric chemistry and dynamic processes
Spacelab series (92-94)	Shuttle-based experiments such as ATLAS, LITE, SRL-1 and SRL-2
TOPEX/Poseidon (op.)	Ocean circulation (joint mission with CNES)
Lageos-2 (with Italy)	Satellite laser ranging for monitoring the crustal motions of the Earth
SeaStar/SeaWiFS (1997)	Ocean color data to monitor ocean productivity
TOMS/EP (1996)	Ozone mapping and monitoring
NSCAT/ADEOS (1996)	Ocean surface wind vectors (with NASDA)
TOMS/ADEOS (1996)	Ozone mapping and monitoring (with NASDA)
TRMM (1997)	Precipitation, clouds, and radiation processes over tropics (with NASDA)
Non-NASA Missions	Mission Objectives
POES series (NOAA)	Earth's VNIR radiation, IR atmospheric sounding, ozone measurements
Landsat-4, -5 (Eosat)	High spatial resolution VNIR radiation and terrestrial surfaces
DMSP series, (DoD)	VNIR and passive microwave atmospheric and surface measurements
ERS-1, op. (ESA)	SAR data, microwave altimeter, sea surface winds and temperature
JERS-1 (NASDA)	SAR data and high spatial resolution surface VNIR radiation
ERS-2, op. (ESA)	Same as ERS-1, plus ozone mapping and monitoring
Radarsat, 1995 (CSA)	SAR data of Earth's surface (joint CSA/NASA mission)
ADEOS (NASDA)	Surface VNIR and microwave radiation, winds, and atmospheric chemistry

Table 178: ESE Phase 1 survey of missions

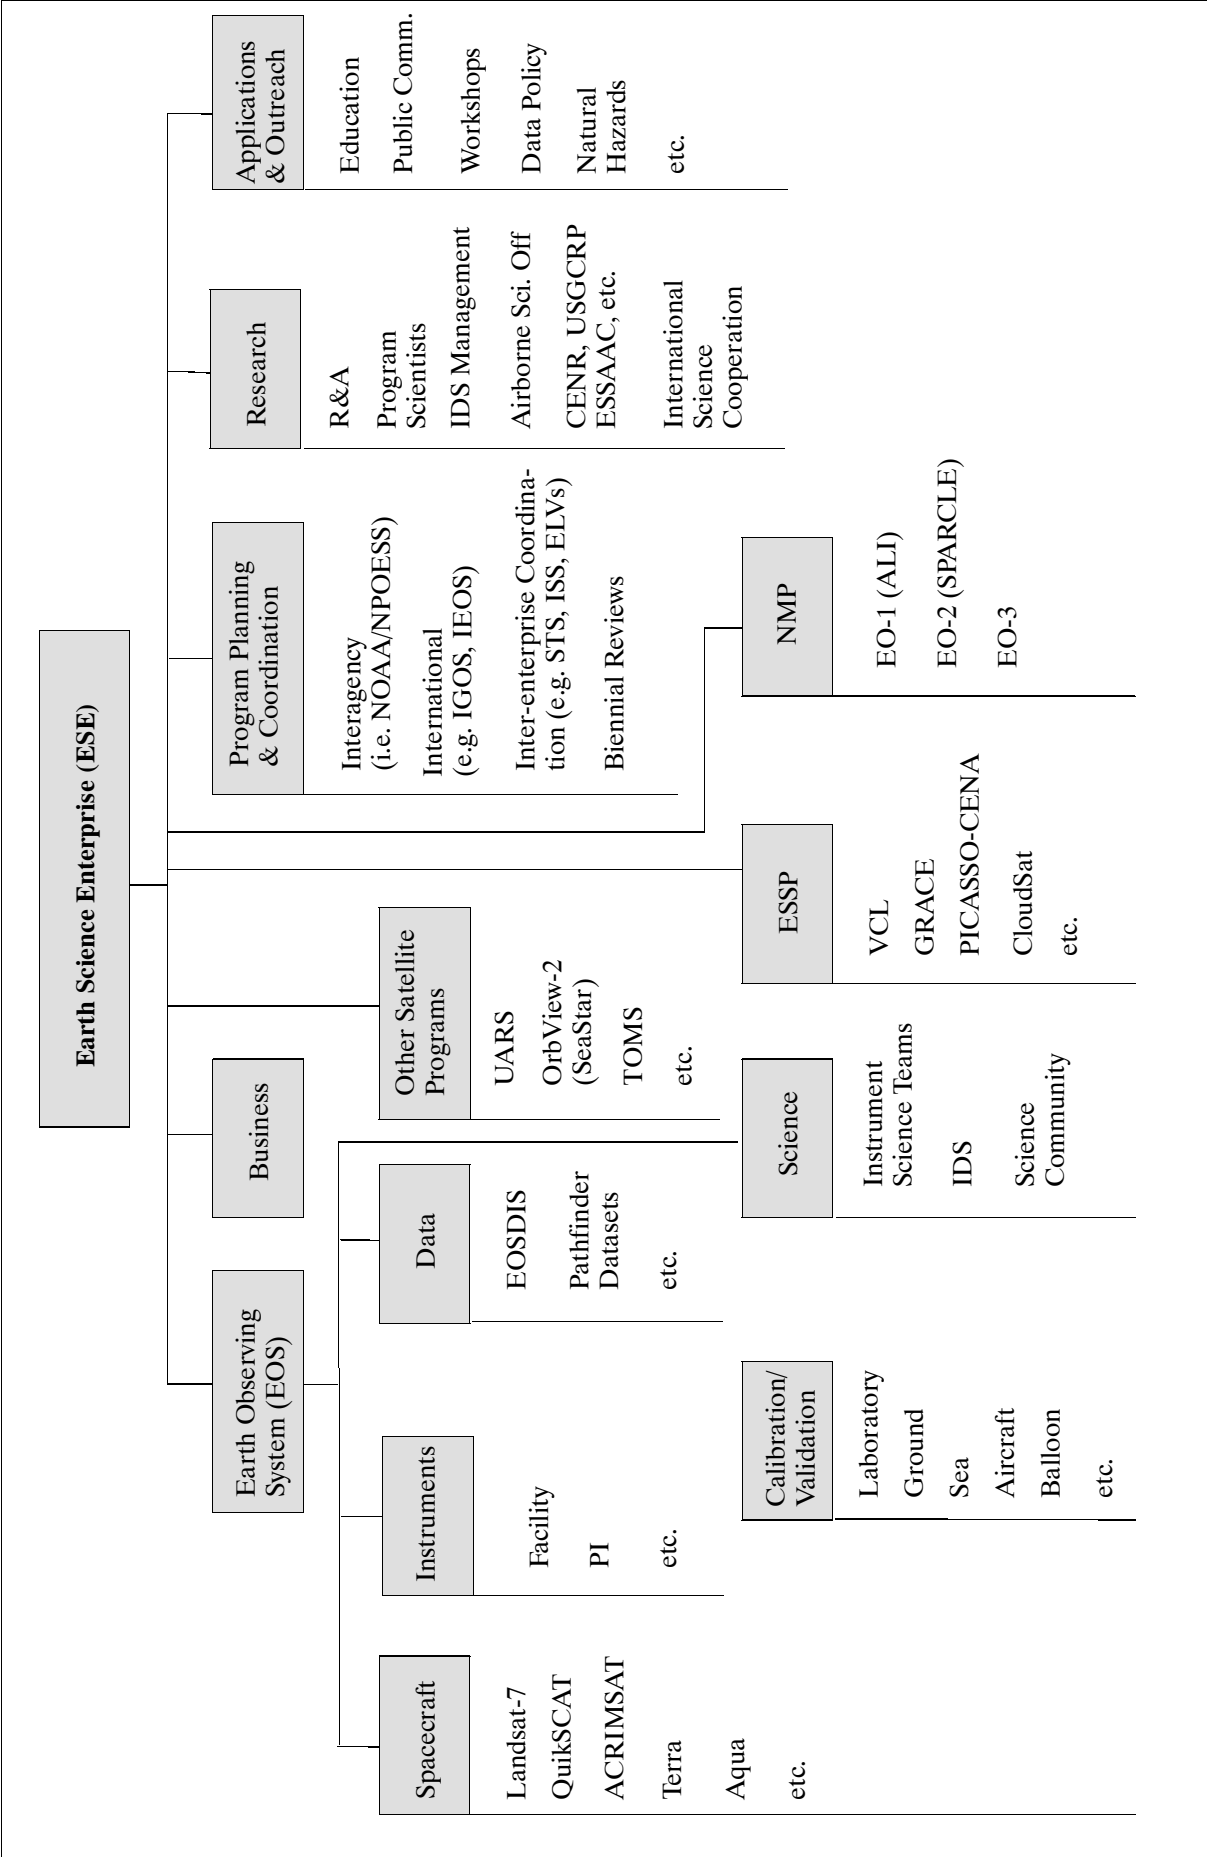

Figure 111: Overview of NASA's Earth Science Enterprise

A survey of ESE Phase 1 missions is given in Table 178, showing the pre-EOS missions up to 1998. The EOS missions for ESE Phase 2 are illustrated in Figure 111 and Table 179 on page 399. There are a number of international elements in the EOS program. In addition there are further international missions fitting into the category of Phase 2 (EOS era) Earth observing missions; they are referred to as IEOS (International EOS). These are: ESA's ENVISAT; NASDA's ADEOS-II, GCOM series (GCOM-A1, GCOM-B1), and ALOS (Advanced Land Observation Satellite); and EUMETSAT's MetOp series.

Landsat-7 (15.4.1999)	ETM+, land surface monitoring in the VIS and infrared regions
QuikSCAT (19.6.1999)	SeaWinds, ocean surface wind vectors
Terra (18.12.1999)	Clouds, aerosols, and radiation balance, characterization of the geo-ecosystem, land use soils, terrestrial energy/moisture, tropospheric chemical composition, volcanoes, ocean primary productivity, etc.
AcrimSat (20.12.1999)	ACRIM-III, monitoring of TSI (Total Solar Irradiance)
EO-1 (21.11.2000)	New ALI instrument. Scene comparison between ALI and ETM+
SAGE-III on Meteor-3M (2001)	Mid-inclination flight of SAGE-III. Global total ozone as well as measurement of SO ₂ in volcanic plumes to investigate the effects of volcanic injections into the atmosphere
Jason-1 (2001)	NASA/CNES altimetry mission, ocean circulation
Envisat (2001)	ESA, atmospheric chemistry and marine biology, ERS continuation
Aqua (EOS/PM-1) (2001)	Atmospheric temperature and humidity; clouds, precipitation, and radiative balance; characterization of terrestrial and oceanic processes including productivity; air-sea fluxes of energy and moisture; and sea-ice and snow-cover extent (includes Brazilian and Japanese instruments)
GRACE (2001)	US-German dual-minisatellite gravity mission with the overall objective to obtain long-term data with unprecedented accuracy for global (high-resolution) models of the mean and the time-variable components of the Earth's gravity field.
ICESat-1 (2001)	Ice sheet mass balance and cloud-top and land-surface topography
SORCE (2002)	Total and spectral solar irradiance
VCL (2002, TBD)	To characterize the 3-D structure of land cover for ecosystem/climate modeling, monitoring, and prediction (mapping of biomass, height of vegetation layer, density profile of the vegetation layer).
Aura (EOS/CHEM-1) (2003)	Atmospheric chemical composition; tropospheric-stratospheric exchange of energy and chemicals; chemistry-climate interactions; air quality (includes joint Netherlands/Finland and joint UK/US instruments)
ISS/SAGE-III (2003) International Space Station	Mid-inclination, low-altitude flight of SAGE-III
PICASSO-CENA (2003) NASA/CNES mission	To profile the vertical distribution of clouds and aerosols and their role in the heating/cooling of the Earth
ALOS (2003) Japanese mission	High-resolution optical and microwave payload for land surface, cartography, and disaster monitoring
CloudSat (2003)	Increase the understanding of the role of optically thick clouds on the Earth's radiation budget
MetOop-1 (2005) EUMETSAT with NOAA	Operational meteorology and climate monitoring, with the future objective of operational climatology
GCOM of NASDA (2006)	Study of global change phenomena (energy cycle, atmosphere/ocean interaction, understanding of ozone and greenhouse mechanisms)

Table 179: Overview of EOS era (first series) remote sensing satellites within ESE

D.13 ERS-1 (European Remote-Sensing Satellite)

ERS = European Remote Sensing Satellite (ESA Program). ERS-1 launch: July 17, 1991 from Kourou (Ariane IV vehicle, Mission Control at ESOC). The ERS program was initiated in 1981; it also includes the build-up of a corresponding ground segment for the exploitation of all data.

The ERS-1 S/C is a three-axis-stabilized Earth-pointing satellite [zero momentum bias with control to 0.11° (pitch/roll) and 0.21° (yaw)]. The platform is a SPOT program platform

(SPOT MK1 bus) modified to meet the needs of the ERS missions. The payload support module has dimensions of 2 m x 2 m x 3 m (high). Attitude is measured by a number of sensors (horizon sensor, narrow-field sun sensors, gyroscopes, wide-field sun sensors). Attitude control by a set of momentum wheels. The payload module consists of PEM (Payload Electronics Module) and ASS (Antenna Support Structure). Thermal control is a passive system complemented by an active heater. Satellite mass = 2380 kg (payload mass about 1000 kg). The single solar panel is 11.7 m x 2.4 m and supports peak payload power of 2600 W. Battery storage capacity is 2650 Wh.

There is worldwide cooperation in the area of data services (reception and exchange). DLR/DFD provides, among other European nation's agencies, a contribution in the area of science data reception (O'Higgins station in Antarctica), and in the area of science data processing at a 'Processing and Archiving Facility' (D-PAF). The other PAFs in the ground segment are provided by France (F-PAF), Italy (I-PAF) and the United Kingdom (UK-PAF). 726) 727) 728) 729)

Application: A broad range of disciplines is covered. Observation of oceans, polar ice, land ecology, geology, forestry, wave phenomena, bathymetry (water depth), atmospheric physics, meteorology, etc. Scientific research: PIPOR (Program for International Polar Ocean Research); PISP (Polar Ice Sheet Proposal). Demonstration of concept and technology for space and ground segments (performance and operational capability).

Orbit: Sun-synchronous polar orbit, 98.52° inclination, 785 km altitude. Nominal mission duration of 2 years, 3rd year reduced mission; there are the following orbit coverage cycles:

1. Reference orbit - 3 day repeat cycle (high repetition change monitoring with dedicated calibration sites; this orbit was used during the commissioning phase)

2. Ice-Orbit - similar 3 day repeat cycle with a slightly different longitudinal phase. The main limitations of a 3 day cycle are the restricted global coverage for the imaging SAR and the wide separation of the RA-1 tracks.

3. Mapping-Orbit - 35 days repeat cycle (guaranteeing full Earth coverage). This enables SAR imaging of every part of the Earth's surface, with at least twice the frequency of the coverage at middle and high latitudes.

ERS-1 status: the satellite was in hibernation since June 1996. Operations were limited to the monitoring of the platform vital elements, the battery maintenance and the periodic checkout of the entire system every 70 days. - To maintain the ERS-1 batteries performance, the SAR image mode was activated once or twice a day. This was used to perform limited ERS-1/2 SAR interferometry acquisitions.

The ERS-1 mission ended on March 10, 2000 by a failure of the on-board attitude control system (ERS-1 was lost when a failed gyro prevented the S/C from maneuvering into an emergency acquisition mode with its solar panels pointed toward the sun to keep the batteries charged). This gives a service life of about 8 1/2 years, more than three times its planned lifetime. The most exiting results of the ERS-1 mission have been in the field of SAR interferometry, where for the first time precise topographic information could be produced in a tandem mission with ERS-2.

Sensor complement:

AMI (Active Microwave Instrument)⁷³⁰⁾ Synthetic Aperture Radar (SAR), built by MMS, France. Two separate radars are incorporated within the AMI, a SAR for 'Image and Wave mode' operation, and a scatterometer (SCAT) for 'Wind mode' operation. This instrument can operate in either one of the following modes:

- a. **AMI in Imaging mode.** Measurement in C-band (frequency = 5.3 GHz (equivalent to 5.66 cm wavelength), bandwidth = 15.55 MHz; polarization = Linear Vertical (LV); PRF range = 1640-1720 Hz in 2 Hz steps; long pulse = 37.12 μ s; compressed pulse = 64 ns; peak power = 4.8 kW; antenna size = 10 m x 1 m; look angle = 23°; radiometric resolution = 5 Bit on raw data (SAR mode), which corresponds to about 30 m spatial resolution; swath width = 100 km. Data rate = 105 Mbit/s.
Imaging mode operating time per orbit = 12 minutes ((12% duty cycle) including four minutes in eclipse).
- b. **AMI in Wave Mode.** Measurement of the changes in radar reflectivity of the sea surface due to surface waves. Provision of images (5 km x 5 km), also referred to as “imagettes,” at regular intervals of 200 km along track. These imagettes are transformed into spectra providing information about the lengths and directions of the ocean wave systems. Characteristics: frequency = 5.3 GHz, polarization = Linear Vertical (LV); incidence (look) angle = 23°; wave direction: 0 - 180°; wavelength = 100-1000 m; direction accuracy = $\pm 20^\circ$; length accuracy = $\pm 25\%$; spatial sampling: 5 km x 5 km every 200-300 km; resolution = 30 m; data rate = 370 kbit/s; duty cycle of 70 %.
- c. **AMI in Wind Scatterometer Mode (AMI-SCAT).**⁷³¹ Use of three separate sideways-looking antennas (fore, mid and aft beams, see Figure 112) to measure sea surface wind speed and direction. Characteristics: wind direction range = 0 - 360°; accuracy = $\pm 20^\circ$; wind speed range = 4-24 m/s; accuracy = 2m/s or 10%, spatial resolution = 50 km; grid spacing = 25 km; swath width = 500 km (same side as SAR imaging); swath stand-off = 200 km to side of orbital track; frequency = 5.3 GHz ± 200 kHz; polarization = LV; peak power = 4.8 kW; incidence angle range = 16-42° (mid), 22-50° (fore), 22-50° (aft); antenna length = 2.3 m (mid), 3.6 m (fore), 3.6 m (aft); data rate = 500 kbit/s. Operation over all oceans. Note: AMI-SCAT cannot be operated in parallel with the AMI SAR imaging mode; however, parallel operation of the wind and waves modes is possible.

Figure 112: ERS-1 Wind Scatterometer observation geometries

The three antenna beams continuously illuminate a swath of 500 km each measuring the radar backscatter from the sea surface for overlapping 50 km resolution cells using 25 km grid spacing. The result is three independent backscatter measurements relating to cell center nodes on a 25 km grid (three different viewing directions, separated by a very small time

delay). This permits surface wind vector determination using ‘triplets’ within the mathematical model. AMI is an instrument providing data for a wide range of research disciplines such as: climatology, oceanography, glaciology, land processes, operational meteorology.

Radar Altimeter (RA-1), operating in Ku-band, consisting of a reflector, waveguide feed, tripod plus supporting structure, horn feed and the waveguide (built by Alenia Spazio, Italy). RA-1 is a nadir-pointing pulse radar taking precise measurements of the echos from the ocean and ice surfaces. Frequency = 13.8 GHz; pulse length = 20 μ s; pulse repetition frequency = 1020 Hz; chirp bandwidth = 330 MHz (for ocean mode) and 82.5 MHz (for ice mode); RF transmit power = 55 W peak; antenna diameter = 1.2 m; max. data rate = 15 kbit/s; instrument mass = 96 kg; power = 130 W. RA-1 operates in 2 modes: ocean mode and ice mode. Beam width = 1.3°; foot print = 16 - 20 km (depending on sea state). RA-1 operates by timing the two-way delay for a short duration radio frequency pulse, transmitted vertically downwards. The required level of range measurement accuracy (better than 10 cm) calls for a pulse compression technique (chirp). The instrument employs frequency modulation and spectrum analysis of the pulse shape. RA-1 provides measurements leading to the determination of: ^{732),733),734)}

- precise altitude (ocean surface elevation for the study of ocean currents, the tides and the global geoid)
- significant wave height
- ocean surface wind speed
- various ice parameters (surface topography, ice types, sea/ice boundaries)

ATSR (Along-Track Scanning Radiometer and Microwave Sounder). ATSR [built by RAL, UK (British Aerospace as prime contractor); CRPE, France, and CSIRO, Australia] consists of two instruments: the MWR (Microwave Radiometer) and the IRR (Infrared Radiometer). A major objective of ATSR is to measure the global SST (Sea Surface Temperature) with the high accuracy required by the climate change research community.

MWR characteristics:

The MWR instrument uses a 60 cm Cassegrain offset-fed antenna to view the Earth in nadir direction in the frequencies of 23.8 and 36.5 GHz. The signals received are compared with those from a reference source at a known temperature to minimize the effects of short-term variations. Additional features are used to calibrate MWR: the sky-horn antenna is pointed toward cold space; the hot reference is obtained internally. IFOV = 20 km (= resolution); each channel has a bandwidth of 400 MHz. Prime objective of MWR is measurements of atmospheric water-vapor and liquid content in order to improve the accuracy of the sea surface temperature measurements and also to provide accurate tropospheric range correction for the RA-1.

IRR characteristics:

The IRR imager has 4 spectral channels: 1.6 (SWIR), 3.7, 10.8 and 12 μm . Spatial resolution = 1 km x 1 km (IFOV at nadir). Radiometric resolution < 0.1 K. Absolute accuracy < 0.5 K by averaging over a 50 km x 50 km area for SST with 80 % cloud cover; radiometric resolution < 0.1 K; swath width = 500 km. The scanning technique enables the Earth's surface to be viewed at two different angles (0° and 47°) in two curved swaths 500 km wide and separated, along track, by about 800 km. Successive scans in the cross-track direction are displaced by about 1 km (along-track) due to the satellite's motion. A rotating mirror scans the two tracks once every 150 ms (total of 2000 pixels per scan, 555 for nadir-view data and 371 for forward-view data) Measurements of: ⁷³⁵⁾

- cloud-top temperature and cloud cover
- sea-surface temperature (prime objective of IRR)

The thermal channels of IRR use an advanced detector cooling system and can be calibrated. Of particular interest is the inclined scanning configuration of IRR. The sensor records a line of off-nadir pixels at a view zenith angle of about 55° and some 900 km along-track. About 2 minutes later, a nadir view is obtained when the S/C is directly over the target. The resultant image data set (after resampling both the nadir and forward view data) consists of two co-registered images with a 1 km spatial resolution on a 500 km swath. The data permit accurate atmospheric correction over oceans by exploiting the information on atmospheric properties derived from successive images of the same area within a short period.

LRR (Laser Retro-Reflector). A passive optical device for accurate satellite tracking from ground (laser ranging stations of the SLR network) to support instrument data evaluation. LRR characteristics: wavelength = 350 - 800 nm (optimized for 532 nm), efficiency: greater than 0.15 at end-of-life, reflection coefficient: > 0.8 end-of-life, FOV: elevation half-cone angle 60°, azimuth of 360°, diameter: \leq 20 cm.

PRARE ⁷³⁶⁾ (Precise Range And Range-Rate Equipment) see also chapter H.7.2. Precise satellite range determination will lead to higher-accuracy altitude measurements that will extend the mission to ocean circulation studies and geodetic applications such as sea-surface topography and crustal dynamics.

Data: The payload data are transmitted by the IDHT (Instrument Data Handling and Transmission) subsystem. The instruments generate data in the form of source packets

⁷³⁵⁾ F. M. Danson, N. A. Higgins, N. M. Trodd, "Measuring Land-Surface Directional Reflectance with the Along-Track Scanning Radiometer," PE&RS, Vol 65, No 12, Dec. 1999, pp. 1411-1417

⁷³⁶⁾ **Note: The on-board PRARE instrument of the ERS-1 payload could not achieve operational status after launch. The instrument worked nominally for five days after launch (five contacts with the command station showed nominal telemetry). A thorough failure analysis came to the conclusion that the most likely cause of the PRARE failure is RAM damage due to radiation (destructive RAM latch-up).**

which in turn are put into transport frames for transmission. Three data streams are transmitted from the IDHT in X-band: Link 1 contains high-rate real-time SAR data at a rate of 105 Mbit/s (8140 MHz); Link 2 contains low-rate real-time data (AMI wave and wind data, RA-1 and ATSR data) at a rate of 1.093 Mbit/s (8040 MHz); Link 3 contains recorder data (all of Link 2) at a rate of 15 Mbit/s. Link 1 is dedicated onto one X-band link, while Link 2 and 3 share the second X-band link. The modulation scheme for Links 1 is QPSK (Quadrature Phase-Shift Keying). The low-rate link uses UQPSK (Unbalanced Quadrature Phase-Shift Keying) to modulate Link 2 and Link 3 data onto a single link. With no recorder dump data BPSK (Bi-Phase-Shift Keying) is used for the real-time data.

The on-board recorder has a capacity of 6.5 Gbit. AMI SAR data cannot be recorded but are downlinked in real-time. Image size for SAR data: 100 km x 100 km (4 Looks Full Digital Image Processing). TT&C operations are in S-band at a data rate of 2 kbit/s.

Ground stations: ESA stations at Kiruna, Fucino, Maspalomas (Canary Islands), and Gati-neau (Canada); national facilities, like the Canadian “Prince Albert” station, the DLR/DFD “O’Higgins” station (in Antarctica) as well as a portable station which can be set up anywhere (DTXS = DFD Transportable X-band Station), the CNES Aussaguel station, the Japanese stations “Hatoyama,” “Kumamoto” and “Syowa” (Antarctica), the Indian (ISRO) station Hyderabad, the Alaska SAR Facility, Fairbanks (NASA), Alice Springs and Hobart (Australia), Tromsø (Norway), Cuiaba (Brazil, INPE), Cotopaxi (Ecuador), Miyun (China, CAS), Ryadh (Saudi Arabia), Bangkok (Thailand), Pretoria (South Africa, CSIR), Chung-li, Taoyuan (Taiwan), West Freugh (Scotland, BNSC), Tel Aviv (Israel, ISA), Parepare (Indonesia, LAPAN), Islamabad (Pakistan), Norman (Oklahoma, Eosat), Singapore (University of Singapore), etc.

Ground stations are equipped with “Fast Delivery” SAR processors, capable of generating quicklook images after reception of the pass. These “Fast Delivery Products” (FDP) are directly mailed to the national PAF’s (Processing and Archiving Facility).

- D-PAF = DLR/DFD in Oberpfaffenhofen, Germany
- F-PAF = CERSAT, Brest, France
- I-PAF = ASI, Matera, Italy
- UK-PAF = RAE, Farnborough, UK

The Earthnet ERS Central Facility (EECF) in Frascati, Italy coordinates all product requests from customers.

Commercial ERS-1 Data Distributors

In 1992 ESA selected three distributors for ERS-1 Data. These are ⁷³⁷⁾:

- Radarsat International of Ottawa, Canada (responsible for commercial sales in Canada and USA)
- EURIMAGE of Rome, Italy (markets in Europe, North Africa, and the Middle East)
- SPOT Image of Toulouse, France (rest of the world)

D.14 ERS-2

ERS-2 is the follow-up mission of ERS-1 which was launched April 21, 1995 (3 year mission design life, prime S/C contractor: DASA/Dornier, Friedrichshafen). ERS-2 has the same mission objectives as ERS-1, plus an atmospheric chemistry mission objective (with GOME). ^{738) 739)}

Orbit: Sun-synchronous polar orbit (retrograde orbit). Altitude = 780 km (mean); inclination = 98.5°, local crossing time of the equator = 10:30 AM, orbital period is about 100 minutes. Repeat cycle = 3 days.

In the orbital tandem configuration ERS-2 follows ERS-1 with an approximate delay (referred to as orbit phasing) of 35 minutes. Due to the phasing and the Earth's rotation, the ground-track patterns of ERS-2 are slightly shifted westwards with respect to those of ERS-1. The orbit phasing is adjusted in such a way that the ERS-2 track coincides exactly with that of ERS-1 24 hours earlier. The benefits of tandem operations are the following:

- When the same area of the Earth is observed by the same instrument on both satellites with a ground-site revisiting interval of 1 or 8 days, the improvements compared to a single satellite are:
 - the number of acquisitions in a repeat cycle (35 days) is doubled
 - the time interval between two successive acquisitions is shorter, being 1 to 8 days rather than 35 days
- For global applications, such as wind scatterometer data, coverage is doubled within a given time period
- When the ground-track pattern of nadir-looking instruments on one satellite overlap ground tracks of side-looking instruments on the other satellite, then their information can be combined, providing synergistic benefits.

The greatest benefit of the tandem mission is seen in SAR interferometry providing excellent temporal (1 day) and spatial coherence. This technique requires two separate images taken of the same ground track by two spatially-separated antennas (the interferometric baseline) to produce phase differences from slightly different viewing angles. For each pixel corresponding to the same area of the ground in both images, the phase values (depending on the satellite-to-ground pixel length) are subtracted to produce a phase difference image known as the 'interferogram.' With the orbit of both satellites known, the phase interferogram can be used to generate a DEM (Digital Elevation Model) of the surface with an accuracy of about 10 m. An additional product of interferometry is the so-called 'coherence image,' which shows bright areas where the coherence between two SAR images is high, indicating no variation in backscatter between the acquisition times of the two images. Dark regions indicate areas where changes have occurred. ERS-1 and ERS-2 have been in tandem operations since mid-August 1995. The tandem mission was completed after nine months of successful operation in May 1996. About 110,000 ERS SAR pairs of data were acquired during the tandem mission, covering nearly the whole global land surface. Over South America and part of Southeast Asia, just one data pair was acquired. As many as five

or six interferometric pairs are available for Europe and North America, allowing greater accuracies to be achieved.⁷⁴⁰⁾

Sensor complement:

Same as ERS-1 (AMI, ATSR-2, RA, PRARE (2)) + GOME (atmospheric chemistry)

ATSR-2 (Along-Track Scanning Radiometer and Microwave Sounder). The IRR instrument of ATSR was upgraded for ERS-2 by adding three more bands in the visible range to provide data for vegetation studies. The channels are accommodated by the addition of a second focal plane assembly (FPA). The center wavelengths of the VIS channels are at 0.555, 0.659, and 0.865 μm (the IR channels are at 1.6, 3.7, 10.85 and 12 μm). The VIS channels are calibrated through a complicated procedure using sunlight.⁷⁴¹⁾

GOME = (ESA instrument, PI: J. P. Burrows, prime contractor: Officine Galileo, Florence, Italy).^{742) 743) 744) 745) 746) 747)}

GOME is a cross-track scanning optical double spectrometer. The double spectrometer operates in the spectral range of 240 nm to 790 nm (1st stage: prism, 2nd stage: grating). The spectral range is split into four channels, each equipped with a 1024-pixel linear array detector. The resulting spectral resolution is 0.2 nm in UV and 0.4 nm in the VNIR spectrum. The objective of GOME is to observe upwelling solar radiation reflected or scattered in the Earth's atmosphere and from its surface. The measured spectrum contains absorption features which can be used to derive quantitative information on the presence of ozone, and of a number of other atmospheric species. In addition to the improved backscattering technique, GOME exploits the full capabilities of the enhanced ATSR-2. The GOME measurement concept is based on 'Differential Optical Absorption Spectroscopy' (DOAS), a technology proven in balloon flights.

747) GOME Global Ozone Monitoring Experiment, Interim Science Report, ESA SP-1151, September 1993

GOME objectives: measurement of total column amounts and stratospheric and tropospheric profiles of ozone. - In addition: measurement of column amounts of H₂O and other gases involved in ozone photochemistry (like NO₂, OClO, BrO, and possibly ClO in anticyclonic conditions, and pollutants like SO₂ and HClO). GOME can also be used to investigate the distribution of atmospheric aerosols and clouds-plus-surface spectral reflectance.

The GOME instrument consists of the following modules: spectrometer, four FPA (Focal-Plane Assembly), calibration unit, SEU (Scan Electronics Unit) assembly, PMD (Polarization Measurement Device), DDHU (Digital Data Handling Unit), optical bench structure, and thermal control unit.

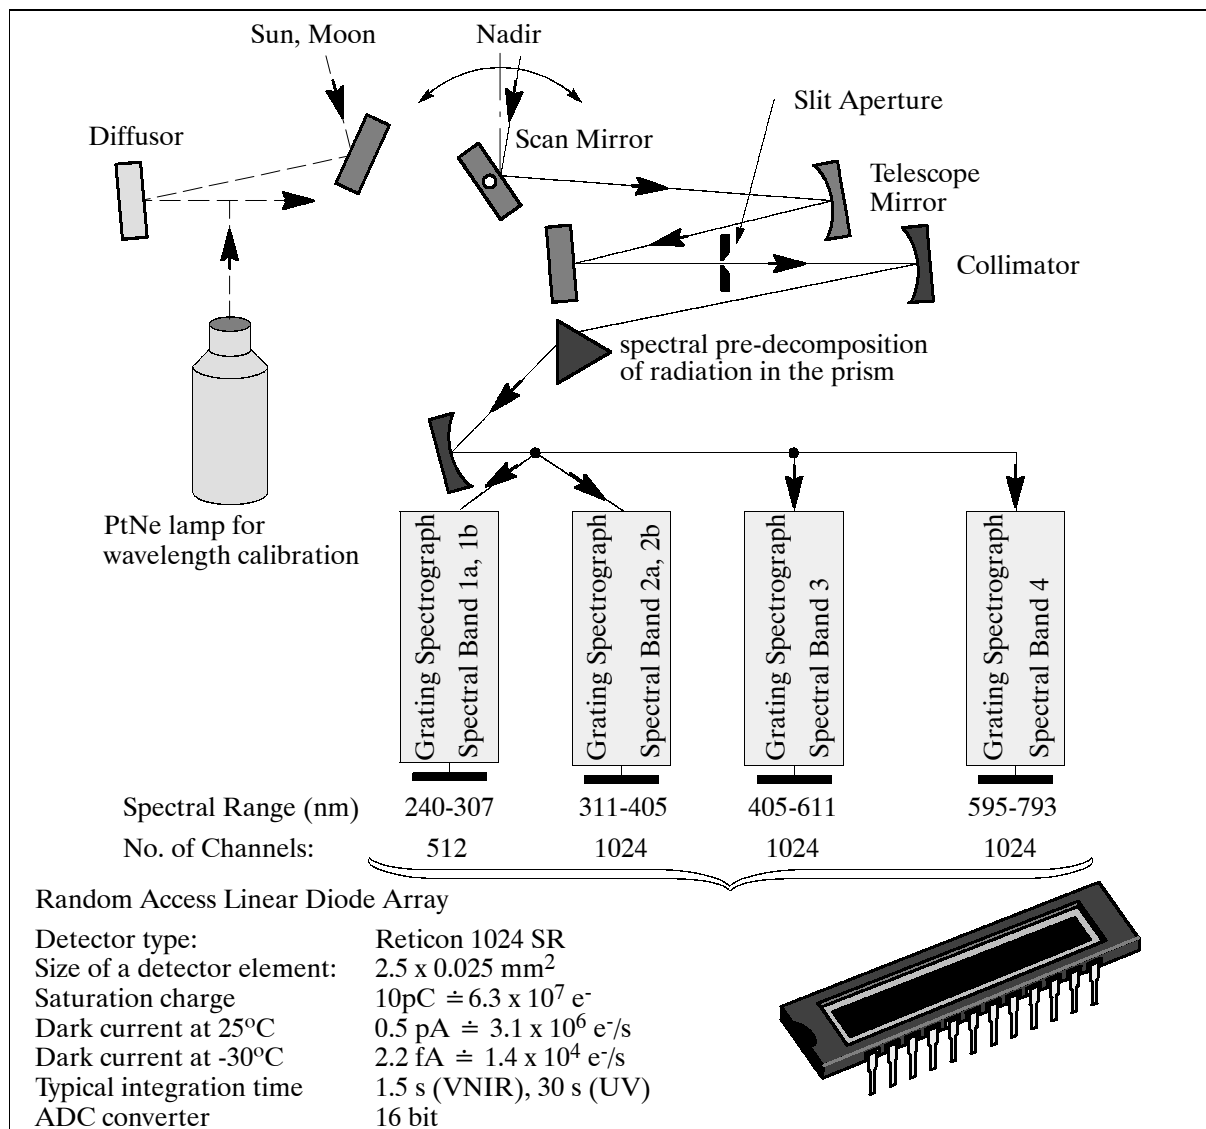

Figure 116: Optical principle of the GOME double-spectrograph

Its main mode of operation is nadir looking, but it is also able to look at the sun and the moon for calibration purposes. For on-board calibration, GOME does not depend on one technique, but seeks to exploit several. Both absolute radiometric and wavelength calibrations are performed. This means that GOME retrieves ozone distributions by exploiting the traditional backscatter approach, as well as by the more novel differential optical absorption spectroscopy.

The IFOV, corresponding to the projection of the spectrometer slit on the Earth, is a narrow rectangle 40 km (along-track) x 1.7 km (across-track). A scan mirror sweeps the IFOV in the

cross-track direction in three steps (normal mode). Maximum swath width = 960 km with corresponding pixel sizes of 40 km x 320 km. Smaller pixel sizes of 40 km x 40 km can be commanded (smaller swath). With the 960 km swath global coverage can be achieved within three days. Calibration is performed with regular views of the sun; in addition, a wavelength calibration lamp is used for wavelength stability. As the instrument is sensitive to polarization of incoming radiation, a polarization detector monitors one polarization direction in the broadband channels corresponding essentially to detectors 2-4. GOME data rate = 40 kbit/s. GOME data are processed, archived and distributed at DLR/DFD.

GOME spectral bands:

- Channel 1 (240 - 295 nm), 512 channels; [the Hartley bands of O₃ and NO emission are the dominant features]
- Channel 2 (290 - 405 nm), 1024 channels; [a variety of target species absorbs in regions such as O₃ (Huggin's band), O₄, NO₂, HCHO, SO₂, BrO and OClO]
- Channel 3 (400 - 605 nm), 1024 channels; [the target molecules for this region are: NO₂, OClO, O₂, O₃, (Chappius band), O₄ and H₂O]
- Channel 4 (590 - 790 nm), 1024 channels; [the target molecules are: O₃ (Chappius band), NO₃, H₂O, and O₂]

A combination of channels 2 to 4 can be used to make measurements of O₂ and O₄ column amounts (radiation penetration depths, cloud top heights).

D.15 HY-1 (Haiyang-1/Ocean-1)

Haiyang-1 is a Chinese minisatellite under development by CAST (Chinese Academy of Space Technology) sponsored by the China Ocean Administration (COA). This satellite was developed on a common minisatellite platform, namely CAST-968, also employed by the SJ-5 satellite. HY-1 is planned to be launched along with FY-1D on a LM-4B launch vehicle in the second half of 2001 (in Aug. 2001 delayed to 2002) from the Taiyuan launch site in China.

Figure 117: Illustration of the HY-1 satellite

The structure of the spacecraft is of hexahedron shape with overall dimensions of 1.2 m x 1.1 m x 0.94 m. The total deployed length of HY-1 is about 7.5 m. The S/C is three-axis stabilized

(Earth pointing) using three magnetorquers and hydrazine propulsion for attitude control and orbit change maneuvers; the attitude accuracy is 0.4° in roll and pitch and 0.5° in yaw. Attitude sensing is provided by a sun sensor and an infrared Earth sensor. S/C power of 450 W (BOL) and 320 W (EOL) is provided by two solar arrays of size 5.67 m². In addition, there are two packs of NiCd batteries of 23 Ah for night phase power supply. Electrical heaters are used for active thermal control. The S/C mass is 365 kg (including 13kg of propellant); payload mass = 87 kg; the design life is two years. ⁷⁴⁸⁾

RF communication. The TT&C communication is in S-band, the downlink data rate is 4 kbit/s, the uplink rate is 2 kbit/s. An on-board storage capacity of 80 Gbit is provided. All payload data are downlinked in X-band using QPSK modulation. Data rate = 5.32 Mbit/s. EIRP = 39.4 dBm.

Orbit: Sun-synchronous orbit, altitude = 798 km, inclination = 98.8°; nodal period = 100.8 minutes; the local time at the descending node is between 10:16 and 10:41 AM (at the end of two year's life). The revisit time for the Ocean Color Scanner is three days; the revisit time for the CCD Camera is seven days.

Sensor complement: The data user of both instruments is COA (China Ocean Administration).

OCS (Ocean Color Scanner), developed by SITP (Shanghai Institute of Technical Physics) of CAS (China Academy of Sciences). The objective is global ocean color monitoring for the study of biological oceanography. OCS consists of the following subsystems: optics, scanner, FPA (Focal Plane Array) and an electronics box. Imagery is provided in 8 VNIR (Visible Near Infrared) and in two TIR (Thermal Infrared) bands with a spatial resolution of 1.1 km. The swath width is 1600 km. The instrument data rate is 0.67 Mbit/s.

D.16 ICESat (Ice, Cloud and land Elevation Satellite)

A NASA/GSFC mission within the ESE (Earth Science Enterprise) program with the prime objective to monitor the mass balance of the polar ice sheets and their contributions to global sea level change. Secondary goals are to measure cloud heights and the vertical structure of clouds and aerosols in the atmosphere, further to measure roughness, reflectivity, vegetation heights, snow-cover, and sea-ice surface characteristics, and to map topography of land surfaces. Note: ICESat is the renamed former “Laser Altimetry-1” mission. A launch is planned on a Delta-2 vehicle (along with CATSAT) for Dec. 2001 from VAFB, CA. 749) 750) 751)

The mission has been developed by a partnership of NASA, industry, and university teams. The S/C integrator is BATC (Ball Aerospace and Technologies Corp.) of Boulder, CO. The ICESat structure is three-axis stabilized and is based on the BCP 2000 (Ball Commercial Platform 2000) series. The S/C configuration uses a simple panel-post aluminum honeycomb structure. The command and data handling subsystem consists of a S/C Control Computer (SCC), a Command and Telemetry Unit (CTU) and two Solid State Recorders (SSR) with a capacity of 32 Gbit. The attitude control and determination subsystem (ACDS) uses two star trackers, redundant inertial reference units (IRU), sun sensors and magnetometers for attitude determination. The pointing accuracy is 100 mrad per axis (1 sigma), the pointing knowledge is 50 mrad per axis (1 sigma), and the pointing stability is 10 $\mu\text{rad/s}$. The geolocation knowledge is <15 m (3 sigma) after ground processing (BlackJack GPS receivers). Four, low-vibration reaction wheels, and three torque rods with redundant windings and drivers are used for control. The electrical power and distribution subsystem employs a fully redundant power control unit, a 40 Ah NiH₂ battery with a spare cell, two 3.2 m single-axis drive solar array panels, and distribution electronics. The S/C design life is 5 years. S/C mass = 970 kg (wet), payload mass = 298 kg. S/C power = 730 W (orbital average) with 350 W for payload operations. The S/C bus permits off-nadir pointing of up to 5°.

Communication: Two separate, redundant X-band downlink transmitters and gimbaled antennas are provided for payload data. The SSR has direct links to the X-band downlink data transmitter. The X-band downlink data rate is 40 Mbit/s at a frequency of 8.100 GHz, modulation type PCM NRZ-M, SQPSK. The CCSDS protocol used is: version 2, grade 3, VCDU header and CRC. TT&C data can be transmitted in S-band or X-band at data rates of: 1, 4, 16 or 256 kbit/s. The uplink is in S-band at 2 kbit/s.

Orbit: Near polar LEO orbit, altitude = 600 km, inclination = 94°. Two primary orbits are used:

- Verification/validation orbit (90-120 days): this orbit has a ground track repeat cycle of 8 days to enable overflights of specific locations on the Earth which will be instrumented to support measurement verification or data product validation
- Mission orbit: this orbit has a ground track repeat cycle of 183 days to enable uniform sampling of the surface with high resolution. At the equator, the separation between ascending tracks will be about 15 km after 183 days.

Figure 118: Illustration of the ICESat spacecraft (+z view top, -z view bottom)

Sensor complement:

GLAS (Geoscience Laser Altimeter System), NASA/GSFC instrument (Science team leader: B. E. Schutz, University of Texas at Austin). GLAS is a descoped version of the former GLRS (Geoscience Laser Ranging System). Objective: GLAS measures ice sheet topography, cloud heights, planetary boundary layer heights, and aerosol vertical structure. In addition, operation of GLAS over land and water provides along-track topography.

GLAS consists of a laser system to measure distance, a GPS receiver, and a star-tracker attitude-determination system. The laser transmits short pulses (4 ns) of infrared light (at 1064

nm) and visible green light (at 532 nm). The instrument is a nadir-viewing frequency-doubled, Q-switched, solid-state Nd:YAG laser with energy levels of 100 mJ (1064 nm) and 50 mJ (532 nm). The pulse repetition rate is 40 pulses/s, and the beam divergence is approximately 0.1 mrad. The infrared pulse is used for surface altimetry, the green pulse is used for atmospheric measurements. The height measurements are determined from the round-trip pulse time. ^{752) 753)}

Parameters or constituents measured	Cloud and aerosol data (extracted from 532 nm laser pulse)
Laser type and transmitter wavelength	Nd:YAG laser with 1064 and 532 nm wavelength, a nadir-viewing frequency-doubled, Q-switched, solid-state Nd:YAG laser
PRF (Pulse Repetition Frequency)	40 Hz
Laser energy/pulse	100 mJ for 1064 nm and 50 mJ for 532 nm

Table 183: Some parameters of the GLAS instrument

Instrument mass = 298 kg, power = 330 W average, duty cycle = 100%, data rate = 450 bit/s, thermal control by radiators supplemented by heaters, heat pipes, thermal operating range: 20° ± 5° C, FOV of telescope = 375 µrad (nadir view only), FOV of instrument = 66 m laser footprint at nadir at 1064 nm, telescope size = 100 cm in diameter (height = 1.75 m).

Figure 119: Various views of the GLAS instrument ⁷⁵⁴⁾

Pointing requirements (platform+instrument):

- Control (3 sigma): 30 arcsec roll, 60 arcsec pitch, 1° yaw
- Post-processed pointing knowledge (1-sigma): 1.5 arcsec (roll and pitch axes, provided by instrument-mounted star trackers laser reference sensor gyroscope)

At 40 pulses per second, the centers of 66 m diameter footprints are separated in the along track direction by 170 m for a 600 km altitude orbit; cross track resolution is determined by

752) “GLAS Geoscience Laser Altimeter System,” ESE Reference Handbook, 1999, NASA/GSFC, pp. 113-114
753) B. E. Schutz, “Laser Altimetry and Lidar From ICESat/GLAS,” IGARSS 2001, Sydney, Australia, July 9-13, 2001
754) Illustration provided by Michael D. King of NASA/GSFC

the 183 day ground track repeat cycle which yields 15 km track spacing at the equator and 2.5 km at 80° latitude.

A small portion of the outgoing laser energy is used for instrument pointing. The extracted energy is input into two CCD cameras: LRS (Laser Reference Sensor) and LPA (Laser Profiling Array). The laser image in the LRS is formed at 10 Hz while the LPA uses the 40 Hz PRF of the instrument. A FOV of 0.5° x 0.5° of stars in the zenith direction is used in LRS. Thus, the LRS provides a combined image of the transmitted laser pulse superimposed on the star background. A third CCD camera, mounted on the GLAS optical bench, is IST (Instrument Star Tracker) at 10 Hz and a FOV of 8° x 8°. IST is used for the spatial orientation of the optical bench with respect to the stars referred to as CRF (Celestial Reference Frame). The LPA provides a shot-by-shot record of the laser far field pattern and the beam direction with respect to the optical bench; the LRS provides a calibration link between the CRF and the optical bench. The system provides a laser pointing accuracy of 1.5 arcsec (knowledge).

The ICESat GPS receiver system is a spinoff of the BJ (BlackJack) dual-frequency receiver developed by NASA/JPL for satellite-based science applications as flown on Jason. Post-processing of the pseudorange and carrier phase recorded by BJ support the determination of the radial component of the GLAS position to an accuracy of 5 cm rms. The ground-based SLR (Satellite Laser Ranging) network provides in addition tracking data to support the validation of the GPS-determined orbit.

D.17 IRS (Indian Remote Sensing Satellites)

IRS is an integrated element of India's NNRMS (National Natural Resources Management System) with the objective to provide a long-term spaceborne operational capability to India for the observation and management of the country's natural resources (applications in agriculture, hydrology, geology, drought and flood monitoring, marine studies, snow studies, and land use). The intent of the program is to create an environment of new perspectives for the Indian research community as a whole, to stimulate the development of new technologies and applications, and to utilize the Earth resources in more meaningful ways.

The program started in the mid 1980s, the first launch of IRS-1A occurred in March 1988.⁷⁵⁵⁾ Eventually, a continuous supply of synoptic, repetitive, multispectral data of the Earth's land surfaces was obtained (similar to the US Landsat program). In 1995, IRS imagery was made available to a larger international community on a commercial basis. The initial program of Earth-surface imaging was extended by the addition of sensors for complementary environmental applications. This started with the IRS-P3 satellite which is flying MOS (Multispectral Optoelectronic Scanner) for the measurement of ocean color. The IRS-P4 mission is dedicated to ocean monitoring.^{756) 757) 758)}

755) Note: The availability of Landsat imagery created a lot of interest in the science community. The Hyderabad ground station started receiving Landsat data on a regular basis in 1978. The Landsat program with its design and potentials was certainly a great model and yardstick for the IRS program.

Table 184: Chronology of IRS-series Earth surface imaging missions and instruments

D.17.1 IRS-1A

IRS-1A (Indian Remote Sensing Satellite-1A). Launch: March 17, 1988 by ISRO (Soviet launch vehicle Vostok from the Baikonur Cosmodrome. The IRSO S/C control center is in Bangalore. TT&C function is provided by ISTRAC (ISRO Tracking Network), supported by DLR (GSOC, Weilheim), NOAA (Fairbanks), ESA (Malindi) and the USSR (Bears-lake) ground stations. Status: nominal S/C operations until the end of 1995. ⁷⁵⁹⁾ ⁷⁶⁰⁾

The S/C is box-shaped (1.6 m x 1.6 m x 1.5 m) with two solar panels (8.6 m²) as shown in Figure 120. The S/C structure is made of aluminum/aluminum honeycomb. The satellite is three-axis stabilized utilizing a zero momentum system. Hydrazine thrusters (80 kg fuel) are also used for control and momentum dumping. The IRS series satellites are built around a zero-momentum reaction wheel based system. Gyro-based attitude reference using quaternion propagation with attitude updates from Earth sensors and sun sensors (CCD-based is used for yaw angle measurements) provide the high-pointing accuracy and stability required for the imaging payload. Attitude is sensed by Earth sensor, sun sensor, star sensor and dynamically tuned gyros. The actuators are reaction wheels (4), magnetic torquers, and hydrazine thrusters (sixteen 1-newton thrusters). A pointing accuracy of 0.3° is achieved in pitch/roll and 0.5° in yaw. Attitude determination accuracy of ±0.1°. Total S/C mass = 975 kg (at launch), power = 700 W, two NiCd batteries (40 Ah) provide power for the eclipse phase of the orbit. The design life is three years.

⁷⁶⁰⁾ IRS NewsLetter, ISRO, Vol. 2 No. 1, March 1991

Orbit: sun-synchronous orbit, nominal altitude = 904 km, inclination = 99.49°, period = 103.2 minutes; the repeat cycle = 22 days; equator crossing at 10:26 AM.

Application: Land use, agriculture, forestry, hydrology, soil classification, coastal wetland mapping, natural resources (in particular pinpointing likely groundwater locations), disaster monitoring, cartography, etc.

Sensor complement:

Parameter	LISS-I	LISS-II A/B
Focal length	162.2 mm	324.4 mm
FOV, IFOV	9.4°, 80 µrad	4.7°+ 4.7°, 40 µrad
Spectral bands (µm)	0.46 - 0.52 (blue) 0.52 - 0.59 (green) 0.62 - 0.68 (red) 0.77 - 0.86 (NIR)	0.46 - 0.52 (blue) 0.52 - 0.59 (green) 0.62 - 0.68 (red) 0.77 - 0.86 (NIR)
Integration time	11.2 ms	5.6 ms
Ground resolution	72.5 m (each band)	36.25 m (each band)
Swath width	148 km	2 x 74 km
Radiometric resolution	7 bit	7 bit
Data rate	5.2 Mbit/s	2 x 10.4 Mbit/s
Instrument mass, power	38.5 kg, 34 W	2 x 80.8 kg, 2 x 34 W

Table 185: Specifications of the LISS-I and -II instruments

LISS = Linear Imaging Self-Scanning Sensor (total of three cameras). ⁷⁶¹⁾ LISS-I and LISS-II are two multispectral camera assemblies, each with a different resolution providing a swath of about 150 km. Each LISS camera consists of the collecting optics, imaging detectors, inflight calibration system, the processing electronics, and data formatting electronics. LISS-I employs four 2048-element linear CCD detector arrays with spectral filters (Fairchild CCD 143A). All cameras use refractive type collecting optics with spectral selection by appropriate filters. The refractive optics were chosen to obtain a large FOV (Field of View). A lens assembly for each spectral band is used for better performance and effective utilization of the full dynamic range of the CCDs. Two LEDs (Light Emitting Diodes) per band are provided for inflight calibration. A LISS-I scene is 148 km x 174 km. The LISS-II A/B assembly features eight 2048-element linear CCD detector arrays with spectral filters (2 parallel swaths of 74 km each for the LISS-II A/B assembly with 3 km overlap, the total swath is 145 km). Four LISS-II scenes cover the area of one LISS-I scene. ⁷⁶²⁾

Data of LISS-I are transmitted in S-band (2217.6 MHz) at 5.2 Mbit/s, PCM/BPSK modulation. Data of the LISS-II assembly are transmitted in X-band, 2 x 10.4 Mbit/s, PCM/QPSK modulation.

IRS-1A data products are being acquired, processed and disseminated by NRSA (National Remote Sensing Agency) Data Center, Hyderabad. These data products compete directly with Landsat TM and MSS data as well as with SPOT Image data on the market.

D.17.2 IRS-1B

IRS-1B is a follow-up satellite of IRS-1A. Launch of the S/C was by a Russian Vostok vehicle from Baikonur on August 29, 1991 (same tracking support configuration as for IRS-1A). The IRS-1B S/C and instruments are practically identical with those of IRS-1A

⁷⁶¹⁾ G. Joseph, IRS-1A Camera - Its Evolution and Realization," brochure of NNRMS (National Natural Resources Management System), Bangalore, India

⁷⁶²⁾ Note: At the time of project initiation, CCD arrays with maturity of production were limited to 2048 elements. Hence the swath of LISS-I was limited to about 150 km. Since LISS-II has a better resolution by a factor of two compared to the LISS-I camera, two LISS-II cameras were needed to produce a swath similar to that of LISS-I.

(satellite mass = 975 kg). IRS-1B is fully operational as of 2001. ⁷⁶³⁾ ⁷⁶⁴⁾

Orbit: Polar sun-synchronous orbit; altitude = 904 km, inclination = 99.49°, period = 103.2 minutes. Repeat cycle: 22 days.

ISRO's policy allows ground stations from other countries to have direct access to the Indian satellite imagery. Any existing ground station equipped to receive data from SPOT or from Landsat will be able to receive IRS-1B satellite data with very minor changes (ISRO can supply the upgrade).

Figure 120: The IRS-1B S/C model

D.17.3 IRS-1E (P1)

A technological mission with the primary objective to test an ISRO-developed launch vehicle by the name of PSLV (Polar Space Launch Vehicle). The launch occurred on Sept. 20 1993, but the satellite failed to achieve orbit (PSVL failure of 2nd stage). Orbit: Sun-synchronous polar orbit with equatorial crossing at 10:30 AM descending node, altitude = 904 km, period = 103 min, repeat cycle = 22 days. ⁷⁶⁵⁾ ⁷⁶⁶⁾

Sensor complement:

LISS-I = Linear Imaging Self-Scanning System. Same definition as under IRS-1A.

MEOSS = Monocular Electro-Optical Stereo Scanner (DLR sensor) with pushbroom CCD technology. MEOSS is a stereo camera system capable of recording three images simultaneously with a single lens by means of linear scanning. The scanner operates in the spectral range of 0.57-0.7 μm . Resolution = 50 m along track, 158 m across track, 45 m in vertical direction; swath width = 510 km, 8 bit quantization. Application: stereo view capability to study topography, geology, terrain analysis and modelling, snow/ice mapping, meteorology (cloud height and movement), etc.

D.17.4 IRS-P2

An ISRO mission with the objective to acquire remote sensing data for oceanographic, land, and atmospheric applications (demonstration of the IRS-1C/1D bus). Launch date:

⁷⁶³⁾ "India Expands Access to Imagery," Space News Aug. 26 - Sept. 8, 1991, p. 22

⁷⁶⁴⁾ "India Calls IRS-1B Launch a Success," Space News, September 9-15, 1991, p. 12

⁷⁶⁵⁾ IRS-1E ME OSS Utilization Plan, ISRO, July 1991

⁷⁶⁶⁾ Note: The satellite designations P1, P2, P3, etc. stand for the launches carried out by PSLV (Polar Satellite Launch Vehicle), the launch vehicle developed by ISRO

October 15, 1994 from SHAR (East coast launch facility of India) with a PSLV launcher. Three-axis stabilized S/C is using conical scanning Earth sensors and dynamically tuned gyros for attitude sensing, and reaction wheels, magnetic torquers and monopropellant hydrazine thrusters as actuators. Inertial attitude referencing with the star sensor updates is one of the major ISRO developments for astronomical X-ray observations. The attitude control system of IRS-P2 provides multipurpose functions by pointing for remote sensing, and inertial pointing for the X-ray observations. S/C mass = 870 kg, solar power = 510 W, two 21 Ah NiCd batteries. ⁷⁶⁷⁾

Orbit: Sun-synchronous circular orbit with an equatorial crossing at 10:30 AM descending node, altitude = 817 km, inclination = 98.7° , repeat cycle = 24 days, period = 101 min.

Sensor:

- **LISS-IIM**= Linear Imaging Self-Scanning System (Modified). Same definition as under IRS-1A. The LISS-IIM instrument is realized with a single optical feed utilizing the full $\pm 5^\circ$ FOV (there are 4 lenses in one optical head). The instrument employs push-broom scanning and a linear CCD line detector array with 4 spectral bands in VNIR (0.45-0.52 μm , 0.52-0.59 μm , 0.62-0.68 μm , 0.77-0.86 μm . Focal length = 324.4 mm. The ground resolution is 32 m (across) x 37 m (along-track). The combined swath is 131 km.

Data: No on-board data storage capability. Downlink broadcast of R/T science data in X-band (8.316 GHz, PCM/QPSK/PM modulation, data rate = 2×10.4 Mbit/s) to a dedicated ground station network and to a general user community. TT&C operations in S-band.

D.17.5 IRS-1C/1D

IRS-1C ⁷⁶⁸⁾ ⁷⁶⁹⁾ ⁷⁷⁰⁾ is an ISRO-built (Indian Space Research Organization) second generation remote sensing satellite with enhanced capabilities in terms of spatial resolution and spectral bands. IRS-1C is a three-axis body-stabilized S/C. The attitude is sensed by star sensors, Earth sensors and gyros. Actuators: four reaction wheels, two magnetic torquers, 16 one Newton hydrazine trusters; one 11 Newton thruster. Pointing accuracy: roll and pitch = $\pm 0.15^\circ$, yaw = $\pm 0.2^\circ$. The S/C structure consists of the main platform and the payload platform (aluminum honeycomb structure). The S/C bus consists of a central cylinder attached to the bottom and the top decks on four sides of the S/C. In addition, a thermally isolated payload deck is introduced (better alignment stability for payload instruments). The S/C mass is 1250 kg; power = 813 W (two sun-tracking type solar panels of 9.6 m²) plus two NiCd batteries of 21 Ah each; S/C design life = 3 years; the on-board recorder capacity is 62 Gbit with an input/output data rate of 42.45 Mbit/s. ⁷⁷¹⁾ ⁷⁷²⁾ ⁷⁷³⁾

Orbit: Polar sun-synchronous orbit; altitude = 817 km, inclination = 98.71° , period = 101.23 min; equatorial local crossing time = 10:30 AM, descending node; 22 day revisit period. Note: the IRS-1D went into an initial elliptical orbit of 817 km x 320 km (slight under-performance of the 4th stage of PSLV). In spite of this handicap, ISRO controllers were able to place the satellite into a functional sun-synchronous (near-circular) orbit of 737 km perigee and 821 km apogee.

The launch of IRS-1C took place on December 28, 1995 with a Russian launcher (Molniya) from Baikonur. The **IRS-1D** launch with an ISRO PSLV-C1 launcher from Sriharikota (SHAR, India) took place on September 29, 1997.

⁷⁷³⁾ "IRS-1C Data Users Handbook," NRSA (India) document provided by Euromap (of GAF), September 1995

Downlink transmission data rate: 40 W of output power (X-band) is used to transmit 42.5 Mbit/s of LISS-III and WiFS data and 85 Mbit/s of PAN data, both links are in X-band with QPSK modulation, TT&C in S-band with PCM/FSK/FM/PM modulation (ISTRAC mission control center at Bangalore, the NRSA data center at Hyderabad is the focal agency for user interfaces).

Availability of IRS data. Space Imaging of Thornton, CO (the Landsat-4 and -5 data distributor) bought the worldwide commercial distribution rights for IRS-1C/D imagery and follow-up IRS series data from Antrix Corp. of Bangalore (the commercial arm of India's Department of Space) in 1995. GAF of Munich, Germany, bought from Space Imaging the IRS distribution rights for Europe. Data reception of IRS-1C data for GAF started in early summer 1996 at the DLR/DFD station Neustrelitz.

Sensor complement:

The three sensors are cameras operating in the pushbroom scanning mode using solid state charge-coupled device (CCD) detectors.⁷⁷⁴⁾

Spectral range	0.5 - 0.75 μm
Spatial resolution	≤ 10 m (6 m at nadir)
Swath width	70 km nadir view (91 km swath for the most inclined cross-track view)
Off-nadir viewing capability	$\pm 26^\circ$ swath steering range (with this a revisit cycle of 5 days is achieved)
Repetition cycle	24 days
SNR at saturation radiance	> 64
Data quantization	6 bit
Integration time	0.8836 ms
Image data rate	84.9 Mbit/s
Instrument mass, power	230 kg, 55-65 W

Table 186: Specifications of the PAN camera

PAN = Panchromatic Camera. PAN uses an all-reflective (off-axis f/4.5) folded mirror telescope (focal length = 982 mm) along with three separately mounted 4096-element CCD arrays, adding up to 12,288 pixels in the cross-track direction (there is some overlapping of the three subscenes of the image requiring special processing). Each detector array has separate interference filters and four LEDs along with a cylindrical lens. Two LEDs are for optical biasing and two are for inflight calibration of the sensor (calibration of CCDs excluding optics). A calibration cycle comprises 2048 lines (1.8 s for calibration cycle). The PAN instrument has a cross-track pointing capability of $\pm 26^\circ$ (body-pointing mechanism), providing a FOR (Field of Regard) coverage of ± 398 km.⁷⁷⁵⁾

LISS-III = Linear Imaging Self-Scanning Sensor. Continuous service multispectral imagery. Application: Land and water resources management.⁷⁷⁶⁾ The pushbroom camera uses refractive optics in four spectral bands (separate optics and detector array for each band). The collecting optics consists of eight refractive lens elements with interference filter in front. A linear CCD array of 6000 silicon-based elements is used for each VNIR band. The SWIR-band device has a 2100 element InGaAs linear array (temperature controlled at -10°C with a passive radiative cooler and an on-off heater control). The SWIR device itself consists of a lattice mismatched heterojunction photodiode array for the detection of SWIR radiation and silicon-based CCD multiplexers for signal readout [seven identical modules are butted together to form a linear array of 2100 elements; each module consists of a two-

sided InGaAs die of 300 photodiodes and two 150-element silicon-based CCD arrays on either side of the photodiode die to multiplex the signal from the photodiodes]. Instrument mass = 171 kg, power = 74-78 W.

Inflight calibration of the LISS-III camera is realized with LEDs (1.55 μm) as illuminating source and operated in pulsed mode to generate six intensity levels. A LED is mounted on either side of the photodiode array. Each LED is followed by diverging optics. A calibration cycle comprises 2048 scan lines (7.3 s for one cycle) and includes six intensity levels. Calibration is normally performed during the eclipse period of the satellite pass.

Spectral bands (4)	0.52 - 0.59 μm (VNIR), 0.62 - 0.68 μm (VNIR), 0.77 - 0.86 μm (VNIR), 1.55 - 1.75 μm (SWIR)
Spatial resolution	23.5 m (VNIR) and 70.5 m (SWIR)
Swath width	142 km (VNIR) and 148 km (SWIR), FOV = $\pm 5^\circ$
Repetition cycle	24 days
SNR at saturation radiance	> 128
Data quantization	7 bit (resolution of 128 grey levels)
Integration time	3.55 ms for VNIR, 10.65 ms for SWIR
Data rate	35.79 Mbit/s for VNIR, 1.39 Mbit/s for SWIR data

Table 187: Specifications of the LISS-III camera

Spectral bands	0.62 - 0.68 μm , 0.77 - 0.86 μm
Spatial resolution	188 m
Swath width	810 km
Repetition cycle	5 days
SNR at saturation radiance	> 128
Data quantization	7 bit (radiometric resolution of 128 grey levels)
Integration time	28.42 ms
Data rate	2.06 Mbit/s

Table 188: Specifications of the WiFS camera

WiFS = Wide Field Sensor (camera), similar to LISS-1. Application: Vegetation index mapping. The camera provides two spectral bands in the VNIR range. The total swath is formed by using two optical heads (i.e., two lenses and two CCDs) per band. The WiFS camera employs refractive collecting optics consisting of eight refractive lens elements with interference filter and neutral density (ND) filter in the frontend assembly. A 2048 element linear CCD array is used. FOV = $\pm 26^\circ$. The two lenses are mounted with their optical axes canted at 13° either side of nadir for each imager. Instrument mass = 41 kg, power = 22 W.

D.17.6 IRS-P3

A follow-up mission to IRS-P2 with the PSLV launcher which was launched March 21, 1996 from Sriharikota, India.⁷⁷⁷⁾ The IRS-P3 S/C structure is of IRS-P2 heritage. The bus structure consists of four vertical panels and two horizontal decks supported on a central load-bearing cylinder of 930 mm diameter and 1188 mm height. The payload is accommodated on the outer side of the upper deck, it is oriented in flight direction. The solar arrays (9.6 m²) provide 810 W of power at end-of-life. The S/C is three-axis stabilized using conical scanning Earth sensors, sun sensors, star sensors, and dynamically tuned gyros, reaction wheels, magnetic torquers and reaction control system. An Earth pointing accuracy of better than 0.20° in all axes and better than 0.05° in all axes for stellar pointing (x-ray observation mode) is provided. Total S/C mass = 922 kg, a hydrazine propulsion system (84 kg of fuel sufficient for three years) with 16 thrusters is used for orbit maneuvers.

⁷⁷⁷⁾ K. Thyagarajan, A. Neumann, G. Zimmermann, "The IPS-P3 Remote Sensing Mission," Small Satellites for Earth Observation, International Symposium of IAA, Berlin, Nov. 4-8, 1996, Walter de Gruyter

The TT&C-system is operating in S-band with PCM/FSK/FM/PM modulation. The telemetry system uses PCM/PSK modulation in S-band (2203 MHz). The payload data is transmitted in S-band (2280 MHz) with BPSK modulation at a data rate of 5.2 Mbit/s.

Orbit: Sun-synchronous circular orbit, altitude = 817 km, inclination = 98.8°, repeat cycle = 24 days, period = 101.3 min, equatorial crossing at 10:30 AM (descending node).

Sensor complement:

WiFS = Wide Field Sensor (camera) of IRS-1C heritage. WiFS is an extended version of 3 channels: 0.62 - 0.68 μm , 0.77 - 0.86 μm , with an additional channel at 1.55-1.75 μm (SWIR). Each band has two detectors centered at a FOV of $\pm 13.6^\circ$ to achieve a swath of 770 km (repeat cycle of 5 days). The optics system consists of eight lenses with spectral bandpass and neutral density filters for each spectral band. The dynamic range in each gain is 7 bits. The absolute radiometric accuracy is better than 10% with relative in-band accuracy of 2%. The data rate for the VNIR data (2 channels) is 2.6 Mbit/s, for the SWIR data it is 1.73 Mbit/s. WiFS has a mass of 25 kg and uses 50 W.

MOS = Multispectral Optoelectronic Scanner (see also MOS-P under PRIRODA, D.28). An advanced imaging spectrometer for the VNIR and SWIR spectrum. MOS is provided by DLR/ISST, Berlin. Objective: Image generation of the Earth surface (surface-atmosphere interaction, ocean color, phytoplankton, regional and global distributions of man-made aerosols and their links to gaseous admixtures, spectral and spatial cloudiness characteristics, etc.) in the VNIR/SWIR region of 0.4 - 1.6 μm .⁷⁷⁸⁾

The sensor apparatus consists of three complementary instruments: (see also Figure 143). MOS operation requires at least one calibration per month (with respect to the sun).

- MOS-A is an atmospheric spectrometer with four narrow channels in the O₂A-absorption band at about 760 nm for the measurement of atmospheric turbidity. The data from MOS-A are used for correction of the atmospheric influence (scattering) on the multispectral data of MOS-B. In addition the O₂A-method permits the measurement of aerosol content and profile.
- MOS-B is a 13-channel spectrometer in the range of 408 to 1010 nm. The center wavelengths of the channels are chosen with the objective for the quantitative retrieval of ocean and coastal zone parameters. They also provide a capability for vegetation signature determination (red edge) and estimation of H₂O (water vapor) content in the atmosphere from the NIR-measurements.
- MOS-C is a line camera at 1.6 μm with a bandwidth of ± 50 nm. The SWIR channel data is used for improved surface term and roughness estimation. In addition the data of the SWIR channel may be used for the following applications: cloud/snow/ice discrimination, cloud type discrimination, estimation of sea surface roughness, and for the improvement of atmospheric correction algorithms.

MOS calibration: In-orbit calibration measurements are performed using internal reference lamps (prior to each data take). In addition sun calibration measurements are performed once a month. This is achieved with a diffuser in front of the entrance optics of the sensor. The following calibration functions are performed:

- DSNU (Dark Signal Non-Uniformity) and PRNU (Photo Response Non-Uniformity)
- Absolute sensitivity calibration
- Linearity control
- Spectral alignment control

MOS in-orbit intercalibrations with sensors from other missions are attempted when orbital opportunities arise for a common target area or test sites. Examples are: MOS on IRS/P3 with MOS on Priroda, or with SeaWiFS on Seastar, or with OCTS on ADEOS.

⁷⁷⁸⁾ G. Zimmermann, A. Neumann, "The Imaging Spectrometer Experiment MOS on IPR-P3 - Three Years of Experience," Journal of Spacecraft Technology, Vol. 10, No 1, Jan. 2000, pp. 1-9

MOS data are received at the following ground stations:: Hyderabad (ISRO, India), Neustrelitz (DLR, Germany), Maspalomas (ESA, Spain - since 1998), Wallops Island (NASA, USA - since April 1999).

Parameter	MOS-A	MOS-B	MOS-C
Spectral range (nm)	755 - 768 nm	408 - 1010	SWIR
No. of channels	4	13	1
Wavelengths (nm)	756.7; 760.6; 763.5; 766.4 (O ₂ A-band)	408; 443; 485; 520; 570; 615; 685; 750; 870; 1010; 815; 945 (H ₂ O-vapor)	1600
Spectral resolution	1.4 nm (FWHM)	10 nm (FWHM)	100 nm (FWHM)
FOV along-track	0.344°	0.094°	0.14°
FOV across-track	13.6°	14.0°	13.4°
Swath width	195 km	200 km	192 km
No. of pixels per row	140	384	299
Spatial resolution	1.57 km x 1.4 km	0.52 km x 0.52 km	0.52 km x 0.64 km
Measuring range L_{min} - L_{max} [$\mu W cm^{-2} nm^{-1} sr^{-1}$]	0.1 - 40	0.2 - 65	0.5 - 18
Data quantization	16 bit		
Data rate	1.3 Mbit/s		

Table 189: Specifications of the MOS instruments

X-Ray Payload. An ISRO astronomy instrument package with the objective to study periodic and aperiodic intensity and spectral variations in x-ray sources. Source observation is achieved by ‘pointed mode observations,’ employing an array of three co-aligned collimated **PPC** (Pointed Proportional Counter). The system operates in mutual anti-coincidence fashion for significant reduction of background noise (cosmic rays and Compton interaction of gamma rays). - Another objective is the study of light curves and the spectral evolution of transient and flaring x-ray sources as well as long-term intensity monitoring of known binary x-ray stars and other bright x-ray sources. This is achieved by means of **XSM** (X-ray Sky Monitor), based on the principle of a pin hole placed above a position sensitive to PPC in anti-coincidence mode.

PPC		XSM	
Energy range	2 - 20 keV	Energy range	2 - 8 keV
FOV	2° x 2°	FOV	90° x 90°
No of PPC	3	Pin hole size	1 cm ²
No of layers per PPC	3	Distance to detector	16 cm
No. of anode cells/layer	18	Detector	32 proportional counters
Size of cell	1.1 cm x 1.1 cm	Detector cell size	1 cm x 1 cm x 32 cm
Entrance window	25 μm , 500 Å, Al coated	Window	25 μm Mylar, Al coated
Filling gas	Ar+CH ₄ , at 800 torr	Filling gas	Ar+CH ₄

Table 190: PPC and XSM instrument specification

D.17.7 IRS-P4 (OceanSat-1)

The objectives of the ISRO IRS-P4 mission are directed at ocean- and atmosphere-related applications, hence it is also referred to as OceanSat-1. The S/C structure (aluminum/aluminum honeycomb with CFRP elements) is of IRS-1C/1D, -P3 heritage. The platform is three-axis stabilized, the pointing accuracies are $\pm 0.15^\circ$ in pitch/roll and $\pm 0.20^\circ$ in yaw; the drift rate is $< 0.0003^\circ/s$. Attitude is measured by Earth sensors, sun sensors, a magnetometer and gyros. Actuators: reaction wheels, magnetic torquers and hydrazine thrusters. An on-board storage capability of 320 Mbit is provided. S/C mass = 1036 kg; power = 800 W at EOL; two NiCd batteries provide 2 x 21 Ah. The S/C size is: 2.8 m x 1.98 m x 2.57 m. The mission design life is 5 years. A launch of IRS-P4 on a PSLV-C2 launcher from SHAR

(along with the secondary payloads of KITSAT-3 and DLR/TUBSAT) took place on May, 26, 1999. This launch service of secondary payloads is regarded as India's "first commercial launch." It is also the first time that an ISRO launcher carried multiple satellites. 779) 780) 781) 782) 783)

The TT&C functions are carried out by the ISRO/ISTRAC control center with ground stations at Bangalore, Lucknow and Hyderabad (payload data and TT&C) in India and from its station in Mauritius. External ground stations at Bearslake (OKB/MEI), Biak (Indonesia) and the DLR station in Weilheim (Germany). The payload data reception stations are operated by NRSA (National Remote Sensing Agency) at Hyderabad and Shadnagar. The real-time data from OCM and MSMR playback data are downlinked in X-band, while the real-time MSMR data as well as housekeeping data are transmitted in S-band. Status: IRS-P4 is operational as of 2001.

Mechanical system	
Structure	Al/Al honeycomb with CFRP elements
Thermal system	Passive/semi-active thermal control with paints, blankets, OSRs and closed loop temperature controllers
Thermal control	Payloads: $15 \pm 2^\circ\text{C}$ for OCM; $20 \pm 10^\circ\text{C}$ for MSMR; battery: $5 \pm 5^\circ\text{C}$; electronics: 0 to 40°C
Mechanisms	Solar panel deployment, OCM hold and release & OCM tilt; MSMR antenna scanning
Power system	
Solar panels	9.6 m ² rigid, sun-tracking type-800 W power at EOL
Chemical battery	2 x 21 Ah NiCd batteries
Power electronics	Two raw buses (28-42V) providing power to all subsystems, modular DC/DC converters
TT&C system (S-band)	
Telecommand	PCM/FSK/FM/PM modulation, time tag command facility
Telemetry	PCM/PSK/PM modulation; ASIC-based system
Transponder	Uplink frequency: 2028.70 MHz; downlink frequency: 2203.20 MHz
AOCS	
Sensors	Earth sensors, sun sensors, magnetometer and gyros
Actuators	Reaction wheels, magnetic torquers, hydrazine thrusters (1N & 11N)
AOCE	Microprocessor-based system
Pointing accuracy	0.15° (pitch and roll); 0.20° (yaw)
Drift rate	$< 3.6 \times 10^{-4}$ °/s
Data handling system	
Baseband data rate	20.8 Mbit/s
RF system	QPSK modulated transmitter
Frequency	X-band (8350 MHz)
On-board recorder	320 Mbit for OCM (coarse resolution) and MSMR data
S/C positioning system	
Positional accuracy	100-150 m (autonomous mode)

Table 191: Overview of IRS-P4 S/C characteristics

Orbit: Sun-synchronous circular orbit, altitude = 720 km, inclination = 98.28° , orbital period = 99.31 min, repeat cycle = 2 days, equator crossing time at 12 noon.

IRS-P4 is the first S/C of the IRS series providing successfully GPS data with an 8-channel C/A code receiver (L1 frequency), referred to as SPS (Satellite Positioning System). The instrument is mounted in the anti Earth view face of the payload to track GPS signals continuously. SPS computes on-board the instantaneous orbit (position, Velocity, time). In addition, pseudo range and delta pseudo range are provided. The on-board GPS measure-

ments along with the GPS positions from the ground reference receiver are used to estimate the IRS orbit.⁷⁸⁴⁾

Sensor complement: The payload includes the OCM (Ocean Color Monitor) and MSMR (Multi-frequency Scanning Microwave Radiometer) instruments. Both instruments are very different from the ones flown in earlier missions and needed new developments in many areas like tilt mechanism (to avoid sun glint) and hold-down and release mechanism for OCM, a CFRP (Carbon Fibre Reinforced Plastic) support structure for MSMR and the mission specific data handling system.

OCM (Ocean Color Monitor). OCM is a solid-state radiometer providing observations in eight spectral bands in the VNIR region (nm): B1: 402-422, B2: 433-453, B3: 480-500, B4: 500-520, B5: 545-565, B6: 660-680, B7: 745-785, and B8: 845-885. The instrument employs pushbroom scanning technology with linear CCD detector arrays (191 6K CCD) of 6000 elements (3700 active detectors, the rest are used to correct for dark current). A swath of 1440 km is provided. An along-track instrument tilt capability of $\pm 20^\circ$ is provided to avoid sun glint. OCM optics is based on one lens per band (wide angle telecentric lens design, refractive system). A scheme of using unused CCD pixels is being utilized as a reference for calibration. The ground resolution is 360 m in the along-track and 236 m in the cross-track direction. Applications are:^{785) 786)}

- Measurement of concentrations of phytoplankton pigments, suspended sediments, Gelbstoff concentration in the euphotic layer. Assessment of their distribution, both spatially and temporally; detection of algal blooms and their dynamic behavior.
- Identification of potential fishery zones
- Delineation of coastal currents and eddies
- Estimation of optical properties and phytoplankton abundance for marine resource and habitat assessment
- Observation of pollution and sediment inputs to the coastal zone and their impact on marine food
- Sediment dynamics, dynamics of estuarine/tidal inlets, prediction of shoreline changes, coastal circulation and dispersion patterns.

Parameter	Value	Parameter	Value
Spectral range (8 bands)	0.4 - 0.9 μm (VNIR)	SNR	> 512 (saturation)
Scan plane tilt	$\pm 20^\circ$, to avoid sun glitter	Effective focal length	20 mm
Camera MTF	> 20% at Nyquist frequency	Absolute radiometric accuracy	< 10%
IFOV at nadir	360 m x 236 m (VNIR)	No of CCD elements	6000
FOV (swath)	1420 km ($\pm 43^\circ$)	CCD element size	10 μm x 7 μm
Tilt capability	$\pm 20^\circ$ along track	Integration time	52.4 ms
Data quantization	12 bit	Exposure levels (gain)	16
Data rate (real-time)	20.8 Mbit/s	On-board calibration	2 LEDs per band

Table 192: Specification of the OCM instrument

The two modes of OCM data transmission are real-time and playback. The playback mode provides a coarser spatial resolution of 2.16 km. The data are averaged on-board (8 scan lines x 4 pixels) and transmitted in the eclipse phase of the orbit at a rate of 0.3 Mbit/s. The instrument mass is 75 kg.

The imaging concept of OCM is an extension of the imaging concept adopted for the IRS LISS instruments. Unlike SeaWiFS or OCTS, OCM does not have common collecting op-

tics coupled to a scan mechanism for realizing the wide swath. OCM has separate wide-angle optics and a linear array CCD detector for each band. The issue of spectral response variation with large incidence angles is overcome by the choice of a telecentric design and the use of a spectral selection filter close to the linear array detector. - The pushbroom approach has enabled the use of a 12 bit digitizer to cover the instruments dynamic range.⁷⁸⁷⁾

Band	Band center and bandwidth (nm)	Saturation radiance (mW cm ⁻² sr ⁻¹ μm ⁻¹)	Applications	NESR (mW cm ⁻² sr ⁻¹ μm ⁻¹)
B1	412, 20	35.5	Yellow substance and turbidity	0.026
B2	442, 20	28.5	Chlorophyll absorption	0.022
B3	489, 20	22.8	Chlorophyll and other pigments	0.017
B4	512, 20	25.7	Turbidity, suspended sediment	0.017
B5	557, 20	22.4	Chlorophyll, suspended sediment	0.015
B6	670, 20	18.1	Chlorophyll absorption	0.01
B7	768, 40	9.0	O ₂ absorption	0.005
B8	867, 40	17.2	Aerosol optical thickness, vegetation, water vapor reference over the ocean	0.008

Table 193: Spectral band definition in the VNIR range

MSMR (Multifrequency Scanning Microwave Radiometer).⁷⁸⁸⁾ Objective: to complement the biological ocean parameters of OCM with some geophysical parameters such as: sea surface temperature (SST), sea surface wind speed (SSW), atmospheric water vapor (WV), and cloud liquid water content (CLW). MSMR is a dual-polarized four-frequency radiometer. It features a conical scanning mechanism with a constant look angle of 43.13° and a scan rate of 11.16 rpm. The various receivers are Dicke-switched with a two-point on-board calibration using hot termination and a cold-space horn antenna. The eight-channel MSMR employs six independent receivers 6.6, 10.6, 18, 21 GHz. MSMR observations are continuous over the mission life. Instrument mass = 65 kg, power = 76 W, the data rate is 6.4 kbit/s.

Parameter	Value	Parameter	Value
Frequencies (GHz)	6.6, 10.65, 18, 21	Antenna diameter	0.862 m x 0.800 m
Polarization	V&H, V&H, VH, VH	3 dB beam width	4.2°, 2.6°, 1.6°, 1.4°
Swath width	1360 km	Spatial resolution (km)	105x68, 66x43, 40x26, 34x22 (for frequency sequence)
Sampling interval	9 ms	Temperature resolution	<1.0 K
Data quantization	12 bit	Dynamic temp. range	3.7 - 330 K

Table 194: MSMR instrument parameters

MSMR has an antenna reflector of size 860 mm x 800 mm, an off-axis parabola, and a corrugated feed to receive the emitted radiation from the Earth and its atmosphere. The antenna reflector is rotated at 11.16 rpm to get a circular scan of 1360 km on the Earth's surface with a constant incidence angle of 49.7°. The receiver signal is detected by a square-law detector and synchronously demodulated. The amplitude of the incoming signals are quite low and hence very sensitive to the temperature stability of the components (often a fraction of a degree). To overcome this difficulty, an onboard calibration scheme has been implemented wherein for each antenna scan, temperature values of critical components are recorded along with payload data. These data are used along with look-up tables on the ground to compensate for the temperature variations on-board, thus improving the determination of the brightness temperature. The MSMR instrument provides a two-day repetitivity thus providing applications in fisheries, meteorology, sea-state, etc. Research applications, like rainfall, soil moisture, and snow cover are also being tested.

787) R. R. Navalgund and A. S. Kiram Kumar, "Ocean Color Monitor (OCM) on Indian Remote Sensing Satellite IRS-P4," ISRO/SAC internal paper provided by George Joseph

788) S. S. Rana, "Multifrequency Scanning Microwave Radiometer of IRS-P4," NNRMS Bulletin-22, May 1998, pp.20-23

The following data products of MSMR are generated on a routine basis:

- Level 0 antenna temperature data
- Level 1 brightness temperature data
- Level 2 geophysical parameter data

The MSMR realization required the following indigenous technical developments: a) a multifrequency polarization feed with a frequency ratio of 1:3.2; b) microwave blackbody targets with an emissivity > 99.9% complete with cryogenic control; c) a precision thermistor-based temperature sensor with an accuracy of 0.1 K and a precision of 0.01 K.

Parameter	Channel	Accuracy	Resolution	Value Range
WV	21 with 18 & 10 (H&V)	0.3 g/cm ²	50 km x 36 km	0.2 - 7.5 g/cm ²
CLW	21 with 18 & 10 (H&V)		50 km x 36 km	0 - 80 mg/cm ²
SSW	10 with 6.6, 18 & 21 (H&V)	1.5 m/s	75 km x 75 km	2 - 24 m/s
SST	6.6 with 10, 18, & 21 (H&V)	1.5 K	150 km x 146 km	273 - 303 K

Table 195: Retrievable geophysical parameters from MSMR

D.17.8 IRS-P5 (CartoSat-1)

The objectives of the IRS-P5 mission are directed at geo-engineering (mapping) applications, calling for high-resolution panchromatic imagery with high pointing accuracies. Hence, IRS-P5 is also referred to as CartoSat-1.⁷⁸⁹⁾

The S/C structure is of IRS-1C/1D and -P3 heritage, having a diameter of 2.7 m and a height of 2.9 m. The S/C mass is 1500 kg (including fuel for five years of operation). The platform is three-axis stabilized (star sensors in loop, magnetic bearing reaction wheels, 16 nozzles with 1 N thrusters, 4 nozzles with 11 N thrusters), the pointing accuracies are $\pm 0.05^\circ$, the stability is $5 \times 10^{-5}^\circ/\text{s}$. A launch of the IRS-P5 mission is planned on a PSLV launcher from SHAR for 2002.

Payload data transmission is in X-band (2 carriers, QPSK modulated, single polarized) at 105 Mbit/s. A new electronically steerable beam phased-array antenna system is being implemented.

Orbit: Sun-synchronous circular orbit, altitude = 617 km, inclination = 97.5° .

Sensor complement:

The payload instrumentation consists of two panchromatic cameras of PAN heritage as flown on the IRS-1C/D satellites. The objective is to obtain fore-aft stereo imagery with two fixed (body-mounted) instruments. The discrimination of elevation differences of better than 5 m make the data particularly suitable for map-making and terrain modeling. **PAN-F** (Panchromatic Forward-pointing Camera), featuring a fixed forward tilt of 26° . **PAN-A** (Panchromatic Aft-pointing Camera), it is fixed at an aft tilt of 10° . Each camera provides a spectral range of 0.5 - 0.75 μm , a spatial resolution of 2.5 m, a swath width of 30 km, and data quantization of 10 bits. The on-board source data rate of the two cameras is 338 Mbit/s. An on-board ADPCM/JPEG compression algorithm of 3.2 : 1 is applied reducing the data rate to 105 Mbit/s (i 52.5 + q 52.5).

The optical system of each PAN camera is designed with a three-mirror off-axis reflective telescope with an off-axis concave hyperboloidal primary mirror and an off-axis concave ellipsoidal tertiary mirror - to meet the required resolution and swath width. The overall size of each PAN camera is 150 cm x 850 cm x 100 cm with a mass of 200 kg.

⁷⁸⁹⁾ Note: ISRO is the only Space Agency anywhere that did not provide any imagery electronically of its spacecraft or of its instruments (in spite of many requests).

D.17.9 IRS-P6 (ResourceSat-1)

The overall objectives of the IRS-P6 mission (**ResourceSat-1**) are for the support of agricultural applications. The LISS-IV camera is the prime instrument of this payload.

The S/C mainframe is of IRS-1C/1D -P3 heritage. The overall S/C size is about 2 m in diameter and 2.1 m in height. The total S/C mass is 1200 kg, including fuel for five years of operation. The platform is three-axis stabilized (star sensors in loop, magnetic bearing reaction wheels, 16 nozzles with 1 N thrusters, 4 nozzles with 11 N thrusters), the pointing accuracies are $\pm 0.15^\circ$, the stability is 3×10^{-4} °/s. A solid-state on-board recorder provides 60 Gbit capacity to store about 10 minutes of LISS-IV data. A launch of the IRS-P6 satellite is planned on a PSLV launcher from SHAR in late 2001.

Orbit: Sun-synchronous circular orbit, altitude = 817 km, inclination = 98.8° .

Sensor Complement:

LISS-IV (Linear Imaging Self-Scanning Sensor-IV). LISS-IV is a three-band pushbroom camera of LISS-III heritage (same spectral VNIR bands as LISS-III) with a spatial resolution of 6 m and a swath of 70 km. LISS-IV features a $\pm 20^\circ$ steering capability in the cross-track direction. The optoelectronic module for LISS-IV is identical to that of the PAN camera of IRS-1C/1D.

LISS-III* (Linear Imaging Self-Scanning Sensor-III*). The instrument is identical to LISS-III on IRS-1C/1D (with regard to lens modules, detectors, and electronics) in the three VNIR bands, each with a spatial resolution of 23.5 m. The resolution of the SWIR band is now also of 23.5 m on a swath of 140 km. The optics design and the detector of the SWIR band are modified to suit the required resolution.

AWiFS (Advanced Wide Field Sensor). AWiFS is a wide-angle medium resolution (70 m) camera with a swath of 740 km ($\text{FOV} = \pm 25^\circ$) of WiFS heritage. The pushbroom instrument operates in three spectral bands which are identical to two VNIR bands (0.62 - 0.68 μm , 0.77 - 0.86 μm) and the SWIR band (1.55-1.70 μm) of the LISS-III camera. The wide swath coverage enables AWiFS to provide a five-day repeat capability.

Sensor	Spectral Bands (μm)	Spatial Resolution	Swath Width	Bit Quantization
LISS-IV	0.52-0.59, 0.62-0.68, 0.77-0.86	6 m	70 km	7 bit
LISS-III*	0.52-0.59, 0.62-0.68, 0.77-0.86 1.55-1.70 (SWIR)	23.5 m 23.5 m	140 km 140 km	7 bit 7 bit
AWiFS	0.62-0.68, 0.77-0.86, 1.55-1.70	70 m	740 km	10 bit

Table 196: Summary of the IRS-P6 instrument parameters

D.18 JERS-1 (Japan Earth Resources Satellite)

JERS-1^{790) 791)} is a joint NASDA/MITI/STA project (NASDA/STA developed the satellite (built by Mitsubishi Electric Co.); MITI sponsored the instruments). The JERS-1 satellite was launched on Feb. 11, 1992 from Tanegashima Space Center by the H-I launch vehicle. JERS-1 carries a two-instrument payload, SAR and OPS (Optical Sensor). JERS-1 (built by Mitsubishi Electric) consists of a net rectangular bus (0.9 m x 1.8 m x 3.2 m) with a single 2 kW solar array (3.5 m x 7.0 m) and an eight-segmented SAR antenna. The S/C is three-axis stabilized with zero momentum bias system using reaction wheels and magnetotorquers. The attitude is sensed by an Earth sensor, an inertial reference unit and two sun sensors

⁷⁹⁰⁾ The Japanese nickname for JERS-1 is Fuyo-1, the name of a Japanese flower.

⁷⁹¹⁾ Y. Nemoto, et al., "Japanese Earth Resources Satellite-1 Synthetic Aperture Radar," Proceedings of the IEEE, Vol. 79, No. 6, June 1991, pp. 800-809

(0.3° attitude knowledge). Hydrazine propulsion system. Nominal mission duration = 2 years. Satellite mass = 1340 kg. Status: On Oct. 11, 1998 a malfunction occurred on JERS-1 causing a termination of satellite operations. Hence, a total of about 6 1/2 years of observation time could be achieved with JERS-1. ⁷⁹²⁾

Figure 121: JERS-1 spacecraft model

Application: Survey of geological phenomena, land usage (agriculture, forestry), observation of coastal regions, geologic maps, environment, disaster monitoring, etc.

Objectives: Generation of global data sets with SAR and OPS sensors in order to survey resources; establishing an integrated Earth observation system, verifying instrument/system performances.

Orbit: Sun-synchronous subrecurrent polar orbit; inclination = 97.7°; repeat cycle = 44 days (westward); altitude = 568 km; period = 96 minutes, local mean time = 10:30 - 11:00 AM (descending node).

Sensor complement:

SAR (Synthetic Aperture Radar). Measurement in L-band (1.275 GHz) in HH polarization. The instrument consists of the following subsystems: antenna, transmitter/receiver, and signal processor. The SAR antenna is composed of eight 2.2 m x 1.5 m panels, measuring 2.2 m x 11.9 m in total. A honeycomb sandwich structure is used. The S/C recorder has a capacity of 7.2×10^4 Mbit (recording time of up to 20 minutes of SAR and OPS data). The signal processor performs several functions. First, it performs the A/D conversion of I and Q video signals from the transmitter/receiver. Secondly, after formatting the A/D converted I and Q data plus other data necessary for processing on the ground, it transmits the I and Q channel data. Finally, it controls itself and the transmitter/receiver based on commands received from the ground stations.

Calibration: SAR on-board calibration is for receiver gain. The parameter derived from the SAR image mode is the normalized radar backscattering coefficient, sigma-zero. The absolute accuracy of the image product is dependant upon the calibration efforts undertaken at each processing facility.

Center frequency	1.275 GHz (L-band, 23 cm wavelength)
Bandwidth	15 MHz
Spatial resolution	18 m (range) x 18 m (azimuth, 3 looks)
Swath width	75 km
Transmitting power	1100-1500 W
Pulse width	35 μ s
PRF (Pulse Repetition Frequency)	1505.8 - 1606.0 Hz
Antenna	Array of 1024 microstrip radiation elements
Polarization	HH
Look angle	35.21°
Antenna gain	> 33.5 dB
Signal to ambiguity ratio	> 14 dB
Data quantization	3 bits
Data rate	60 Mbit/s

Table 197: Performance parameters of the JERS-1/SAR instrument

OPS = Optical Sensor . OPS is a high-resolution radiometer with the objective to measure sunlight reflected by the Earth's atmosphere in eight bands (color imagery). OPS consists actually of two independent radiometers: the VNIR band instrument and the SWIR radiometer. Swath width = 75 km, spatial resolution = 18.3 m (cross-track direction) x 24.2 m (along-track direction). Band 4 is for off-nadir viewing (15.33° forward in flight direction); bands 3 and 4 make a stereo pair. The stereo images are useful for geomorphology and digital elevation model (DEM) construction. Data from the 4 SWIR bands allow hydrothermal, vegetation, and soil moisture mapping as well as discrimination between snow and cloud coverage. IFOV=32.2 μ rad, FOV=7.55°, stereoscopic view angle=15.33° (B/H=0.3), Nr. of pixels=4096 per band, data rate=30 Mbit/s in two channels (each), data quantization=6 bits. The following spectral bands are defined:

- Band 1 = 0.52 - 0.60 μ m
- Band 2 = 0.63 - 0.69 μ m
- Band 3 = 0.76 - 0.86 μ m
- Band 4 = 0.76 - 0.86 μ m (forward viewing)
- Band 5 = 1.60 - 1.71 μ m (SWIR)
- Band 6 = 2.01 - 2.12 μ m (SWIR)
- Band 7 = 2.13 - 2.25 μ m (SWIR)
- Band 8 = 2.27 - 2.40 μ m (SWIR)

The VNIR radiometer has a telescope with aspherical lenses (refractive optics) and a dichroic prism. The telescope aperture is 43 mm in diameter with an f/Nr.5 and a focal length of 215 mm. The Si-CCD detectors have 4096 elements. There are four detectors, one for each band. A reference light source unit emits a calibration light during the eclipse period of the orbit to check the radiometric performance of the radiometer. The VNIR instrument mass is 32 kg.

The SWIR radiometer telescope uses reflective and refractive optical systems. The aperture is 200 mm in diameter with an f/Nr.1.55 and a focal length of 310 mm. Detectors: PtSi Schottky CCDs with 2048 pixels per row and 4096 pixels per band. The CCDs are cooled to 77-82 K. A reference light source provides sensor calibration. The SWIR mass is 60 kg. The total instrument mass (common electronics = 82 kg) is 174 kg. The total instrument power is 250 W.

Data:

Mission (sensor) data is downlinked in X-band ($f_1 = 8.15$ GHz, $f_2 = 8.35$ GHz) in QPSK modulation at a data rate of 60 Mbit/s by a right-hand circular polarized antenna onboard the S/C. Provision of on-board data recording. The JERS-1 ground system consists of TACC (Tracking and Control Center) at the Tsukuba Space Center, NASDA/EOC (Earth Observation Center) for data acquisition, processing, distribution and archiving, and a

number of licensed foreign receiving stations. Some ground stations which receive JERS-1 data are:

NASDA/EOC (Hatoyama, Japan)
Tokai University (Kumamoto, Japan)
National Institute of Polar Research, Japan (Syowa, Antarctica)
Alaska SAR Facility (ASF, Fairbanks, Alaska)
Canada, CCRS (Gatineau, Prince Albert)
ESA (Kiruna, Tromsø)
National Research Council of Thailand (Bangkok, Thailand)
ACRES (Australia)
DLR/DFD station (O'Higgins, Antarctica)
etc.

Table 198: Data Products of JERS-1 SAR and OPS instruments ⁷⁹³⁾

D.19 KITSAT Program

In the late 1980s, the Satellite Technology Research Center (SaTReC) of the Korea Advanced Institute of Science and Technology (KAIST) was given the task of defining a national satellite program. The major objectives of the program were to develop a capability and to create an environment for state-of-the-art space age technology and research. Economic considerations implied an affordable program in microsatellite technology. A need in project experience and associated activities for all phases of successful space missions resulted in an on-the-job traineeship/development of a Korean microsatellite for a team of SaTReC engineers at SSTL (University of Surrey), UK. The first satellite in this cooperative program was named KITSAT-1 (Korea Institute of Technology Satellite-1), it was launched August 10, 1992 on Ariane-4 ASAP (V.52, piggyback), along with the Topex/Poseidon S/C as the prime payload (KITSAT-1 is defined under D.40.6).

D.19.1 KITSAT-2 (Korea Institute of Technology Satellite-2)

KITSAT-2 was designed and built at KAIST/SaTReC in Korea (based on the UoSAT bus). It was launched on Ariane-4 (along with PoSAT-1 and HealthSAT-2), September 26, 1993 as an auxiliary payload on the SPOT-3 launch from Kourou.

The microsatellite has dimensions of 35.2 x 35.6 x 67 cm and a mass of 47.5 kg. GaAs solar panels on four sides of the structure provide 30 W of power. The S/C is spin-stabilized with

⁷⁹³⁾ K. Maeda, M. Nakai, O. Ryuguji, "JERS-1/ERS-1 Verification Program and Future Verification Program," Advanced Space Research, Vol. 12, No. 7, pp. 327-331, 1992

the help of a gravity-gradient boom and three magnetorquers (attitude knowledge from one Earth sensor, two sun sensors, and two horizon sensors). Data transmission via three VHF uplinks and two UHF downlinks (amateur radio services are provided). S/C operations are performed at SaTReC. Nominal operations are conducted as of 6/1998.

Orbit: Sun-synchronous, perigee = 791.1 km, apogee = 805.4 km, inclination = 98.64°, period = 100 minutes.

Sensor complement:

CEIS (CCD Earth Imaging System). CEIS consists of two planar CCD array cameras: a narrow angle camera (NAC) with 200 m ground resolution and a wide angle camera (WAC) with 2 km ground resolution. WAC is a color camera developed in cooperation with Samsung Electronics.

The NAC system uses a filter with 80 nm bandwidth at 650 nm with 60% peak transmission (spectral range from 610 - 690). FOV = 6°, providing a target area of 120 x 100 km. The WAC system uses a single-chip color chip (KC73125) and detector array of 511 x 492 with one of four selectable optical filters. The main bandpass filter which passes the visible band (with optical low pass filter) is located between the sensor and the lens system. The output is sampled as 8 bit per pixel. Transform algorithms are used to convert the 8-bit gray level color matrix information into RGB color information. The WAC system has a mean ground pixel resolution of 2 km before color transformation and 4 km resolution after transformation into the color image. FOV = 68°. ⁷⁹⁴⁾

DSPE (Digital Signal Processing Experiment). The sensor is very similar to DSPE on PoSAT. DSPE uses software digital signal processing techniques to implement a high speed modem. The experiment aims to improve the quality of communications between the satellite and the ground, and also provides a software-controlled method for selecting the data rate and the modulation technique to be used.

IREX (Infrared Experiment). IREX monitors the effects of the space environment on a KAIST-developed infrared sensor. The experiment is designed to operate in a minimum temperature environment with the assistance of a passive cooling system.

LEED (Low Energy Electron Detector). LEED measures the distribution of low energy electrons (less than 6 keV) at the orbit altitude of 800km. This experiment uses a 3000 V spiral electron multiplier with 16 measurement channels. The data from this experiment is used for studying the effects of solar activities on the space environment around the Earth.

DSFCE (Digital Store-and-Forward Communication Experiment).

KASCOM (KAIST Satellite Computer). KASCOM is an experimental on-board computer system based on an 8 MHz 32 bit Intel 80960 microprocessor with 10 MByte CMOS SRAM. The experiment tests the operations of this new computer in the space environment and provides data for future systems to be used in the next generation satellites.

Downlink frequency	Transponder/Beacon	Mode
435.175 MHz	T	9.6 kbit/s FSK FM digital
436.500 MHz	T	9.6 kbit/s FSK FM digital
Uplink frequency	Transponder/Beacon	Mode

D.19.2 KITSAT-3 (Korea Institute of Technology Satellite-3)

KITSAT-3, or Wooribyul-3 ('our star'), is a KAIST (Korean Advanced Institute of Science and Technology)/SaTReC (Satellite Technology Research Center) microsatellite develo-

⁷⁹⁴⁾ SK Yoo, S. Lee, et al., "The KITSAT-2 CCD Earth Imaging Experiment," Proceedings of SPIE Conference on Small Satellite Technology and Applications IV, Vol. 2317, Rome, September 1994

ped on a new modular bus structure (no heritage to the KITSAT-1 and -2 bus of SSTL). The main objective of KITSAT-3 is to test the new satellite bus and its payloads. KITSAT-3 is three-axis stabilized providing a pointing accuracy of $<0.5^\circ$. Attitude of the box-like satellite (495 mm x 604 mm x 852 mm) is sensed by a sun sensor (two-axis), Earth horizon sensor, star sensor (CCD type), fiber optic gyro, and a three-axis magnetometer; control is provided by a three-axis magnetorquer and a reaction wheel as actuators. S/C mass = 110 kg, power = 150 W (deployable solar panels). KITSAT-3 was launched on an ISRO PSLV-C2 launch vehicle as a piggyback payload from SHAR, India, on May 26, 1999 (the prime payload was IRS-P4, also referred to as OceanSat-1 of ISRO).^{795) 796)}

Figure 122: Illustration of KITSAT-3

Communication: VHF receiver at 1200/9600 bit/s, AFSK/FSK modulation, frequency of 148 MHz in uplink. UHF transmitter at 1200/9600 bit/s, AFSK/FSK modulation, frequency of 401 MHz downlink. S-band transmitter at 9.6/38.4 kbit/s, FSK modulation, frequency of 2.2 GHz. X-band transmitter (for imagery transmission) at 3.2 Mbit/s, QPSK modulation, frequency of 8.2 GHz. On-board image data compression in JPEG, GIF and DPCM. An on-board data storage capability of 10 Gbit is provided (2 Gbit SRAM, 8 Gbit flash memory).

⁷⁹⁵⁾ KITSAT-3 brochure provided by Dongseok Shin of SaTReC, Taejon, Republic of Korea

⁷⁹⁶⁾ B. J. Kim, H. Lee, S. D. Choi, "Three-Axis Reaction Wheel Attitude Control System for KITSAT-3 Microsatellite," Pergamon, Space Technology, Vol. 16, No 5/6, pp. 291-296, 1996

Orbit: Sun-synchronous circular orbit, altitude = 720 km, inclination = 98.37°.

Sensor complement: (one remote sensing instrument and an experiment package referred to as SENSE (Space Environment Scientific Experiments), consisting of REME, HEPT, SMAG, and ETP.

MEIS (Multispectral Earth Imaging System), developed by SaTReC in cooperation with Stellenbosch University, South Africa (see the HRI instrument of SUNSAT, N.18). The objective is to acquire multispectral high-resolution Earth surface imagery. MEIS consists of a single 10 cm diameter optical tube assembly (a catadioptric telescope), a lens system, pentaprism with a dichroic color splitter, three vertically mounted linear CCD detectors (TC104 of Texas Instruments), and their clock drivers and output buffers. The camera optics parameters are: 570 mm focal length, 100 mm aperture diameter and f/5.7 relative aperture. The camera employs a beam splitter and three linear CCD detector arrays with 3456 pixels in the cross-track direction (one CCD per band), offering a swath width of 50 km (FOV=3.8°) with a spatial resolution of 15 m (IFOV = 19.1 μ rad). Spectral band coverage: 510-620, 620-690 and 730-900 nm. For operational purposes the imagery is subdivided into manageable volumes of data, a scene is defined as 50 km x 30 km (or 3456 pixels x 2048 lines along-track), a maximum of 12 consecutive scenes may be scanned during any one pass. The source data rate is 40 Mbit/s. Further instrument parameters: instrument mass = 6.5 kg, power = 15 W.

REME (Radiation Effect on Micro-Electronics). REME is designed to test non-space qualified electronic components, such as memory ICs and discrete components. This experiment consists of two sub-experiments, namely: **TDE** (Total Dose Effect) and **SEU** (Single Event Upset) monitoring.

- **TDE** measures the long-term accumulated ionizing radiation dose (in SiO₂) for three locations on-board the S/C. The sensing elements are RADFET dosimeters. Each RADFET sensor consists of a matched pair of p-channel MOSFETs. One of them is biased during exposure, the other remains unbiased. Exposure to radiation causes the formation of trapped holes (positive charge) in the gate oxide, which in turn causes a gradual shift in the threshold voltage with accumulated dose. The radiation shielding effect can be calculated and modeled according to the sensor locations.
- **SEU**. The objective is to monitor trapped particles in the radiation belts, solar flare protons, and galactic cosmic rays (all of which can cause single-event upsets within micro-electronic devices). A series of tests are performed with memory chips to measure the SEU characteristics. Discrete components are connected to appropriate measurement circuits, and variations of their characteristics are monitored together with the total dose measurement.

HEPT (High Energy Particle Telescope). The objectives are to study the physics of energetic particles in the Earth's radiation belts (sources, sinks, transport, and lifetimes). The HEPT module provides seven measurement channels. The pointable instrument features a cone-shaped structure (funnel) which limits the incident angles of particles to be measured. The signals from four parallel-positioned sensors are combined and processed to identify the energy and type of a particle. Measured pitch angle distributions (pitch angles are calculated using the sensor's look directions and the magnetic field direction, determined by the on-board magnetometer) can be used for developing models of the populations of both the static and dynamic radiation belts.

SMAG (Scientific Magnetometer). The objectives are to provide look angle information (1° pitch angle resolution) for the particle experiments, to utilize it as a diagnostic tool for the detection of geomagnetic disturbances, to measure low-frequency waves in the ambient environment, and to provide a secondary source for S/C attitude information. SMAG measures the projections of the ambient field in three orthogonal direction with a resolution of about 5 nT.

ETP (Electron Temperature Probe). The objectives are to measure the electron (plasma) temperature in high latitude regions, in particular in the polar cusp, to study anomalous heating in SAA (Southern Atlantic Anomaly), and to find a relation with other plasma parameters. The electron temperature is determined from the voltage difference between the modulated probe potential and the floating potential.

D.19.3 K-4 (KAISTSAT-4)

KAISTSAT-4 (Korean Advanced Institute of Science and Technology Satellite-4) is a low-cost KAIST/SaTReC minisatellite technology demonstration mission, funded by the Ministry of Science and Technology of Korea, a follow-up mission in the KITSAT program.⁷⁹⁷⁾⁷⁹⁸⁾ The objective is to develop and test a minisatellite bus, along with a new star sensor in a three-axis attitude control subsystem, to demonstrate the performance of new science instruments, and to deploy a newly developed DCS (Data Collection System). The spacecraft mass is about 120 kg, power = 200 W, the mission design life is three years. A launch of KAISTSAT-4 (as a secondary payload) is planned for 2002.

The S/C structure resembles a box of approximate size: 60 cm x 60 cm x 80 cm. It is three-axis stabilized. The S/C pointing requirements call for a pointing accuracy of 0.5° , an attitude knowledge of 5 arcmin, and a stability of about 5 arcmin/s. In addition, the S/C requires a complex set of attitude maneuverability in support of its mission objectives. Hence, the ADCS (Attitude Determination and Control Subsystem) consists of four fiber optic gyros (FOG), two precision star trackers, a coarse sun sensor and two three-axis fluxgate magnetometers for attitude sensing.⁷⁹⁹⁾ Magnetic torquer coils are used for momentum unloading of the four reaction wheels as well as for spin-rate control for the initial phase after spacecraft separation. A GPS receiver is used to provide S/C position, velocity and timing. Attitude determination is based on an extended Kalman filter algorithm considering the bias drift of the gyroscope.

Figure 123: Exploded view of KAISTSAT-4 and ADCS

797) J. Seon, K. I. Deon, S. H. Kim, et al., "Brief Reports on KAISTSAT-4 Mission Analysis," Journal on Astronomy and Space Sciences, Vol. 17, No. 2, 2000, pp. 1-9

798) J. Seon, H. S. Kim, B. J. Kim, Y. S. Chang, K.-M. Park, et al., "Preliminary results from mission analysis on KAISTSAT-4," SaTReC paper provided by Woo-Kyung Lee

799) H.-W. Lee, B. J. Kim, M.-J. Tahk, D.-J. Park, "Attitude Determination and Control of KAISTSAT-4 Satellite," internal paper of SaTReC provided by Woo-Kyung Lee

There are four operational modes of KAISTSAT-4 to achieve the scientific objectives; these are: a) pointed observation mode (observation of selected and extended galactic sources with FIMS during eclipse phases of the orbit), b) sky-survey mode (observation of the entire sky, the S/C spins around the axis parallel to the slit of FIMS), c) aurora observation mode (FIMS is being pointed in the nadir direction over the north and south poles), and d) air-glow mode (FIMS is being pointed to an inertial or to a nadir direction).

Orbit: Sun-synchronous circular orbit, altitude = 800 km, inclination = 92°.

RF communication: All TT&C communications are provided in UHF (prime). In addition, an S-band link is installed (first attempt in KITSAT series). The S-band downlink data rate is 38.4 kbit/s (uplink 9.6 kbit/s). An X-band downlink is used for payload downloads with a data rate of 3.2 Mbit/s. The on-board recorder has a capacity of 2 Gbit. All mission operations are performed at SaTReC, including data acquisition, distribution and archiving.

Sensor complement:

FIMS (FUV Imaging Spectrograph). The objective of FIMS observations is to study the diffuse hot interstellar matter. The overall goals of FIMS are 1) to map the spatial distribution of hot Galactic plasmas through a one-year sky survey, 2) to determine the physical states of hot interstellar matter such as superbubbles and supernova remnants with pointed observations, and 3) to test the models presently available for the Galactic evolution.

The instrument allows the detailed mapping of the spatial distribution of the hot galactic plasmas and the determination of the physical states of hot interstellar matters as well as the detection of the various emission lines from the Earth's upper atmosphere. FIMS employs a dual bandpass (900-1175 Å and 1335-1750 Å), high resolution (1.5 Å and 2.5 Å, respectively) imaging spectrograph with a 8° x 5' FOV (Field of View) and a 5' (five minutes) spatial (angular) resolution. FIMS is sensitive to emission line fluxes that are fainter than any previous detection by an order of magnitude. The observation data permits the determination of the thermal and ionization equilibrium state in hot Galactic plasmas.

The FIMS instrument consists of two elements, the spectrograph and the electronics unit. The spectrograph has the following subassemblies: Contamination Door Mechanism, Entrance Baffle Assembly, Filter Wheel Assembly, and Detector Assembly. The electronics unit houses circuits for experiment power, control and communication. FIMS generates about 500 Mbit of data per day. The instrument mass is 20 kg, the power is 20 W.

PIP (Plasma In-situ Package) of three instruments: SST (Solid State Telescope), LP (Langmuir Probe), and SM (Scientific Magnetometer). The science objectives are to provide a fast-sampling capability of high-energy magnetospheric plasma components, of cold ionospheric plasmas, and to measure the Earth's magnetic fields. Particular objectives are:

- Detection of directly penetrating solar wind plasmas and up-flowing, cold ionospheric electrons
- Investigation of sub-km scale structures of the Earth's polar regions
- Comparison of the in-situ measurements with the FIMS spectrographic images ($\Delta\lambda/\lambda$ of about 500) of the Earth's aurora in the far-ultraviolet ranges.

SST measures the high-energy components of auroral particles. It permits research on particle acceleration mechanisms in the magnetosphere. In addition, plasma fluxes are studied flowing in and out of the Earth's magnetosphere.

DCS (Data Collection System). A DCS is being developed in a cooperative effort between SaTReC and ITR (Institute for Telecommunications Research) of the University of South Australia in Adelaide and CRCSS in conjunction with FedSat-1. In FedSat-1 terminology, the system is called ADAM (Advanced Data Acquisition and Messaging System). The objectives of the KAISTSAT-4 DCS are:

- Deployment of a satellite-based data collection system for environment monitoring, wildlife tracking and transportation monitoring
- Demonstration of LEO satellite communication technology by adopting new protocols for bi-directional messaging, on-board modem algorithms and architectures
- Establishment of bi-directional communication between the on-board DCS and the ground segment, consisting of many DCPs (Data Collection Platforms). The DCPs are also referred to as MTs (Mobile Terminals). A TDMA (Time Division Multiple Access) protocol is being used in the uplink to collect the data from various DCPs simultaneously.
- Acquisition of the combined operations between KAISTSAT-4 DCS, MTs, data receiving stations and those of FedSat-1 (Australia).

D.20 KOMPSAT (Korea Multi-Purpose Satellite)

The KOMPSAT program was initiated in 1995 as a major space investment in Korea. Its objective is the development of a national space segment in Earth observation along with an efficient infrastructure and ground segment to provide valuable services to remote sensing users in various fields of applications. According to the national long-term space development plan by the Korean government, eight satellites of the KOMPSAT series are to be developed and launched until 2015.

D.20.1 KOMPSAT-1

KOMPSAT-1 is a minisatellite, funded by the government of Korea and developed by KARI (Korea Aerospace Research Institute) in Taejeon, along with seven Korean companies/institutes as well as by TRW of Redondo Beach, CA.⁸⁰⁰⁾⁸⁰¹⁾

The KOMPSAT-1 spacecraft is based on a TRW-developed standardized bus (including a MIL-STD-1555B communications bus) that can be easily modified to support a variety of mission requirements. A core module houses the housekeeping functions - power, telemetry and data handling, attitude control - needed on all space missions. A payload module hosts mission-unique equipment, KOMPSAT's imaging instruments and space physics experiments. A third module, housing a monopropellant hydrazine propulsion system, provides on-orbit thrust and station-keeping.

The S/C size of KOMPSAT-1 is 1.33 m in diameter and 2.33 m in length. The platform uses a three-axis stabilized bus with a reaction control subsystem module, providing a 2-sigma pointing accuracy of 0.08° (knowledge) and 0.10° (control). The S/C mass is 510 kg (including 73 kg hydrazine), power = 630 W (500 W EOL), the S/C design life is three years. The KOMPSAT-1 satellite was launched on a Taurus booster (along with ACRIMSAT) from VAFB, CA on Dec. 20, 1999.

Communication: S-band, downlink data rates are at 1.5 Mbit/s (playback) or 2.048 kbit/s (real-time), the uplink data rate is at 2 kbit/s. A second downlink in X-band provides data rates of 45 Mbit/s. The CCSDS protocol standards of CEOS are implemented for all communications. KOMPSAT-1 features a 1 Gbit on-board mass memory storage and a 2.5 Gbit solid-state recorder.

Orbit: Sun-synchronous circular polar orbit, altitude = 685 km, inclination = 98.13°, period = 98.46 min, ascending node at 10:50 AM, 14 17/28 orbits per day, revisit time = 28 days.

Status as of May 2001. KOMPSAT-1 is fully operational.

⁸⁰⁰⁾ <http://www.kari.re.kr/>

⁸⁰¹⁾ Information provided by H. Paik and G. H. Choi of KARI

Figure 124: Illustration of the KOMPSAT-1 S/C

Sensor complement.

EOC (Electro-Optical Camera). The objective is to obtain cartographic imagery of Korea (may be extended to other regions of the globe) at 1/25,000 scale. EOC collects panchromatic imagery (spectral region of 510 - 730 nm) with a ground sample distance (GSD) at nadir of 6.6 m and a swath width of 17 km by pushbroom scanning. The S/C features a cross-track pointing capability (body pointing) of up to $\pm 45^\circ$, thereby extending the field of regard for imagery collection. Some instrument parameters: MTF > 10% at Nyquist frequency, SNR > 50 over entire FOV, FPA has a CCD line array of 2592 pixels, data quantization of 8 bits, total instrument mass is 35 kg, power = 46 W, the source data rate is equal to or less than 25 Mbit/s. - Calibration: use of a built-in dark calibration function. In addition, ground reference targets of known brightness can be used for white calibration.

OSMI (Ocean Scanning Multispectral Imager).^{802) 803)} The objective is global ocean color monitoring for the study of biological oceanography. OSMI is a whiskbroom-type⁸⁰⁴⁾ imager generating imagery in up to six spectral bands (in the region of 400 - 900 nm) with a capability for bandwidth and band center selection on command. The center of each band can be varied within steps of 2.6 nm, and bandwidth ranges from 5.2 nm (min) to 166.4 nm (max) can be assigned. The ground resolution is 1 km in a swath of 800 km (0.85 km at nadir and about 1 km at the edge of the swath). The scanner assembly features a line array of 96 detectors (Si), positioned in the along-track direction, thus providing an instantaneous parallel ground coverage of 96 km in one cross-track scan with the whiskbroom configuration. This wide along-track coverage permits sufficient integration time for all cells in each scan sweep of about 15 seconds. Naturally there is some overlap for successive scans. The ensuing collecting optics perform the spectral separation of the radiation received. The bands B0

802) Y. M. Cho, S. S. Yong, et. al., "Ocean Scanning Multispectral Imager (OSMI)," Proceedings Fifth International Conference on Remote Sensing for Marine and Coastal Environments, San Diego, CA, Oct. 5-7, 1998

803) Y. M. Cho, "Ocean Scanning Multispectral Imager (OSMI), Post-launch Radiometric Responsivity Analysis," Proceedings of IEEE/IGARSS 2000, Honolulu, HI, July 24-28, 2000

804) Note: Preference is given to a whiskbroom imager (the older imaging technology) because the optics for push-broom operation must always cover FOV (the total field of view) while the optics for whiskbroom operation deal with IFOV (instantaneous field of view) which is much smaller than FOV. Hence, there are less distortions at the swath edge.

through B4 provide ocean color data, the other bands provide information for atmospheric (aerosol) corrections. Some instrument parameters: MTF is about 20% at Nyquist frequency, SNR is between 350 and 450 over entire FOV, data quantization = 10 bits, instrument mass = 15 kg, power = 30 W, the source data rate is 600 kbit/s. The duty cycle for image collection is 20%. - Calibration: A solar calibration is performed with an on-board spectralon once per orbit (note: a spectralon is a kind of optical diffuser which can be used as a Lambertian source). Dark calibration is performed before and after each imaging period.

Spectral bands	B0	B1	B2	B3	B4	B5	BX	B6
Center wave length (nm)	412	443	490	510	555	670	765	865
Nominal bandwidth (nm)	20	20	20	20	20	20	40	40

Table 200: Spectral parameters of the OSMI instrument

SPS (Space Physics Sensor). The SPS package consists of two instruments: **HEPD** (High Energy Particle Detector) and **IMS** (Ionosphere Measurement Sensor). The objective for HEPD is to characterize the low-altitude high-energy particle environment and to study the effects of the radiation environment on microelectronics. The objective of IMS is to measure in-situ densities and temperature of electrons in the ionosphere.

- HEAD in turn consists of the following instruments: PES (Proton and Electron Spectrometer), LET (Linear Energy Transfer Spectrometer), TDM (Total Dose Monitor), and SEM (Single Event Monitor).
 - PES identifies the particle types detected and measures their energy in seven channels. Objective: distribution of energetic electrons and proton in the radiation belts.
 - LET measures particle populations, providing information of radiation effects on electronic components (comparison with TDM and SEM data).
 - TDM measures with RADFET dosimeters the long-term ionizing dose of radiation (in SiO₂) accumulated at SPS. The threshold voltage provides information with respect to dose accumulation.
 - The objective of SEM is to test exposed non-space qualified static RAM components in the radiation environment of KOMPSAT-1 for future space missions. The experiment uses four static RAM chips (4 Mbit), connected to appropriate circuitry, to measure SEU (Single Event Upset) characteristics.

Channel	Particle	Energy Range (MeV)
pE1	Proton	30-38
pE2	Proton	15-30
pE3	Proton	6.4-15
eE1	Electron	2.0 <
eE2	Electron	0.72-2.0
eE3	Electron	0.25-0.7
AA	Alpha particle	15-60

Table 201: Specification of PES channels

- The IMS instrument contains an electron temperature sensor (ETS) and an electron density sensor (EDS), measuring temperature and density distributions of electrons (ionospheric plasma). EDS is a modification of a Langmuir Probe. The measurement range for ETS is 0 - 1 eV, for EDS the range is 10 - 10⁶ e/cm³.

D.20.2 KOMPSAT-2

KOMPSAT-2 is being developed by KARI to continue the observation program of KOMPSAT-1. The main mission objectives of the KOMPSAT-2 are to provide a surveillance capa-

bility for large-scale disasters by acquiring high-resolution imagery for GIS (Geographic Information Systems) applications. A launch of the KOMPSAT-2 spacecraft is planned for 2004. ⁸⁰⁵⁾

The spacecraft design is based on the KOMPSAT-1 heritage making extensive use of existing hardware, software, tools, and facilities; it allows parallel integration of the payload, equipment, and propulsion modules. The attitude and orbit control subsystem provides three-axis stabilization with high accuracy for roll, pitch and yaw pointing. Star trackers, gyro reference assemblies, and reaction wheels are used for attitude control. The spacecraft bus offers a cross-track body-pointing capability through roll maneuvers. The propulsion subsystem makes use of re-used components. A MIL-STD-1553B data bus interfaces most of the spacecraft bus and payload to the on-board computer. GPS receivers provide the time, satellite position and velocity. The spacecraft mass is <800 kg (including propellant), the power is 955 W (EOL).

Orbit: Sun-synchronous circular orbit, altitude = 685 km, inclination = 98.13°, period = 98.46 min.

RF communications: S-band and X-band communications are provided for all data transmission to the ground.

Sensor complement:

MSC (Multi-Spectral Camera). The objective is to collect high-resolution panchromatic and multispectral imagery of the Earth's surface. MSC is an optoelectronic pushbroom instrument with a single nadir-pointing telescope. The Pan band has a spectral range of 500-900 nm, the four MS bands are in the 450-900 nm range. The spatial resolution of the Pan data is 1 m (GSD), the MS data has a GSD of 4 m. The swath width is 15 km. A FOR (Field of Regard) in the cross-track direction is provided through body pointing.

Note: The project management of KOMPSAT-2 denied any further information on the specification of the spacecraft and its sensor complement.

D.21 LANDSAT

A pioneering US land remote sensing satellite program which has provided a continuous supply of synoptic, repetitive, multispectral data of the Earth's land surfaces since 1972. Over the years a large international user community evolved along with the Landsat series. The program opened entire new fields of research, providing insights into geologic, agricultural, and land-use surveys, and led eventually to new paths of resource exploration - in all, for a better understanding of the Earth system. The success of the Landsat program stimulated new approaches to data analysis and gave impetus to new sensor designs. In addition international participation was fostered on many levels which spawned other Landsat-like programs such as the SPOT series of France, the Resurs series of Russia, and the IRS series of India.⁸⁰⁶⁾

Background: NASA launched ERTS-1 (Earth Resources Technology Satellite) on July 23, 1972. This satellite was subsequently renamed Landsat-1. The Landsat system remained a research/experimental NASA program until 1983. The system was then declared operational and its management was turned over to NOAA (LS-4 in 1983 and LS-5 in 1984). The Land Remote-Sensing Commercialization Act of 1984 almost immediately authorized a phased commercialization of remote sensing data. Following to a contentious commercialization effort, the Land Remote-Sensing Policy Act of October 1992 reversed the 1984 decision to commercialize the Landsat system. The 1992 Policy Act created a new "Landsat Program Management" under NASA and DoD leadership. Due to difficulties with the Landsat-7 development program, DoD withdrew from the Landsat Program Management in early 1994. In spring 1994 the Landsat-7 program was restructured and in May 1994 it was put under joint NASA/NOAA/USGS management by Presidential Decision Directive, with NASA responsible for the development of the LS-7 S/C, instrument, and ground system; NOAA is responsible for LS-7 S/C and ground system operations; and USGS is responsible for maintaining the national archive of LS data and data distribution to the user community (EDC is prime US receiving station of LS-7 data).⁸⁰⁷⁾

Date	Landsat Program Event/Action
Mar. 1, 1984	NASA launches LS-5, NOAA provides LS-4 and LS-5 operation
Sept. 1985	Eosat selected by NOAA to operate the LS system (LS-4 and LS-5), to market LS data, and to build and launch LS-6
Sept. 1992	Eosat loses capability of processing MSS data (no further acquisition of MSS in USA)
Oct. 1992	Land Remote Sensing Policy Act (Congress) LS program management under NASA and DoD (develop and launch LS-7)
Oct. 1992	DoD signs contract with Martin Marietta Astro Space to build HRMSI for LS-7
Oct. 5, 1993	LS-6 launch failure
Spring 1994	DoD withdraws from the LS program (HRMSI is withdrawn from LS-7)
April 1994	LS program management and Eosat agree for continued operation of LS-4 and LS-5
Aug. 10, 1994	Management Plan for the Landsat Program (LS-7 objectives and beyond). LS program responsibilities are with NASA (S/C), NOAA (operations), and USGS (archive)
Dec. 1994	NOAA and Eosat sign a contract to extend LS-5 operation
Nov. 1995	Eosat completed maneuvers to correct the equatorial crossing time of LS-5 (to 9:30 AM)

Table 202: Chronology of major Landsat program events since 1984

The Landsat satellite family is managed and procured by NASA [built by GE Astro Space of East Windsor, NJ (S/C), and Raytheon Santa Barbara Remote Sensing, formerly a Hughes Santa Barbara Research Center Division. (sensors)]. In 1985 the functions of Landsat S/C operation and data handling were handed over from NOAA to a commercial contractor company: Eosat (Earth Observation Satellite Company, of Lanham, MD; Eosat is a Division of Lockheed Martin Space Imaging. The science data (of LS-4 and LS-5) are processed

and archived by Eosat and commercially distributed. The LS-4 and LS-5 S/C and sensors are regarded as second generation technology in the LS program, following the early MSS sensor series. MSS was carried for the last time on LS-5, and LS-7 carries an improved Thematic Mapper sensor known as the Enhanced Thematic Mapper Plus (ETM+).^{808) 809) 810)}

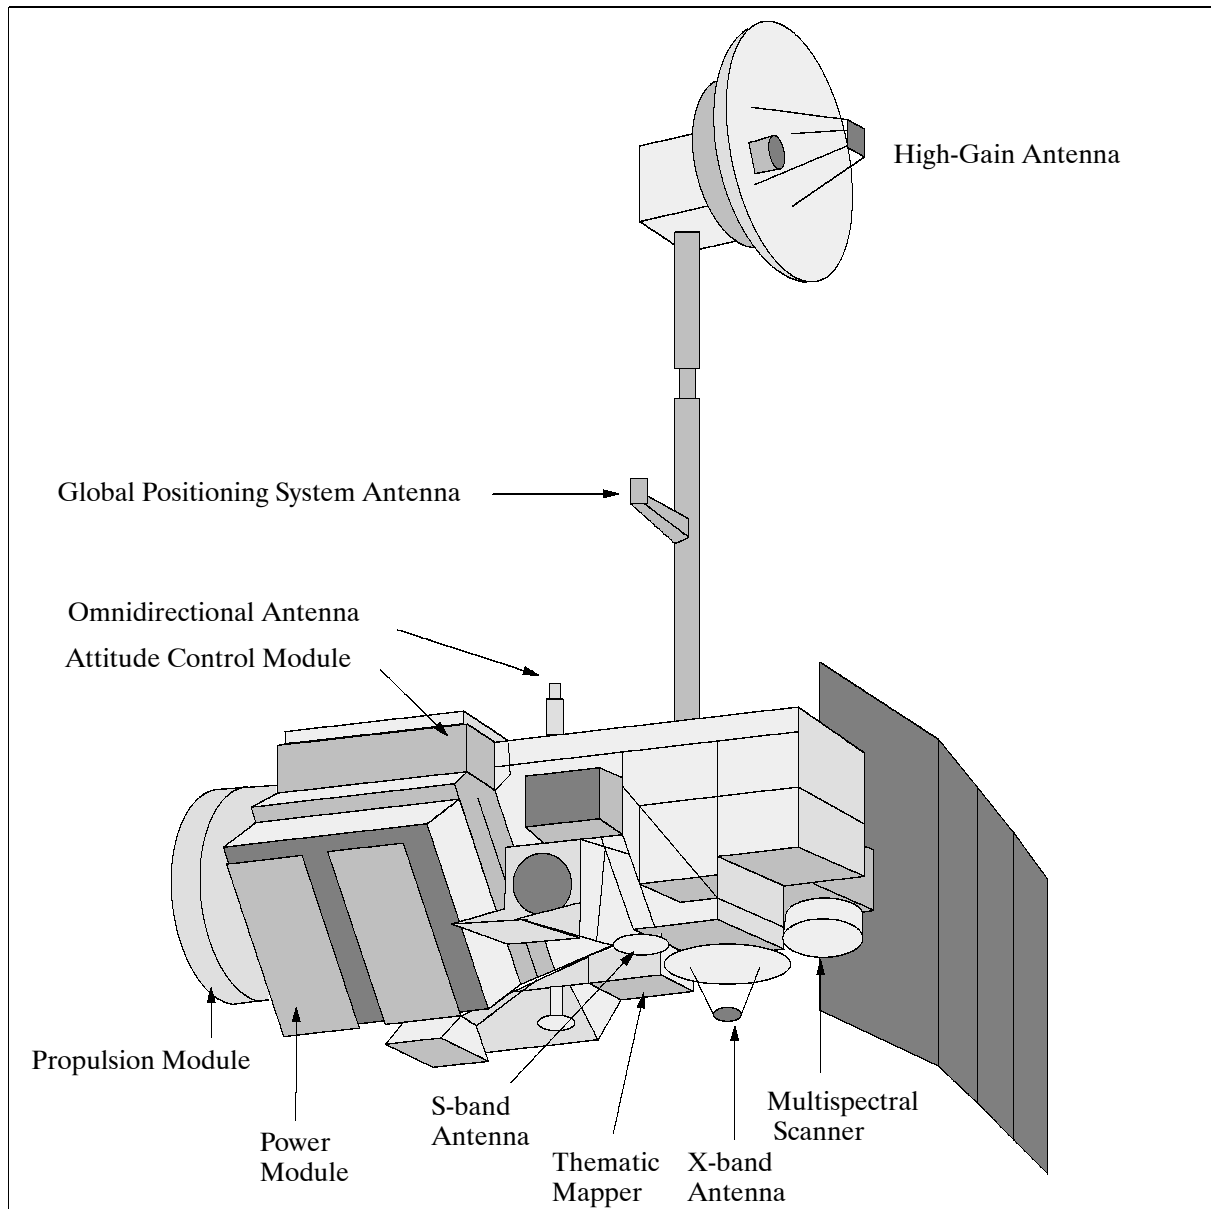

Figure 125: Model of the Landsat-4 and 5 spacecraft

Application: Land use, agriculture, forestry, geology, water resources, mapping, etc. Landsat data are particularly suited to long-term estimation and monitoring of standing vegetation biomass, biological productivity, and the movement of fragile ecosystem boundaries.

The purchase of Landsat imagery became rather expensive to the user community with S/C operations and data distribution in the hands of Eosat. NOAA and Eosat agreed in November 1990 that all Landsat data older than 10 years return to the “Public Domain” category, hence affordable for research. The “Public Domain” data is provided and distributed by the EROS Data Center (EDC), Sioux Falls, S D. All MSS data is in the public domain at EDC, effective as of February 1993.

LS-7	Apr. 15, 1999	ETM+	15 (PAN) 30 (MS)	DD with re- corders	705 km	NOAA	

Table 203: Overview of Landsat S/C series

D.21.1 Landsat-1 to -5

The LS-1 satellite was a modified version of Nimbus-4, a three-axis stabilized Earth-oriented platform. An advanced attitude control system, consisting of horizon scanners, sun sensors, and a command antenna combined with a Freon gas propulsion system permitted the spacecraft's orientation to be maintained within plus or minus 0.7° in all three axes. Spacecraft communications included a command subsystem operating at 154.2 and 2106.4 MHz and a PCM narrow-band telemetry subsystem, operating at 2229.5 and 137.86 MHz, for spacecraft housekeeping, attitude, and sensor performance data. Video data from the three-camera RBV system was transmitted in both real-time and tape recorder modes at 2265.5 MHz, while information from the MSS was constrained to a 20 MHz RF bandwidth at 2229.5 MHz. Two WBVTR (Wideband Video Tape Recorder) were installed on LS-1 through LS-3. Each WBVTR was capable of recording 30 minutes of either 3.2 MHz video (analog) data from RBV, or 15 Mbit/s digital data from the MSS multiplexer. On LS-1 the WBVTR-1 lasted until July 1974, while WBVTR-2 operated for only 10 days.

S-band image data transmission characteristics: frequency = 2229.5 MHz (LS 1-3), 2265.5 MHz (LS 4-5); transmitter power = 10 W; MSS data rate = 15.06 Mbit/s.

Data: image size: 2583 lines x 5500 pixel (EDIPS format); image size: 2286 lines x 3600 pixel (Telespazio format).

The LS-1 to -3 satellites were modified Nimbus S/C. The different S/C had the following on-orbit dry masses: LS-1 = 1800 kg; LS-2 = 816 kg; LS-3 = 960 kg; LS-4 = 1407 kg; LS-5 = 1407 kg; LS-6 = 2750 kg. A new S/C design (2nd generation) was introduced with LS-4. The flight segment consisted of two major systems:

- The instrument module, containing the instruments together with the mission unique subsystems, such as the solar array and drive, the TDRS antenna, the wide-band module, and the global positioning system (GPS)
- The multimission modular spacecraft that contained the modularized and standardized power, propulsion, attitude control, and communications and data handling subsystems. The flight segment was designed with 3 years nominal lifetime.

The DCS systems of LS-1 to -3 were replaced by experimental GPS systems (DoD program) on LS-4 and LS-5. The GPS assembly on LS-4 operated in two phases. The first phase (approximately 90 days) was an experimental one to validate and calibrate the position and timing information provided by the GPS assembly. The second phase called for operational use of the GPS data by LS-4.

Sensor complement: ⁸¹¹⁾ ⁸¹²⁾

MSS (Multispectral Scanner built by SBRC of Hughes) on LS 1-5. MSS is an opto-mechanical scanning instrument. The sensor operates by repeatedly scanning a 24-element fiber-optic array (arranged in 6 x 4 elements) from west to east across the Earth's surface, the orbital motion provides the natural north-south scanning motion. A separate binary-number array is generated for each spectral band. Mirror scan rate: 13.6 Hz (74 ms period); telescope: 22.9 cm diameter, f/3.6, Ritchey-Chretien type telescope; size 53 x 58 x 127 cm; six detectors were employed in each of the four spectral bands; ⁸¹³⁾ bands 4 to 6 used photomultiplier tubes (PMT) as detectors, and band 7 used silicon photodiodes; instrument mass = 64 kg; power = 50 W; quantization = 6 bit; spatial resolution = 80 m across-track and 56 m along-track; swath width = 185 km; four spectral bands: 0.5 - 0.6 μm , 0.6 - 0.7 μm , 0.7 - 0.8 μm , and 0.8 - 1.1 μm ; a gray-lamp sensor calibration is performed during every second retrace period of the scan mirror. Note: LS-1-3 orbits were at an average altitude of 908 km while LS-4 and LS-5 orbits were positioned at an altitude of 705 km. For reasons of compatibility the optics of LS-4 and LS-5 were adjusted to keep the spatial (cross-track) resolution at 80 m.

Channel designation on Landsat S/C		Spectral Range (nm)
LS-1 through LS-3	LS-4 and LS-5	
Channel 4	Channel 1	500 - 600
Channel 5	Channel 2	600 - 700
Channel 6	Channel 3	700 - 800
Channel 7	Channel 4	800 - 1100
Channel 8 (channel 8 only on LS-3 for test purposes until July 11, 1978)		10400 - 12600

Table 204: MSS spectral channels on Landsat series

RBV (Return Beam Vidicon Camera). This instrument was only flown on LS-1 to LS-3. It consisted of three coaligned television cameras, one for each spectral band. RBV measurements of reflected solar radiation were only conducted in daylight. The three earth-oriented cameras were mounted to a common base, which was structurally isolated from the spacecraft to maintain accurate alignment. Each camera contained an optical lens, a 5.08 cm RBV, a thermoelectric cooler, deflection and focus coils, a mechanical shutter, erase lamps, and sensor electronics. The cameras were similar except for the spectral filters contained in the lens assemblies that provided separate spectral viewing regions. The viewed ground scene, 185 by 185 km in area, was stored on the photosensitive surface of the camera tube, and, after shuttering, the image was scanned by an electron beam to produce a video signal output. Each camera was read out sequentially, requiring about 3.5 s for each of the spectral images. The cameras were operated every 25 s to produce overlapping images along the direction of spacecraft motion. Video data from the RBV were transmitted (2265.5 MHz) in both real-time and tape recorder modes.

A later variant of the RBV system for LS-3 utilized two cameras with panchromatic spectral response and higher spatial resolution (40 m) to complement the multispectral coverage provided by MSS. The vidicon camera was equipped with an electron tube in which the opti-

⁸¹¹⁾ S. C. Freden, F. Gordon, "Landsat Satellites," Chapter 12 of 'Manual of Remote Sensing,' 2nd edition, Vol I, published by the American Society of Photogrammetry, 1983, pp. 517-570

⁸¹²⁾ A. M. Mika, "Three Decades of Landsat Instruments," PE&RS, July 1997, pp. 839-852

⁸¹³⁾ Note: the line array of six detectors was positioned in the along-track direction, thus providing an instantaneous parallel ground coverage of 336 m in one cross-track scan with the whiskbroom configuration. This wide along-track coverage permits sufficient integration time for all cells in each scan sweep.

cal image is projected onto a photoconductive detector scanned by the electron beam. Note: Starting with LS-4 the MSS bands were renumbered to bands 1 through 4 (from 4 through 7 on LS-1 to 3).

RBV Instrument	
Spectral bands (μm)	1) 0.48 - 0.58, 2) 0.58 - 0.68, 3) 0.70 - 0.83 (bands 1 through 3)
Spatial resolution	80 m
Three coaligned cameras	image of 185 km x 185 km (framing cameras)
Radiometric signal	Analog video signal transmission, 33 dB SNR in bands 1 and 2, 30 dB in band 3
MSS Instrument	
Spectral bands (μm)	4) 0.5 - 0.6, 5) 0.6 - 0.7, 6) 0.7 - 0.8, 7) 0.8 - 1.1 (bands 4 through 7)

Swath	185 km (continuous strip image)
Radiometric signal	Digital video signal transmission; 6 bit per pixel, linear coding;; logarithmic coding also available on bands 4), 5), and 6)

Table 205: Specification of RBV and MSS instruments

DCS (Data Collection System) on LS-1 through LS-3. Heritage of IRLS (Interrogation, Recording, and Location System- of Nimbus-3). An experimental system with the objective to collect and retransmit data from remote data collection platforms (DCPs). The on-board DCS initially serviced only a pilot group of only six DCPs, with user agencies procuring, instrumenting, and developing additional platforms according to their needs. The DCP uplink frequency to the Landsat S/C was at 401.55 MHz. The on-board DCS equipment, essentially a receiver, received and retransmitted data (at 2287.5 MHz, DCS data on 1.024 MHz subcarrier) to selected ground receiving stations. There was no signal multiplexing or data processing on the satellite. From a nominal orbital altitude of approximately 900 km, the S/C was capable of acquiring data from DCPs within a radius of approximately 3000 km from the subsatellite point, thus allowing data to be obtained from any remote platform at least once every 12 hours.

TM (Thematic Mapper, built by SBRC of Hughes).^{814) 815)} TM is a multispectral mechanically scanning optical imager operating in the visible and infrared ranges. The instrument consists of the following subsystems: Scan Mirror Assembly, Telescope, Scan Line Corrector, Primary Focal Plane Array, Relay Optics, Cooled Focal Plane Array, and the Internal Calibrator. The telescope is of the type Ritchey-Chretien with 40.6 cm in diameter [primary mirror clear aperture diameter = 41.15 cm, secondary mirror baffle diameter = 15.7 cm, telescope clear aperture = 1056 cm², effective focal length = 243.8 cm (f/6)]. The scan line corrector compensates for the forward motion of the S/C, allowing the scan mirror to produce usable data (parallel scans) in both scan directions. The bidirectional scan and the use of detector arrays for each spectral band provides scan efficiency. Scan period = 7 Hz cross-track; FOV = $\pm 7.2^\circ$ (swath width = 185 km); IFOV = 42.5 mrad; overall instrument size of 2.0 m x 1.1 m x 0.7 m with a mass = 258 kg; power = 385 W (peak); quantization = 8 bit. Design life = 2 years (with a goal 3 years). Instrument inflight calibration is done at the start and end of each scan by using solar and lamp-based approaches (three lamps) for the solar reflective bands. On-board blackbodies are used to calibrate the thermal bands. TM instruments are operational since 1982 (first flight on LS-4).

Background: The Thematic Mapper got its name from the intended “thematic” applications of its data. Its images were used to produce maps tailored to different Earth-observation themes, such as agriculture, hydrology, geology, etc. In addition, the TM bands were chosen on the basis of a comprehensive analysis of spectral reflection features for a variety of vegetation types and surface minerals. Spectral classification accuracy was a key determi-

815) P. N. Slater, “Remote Sensing Optics and Optical Systems,” Addison-Wesley, Reading, MA, 1980

nant for selecting the specific band edges and bandwidths. In this context, band number 7 (2.08 - 2.35 μm) was added to the TM specifications much later in the design process than the other bands. It was an extra for the geology community, therefore it required contract modifications.

Applications: LS TM data may be used in fields such as: global change research, agriculture, forestry, geology, resources management, geography, water quality, and oceanography.

- Band 1: Coastal water mapping, soil/vegetation differentiation, deciduous/coniferous differentiation, chlorophyll absorption
- Band 2: Green reflectance, peak of healthy vegetation, plant vigor
- Band 3: Chlorophyll absorption, plant type discrimination
- Band 4: Biomass surveys, water body delineation
- Band 5: Vegetation moisture measurement, snow/cloud differentiation
- Band 6: Plant heat stress, thermal mapping, soil mapping
- Band 7: Hydrothermal mapping, geology

Band No.	Bandwidth (μm)	Detectors	Resolution (m)	SNR (average)
1	0.45-0.52 (VIS, blue)	SiPD (16)	30	60
2	0.52-0.60 (VIS, green)	SiPD (16)	30	60
3	0.63-0.69 (VIS, red)	SiPD (16)	30	46
4	0.76-0.90 (NIR)	SiPD (16)	30	46
5	1.55-1.75 (SWIR)	InSb (16)	30	36
7	2.08-2.35 (SWIR)	InSb (16)	30	28
6	10.4-12.5 (TIR)	HgCdTe (4)	120	

Table 206: TM parameter definition (LS-4/5)

TM data image size: 185 x 172 km; 5760 lines x 6928 pixels. Transmission: frequency = 8215.5 MHz (X-band); data rate = 84.9 Mbit/s (246 MByte per scene). There is no capability for on-board recording of TM data. Data transmission from the S/C to the ground is in realtime via a network of licensed X-band stations. An alternate data transmission link is via TDRSS (Ku-band) to GSFC (Note: LS missions with TDRSS support do not provide an on-board recorder).

As of 2000 Landsat-5 is still able to acquire TM data. Landsat-5 has no operational TDRSS support. Data transmission to the ground is by X-band direct downlink only. On the other hand, Landsat-7 has been providing data since April 1999.

D.21.2 Landsat-6

The LS-6 payload⁸¹⁶⁾ was launched on October 5, 1993 with a Titan 2 booster from Vandenberg Air Force Base, CA. S/C builder and integrator: Martin Marietta Astro Space (formerly General Electric Astro Space), S/C procurement and management by Eosat. The S/C structure consists of aluminum with graphite struts. Hydrazine propulsion system. Single solar array with 1-axis articulation produces 1430 W, two NiCd batteries provide 100 Ah total. Data stored on-board using tape recorders for direct downlink to ground stations at 85 Mbps. LS-6 is three-axis stabilized, zero momentum with control to 0.01° using reaction wheels. - The satellite failed to achieve its orbit; communication with the satellite was never established. A formal review was conducted by NOAA to investigate the failure.

Orbit: Altitude = 705 km, polar sun-synchronous orbit, inclination = 98.2° , period = 99 min, repetition cycle (repeat coverage) = 16 days, equatorial crossing time: 9:45 AM. Nominal life = 5 years.

⁸¹⁶⁾ "Satellite Loss Raises Questions for Eosat's Future," Space News, October 11-17, 1993, p. 3

Figure 126: The Landsat-6 S/C model

Sensor:

LS-6 was designed to carry a single sensor, the Enhanced Thematic Mapper (ETM), which includes several new features to significantly improve data quality. Instrument mass (scanner assembly) = 288 kg, auxiliary electronic module = 81 kg, power = 490 W (max).

ETM (Enhanced Thematic Mapper)

LS-6 functional capabilities: Note: an attempted pushbroom version upgrade for the instrument failed due to severe budget constraints.

- ETM (seven TM bands, plus an additional panchromatic band). An instrument upgrade had the following features: Use of a single, monolithic silicon detector array for all the VNIR spectral bands. All detectors were on a common silicon substrate, this approach provided a better band-to-band geometric registration and stability (TM used four separate detector arrays).
- Two on-board recorders (playback to ground in X-band); each recorder is capable of recording/reproducing at a rate of 85 Mbit/s, and each can store ≈ 15 minutes worth of image data, or 29 scenes.
- Three pointable antennas
- Simultaneous acquisition of TM and PAN data
- ETM generates three different data streams:
 - Mode 1 Seven spectral bands
 - Mode 2 Panchromatic band (PAN) + channels 4, 5, and 6
 - Mode 3 Panchromatic band (PAN) + channels 4, 6, and 7

Spectral ranges:

- Channel PAN (8) : 500 - 900 nm, 15 m resolution; applications: cartography
- Channel 1: 450 - 520 nm (VIS, blue); applications: water penetration, bathymetry (water depth), chlorophyll absorption, distinguishes deciduous/coniferous forests
- Channel 2: 520 - 600 nm (VIS, green); applications: matches green reflectance, peak of healthy vegetation, assessment of plant vigor
- Channel 3: 600 - 690 nm (VIS, red); applications: chlorophyll absorption, plant type discrimination
- Channel 4: 760 - 900 nm (VNIR); applications: plant cell structure, plant vigor, complete absorption by water, shoreline mapping
- Channel 5: 1550 - 1750 nm (SWIR); applications: moisture content, soil mapping, thin cloud penetration

- Channel 7: 2080 - 2350 nm (SWIR); applications: hydroxyl ion absorption, geology
- Channel 6: 10.4 - 12.5 μ (TIR); applications: brightness temperature, soil moisture, plant heat stress.

Ground pixel resolution: 15 m (panchromatic), 30 m (channels 1-5, channel 7) 120 m (channel 6). Ground image size: 185 x 185 km.

Band No.	Wavelength (μ m)	Detectors	IFOV (μ rad)	Ground Res. (m)
PAN (8)	0.50 - 0.90	SiPD (32)	18.5 x 21.3	13 x 15
1	0.45 - 0.52	SiPD (16)	42.5	30

Table 207: Summary of Landsat-6 ETM bandwidth specifications

Data: Landsat-6 has three X-band frequencies for downlink (8082.5, 8212.5, and 8342.5 MHz) to allow combinations of up to two real time data links (TM and/or a panchromatic mode) and two tape recorder dumps. The ETM outputs two 85 Mbit/s serial composite streams, each consisting of the digital image area, internal ETM calibration data, image-related timing data, S/C time code, ephemeris, and attitude data. The ancillary timing, calibration, and attitude data are used by the Landsat-6 Image Data Processing System S/W to perform geometric image corrections. The X-band downlink communications subsystem permits simultaneous downlinks to three stations using pointable antennas.⁸¹⁷⁾

As of 1995 Landsat-5 is the only remaining Landsat system acquiring TM data (S/C operated by Eosat). Landsat-5 has no operational TDRSS support and no on-board storage. Data transmission to the ground is by X-band direct downlink only.

D.21.3 Landsat-7

The Landsat-7 satellite is part of NASA's ESE (Earth Science Enterprise) program. The mission is to extend and improve upon the long-term record of images of the Earth's continental surfaces provided by the earlier Landsat satellites. The S/C and payload were developed under NASA/GSFC management/procurement responsibility (Landsat Project Scientist: D. Williams). The LS-7 satellite was built by LMMS (Lockheed Martin Missiles and Space) at the facility in Valley Forge, PA. The S/C features the Landsat-6 bus; an on-board recorder in solid state memory (378 Gbit capacity to capture data beyond the range of ground receiving stations, recording rates of 150 Mbit/s, playback with 300 Mbit/s), and a single observation instrument: ETM+. The HRMSI instrument was removed from the S/C due to funding constraints when DoD withdrew from the "Landsat Program Management" team in 1994. The HRMSI instrument is kept in this text for reference only. A launch of Landsat-7 took place on a Delta 2 vehicle from VAFB on April 15, 1999.

The Landsat-7 S/C is very similar in design to the Landsat-6 S/C. It features three-axis stabilization with a pointing capability of 180 arcsec (3 sigma) and a pointing knowledge of 45 arcsec (1 sigma). Attitude control with four reaction wheels and two torque rods, attitude is sensed with a static Earth sensor, 2 magnetometers and gyros. S/C mass = 2200 kg, dimensions: 4.3 m in length and 2.8 m in diameter, power = 1550 W (about 1000 W average, provided by a silicon cell solar array and a nickel hydrogen battery power subsystem). S/C design life = 7 years. Landsat-7 communication:

- S-band (2 omni-directional antennas), 5 W, with real-time telemetry data rates of 1.2 kbit/s and 4.8 kbit/s, and 256 kbit/s of playback data, 2 kbit/s of command data. S-band frequencies of 2106.4 MHz (uplink) and 2287.5 MHz (downlink).

- X-band (3 steerable antennas), 3.5 W; each antenna transmits data on two channels, with each channel carrying 75 Mbit/s (total of 150 Mbit/s per antenna); up to three separate links are supported. X-band frequencies: 8082.5 MHz, 8212.5 MHz, 8342.5 MHz.

Orbit: Sun-synchronous polar orbit (AM orbit), altitude = 705 km, inclination = 98.2°, period = 99 minutes, repeat coverage = 16 days (same as Landsat-5), a nominal 10 AM descending equator crossing time. The ground track is referenced to WRS (worldwide Reference System) with a repeat accuracy of ± 5 km.⁸¹⁸⁾

A coordinated tandem orbit of Landsat-7 with EO-1 (a few minutes apart) is considered by NASA for reasons of data calibration and synergetic use of data.

Sensor:

ETM+ = Enhanced Thematic Mapper Plus (built by Raytheon Santa Barbara Remote Sensing, Goleta, CA.^{819) 820)} ETM+ is a whiskbroom scanning radiometer.⁸²¹⁾ The principal functional differences between the ETM and the former TM series are the addition of a 15 m resolution panchromatic band and two 8-bit “gain” ranges. The ETM+ adds a 60 m resolution thermal band, replacing the 120 m band on ETM/TM (Band No. 6, see Table 207). Design life = 7 years. The ETM+ also includes a number of radiometric enhancements to achieve an absolute radiometric uncertainty of <5% (bands 1-4). Two new calibration devices were added: FAC (Full Aperture Calibrator), and PAC (Partial Aperture Calibrator). ETM+ uses three independent on-board calibration systems (plus preflight calibration), representing a significant step forward in absolute radiometric calibration accuracy.

- A full-aperture solar diffuser (FAC) on the inner surface of the aperture door that illuminates the focal planes with diffusely reflected solar energy when commanded into position
- A partial-aperture solar reflector (PAC) that illuminates the focal planes with attenuated solar energy, once per orbit
- Calibration lamps that project calibrated energy onto the focal planes via the main calibration shutter, once per scan, during the scan mirror turnaround.

Band No.	Wavelength (μm)	Detectors	IFOV (μrad)	GSD (m)	SNR (at min signal radiance)
8 PAN	0.50 - 0.90	SiPD (32)	18.5 x 21.3	13 x 15	15
1 VIS	0.45 - 0.52	SiPD (16)	42.5	30 x 30	32
2 VIS	0.53 - 0.61	SiPD (16)	42.5	30	35
3 VNIR	0.63 - 0.69	SiPD (16)	42.5	30	26
4 VNIR	0.78 - 0.90	SiPD (16)	42.5	30	32

821) Note: The detector line arrays (16 for VNIR bands, 32 for PAN, and 8 detectors for TIR) of the whiskbroom scanner are oriented in the along-track direction. This arrangement provides a parallel coverage of 480 m along-track in one scan sweep (cross-track direction). The wide along-track coverage permits sufficient integration time for all cells in each scan sweep.

Scanning method	Bidirectional cross-track, scan frequency = 7 Hz
Swath width	185 km (15° FOV from 705 km orbit)
Telescope	40.6 cm aperture, Ritchey-Chretien
Instrument size	Scanner assembly: 1.5 m x 0.7 m x 2.5 m Auxiliary electronics module: 0.4 m x 0.7 m x 0.9 m
Instrument mass	Scanner assembly: 298 kg, AEM = 103 kg, cable harness = 20 kg
Power	590 W
Data quantization	9 bit A/D conversion, 8 bit/pixel transmitted (2 gain states)
Data rate	150 Mbit/s (2 x 75) by each of three directional X-band antennas, CCSDS format

LS-7 data handling policy:

Landsat-7 data is received and distributed to the user community by USGS (capturing and processing 250 Landsat scenes per day and delivering at least 100 of the scenes to users each day). NASA/GSFC performs on-orbit mission operations until Oct. 1, 2000; after that

responsibility for flight operations transfers to the USGS. The operating philosophy changed to the effect that ETM+ data covering the global continental surfaces are being archived in the USA. The ETM+ archive is continually being updated as data become available. This data policy differs from the past (Landsat-4 and -5), where data was only acquired from the S/C on the basis of customer requests. The new archiving policy will substantially increase the amount of data available to the user community.^{822) 823) 824)}

Table 211: Overview of Landsat series imaging instrument parameters

The Landsat-7 ground system design includes an Image Assessment System (IAS) to provide users with ancillary information needed to generate useful, radiometrically calibrated and geometrically corrected ETM+ digital imagery. Another aspect of the new data handling policy is that ETM+ data will be distributed from the archive in an essentially raw form. Users are responsible for the task of preprocessing their imagery (i.e. radiometric and geometric corrections). The price tag for Landsat-7 imagery is substantially lower than for the commercial products of Landsat-4 and -5.

The direct downlink service to a global network of existing Landsat ground stations (in X-band via each of three directional antennas) is maintained. All real-time image data (within view of a licensed ground station) are directly downlinked via the three X-band links. TDRSS may be used for TT&C data relays in S-band (backup). The prime (US) ground receiving station for the Landsat-7 archive is located at the EROS Data Center (EDC) in Sioux Falls, South Dakota. A second (US) reception facility near Fairbanks, AK, acquires coverage of Alaska and international coverage using the on-board recorder. An additional receiving station in Spitzbergen (Norway) provides backup reception. All data received at either Fairbanks or Spitzbergen will be shipped to EDC for archiving and distribution.

D.22 Lewis and Clark Missions

The Lewis and Clark⁸²⁵) satellite missions are part of the NASA SSTI (Small Spacecraft Technology Initiative) program which in turn has the following objectives:

- Demonstrate a new approach to technology integration that includes performance-based design specifications with the ability to incorporate commercial standards into the design and qualification process
- Proof the concept of a small spacecraft designed to envelope a range of mission requirements and develop standard hardware and software interfaced for various applications
- Enable low-cost common bus manufacturing concepts with large savings to future mission applications.

Within this framework NASA awarded in June 1994 two contracts to two industry teams, one led by TRW of Redondo Beach, CA and the other by CTA of McLean, VA, with the objective to design, build, launch and operate one spacecraft each, with a minimum set of requirements (no phase A or B design with the customer) and a contract-to-launch period of \leq two years (each S/C < \$ 60 million). A large, broad-based team of industry, small business, NASA centers and universities will use the data to develop commercial products and to stimulate further research. The SSTI concept required NASA to streamline its contract management and procurement procedures in many ways.

D.22.1 Lewis S/C

The Lewis S/C was designed and built by the team led by TRW, Redondo Beach, CA. The S/C features a small-satellite modular design, pulse tube cryocooler technology, solid-state recorder (2 Gbit); fiber-optic data bus; WFOV star tracker; magnetically suspended reac-

⁸²⁵) The satellite missions are named in honor of Meriwether Lewis (1774-1809) and William Clark (1770-1838), who headed the first overland expedition of about 40 persons (1804-06) to the Pacific coast and back, starting in St. Louis, Missouri. The expedition was initiated by President Thomas Jefferson, who wanted a first survey (information in the form of maps and diaries) of the territory west of the Mississippi acquired by the Louisiana Purchase in 1803 from France.

tion wheel; a lightweight structure with integrated thermal control; GPS attitude determination; three-axis stabilized (zero momentum bias); design life of 3 years, mass = 288 kg; power = 550 W. The S/C was launched successfully on August 23, 1997 with a Lockheed Martin Launch Vehicle (LMLV-1) from VAFB, CA. ⁸²⁶⁾

The GNCS (Guidance Navigation and Control Subsystem) consists of the following components: 1) the coarse sun sensor (TOMS heritage) provides full view to locate the sun; 2) NSTA (Narrow-FOV Star Tracker) tracks up to six stars with an accuracy >8 arcsec; 3) TAM (Three Axis Magnetometer); 4) GRA (Gyro Reference Assembly) three tuned-rotor two-axis systems; 5) Earth sensor assemblies, used for roll/pitch determination; 6) GAD-FLY (GPS Attitude Determination Flyer), a NASA experiment consisting of the following hardware: four GPS antennas and pre-amplifiers, cross-strapped to two GPS Tensor (SS/L) receivers; 7) reaction wheels and magnetic torquers; 8) single axis solar drive array assemblies, used to continuously point the solar arrays at the sun; 9) valve drive electronics, the propulsion system is used for orbit raising. All functions are controlled by an on-board computer (R3000 CPU). ⁸²⁷⁾

The initial nominal orbit was 300 km. On-orbit check-out commenced in preparation for its final orbit transfer maneuver. However, on Aug. 26 (three days after launch), an inflight anomaly led to the loss of attitude control and a discharged battery (contact was lost when Lewis entered a spin that disrupted the satellite's power-generating capability. The spin was thought to be caused by a stray firing of one of the attitude control thrusters). Controllers were unable to rescue to mission. The S/C was lost and reentered the atmosphere Sept. 28, 1997. The review board found that the S/C was lost as a direct result of the implementation of a technically flawed safe mode in the attitude control system, compounded by the limited control and monitoring of the S/C after launch.

Figure 129: The Lewis S/C model

Applications: the S/C data may be used in a number of areas such as agriculture (cropstress management, crop maturity, etc.), forestry, land management, environmental assessment, resource exploration, etc.

⁸²⁶⁾ Information provided by J. S. Pearlman and S. K. Manlief of TRW, Redondo Beach, CA

⁸²⁷⁾ P. Parry, "The SSTI Lewis Better, Faster, Cheaper Guidance Navigation, and Control Subsystem," Proceedings of the 10th AIAA/USU Conference on Small Satellites, Sept. 16-19, 1996, Logan, UT

Orbit: Sun-synchronous circular orbit, altitude = 523 km, inclination = 97.45°

Sensor Complement:

HSI (Hyper-Spectral Imager, TRW instrument)

The spaceborne HSI instrument has evolved from the TRWIS airborne sensor family. HSI is a nadir-pointing imaging spectrometer generating 384 spectral bands in the VNIR and SWIR regions (0.4 - 2.5 μm) and in addition a visible panchromatic image (the 384 spectral bands can be selected in any combination). The instrument has a minimum design life of 3 years (goal 5 years), it consists of three independent imaging systems providing parallel near-instantaneous image capture. HSI features:

- Foreoptics: 12.5 cm aperture, 1 m effective focal length), three mirror design. The optical design utilizes shared foreoptics to generate three line images separated slightly in field
- The spectrometers provide constant bandwidth
- Pushbroom dual-grating spectrometers, common design, 2 slits
- PAN (panchromatic visible channel): 2592 x 1 CCD, 10 μm pixels (the panchromatic channel allows for additional spatial sharpening of the 30 m hyperspectral images during ground processing)
- VNIR: 128 bands of 5 nm, 256 x 128 CCD array, 60 μm aggregated pixels. The CCD focal planes are cooled slightly, to 273 K, to reduce dark current noise.
- SWIR: 256 bands of 6.38 nm, 256 x 256 HgCdTe detector array, 60 μm pitch, 250 Hz frame rate, cooled at 115 K
- Mechanisms: cover/diffuser, pulse tube cryocooler for low noise in SWIR
- Electronics: FPA readout and A/D conversion, spectral band selection
- Instrument pointing: HSI can be pointed across-track up to $\pm 20^\circ$ from nadir
- Calibration: Cover in calibration position (Lambertian diffuser inside cover). Three current-controlled lamps illuminate the diffuser over the full dynamic range (0.8-2.5 μm); sun reflects off diffuser for solar calibration (0.4-2.5 μm); calibration of entire optical train; spectral calibration uses atmospheric absorption in SWIR, solar spectra in VNIR. The absolute radiometric accuracy of HSI is better than 6%.

Parameter	PAN	VNIR	SWIR
Spectral range	0.48 - 0.75 μm	0.4 - 1.0 μm	0.9 - 2.5 μm
No. of spectral bands	1	128	256
Spectral resolution	-	5 nm	6.38 nm
Spatial resolution (IFOV in μrad)	5 m (10)	30 m (60)	30 m (60)
Swath width (at 523 km altitude, nadir)	12.9 km	7.7 km	7.7 km
Saturation radiance (% albedo)	100	100	100
Quantization	8 bit	12 bit	12 bit
Radiometric accuracy			
Pre-launch (%absolute)	15	5	5
Lifetime drift on orbit (%)	5	2	2
Drift between on-orbit calibrations	1	0.5	0.5
Data selectivity	any combination of bands		
Maximum data rate	327 Mbit/s		
Instrument mass, power	23 kg (including cryocooler), 50 W		

Table 212: HSI instrument parameters

LEISA (Linear Etalon Imaging Spectrometer Array, NASA/GSFC sensor, PIs: D. C. Reuter and D. Jennings). The major science objectives are to map reflectance spectra of surface and atmospheric features (eg., vegetation types and health, snow/ice/cloud discrimination, possibly snow depth, grain size, age), industrial pollution (eg., oil spills on water), cloud studies (phase, particle seize), cloud editing for HSI, aerosols, and nightglow/aurora studies. LEISA is also a technology demonstration for a similar spectrometer planned for a future Pluto mission.

LEISA is a very low-mass, low-power infrared hyperspectral spectral imager; spectral region: 1 - 2.5 μm ; spectral resolving power $\lambda/\Delta\lambda \geq 250$; nadir pixel size = 300 m (IFOV). The instrument is based on a newly-developed spectral filter known as LVE (Linear Variable Etalon) which is placed directly over a 256 x 256 IR [NICMOS 3 technology (NICMOS= Near Infrared Camera and Multi-Object Spectrometer)] detector array (HgCdTe).⁸²⁸⁾ The active area of this array has a size of 1.024 cm by 1.024 cm. The LEISA instrument is being pointed with an optical pointing assembly and cooled with a pulse-tube cooler (both are provided by TRW).

An image is formed having 2-D spatial and 1-D spectral information content (an image cube with a 256 x 256 spatial dimension and 256 spectral images). A complete spectral image is formed by sweeping the array in a cross-track direction and by the forward motion of the S/C. It takes about 9 seconds to complete a full image cube of a given scene. Swath width = 77 km x yyy km in length, where yyy is determined by the on-board memory available (4 Gbit max) and by the amount of data compression used. The instrument has a steerable mirror allowing off-track viewing. Note: a complete spectral image consists of 256 frames - for an area of 77 km x 77 km this amounts to about 270 Mbit of data. Within the infrared region the LEISA data is regarded as complementary to HSI.

UCB (Extreme Ultraviolet Cosmic Background Explorer; built at the Space Sciences Laboratory of the University of California at Berkeley, PI: J. Edelstein). Objectives: Measurements of diffuse emission line spectra of EUV radiation with a sensitivity exceeding that of previous work by several orders of magnitude. Studies of physical conditions of matter in the local interstellar medium, cosmological theories of dark matter, observation of the solar-excited interstellar medium, measurement of energetic geocoronal plasma phenomena.

The instrument has a full bandpass coverage from 55 - 105 nm, with prime bandpass in the range from 58.5 - 95.0 nm. Spectral resolution in the prime bandpass of 0.5 nm, 3σ sensitivity to diffuse line emission ≤ 2000 photons/s/cm²/sr. Observations are integrated over the orbital eclipse, viewing into the anti-sun direction. FOV = 8.4° x 25.6°.

The UCB design features the following technology: unique diffuse spectrograph optical design, metal substrate diffraction grating, lightweight ceramic-metal microchannel plate photon counting detector, energetic particle anticoincidence scintillator/PMT system, low noise detector charge amplifiers with particle overload peak restoration and charge-pulse anode particle cleaning.

Photons enter the optics chamber by way of a 0.15 mm x 60 mm slit. The slit is gated by a rotating filter-wheel mechanism. The filter wheel has four operational positions: 1) closed, 2) open, 3) MgF crystal, 4) Al thin film. Measurements of: a) detector background noise, b) low-energy EUV radiation signal, c) 1216 Å airglow radiation noise, d) high-energy EUV radiation signal. Light in the optics chamber encounters baffles, a diffraction grating, more baffles, and then the sensor. The slit, baffles and grids are polarized at low voltage to further reject charged particle noise.

Data: Downlink telemetry in S-band at a transmission rate of 2 Mbit/s to a number of ground stations (GSTDN compatible). This rather low data rate limits the operation of the HSI and LEISA instruments to selected areas only.

Title of Experiment	Short Description	PI / Agency
Data Compression	Demonstrate on-orbit compression of image data with and without loss	W. Miller/ GSFC
S/C Loads & Acoustic Measurements (SLAM)	Measure S/C environment during launch sequence	GSFC
Radiation & SEU Monitoring	Measure LET (Linear Energy Transfer) spectrum with gas proportional counter; Correl. With processor memory SEUs	J. Shinn/ LaRC

⁸²⁸⁾ Note: The NICMOS3 array is being developed for the next-generation IR instruments for the Hubble Space Telescope.

Title of Experiment	Short Description	PI / Agency
GPS Attitude Determination (GADFLY)	Demonstrate a 0.15° attitude determination by interferometric measurement of the GPS signal	F. Bauer/GSFC
Wide FOV Star Tracker	Demonstrate a 20° FOV star tracker with a 6-star capability	Hughes
Micromachined Accelerometers	Demonstrate the use of micromachined technology for S/C loads measurements	U. of Cincinnati
R-3000 Processor and 4-Gbit Solid State Recorder	Demonstrate on-orbit operation of R-3000 processor/SSR combination	TRW
Fiber Optic Data Bus	Demonstrate on-orbit operation of a high speed fiber optic data bus	HI/TRW
Pulse-Tube Cryocooler	Demonstrate on-orbit operation of a compact, low-vibration cryocooler	TRW
Optical Pointing Assembly	Demonstrate on-orbit operation of a precision steerable mirror	TRW
Advanced Solar Cell Experiment (ASCE)	Measure on-orbit performance of multi-junction GaAs and amorphous silicon solar cells	E. Gaddy/GSFC/TRW
Metal Matrix Composition Heat Strap	Measure on-orbit performance of graphite/aluminum matrix for thermal control	G. Castro/GSFC
Magnetically Suspended Reaction Wheel	Demonstrate on-orbit performance of magnetically suspended reaction wheel	TRW
Autonomous Orbit Control	Demonstrate on-orbit autonomous maintenance (ΔV) capability (calculation only)	Microcosm
Cloud/Feature Identification	Use HSI and LEISA data to develop algorithms for cloud, snow, etc. identification	R. Davis/LaRC
Enhanced ACS Experiment	Demonstrate on-orbit MIMO (Multi-Input/Multi-Output) attitude control S/W	P. Maghami/LaRC
On-Orbit Identification Experiment	Assess S/C dynamic performance	K. Elliot/LaRC
EPS Regulator	Measure on-orbit performance of a regulator designed for small satellites	LeRC
Advanced Packaging Experiment	Measure on-orbit operation of RH-32 processor using MCM (Multichip Module) technology	JPL/TRW

Table 213: Technology demonstrations on Lewis S/C

D.22.2 Clark S/C

The Clark S/C is designed and built by a consortium headed by CTA Space Systems of McLean, VA. The S/C has an integrated graphite structure and two solar array wings driven by a solar array drive. Attitude knowledge is on the order of 5 arc-seconds. GPS is used for autonomous orbit determination and for coarse attitude knowledge (GADFLY). A new coarse sun sensor is used for sun pointing.⁸²⁹⁾ A star tracker provides accurate attitude knowledge; a gyro is used to interpolate between star fixes. The S/C is three-axis stabilized (0.5° to 2° of control and 0.03° to 0.15° of attitude knowledge), mass = 305 kg (including fuel), power = 235 W (orbit average), propulsion = hydrazine blowdown, design life = 1 year for mission with a 3-year life of the S/C. A launch was projected for June 1996 aboard an LLV1 launch vehicle from VAFB, CA.⁸³⁰⁾

Note: At the end of Feb. 1998, NASA cancelled the Clark mission due to severe cost overruns and launch delays. NASA will keep the S/C and its instruments and use them for other projects.⁸³¹⁾

The Clark S/C represents a demonstration of 36 advanced technologies, among them: minimizing of ground processing for instrument data, on-board data compression with lossy algorithms, on-board imaging processing, use of new detectors in space (silicon and CdZnTe), 3-D tomographic mapping of the atmosphere, etc.

Orbit: Sun-synchronous circular orbit, altitude = 496 km, inclination = 97.3°, period = 92.25 minutes, nonrepeating ground track, nodal crossing time = 11:25 AM descending node, revisit time = 4.7 days for off-nadir and 20 days for nadir.

Data: An on-board digital recorder is employed with a storage capacity of 172 MByte. Downlink imagery communications via X-band at 8.03-8.04 GHz and a data rate of 25 Mbit/s; imagery downlink to mobile users in S-band at 2300 MHz and a data rate of 500 kbit/s; the TT&C data are in UHF-band at 402 MHz and a data rate of 19.2 kbit/s.

CTA and Earthwatch provide the ground stations for telemetry reception and S/C control. CTA's master control station is located in McLean, VA; Earthwatch's stations are in Fairbanks, AK, Tromsø, Norway, and Longmont, CO. Image data collection and processing is provided by Earthwatch.

Clark is designed to support proof-of-concept technology demonstrations rather than production operations for the acquisition and distribution of large quantities of image data. Archived imagery may be obtained from the EROS Data Center, Sioux Falls, SD.

Sensor complement:

Earthwatch Imager (built by Earthwatch of Longmont, CO). The instrument is the prime S/C sensor with the objective to provide high-resolution panchromatic and multispectral imaging data (simultaneously) of the Earth's surface. The imager employs a staring focal plane array technology and features a gimbaled mirror with a 30° pointing capability from nadir into any direction. The registration of the panchromatic and multispectral scenes is fixed, but it is possible to take first a multispectral scene and then a panchromatic scene, so in effect the panchromatic scene can be placed anywhere within the multispectral scene. The cameras may also be used for stereo imaging by slewing the gimbal mirror fore and aft in the S/C flight direction. Images are stored on-board in a solid state memory and dumped at 25 Mbit/s to one of several ground stations upon overflight (store-and-forward operation). The downlink is encrypted. The on-board processor provides real-time radiometric/geometric calibration and image compression for all imaging data.

Parameter	Panchromatic Camera	Multispectral Camera
Spectral range	0.45 - 0.80 μm	0.50-0.59, 0.61-0.68, 0.79-0.89 μm
Spatial resolution (GSD)	3 m at nadir, 3.5 m off-nadir	15 m at nadir, 17.3 m off-nadir
Footprint (or scene)	6 km x 6 km per exposure	30 km x 30 km per exposure
Swath width	12 km in strip mode (note: with step stare, swath width is variable so a wider swath may be collected over short intervals)	
Instrument (mirror) pointing	$\pm 30^\circ$ (along-track/across-track) providing a 560 km wide field of regard	
Stereo imaging	maximum base/height ratio = 1	
Data quantization	8 bit	
Array size	4 10^6 pixel	4 10^6 pixel (x 3)
Data size/scene	4 MByte (uncompressed)	12 MByte (uncompressed)
Data volume	~ 50 scenes per day	

Table 214: Performance characteristics of the Earthwatch Imager

MicroMAPS (Micro-Measurement of Air Pollution from Satellites), built by Resonance Ltd of Alliston, Ontario, Canada, PI: G. Walberg. The miniaturized sensor got its name from the much larger MAPS instrument which was flown on Shuttle missions STS-2 (1981), STS-59 (April 1994), and STS-68 (Oct. 1994). The objective of MicroMAPS is to measure the CO content of three altitude bands in the troposphere and to provide N₂O cloud mapping. The instrument provides the following capabilities:

- Nadir-viewing gas filter radiometer
- Operation in 4.67 μm CO band
- Simultaneously views of several spectral lines
- High spectral resolution with high throughput

- Internal comparison of incoming radiation to that seen through gas cells containing gases of interest
- Obtaining mixing ratios of CO and N₂O (for cloud editing)

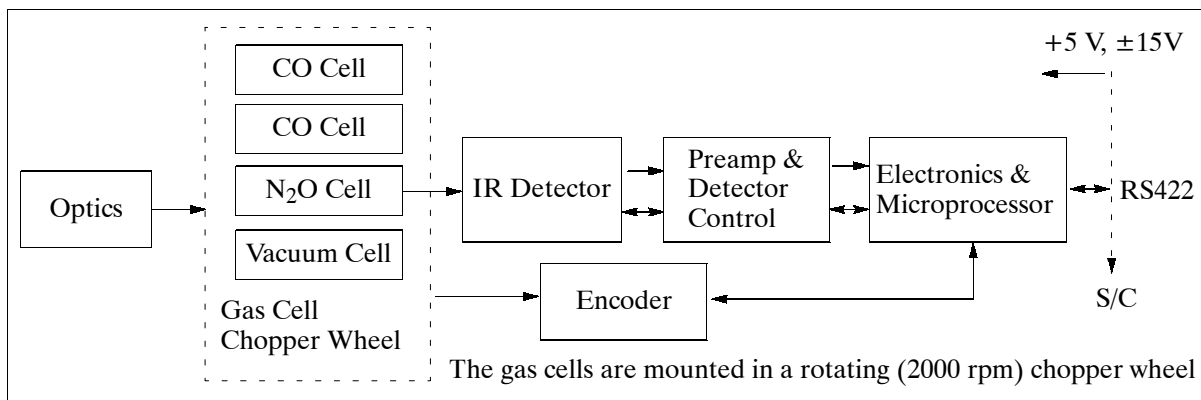

Figure 130: Functional diagram of MicroMAPS

Parameter	Value	Parameter	Value
Telescope aperture	5.2 cm ²	Element/material coating	Ge/AR coated > 99% T at 4.67 μm
Telescope FOV	2.4°	Etendue (AΩ)	7.2 10 ⁻³ cm ² sr
Optical magnification	27	Gas cell clear aperture	2 cm circular
Ray collection efficiency	> 90%	Beam size at gas cell chopper	0.5 cm (approx. square)
No. of elements	5	Detector size/type/temp	0.75 mm ² / PbSe/ -70°C

Table 215: Parameters of MicroMAPS

Instrument	MAPS (on Shuttle)	MicroMAPS (on Clark)
Spectral band	2080 to 2220 cm ⁻¹ (4.5 - 4.8 μm)	4.67 μm band
Resolution (NER)	1.7 10 ⁻⁷ W cm ⁻² sr ⁻¹ in the rad. channel 5.7 10 ⁻⁹ W cm ⁻² sr ⁻¹ in the difference channel	
FOV	5°	1°
No. of altitude bands	1	3
Swath width	20 km (corresponds to spatial resolution)	
Data rate	43 bit/s	9600 bit/s
Data storage	19 kByte	512 kByte
Earth coverage	sparse, ±57° latitude	continuous global
Mission duration	7 to 14 days	≥ 1 year
Sensor mass	40.4 kg	6.13 kg
Power	65 W	12 W

Table 216: Performance parameters of MAPS versus MicroMAPS

XRS (X-Ray Spectrometer), built by NASA/GSFC, PI: R. Starr. The objective is to demonstrate state-of-the-art detector technology using two new solid-state sensors that operate near room temperature: APD (Avalanche Photodiode) and CdZnTe (Cadmium, Zinc, Telluride) detectors. The instrument is mounted for the zenith-pointing direction in order to view the sun each orbit for about 10-15 minutes. Energy range = 2-25 keV (APD), 10-80 keV (CdZnTe), resolution = 1 keV (ADP), ~6 keV (CdZnTe), FOV = ±20° in transit direction, instrument mass = 5.2 kg, power = 5 W, detector array size = 8 APD and 12 CdZnTe, each 8 mm x 8 mm.

ATOMS (Atmospheric Tomography Experiment), built by IsComp Systems Inc., PI: J. Butts. Three-dimensional atmospheric tomography is an absorption technique used in identifying, monitoring, tracking, and modeling air pollutants generated by industry or in large population areas. In an operational system, a laser mounted on a satellite transmits a

beam through the atmosphere to the ground where a network of retroreflectors reflect the beam back to the satellite receiver. Multiple-pass-monitoring over dedicated sites enables the generation of 3-D images of selected atmospheric constituents based on long-path absorption measurements. The resolution of these 3-D images depends on the number of retroreflectors on the ground and on other system parameters (see also RIS in the ADEOS sensor complement, D.1).

ATOMS is a low-cost proof-of-concept demonstration program on Clark employing the atmospheric tomography technique in an 'upside-down' fashion. This means the corner reflector is on the S/C rather than on the ground; the experiment uses a ground-based laser which is reflected off the S/C corner reflector. Two-dimensional maps (planes) of trace gas measurements are generated during each pass of the S/C over the ground station. The ATOMS experiment uses the AMOS (Air-Force Maui Optical Station) site, located at the summit of Mount Haleakala on the island of Maui, Hawaii, to take advantage of existing laser tracking mounts and receivers. Measurements will be made with the DIAL (Differential Absorption Lidar) technique and by exploiting the Doppler shift of the reflected beam due to the varying range rate of the satellite pass. The abundance of CO is measured using a frequency-doubled CO₂ laser at 4.65 μm , matching the strong CO absorption line. Absorption measurements are obtained along many different lines-of-sight, receiving density profiles of CO versus altitude.

Figure 131: The Clark S/C model

D.23 MOS (Marine Observation Satellite)

MOS = Marine Observation Satellite. MOS-1 is Japan's (NASDA) first experimental Earth observation mission, also referred to as Momo-1 (peach tree). MOS-1 has been operational since Feb. 1987 (launch Feb. 19, 1987). The MOS-1 S/C ceased mission operations in April 1995. ESA/Earthnet is a data distributor of MOS-1.

The follow-up mission was **MOS-1B**, launch: Feb. 7, 1990. The operational life of MOS-1B mission was up to April 17, 1996.

Application: Observation of ocean surfaces (color), vegetation, land ecology, measurement of water vapor in the stratosphere, measurement of surface temperatures, etc.

The MOS S/C (NEC Corp. prime contractor) is three-axis stabilized with momentum wheels and hydrazine thrusters, consisting of a box-shape bus (1.3 m x 1.5 m x 2.4 m) with a single solar array (2.0 m x 4.5 m), its mass is 745 kg. Design life = 2 years.

Orbit: Sun-synchronous with a repeat cycle of 17 days; inclination = 99.1°; altitude = 908 km; period = 103 min; local sun time = 10:15 for MOS-1 and 10:33 for MOS-1B.

Sensor complement: (MOS-1 and MOS-1B)

- **MESSR** (Multispectral Electronic Self-Scanning Radiometer) two instruments are installed; 50 m resolution on ground, measurement in four channels, visible and near-infrared ranges. Bands: 0.51-0.59 μm , 0.61-0.69 μm , 0.73-0.80 μm , 0.80-1.10 μm . Swath width = 100 km (185 km when both camera systems are operating). MESSR is a CCD array instrument. The swaths of both instruments are slightly overlapped (15 km) providing stereo viewing in this region. Instrument mass = 70 kg (one unit).
- **VTIR** (Visible and Thermal Infrared Radiometer, mechanically scanning mirror instrument); resolution = 900 m on the ground in the visible range and 2700 m within the three infrared ranges. Bands: 0.5-0.7 μm , 6.0-7.0 μm , 10.5-11.5 μm , 11.5-12.5 μm . Swath width = 1500 km for all bands. Instrument mass = 25 kg.
- **MSR** (Microwave Scanning Radiometer, mechanical); MSR is a microwave sensor measuring (scanning) the Earth's surface in flight direction. Frequency bands: 23.8 GHz, 31.4 GHz. Resolution: 23 km (at 31 GHz) and 32 km (at 23 GHz). Swath width = 320 km. Instrument mass = 54 kg.

Data:

- MESSR = 9 Mbit/s
- VTIR = 0.8 Mbit/s
- MSR = 2 kbit/s

Figure 132: The MOS-1B S/C model

D.24 MTI (Multispectral Thermal Imager)

MTI is a US DOE-funded (Department of Energy) satellite mission, an R&D program and a demonstration mission of DOE/NN (Nonproliferation and National Security) with the objective to develop a broad range of new technologies, and to demonstrate the efficacy of highly accurate multispectral imaging for passive characterization of industrial facilities and related environmental impacts from space. The MTI program is managed by SNL (Sandia National Laboratories), LANL (Los Alamos National Laboratory) and SRTC (Savannah River Technology Center), representing DOE National Laboratories. Other program participants include: USAF Space Test Program (launch provision), AFRL (Air Force Research Laboratory), and universities. Major industrial partners are: Raytheon Optical Systems, Ball Aerospace, SBRC (Santa Barbara Research Center), and TRW.^{832) 833)}

The MTI satellite, with the bus built by Ball Aerospace, is three-axis stabilized. S/C dimensions (stowed for launch) are 1.4 m diameter and 2.4 m in height. The S/C attitude is measured by multiple sun sensors, a horizon sensor, and gyros. Actuators are reaction wheels and torque rods. A pointing accuracy of 0.25° is provided. The S/C is agile and can be body-pointed up to $\pm 50^\circ$ in all axis. This feature provides a FOR (Field of Regard) of ± 200 km for cross-track coverage (the nominal swath width of the imager is 12 km). The body-pointing feature may also be used for along-track stereo imaging support. The S/C mass is 650 kg, average total power of 575 W, with 11 battery cells (plus one spare) for ecliptic operations support. The S/C design life is three years. A launch of MTI on a Taurus vehicle from VAFB occurred on March 12, 2000.

Orbit: Sun synchronous polar orbit, altitude = 575 km, inclination = 97.52° , with a local crossing time of 13:00 on ascending node. The S/C has no orbit maintenance capability, resulting in an orbit decay over time.

Figure 133: Illustration of the MTI satellite

833) <http://nis-www.lanl.gov/nis-projects/mti/>

Communication: Downlink data transmission in X-band. The CCSDS protocol is used for uplink and downlink communication. S/C operations are performed at SNL (ground station). The DPAC (Data Processing and Analysis Center) function is provided by LANL.

Sensor complement:

MTI (Multispectral Thermal Imager).^{834) 835)} The overall instrument design objective is to support and evaluate advanced multispectral and thermal imaging, image processing and associated technologies. The instrument consists of the following elements: a telescope assembly, a cryogenically cooled focal plane with 15 linear spectral-sensitive pushbroom detector arrays, a complex built-in calibration hardware designed to collect radiometrically calibrated images with accuracies currently achievable only in the laboratory, and associated readout and control electronics. MTI features 15 spectral bands, ranging from the visible to the thermal infrared (TIR). The nominal FOV = 12 km x 12 km.

Imaging of a nominal nadir ground sample time in the along-track direction takes 715 μ s for bands A-D, and 2.86 ms for bands E-O. The integration times for all bands are variable, up to 12 μ s less than the pixel readout rate. A single detector array scans a 12 km image in about 1.7 seconds. The detectors are staggered in the along-track direction, so the system images a given ground point at slightly different times for each spectral band. A single 12 km x 12 km image requires about 4.5 s. - An average revisit time of one week for all target areas considered is provided with the body-pointing feature of the S/C.

Instrument calibration: The strategy is based on accurate pre-launch calibration in the LOs Alamos Radiometric Calibration Facility, plus on-orbit maintenance using sources built into the payload plus vicarious calibrations. The built-in calibration system uses instrumented ground sites, the sun, the moon and cold space looks to maintain long-term calibration. A more limited limited calibration sequence is performed before and after each imaging sequence.⁸³⁶⁾

The spectral coverage of MTI permits daytime and nighttime observations. The MWIR and TIR bands are in particular suited for nighttime measurements. During its three-year demonstration mission, MTI records periodically images of participating government, industrial, and natural sites, mostly within the continental US. These sites are instrumented to record ground-truth data by a team of scientists and technicians from SRTC (Savannah River Technology Center) and by site owners and operators.

Spectral band	Spectral range (μ m)	GSD (Ground Sample Distance)	Radiometric accuracy (%)	NER W/(cm ² sr μ m)
A	0.45 - 0.52 VIS	5	3	4.4 10 ⁻⁵
B	0.52 - 0.60 VIS	5	3	2.8 10 ⁻⁵
C	0.62 - 0.68 VIS	5	3	3.2 10 ⁻⁵
D	0.76 - 0.86 VIS	5	3	2.3 10 ⁻⁵
E	0.86 - 0.90 NIR	20	3	3.0 10 ⁻⁵
F	0.91 - 0.97 NIR	20	3	6.0 10 ⁻⁶
G	0.99 - 1.04 NIR	20	3	1.7 10 ⁻⁵
H	1.36 - 1.39 SWIR	20	3	5.2 10 ⁻⁷
I	1.55 - 1.75 SWIR	20	3	4.8 10 ⁻⁸
J	3.50 - 4.10 MWIR	20	1	1.3 10 ⁻⁷
K	4.87 - 5.07 MWIR	20	1	6.6 10 ⁻⁷
L	8.00 - 8.40 TIR	20	1	4.4 10 ⁻⁶
M	8.40 - 8.85 TIR	20	1	3.2 10 ⁻⁶
N	10.2 - 10.7 TIR	20	1	3.9 10 ⁻⁶
O	2.08 - 2.35 SWIR	20	3	1.2 10 ⁻⁶

836) W. B. Clodius, et al., "MTI On-Orbit Calibration," SPIE Vol. 3753, Denver, CO, July 19-21, 1999, pp. 380-391

Optical telescope assembly	36 cm aperture, off-axis TMA (Three Mirror Anastigmatic), f/3.5, FOV = 1.38° in the cross-track direction, and 1.82° in along-track
FPA (Focal Plane Assembly)	Consists of SCAs (Sensor Chip Assemblies), optical filters, and a vacuum enclosure; six SCAs are mounted on 3 motherboards; 3 SCA pairs are needed to provide cross-track coverage in all bands
Detectors at 75 K	Monolithic silicon PIN diodes for VNIR bands Backside illuminated photovoltaic InSb for NIR/SWIR/MWIR bands Backside illuminated photovoltaic HgCdTe for TIR bands
Cryogenic cooler	Pulse-tube cryogenic cooler (>3 W of cooling at 65 K)
Calibration sources	Blackbody, QLCS (Quick Look Calibration Source), QTH (Quartz Tungsten Halogen)
Readout/control electronics	12 bit data quantization, 266 Mbit/s of source data rate (all bands), Image data compression by USES (Universal Source Encoder for Science data) chip for lossless compression (Rice coding algorithm). A compressed 2-look image is about 500 Mbit with a 2.5:1 compression ratio
Mass storage unit	4.1 Gbit capacity
Instrument mass, power	240 kg, 350 W

Table 218: Performance parameters of the MTI instrument

HXRS (Hard X-Ray Spectrometer). The instrument is a joint endeavour by the Astronomical Institute of the Academy of Sciences of the Czech Republic and NOAA/SEC (Space Environment Center) in Boulder, CO. The instrument was built in Prague by Space Devices, Ltd. HXRS has the following objectives: a) to record with a high time-resolution a rare species of solar flare associated with high-energy proton storms known to damage satellites and potentially endanger astronauts, b) to evaluate the efficiency of this type of instrument to predict interplanetary proton events, and c) to test the effectiveness of new shielding methods. NOAA hopes to obtain information needed to design a system capable of forecasting such storms. ⁸³⁷⁾ ⁸³⁸⁾

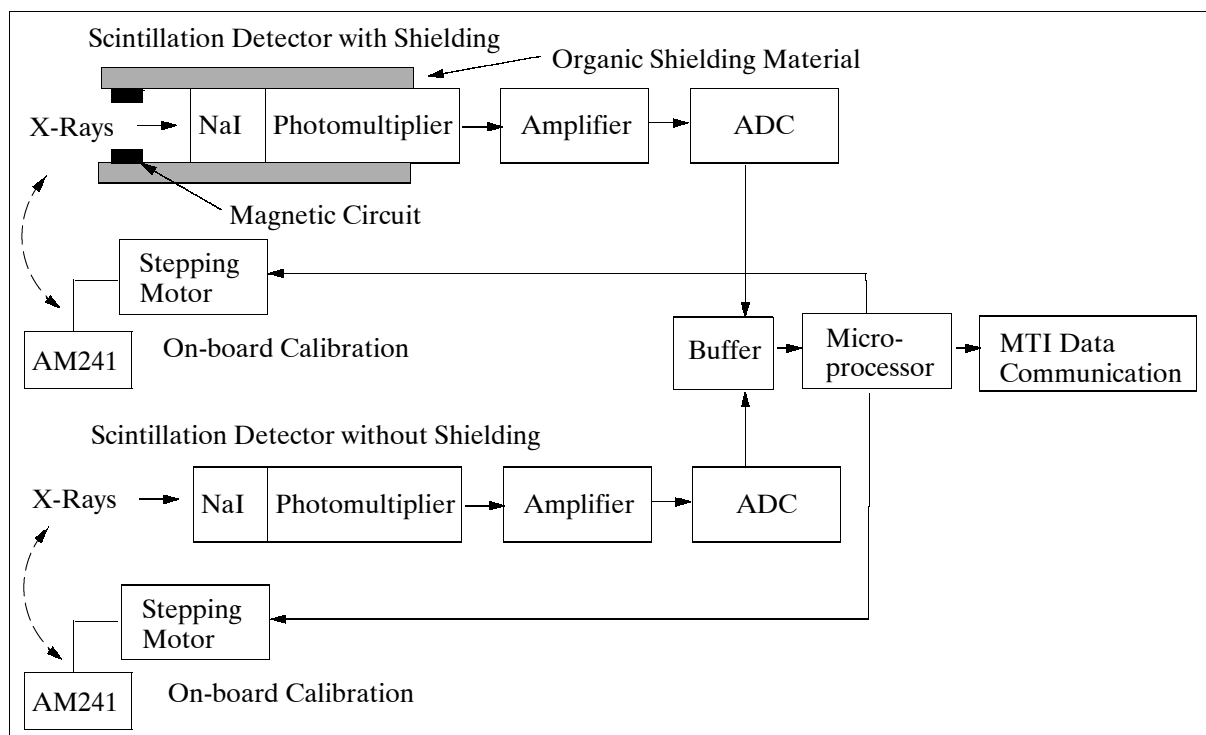

Figure 134: Schematic illustration of HXRS instrument components

837) F. Fárnik, H. Garcia, A. Kiplinger, "Solar Broad-band Hard X-Ray Spectrometer Onboard the MTI Satellite," Proceedings of 'A Crossroads for European Solar & Heliospheric Physics Conference,' Tenerife, March 23-27, 1998, pp. 305-308, ESA SP-417

838) H. A. Garcia, F. Fárnik, A. L. Kiplinger, "Hard x-ray spectroscopy for proton flare prediction," Proceedings of the SPIE Conference on Missions to the Sun II, San Diego, CA, July 1998, Vol. 3442, pp. 210-216

HXRS measures hard X-ray emissions of the sun in eight energy bands with time resolutions of up to 200 ms. The instrument consists of two identical scintillation detectors, one with shielding and one without, mounted side by side. Shielding is provided by a strong permanent magnet and a thick layer of plastic material. Each detector consists of a NaI crystal (25 mm diameter, 4.5 mm thick) coupled with a photomultiplier (Hamamatsu). Note: NaI (Tl) is a crystal of sodium-iodide activated by thallium. Such crystals are commonly used as X-ray detectors (coupled with photomultipliers).

Each detector is automatically calibrated in-flight by means of a radioactive source (AM241) on a movable arm. A 16-bit microprocessor controls all instrument functions and operations. The instrument data rate depends very much on the solar activity, i.e. on the number of hard X-ray events. During an event when all energy bands register with 200 ms time resolution, there are 10 channels that are read at 5 times/s (or 50 words/s). During quiet periods the data rate is about 1/10. The HXRS instrument mass is 7.695 kg, the power consumption is 5 - 6.5 W.

Incident X-ray photons create optical pulses in the crystals, they are converted into electrical signals and amplified by the photomultipliers. Pulse height (amplitude) discriminators measure the signal which is proportional to the incident photon energy. The number of pulses in each energy band counted per observation time interval is registered and send to the telemetry processor.

The MTI S/C spends a major portion of its time in standby mode (i.e., when the MTI instrument is not observing); during standby the S/C is always sun-pointing within 1° to collect solar energy. HXRS observations coincide with this standby mode.⁸³⁹⁾

Band Number	Energy Range (keV)	Max. Counts	Band Number	Energy Range (keV)	Max. Counts
S0	12.6 - 19.0	65535	S5	100.2 - 147.2	2047
S1	19.0 - 29.0	32767	S6	147.2 - 219.5	1023
S2	29.0 - 44.0	16383	S7	219.5	511
S3	44.0 - 67.2	8191	S8	249.5	255
S4	67.2 - 100.2	4095	SA	12.6	65535

Table 219: Definition of the HXRS energy bands

The “S” in “Band Number” of Table 219 signifies a “shielded detector.” In parallel, the same energy bands are also part of the other (non-shielded) detector of the instrument.

D.25 NEMO (Navy EarthMap Observer)

The NEMO program (started in 1997) is a cooperative US government/industry satellite program, sponsored by ONR (Office of Naval Research) and DARPA as well as commercial investments, between the Navy’s NRL (Naval Research Laboratory) on the government side as the program manager in partnership with commercial developers, a consortium led by STDC (Space Technology Development Corporation) of Alexandria, VA. In 1999, STDC was acquired by Earth Search Sciences Inc. (ESSI) of Kalispell, MT.⁸⁴⁰⁾

The overall objective is the development/demonstration of hyperspectral technology and the collection/processing of moderate-resolution hyperspectral imagery for military and commercial use. The emphasis is on broad-area, synoptic, and unclassified hyperspectral imagery. The prime military interest is to obtain imagery of the coastal regions on a global scale (littoral modeling, shallow water bathymetry, topography, bottom type composition,

⁸³⁹⁾ http://www.asu.cas.cz/english/new/HXRS_descr.htm

⁸⁴⁰⁾ T. Wilson, C. Davis, “Naval EarthMap Observer (NEMO) Satellite,” Proceedings of SPIE, Vol. 3753, Denver, CO, July 19-21, 1999, pp. 2-11

detection of underwater hazards, water clarity and visibility, etc.), while the civil needs call for imagery supporting such applications as land use management, agriculture, environmental studies, and mineral exploration. Contract agreements call for STDC and its industry partners to provide the commercial satellite bus, selected flight avionics components, launch services, and long-term flight operations. NRL provides the design and integration of the NEMO sensor imaging payload with the commercial satellite bus, bus modifications, the on-board processor, ORASIS (Optical Real-time Adaptive Signature Identification System), and systems engineering. NRL has responsibility for calibration software and calibrated radiances; development of at-launch algorithms including those for atmospheric correction; on-board data compression software and related software for the ground data system; some data processing; and data archiving. The planned products of at-launch algorithms are water clarity (probably diffuse attenuation coefficient at 490 nm), concentration of chlorophyll, absorption coefficient of colored dissolved organic matter, concentration of suspended sediments, bathymetry, and bottom characteristics. ⁸⁴¹⁾ ⁸⁴²⁾ ⁸⁴³⁾ ⁸⁴⁴⁾

Subsystem	Short Description
ADCS (Attitude Determination and Control Subsystem)	3-axis stabilized for all modes; 0.07° control Geolocation: 30 m with a Circular Error of Probability (CEP) of 0.9 2 star trackers and 1 inertial reference unit for attitude determination 4 reaction wheels and 2 electromagnetic torquers for attitude control
EPS (Electrical Power Subsystem)	2 gimbaled (single axis) solar array panels 4 for 3 redundant power control box 64 Ah nickel hydrogen battery Approximately 1500 W power
RCS (Reaction Control Subsystem)	Monopropellant hydrazine blowdown system 1 propellant tank (76.5 kg capability) 5 x 1N thrusters for orbit correction/orbit maintenance
TCS (Thermal Control Subsystem)	Passive thermal control with heater augmentation Battery and payload panels thermally isolated from bus
Structural Subsystem	Primary structure is a combination of a rigid aluminum tubular frame and aluminum honeycomb shear panels Kinematically decoupled optical bench S/C mass: 496 kg dry; 547 kg wet; payload mass: 292 kg
Mechanisms Subsystem	Optical bench launch restraints Contamination covers for sensors Solar array drive mechanisms for gimbaling arrays Launch vehicle separation Two redundant main electrical umbilical connectors
CT&DH (Command, Telemetry, and Data Handling Subsystem)	On-Board Processing Electronics (OBPE) primary controller: MIL-STD-1750A radiation-hardened processor Payload controller: R3000 processor (12 MIPS) Imagery On-Board Processor (IOBP): multiple Super Harvard Architecture RISC Computing (SHARC) processors in a parallel array Solid state data recorder with a capacity of 56 Gbit
Communications Subsystem	Data downlink in X-band, data rate of 131 Mbit/s; 20 watt; 8025-8400 MHz, with embedded housekeeping telemetry Command uplink in S-band, data rate of 2 kbit/s, 2074.1 MHz Low-rate downlink in S-band, data rate at 1.024 Mbit/s, 2252.5MHz, supports tactical imagery demonstrations
Software Subsystem	On-board task scheduling capability, FDIR (Embedded fault Detection, Isolation, and Recovery)

Table 220: Spacecraft subsystem characteristics

A launch of NEMO is planned for 2003. Launch vehicle is TBD.

The satellite consists of eight hardware subsystems and a software subsystem that collectively accommodate the payload and meet the mission and science requirements (Table

⁸⁴¹⁾ <http://nemo.nrl.navy.mil/public/index.html>

⁸⁴²⁾ C. O. Davis, K. Carder, "Requirements Driven Design of an Imaging Spectrometer System for Characterization of the Coastal Environment," Proceedings of SPIE, Vol. 3118, San Diego, CA, 1997

220). The satellite platform selected is a commercial bus (LS-400) from SS/L. The satellite is three-axis stabilized and consists of a trapezoidal main body and two deployable solar arrays. STDC has responsibility for ground data processing system architecture, some data processing and merging, data archiving, and a web-based database interface. The S/C design life is five years (minimum of three year on-orbit mission life).

Orbit: Sun-synchronous circular orbit, altitude = 605 km, inclination = 97.81° , nodal equator crossing at 10:30 AM (ascending node), repeat cycle = 7 days with a 2.5 day global average re-access capability when S/C pointing ($\pm 30^\circ$) in the cross-track direction is used.

Figure 135: Illustration of the NEMO S/C

Sensor complement:

COIS (Coastal Ocean Imaging Spectrometer), a hyperspectral (ocean color - land surface) imager provided by NRL (built by SAIC). The instrument employs a TMA (Three-Mirror-off-Axis) anastigmatic design, a 15 cm diameter aperture telescope, a dichroic beam splitter, and two spectrometers (VNIR and SWIR). The overall spectral range of COIS is from 400 to 2500 nm with 10 nm spectral resolution (210 bands). A FOV of 2.86° provides a swath width of 30 km. COIS uses Offner convex grating spectrometers. The two spectrometers are:

- A Visible Near Infrared (VNIR) spectrometer that disperses the 400 to 1000 nm radiation into 60 spectral bands (10 nm wide) and onto a Focal Plane Array (FPA). This provides a resolution of 1.0 - 1.5% of the band and 60 spectral bins.
- A Short-Wave Infrared (SWIR) spectrometer that disperses the 1000 to 2500 nm radiation into 150 spectral bands (10 nm wide) and onto an FPA. This provides a resolution of about 0.6% of the band and 150 spectral bins. A cryocooler provides active cooling at 110 K.

The COIS instrument provides very high SNR environmental products for imaging the low-reflectivity ocean surface. The NEMO platform can implement Ground Motion Compensation (GMC) sufficient to reduce the apparent ground speed by a factor of 5. This provides the required dwell time to give a high SNR at a GSD of 30 m. COIS is also capable of producing 60 meter GSD, high SNR data products without GMC by using spatial binning of the hyperspectral FPAs. - COIS calibration is maintained by on orbit by monthly imaging of the full moon and weekly imaging of uniform ground reference targets.⁸⁴⁵⁾

A typical COIS scene is 30 km wide by 200 km in length, with 30 m by 30 m pixel resolution, yielding nine image strips per orbit (number of strips limited by on-board data storage capacity). An alternate pixel size is 60 m x 60 m, yielding a 30 km wide swath as long as 8000 km per orbit.

⁸⁴⁵⁾ M. Corson, "Calibration of the NEMO sensor imaging payload," SPIE Proceedings, Vol. 3437, 1998

Figure 136: Exploded bus view with COIS instrument

Spectral coverage	400 - 2500 nm with a 10 nm spectral resolution (total of 210 spectral bands)
Spatial resolution	30 m or 60 m (for high SNR data products)
SNR (Signal-to-Noise)	>200 for VNIR data (5% reflectance target which is typical of the ocean) >100 for SWIR data at 30% reflectance (typical)
Pointing capability	$\pm 30^\circ$ in the cross-track and along-track directions (body pointing) The pointing is used to increase integration time when sampling in the 30 m mode
Detector arrays	FPA of 1024 x 1024 pixels for VNIR (silicon CCD) and SWIR (MCT detector)
Pixel summing	Pixels are summed by 6 in VNIR and SWIR to achieve the desired spectral resolution
Data volume	Estimated average daily imagery is about 227 Gbit

Table 221: Some performance parameters of COIS

Parameter	COIS - VNIR	COIS - SWIR	PIC
GSD (Ground Sample Distance)	30 m with 5:1 GMC 60 m with no GMC	30 m with 5:1 GMC 60 m with no GMC	5 m (with or without GMC)
Spectral range	0.4 - 1.0 μm	1.0 - 2.5 μm	0.45 - 0.69 μm
Spectral bands	60	150	1
FOV, swath width	2.86°, 30 km	2.86°, 30 km	2.86°, 30 km
Swath length	200 km at 30 m GSD Continuous at 60 m GSD	200 km at 30 m GSD Continuous at 60 m GSD	Continuous
Aperture diameter	15 cm	15 cm	16.4 cm
Focal length, f/Nr.	36 cm, f/2.4	36 cm, f/2.4	120 cm, f/7.32
Pixel size	18 μm	18 μm	10 μm
Nr. of pixels/band	6	6	N/A
Data quantization	12 bits	12 bits	12 bits
Detector material	Silicon	MCT	Silicon

Table 222: Characteristic parameters of COIS and PIC

PIC (Panchromatic Imaging Camera). The instrument uses an off-axis telescope to simultaneously image the same 30 km swath as the COIS instrument onto a 6000 pixel CCD linear array (PIC data is co-registered with COIS data). The spectral range is from 0.45 - 0.69 μm . The panchromatic imagery has a resolution of 5 m GSD. The moderate COIS GSD matches the spatial scale of natural objects in the littoral zone, while the high resolution PIC provides simultaneous context and sharpening and supports civil land imaging requirements. The 30 km ground swath of COIS and PIC spans the near-shore littoral region of land, beach, and ocean. COIS and PIC use a single optical bench to minimize optical boresight drift.⁸⁴⁶⁾

Mission operations:

NEMO uses a combination of commercial/industry operations and an existing DoD infrastructure ground segment to provide the user communities (military and civil) with data services. The ground segment consists of the following elements:

- ASOC (Advanced S/C Operations Center), located in Washington, DC area. ASOC is the central hub for all mission planning, S/C operations, and data processing
- TAGS (Transportable Autonomous Ground Stations), located at Fairbanks, AK and elsewhere. Downlinked data is maintained on mass storage devices at the TAGS until final receipt of the IPC is verified.
- IPC (Image Processing Center). The IPCs perform quick-look data processing to level 1B and data archive functions.
- NCC (NRL Control Center). NCC is the science hub for the NEMO program. Also data distribution function for the military side.

Adaptive Spectral Signature Recognition.

The NEMO S/C employs **ORASIS** (Optical Real-time Adaptive Signature Identification System) developed by NRL, an automated and patented end-to-end HSI (Hyperspectral Imaging) algorithm and advanced processing system that performs on-board data compression, thereby significantly reducing the capacities needed for on-board storage and for downlink transmission.

ORASIS identifies the spectral signatures corresponding to physical objects in the scene without supervision or a priori knowledge. The approach is to analyze each spectrum in the scene sequentially, discarding duplicate spectra, and working only with the unique spectra. Using convex set methods and orthogonal projection techniques, each observed spectrum is then analyzed in terms of the set of spectra that represent the physically meaningful patterns or end-members that have combined to make the observed spectrum. Matched filters (Filter Vectors) are created, they can be used to de-mix the image.⁸⁴⁷⁾

The ORASIS processor, hosted on IOBP (Imagery On-Board Processor), is based on the SHARC (Super Harvard Architecture Computer), it has 32 processors for data handling and a processing capability of up to 2.5 GFLOPS. The on-board processing minimizes subsequent ground processing and data exploitation, and enables the on-board production of data products, such as maps of identified features. An important benefit of ORASIS processing is a **greater than tenfold data compression**, relieving the bottlenecks of on-board data storage, transmission to the ground, and beyond.

D.26 OKEAN-O

A USSR/Ukrainian (prior/after 1992) satellite series (OKEAN=Ocean) for the operational monitoring of ocean surfaces (sea surface temperatures, wind speed, sea color, status of

⁸⁴⁶⁾ A. Myers, "NEMO satellite sensor imaging payload," SPIE Proceedings, Vol. 3437, 1998

⁸⁴⁷⁾ J. Bowles, et al., "Hyperspectral Data Compression and Science Algorithms for the NEMO Satellite," Proceedings of 1st EARSeL Workshop on Imaging Spectroscopy, University of Zürich, Switzerland, Oct. 6-8. 1998, pp. 183-190

ice coverage, cloud coverage and precipitation) day and night operation. The Okean-O series with their polar orbits provides valuable complementary data on the arctic and antarctic regions, which are not visible from geostationary meteorological satellites. Launches of the series are conducted from the Plesetsk Cosmodrome by the Tsyklon-3 launch vehicle.

Orbit: Sun-asynchronous polar orbit, altitude = 660 km, inclination 82.5° , period = 98 minutes.

The OKEAN program started in 1979 with the pre-operational (i.e. experimental) Cosmos program.⁸⁴⁸) Mission objective: a major interest was in the operation of active and passive microwave sensors. The active MW sensor provides all-weather observation capability.

D.26.1 Experimental Cosmos Program

The predecessor series of the Okean series was the experimental Cosmos series.

- Cosmos 1076 (also referred to OKEAN-E); launch from Plesetsk on a Tsyklon vehicle on Feb 12, 1979; orbit: altitude = 660 km; inclination = 82.6° ; S/C mass = 1950 kg. A test mission of the Okean satellite without the radar. Objective: Development of methods for obtaining operational information on the Pacific Ocean. Operations were terminated on March 13, 1980.
- Cosmos 1151 (OKEAN-E); launch from Plesetsk on a Tsyklon vehicle on Jan. 23, 1980; orbit: altitude = 660 km; inclination = 82.6° ; S/C mass = 1950 kg. The second test mission of the OKEAN satellite without the radar. Operations were completed on Oct. 13, 1981.
- Cosmos 1500 (also referred to as OKEAN-OE); launch from Plesetsk on a Tsyklon vehicle on Sept. 28, 1983; orbit: 649 x 679 km, inclination = 82.6° ; S/C mass = 1950 kg. The S/C was operational until July 16, 1986.
- Cosmos 1602 (also referred to as OKEAN-OE); launch from Plesetsk on a Tsyklon vehicle on Sept. 28, 1984; orbit: 629 x 664 km, inclination = 82.5° ; S/C mass = 1950 kg. The S/C was operational until Dec. 5, 1986.
- Cosmos 1766 (also referred to as OKEAN-N1); launch from Plesetsk on a Tsyklon vehicle on July 29, 1986; orbit: 601 km x 631 km, inclination = 82.5° ; S/C mass = 1950 kg. The S/C was operational until Oct. 24, 1988.
- COSMOS 1869 (also referred to as OKEAN-N2); launch from Plesetsk on a Tsyklon launcher on July 16, 1987; orbit: 602 km x 632 km, inclination = 82.5° ; S/C mass = 1950 kg. The S/C was operational until May 30, 1989.

Cosmos satellites 1076 and 1151 carried the following sensors:

The simultaneous spectral measurements in several wavelengths provide a means of evaluating the hydro-physical parameters of the sea surface, the meteorological parameters of the atmosphere as well as of the sea surface. The parameters are: sea surface temperature, wind speed at the sea surface boundary, liquid vapor content in clouds, integrated water vapor, etc.

- **Device ν** = Passive MW Radiometer (NPO Vega) measuring the emission radiation of the atmosphere/ocean system at the following (micro) wavelengths/frequencies: 0.8 cm (37.5 GHz), 1.35 cm (22.22 GHz), 3.2 cm (9.37 GHz), and 8.5 cm (3.53 GHz). Nadir pointing.
- **Device π** = a non-scanning polarimeter measuring radiation at wavelength 3.2 cm (with two orthogonal polarizations at a look angle of 53° relative to nadir, and with one polar-

⁸⁴⁸) Verbal information provided by B. Kutuza of IRE (Russian Academy of Sciences), Moscow

ization at nadir). Along-track footprints of 12 m distance and 6 m normal to the orbital track are generated.

- **Device 174 K** = IR spectrometer.
- **MSU-M**. A four-band (VIS) multispectral scanner for monitoring ocean color. Swath width = 1900 km, resolution = 1.8 km.

S/C Name	Launch Date	Remarks	Instrument complement
Cosmos-1500 (OKEAN-OE-N1)	Oct. 28, 1983	June 12, 1986	RLSBO(3.2 cm), RM-0.8, 3-cha. MWR (0.8, 1.35 and 8.5 cm), RTVK
Cosmos-1602 (OKEAN-OE-N2)	Oct. 28, 1984	Nov. 10, 1985	RLSBO(3.2 cm), RM-0.8, 3-cha. MWR (0.8, 1.35 and 8.5 cm), RTVK
Cosmos 1766 OKEAN-O1-N1	July 29, 1986	operational until 1988	RLSBO(3.2 cm), RM-0.8, MWP (3.2 cm), RTVK, MSU-SK, Kondor
Cosmos 1869 OKEAN-O1-N2	July 16., 1987	operational until 1989	RLSBO(3.2 cm), RM-0.8, MWP (3.2 cm), RTVK, MSU-SK, Kondor (SLAR did not work)
OKEAN-O1-N3	July 5, 1988	operational until 1990	RLSBO(3.2 cm), RM-0.8, MWP (3.2 cm), RTVK, MSU-SK, Trasser, Kondor
OKEAN-O1-N4	June 9, 1989	launch failure	RLSBO(3.2 cm), RM-0.8, MWP (3.2 cm), RTVK, MSU-SK, Kondor
OKEAN-O1-N5	Feb. 28, 1990	operational until 1991	RLSBO(3.2 cm), RM-0.8, MWP (3.2 cm), RTVK, MSU-SK, Kondor
OKEAN-O1-N6	June 4, 1991	operational until 1993	RLSBO(3.2 cm), RM-0.8, MWP (3.2 cm), RTVK, MSU-SK, Kondor
OKEAN O1-N7	Oct. 11, 1994	operational 1/1996	RLSBO(3.2 cm), RM-0.8, MWP (3.2 cm), RTVK, MSU-SK, Kondor
SICH-1 (OKEAN-O1-N8)	Aug. 31, 1995	operational 1/1996 Russian/Ukrainian joint venture	RLSBO(3.2 cm), RM-0.8, MWP (3.2 cm), RTVK, MSU-SK, Kondor
OKEAN-O-1	July 17, 1999	OKEAN-O-1 stopped operations in the fall of 2000 due to S/C attitude control problems	RLSBO (2 units), MSU-M, MSU-SK, MSU-V, Delta-2D, R225, R-600, Trasser-O

Table 223: OKEAN-O1 series designations

The Cosmos satellite series 1500 - 1869 was equipped with a subset of instruments of the first series, i.e. one or two passive MW radiometers per satellite measuring the emission radiation of the atmosphere/ocean system. Cosmos 1500 was the first Soviet satellite equipped with a side-looking, all-weather radar, namely **RLSBO** (or SLAR).

D.26.2 OKEAN-O1 Operational Series

A S/C series, built by Yuzhnoye (Research and Production Association) of Dnepropetrovsk, Ukraine. The S/C bus is a three-segmented, vertically oriented cylinder, three meters tall with a base diameter of 1.4 m and an upper diameter of 0.8 m. OKEAN's primary structure is pressurized and maintained at normal temperatures to protect the support system and payload electronics housed within. Two small, rotatable solar arrays (1.6 m x 2.0 m) provide a modest 110–270 W average daily power to the payload. The S/C is three-axis stabilized (nadir pointing), stabilization is also partially provided by a gravity-gradient boom extended from the top of the satellite. At the bottom, four large panels (1.0 m x 2.9 m), attached at 90° intervals, support a number of payload receivers and transmitters. A narrow, 11 m long radar antenna is fixed to the base of one panel. The overall S/C mass is about 1950 kg with a payload capacity of 550 kg.

Operational series (design life is 2 years):

- Okean-O1-1; launch: July 5, 1988; orbit: 635 x 666 km; inclination = 82.5°
- Okean-O1-2; launch: Feb. 28, 1990; orbit: 639 x 666 km; inclination = 82.5°
- Okean-O1-3; launch: June 4, 1991; orbit: 664 x 684 km; inclination = 82.5° (conditional operation since Jan. 1992, RLSBO is not working!)
- Okean-O1-4; launch: October 4, 1994
- Sich-1; launch: August 31, 1995

Sich is the Ukrainian name for 'Owl'. Sich-1 has the same orbit and sensor complement as the Okean-O1-1 to O1-4 S/C series. As of January 1996 all instruments of Sich-1 are operational.

Figure 137: The OKEAN-O1 series S/C model

Sensor complement: (Okean-O1 Series)

RLSBO = Side Looking Real Aperture Radar (Kharkov IRE, Ukraine, PI: Kalmykov), prime sensor of the Okean series (11.1 m antenna length). Wavelength/frequency: 3.2 cm/9.7 GHz, X-band; resolution = 2.1 km - 2.8 km in flight direction, = 1.2 km - 0.7 km in cross track direction; swath = 450 km.

- impulse duration = 3 μ s
- impulse peak power = 100 kW
- pulse repeat frequency = 100 Hz
- polarization = V (vertical)

RM-08 = Passive Microwave Scanning Radiometer (Kharkov IRE, Ukraine). Wavelength/frequency: 0.8 cm / 36.6 GHz; resolution = 15 x 20 km, swath = 550 km. Objective: monitoring atmospheric vapor, sea ice, and ocean surface temperature with an accuracy of 1-2 K.

MSU-M = Multispectral Scanner of low resolution (ISDE, Moscow). Resolution = 1.0 x 1.7 km, swath = 1900 km. Objective: cloud monitoring and sea surface temperature. Spectral ranges: 0.5 - 0.6 μm ; 0.6 - 0.7 μm ; 0.7 - 0.8 μm ; 0.8 - 1.1 μm

MSU-S = Multispectral Scanner of moderate resolution (ISDE, Moscow). Two spectral ranges: 0.6 - 0.7 μm , 0.7 - 0.9 μm ; resolution = 250 m; swath = 1100 km.

Kondor = DCPs data collection system

Table 224: Observation geometries for OKEAN instruments (shown to one side only)

One of the features of Okean type satellites is the possibility of direct data reception by various users having only simple hardware and software for data processing. The downlink frequency of 137.4 MHz (carrier frequency with 2.4 kHz subcarrier frequency) is used for direct broadcasts of RLSBO and MSU-M imagery with reduced resolution to any of the CIS APT stations as well as to foreign users. The second science data downlink has a carrier frequency of 466.5 MHz.

Data collected are transmitted to receiving stations at Moscow, Novosibirsk, and Khabarovsk (Pacific region). Maps can be readied in 10 days and ice forecasts sent directly to ships at sea.

D.26.3 OKEAN-O Series

The OKEAN-O series, a joint Ukrainian/Russian program, is an upgrade over the OKEAN-O1 series with regard to the sensor complement (the S/C is also considerably larger). The OKEAN-O-1 S/C was sponsored by RKA and NKAU (National Space Agency of Ukraine), designed by the Yangel Yuzhnoye State Design Office, and built by NPO Yuzhny Machine-Building Plant Production Association in Dnepropetrovsk, Ukraine. The satellite is three-axis stabilized with an attitude pointing accuracy of ± 10 arcmin and an angular stabilization velocity of $\pm 0.0015^\circ/\text{s}$. Solar power of up to 3.5 kW. S/C mass of 6150 kg, the mass

of the on-board special complex (BSC) is 1520 kg. The design life is three years. ⁸⁴⁹⁾ ⁸⁵⁰⁾

OKEAN-O-1 was launched on a Zenit-2 vehicle from Plesetsk on July 17, 1999.

Orbit: Near-circular orbit, 620 km (perigee) x 652 km (apogee), inclination = 82.5°, the re-visit time is between 4 to 16 days.

Operational status as of April 2001: OKEAN-O-1 stopped all operations in the fall of 2000 due to attitude control problems of the spacecraft. Both space agencies, NKAU and RKA (or Rosaviakosmos), do not provide any funding for the development of a further OKEAN spacecraft due to the current economic situation in the Ukraine and in Russia.

Figure 138: The OKEAN-O-1 spacecraft illustration

S/C Communication.

- 1) BISU-P (On-board Information System Unified). This is a digital system with an X-band downlink, the frequency is 8.2 GHz. The transmission rate is 61.44 Mbit/s (4R) or 15.36 Mbit/s. The on-board data recorder has recording rates of 15.36 Mbit/s or 0.96 Mbit/s.
- 2) RTVK-M (Radio and Television Complex). This is an analog system in VHF-band with a downlink frequency of 137.4 MHz and a bandwidth of 2.4 kHz.
- 3) BITS-2-7 (On-board Information and Telemetry System). This is a digital system in the UHF-band with a downlink frequency of 600 MHz.

Sensor complement:

The payload instruments are part of BSC (On-board Special Complex).^{851) 852)}

MSU-V = High-Resolution Multispectral Scanner (Kazan) with photodiode detectors. The instrument has a swath width of 195 km.

Band Nr.	Spectral Range	Spatial resolution
Band 1	0.45 - 0.52 μm (VIS)	50 m
Band 2	0.54 - 0.61 μm (VIS)	50 m
Band 3	0.63 - 0.73 μm (VIS)	50 m
Band 4	0.78 - 0.92 μm (VIS)	50 m
Band 5	0.91 - 0.997 μm (NIR)	50 m
Band 6	1.47 - 1.62 μm (SWIR)	100 m
Band 7	2.06 - 2.38 μm (SWIR)	300 m
Band 8	10.6 - 12.0 μm (TIR)	250 m

Table 225: Spectral parameters of MSU-V

MSU-SK = Multispectral Scanner of Moderate Resolution with conical scanning (ISDE, Moscow). Swath width = 620 km for each instrument; there are 5 spectral bands: 0.53 - 0.59 μm , 0.59 - 0.72 μm , 0.72 - 0.81 μm , 0.81 - 1.1 μm , 10.4 - 12.6 μm (TIR). Spatial resolution = 157 m x 245 m (across-track and along-track) in VNIR and 590 m x 820 m in TIR. There are two units on-board: MSU-SK1 is a forward-looking instrument, while MSU-SK2 is an aft-looking instrument - the off-nadir angle for each instrument is 39°.

MSU-M = Multispectral mechanical scanner of low resolution (ISDE, Moscow). Resolution = 1.5 km x 1.8 km, swath = 2000 km. Objective: cloud monitoring and sea surface temperature. Spectral ranges: 0.5 - 0.6 μm ; 0.6 - 0.7 μm ; 0.7 - 0.8 μm ; 0.8 - 1.1 μm . There are two units - prime and spare.

RTVK-M (Radio and TV Complex), part of MSU-M (ISDE, Moscow). The MSU-M and RLSBO instruments are integrated into one complex. Data from RLSBO (R or L) and MSU-M (1 among 4 channels) may be selected. Their information may be transmitted via a VHF (137.4 MHz) downlink to users in real-time. There are over 1000 VHF receiving stations in the ground segment.

RLSBO = Side Looking Real Aperture Radar. Wavelength = 3 cm (X-band). Resolution: 1.3 km cross-track and 2.5 km along-track. The swath width is 455 km for each instrument. There are two instruments, one looking to either side of the ground track. The near angle of incidence is $\pm 20^\circ$. Both instruments operate in parallel.

Trasser-O (Polarization Spectroradiometer-OKEAN), designed and built by STCUI-RAS (Scientific Technological Center of Unique Instruments - Russian Academy of Sciences), Moscow.⁸⁵³⁾ A non-scanning demonstration device with an off-nadir angle of 20°. Trasser introduces the technology of AOTF (Acousto-Optic Tunable Filters) in acousto-optic spectrometers (AOS). The measurement concept is based on collinear diffraction of light by ultrasonic waves propagating in an anisotropic crystal (optical radiation diffraction on bulk phase grating being generated in the quartz crystal). The AOTF technique offers a means of high-accuracy spectral monitoring in the spectral region from about 250 nm (UV) to about 4.4 μm (MWIR). The relatively new AOTF technique of optical spectra detection (by absorption, emission or scattering of light) may be employed for a number of applications such as: monitoring of atmospheric trace gases, of sea surface characteristics (biopro-

853) Information provided by V. I. Pustovoi, V. E. Pozhar, and V. N. Zhogun of STCUI-RAS

ductivity of ocean surfaces, detection of polluted ocean surfaces), and of vegetable canopies on land. ⁸⁵⁴⁾

Background: The first spaceborne AOS instrument by the name of Trasser was flown on OKEAN-O1-N3 with a launch on July 5, 1988. The instrument was operational until 1990. In parallel to Trasser, there was an airborne AOS instrument by the name of **POLAS-128** (Polarization-sensitive Acousto-optic Spectrometer) which was also used for underflights of Trasser. Both instruments operated in the visible band. They were developed and built by VNIIFTRI (All-Russian Scientific Research Institute of Physical and Radio-Engineering Measurements). Later on (1996) the Trasser work was continued at STCUI-RAS.

Spectral range	430 - 800 nm
Polarization channels	2 (H and V)
Spectral channels	62 x 2 (for each polarization channel)
Bandwidth	From 3 nm at 430 nm to 12 nm at 800 nm
Detection range on radiance spectral density	0.13-26 $\mu\text{W}/(\text{cm}^2 \times \text{nm} \times \text{sr})$
Sampling time	3.3 s per spectrum
Input angle	2° (corresponding to a spatial resolution of 45 km at spacecraft altitude of 668 km)
Off-nadir angle	20°
Detector type	PMT (Photomultiplier Tube)
Data quantization	12 bit
Sample rate	2 Hz
Size of optical head	300 mm diameter x 702 mm
Data rate	14 kbit/channel
Mass of instrument unit	15 kg optical head, 16.5 kg signal processing unit, 5 kg control unit, 9 kg power supply commutator
Instrument mass, power	30 kg, 285 W

Table 226: Technical characteristics of Trasser-O

Trasser-O consists of the following elements (see Figure 140):

- A double-channel (H,V) spectrometer
- A calibration system consisting of an internal gray lamb and a sun view through a milky glass
- A three-position movable mirror
- AOTF (Acousto-Optic Tunable Filter - virtually a tunable monochromator) consisting of two polarizers (H, V) and an acousto-optic cell. An external RF reference signal is introduced via a piezotransducer for elasto-optic crystal excitation.

AOTF principle: AOTF is a spectral element containing an elasto-optic crystal with piezo-transducer attached and two polarizers. It allows selecting radiation in the narrow spectral band with the wavelength controlled by the frequency of ultrasound supplied to the crystal. In AOTF, an anisotropic diffraction of the light beam takes place at phase volume grating caused by a running acoustic wave. Two features of this physical effect are critical for the selection. The first one is the resonance nature of acousto-optic interaction: the synchronism wavelength of light is tuned by acoustic frequency. The second feature is changing the polarization and direction of diffracted wave that permits to separate it by polarizers or diaphragms.

The current non-scanning design of Trasser instruments offers a rather limited observation coverage, a footprint of about 25 km in diameter which progresses in the along-track direction as the spacecraft moves in its ground track. This renders a coverage scheme very similar in scope to altimetric measurements. However, the overall goal of Trasser-type instruments

⁸⁵⁴⁾ V. I. Pustovoi, V. E. Pozhar, "Acousto-optical spectrometers for Earth remote sensing," Proceedings of SPIE 44th Annual Meeting, International Symposium on Optical Science, Engineering, and Instrumentation, Denver, CO, July 18-23, 1999

is to provide eventually an alternate measurement approach to conventional hyperspectral imaging systems, namely AOS imagers. For Trasser, this requires the addition of an optical front-end to the current instrument configuration, permitting a spatial cross-track scan to obtain spatial/spectral image cubes.

Figure 139: The Trasser-O instrument along with power and electronic units

Figure 140: Optical scheme of a collinear AOS (Acousto-Optical Spectrometer)

Delta-2D = Scanning Microwave Radiometer with conical scanning (SRB/MPEI, Moscow). Objective: Measurement of sea surface temperatures (SST) and monitoring of Earth surface temperatures, characteristics of arctic ice, etc. The instrument is an improved version of IKAR-P heritage flown on Priroda, providing four frequency bands. The swath width of Delta-2D is 1130 km, there are two polarizations, the off-nadir angle is 40°.

Frequency (GHz)	Wavelength (cm)	Polarization	Resolution	Noise temp. measurement error
37.5	0.8	V, H	17 km x 21 km	0.15 K
22.3	1.35	V, H	28 km x 37 km	0.15 K
13.0	2.2	V, H	49 km x 65 km	0.1 K
6.9	4.5	V, H	91 km x 120 km	0.1 K

Table 227: Parameters of the Delta-2D instrument

R-600 = Passive Microwave Radiometer, built by MPEI, Moscow. Objective: measurement of emissive microwave radiation at the atmosphere/sea surface interface. Wavelength (frequency) = 6 cm (5 GHz); The footprint of the instrument is about 165 km in diameter. There are two polarizations, the off-nadir angle is 42°.

R-225 = Passive Microwave Radiometer (built by MPEI, Moscow). Wavelength (frequency) = 2.25 cm (13.3 GHz); The footprint of the instrument is about 130 km in diameter. There are two polarizations, the off-nadir angle is 42°.

Kondor-2 is an on-board data collection system. The objective is to provide collection services for the Kondor-1 DCPs (Data Collection Platform) at 1533 MHz as well as to Kondor-3 receiving stations at 460 MHz. The data receiving rate of Kondor-2 is 500 bit/s, the transmission rate is 2 kbit/s. Kondor-2 has an on-board storage capacity of 64 kbit. - The positioning accuracy of Kondor-1 DCPs is about 3.5 km x 2.5 km in polar regions, and about 3.5 km x 20 km in the other regions.

D.27 OrbView-2/SeaStar

See OrbView-2 description under B.8.2.

D.28 PRIRODA

PRIRODA ⁸⁵⁵⁾ ⁸⁵⁶⁾ ⁸⁵⁷⁾ (=Nature) is a multisensor research module for Russia's orbital MIR station dedicated to the observation of the environment. Major institutes involved: RKA, RKK Energia, IRE-RAN, NPO Planeta, DLR/DFD. The launch of the Priroda module took place on April 23, 1996 aboard a Proton-K launch vehicle from Baikonur (MIR docking on April 26, 1996). Nominal mission life = 2-3 years.

Application: Geoecology (radiophysical methods for the study of the environment), infrared-spectroradiometric methods for the study of spatial IR-radiation of the atmosphere, spectroradiometric methods for the study of reflected solar irradiation (VNIR) in particular in the region 'atmosphere - Earth surface,' oceans, hydrology, meteorology, geology, etc.

The Priroda mission has an extensive science program. The basic mission objectives are of a research nature in the following fields:⁸⁵⁸⁾

- Land surface exploration
 - Snow cover
 - Soil investigations
 - Vegetation

⁸⁵⁵⁾ "PRIRODA," Ein Forschungsmodul der sowjetischen Orbitalstation MIR zur Fernerkundung der Erde, Wissenschaftliche Nutzlast Technische Beschreibung, Institut für Kosmosforschung (IKF), Berlin, 1990

⁸⁵⁶⁾ "PRIRODA-Experimente," Programm zur Beschaffung, Verarbeitung, Bewertung und Anwendung von Daten des Multisensorsystems PRIRODA der sowjetischen Orbitalstation MIR, 1992 -94, DARA, Berlin, Mai 1991

⁸⁵⁷⁾ "Complex for Remote Sensing of the Earth," Science Program, DLR paper 1991

⁸⁵⁸⁾ Orbital Station MIR, Complex of Remote Sensing of the Earth "PRIRODA," Scientific Program, IRE brochure, Moscow, 1991

- Earth surface mapping at different wavelength ranges for solid Earth research
- Ocean exploration
 - Global survey by using passive sensing techniques
 - Sea surface temperature determination
 - Wind speeds and direction
 - Surface roughness due to wind
 - Ocean color characteristics
 - Ocean bioproductivity investigations
 - Ice cover determination

Figure 141: Model of the PRIRODA module on the MIR station

- Atmosphere investigations
 - Large-scale atmospheric processes
 - Atmosphere-ocean interactions
 - Lower stratosphere and troposphere physical parameters
 - Ozone experiment
- Ecological investigations

The great variety of observation techniques employed by the various instruments provides synergies on many levels in the evaluation and interpretation of the data (for instance: the combination of SAR and radar altimeter data with MW radiometer data in ocean research).

Orbit (same as that of MIR): Altitude = 300 to 400 km, 51.6° inclination.

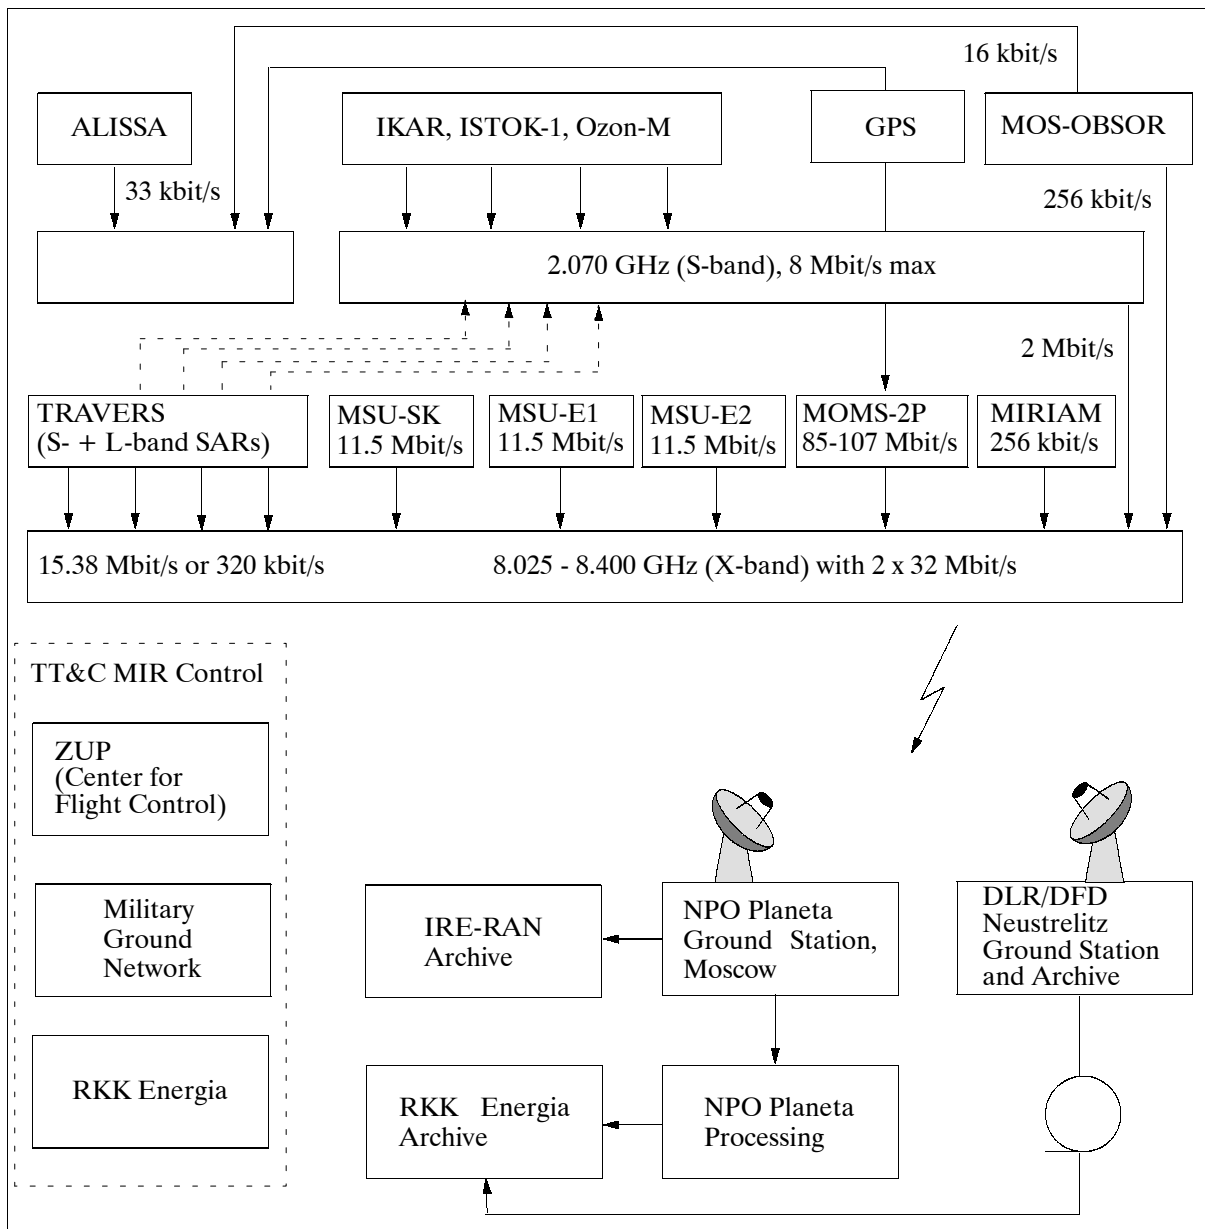

Figure 142: PRIRODA data distribution

Sensor complement:

- PRIRODA passive microwave instruments** (developed and built by SRB/MPEI (Special Research Bureau/Moscow Power Engineering Institute), consisting of the following instrument blocks: IKAR-N, IKAR-D, IKAR-P, and a scanning radiometer.⁸⁵⁹⁾

IKAR-D (DELTA): - a three-channel scanning radiometer at wavelengths of 0.3, 0.8, and 1.35 cm and a look angle of 40° from nadir.

IKAR-P: - (Panorama) a three-channel scanning microwave radiometer (RP-225) at a wavelength of 2.25 cm, and a five-channel panorama radiometer RP-600 at 6.0 cm. Both with a look angle of 40° against nadir. Objective: Measurement of sea surface temperatures (SST). Scanning is performed by a rotating reflector, a non-symmetric truncated paraboloid with a diameter of 700 mm. Conical horns serve as exciters, they separate each waveband. The reflector (mass <0.3 kg) consists of two layers of glass fiber and a radio-reflecting layer in the form of nickel coating. The look angle is 40° against nadir. The swath width is about 680 km. A full scan cycle is 2.56 s. Calibrations are performed during each scan cycle

⁸⁵⁹⁾ G. Zimmermann, "Mission PRIRODA," German Proposals to Scientific Program, DARA Bulletin, Dec. 1991

by internal noise generators and antenna views to cold space. A flat mirror, not interfering with the measurement process, is used for cold space calibrations.⁸⁶⁰⁾

Frequency (GHz)	Polarization	Beamwidth angle (3 dB)	Spatial resolution (km)	Noise temperature measurement error
36.5	H, V	1.1°	8 x 12	0.5 K
22.3	V	1.7°	15 x 20	0.5 K
13.0	H, V	3°	25 x 33	0.5 K

Table 228: Parameters of the IKAR-P instrument

The receivers are Dicke-type radiometers. The control of modulators, the synchronization of drive engine operations and the control of standard noise generators is supervised by a digital data processing unit.

IKAR-N (Nadir): - five microwave radiometers (R-30, R-80, P-135, R-225P, and RP-600) at wavelengths of 0.3 cm, 0.8 cm, 1.35 cm, 2.25 cm, and 6.0 cm in nadir direction. R-225P can also measure different polarizations. Objective: Measurement of microwave radiation (emission) at the atmosphere/sea surface interface. The IKAR-N instrument is similar to the radiometers of the IKAR-P complex. Some differences are in the construction of the receiving equipment (rectangular horns, are used for each frequency).

Frequency (GHz)	Polarization	Beamwidth angle (3 dB)	Noise temperature measurement error
89.0	V	9°	0.5 K
36.5	V, H	8°	0.5 K
22.3	V, H	8°	0.5 K
13.0	V, H	7.5°	0.5 K

Table 229: Parameters of the IKAR-N instrument

R-400: - a one-channel polarization scanner microwave radiometer. Wavelength of 4.0 cm (7.5 GHz). Look angle also 40° against nadir. Objective: Measurement of the thermal radiation of the Earth surface (radio wave range).

2) PRIRODA active microwave equipment

Travers (RSA)= Sideview radar system with synthetic aperture (SAR, measurement in two frequencies). Russian sensor, built by MEI (Moscow Power Engineering Institute). Objective: generation of radar images of the Earth's surface (land and ocean). Wavelengths of scanning beam: 9.2 cm (3.28 GHz, S-band), and 23 cm (1.28 GHz, L-band).

Parameter	S-band SAR	L-band SAR
Frequency	3.28 GHz	1.28 GHz
Wavelength	9.2 cm	23 cm
Bandwidth	5 MHz	
Peak power	300 W	1000 W
Impulse power	250 W	600 W
Compressed pulse width	0.4 ms (effective pulse), 25 ms (total duration)	
Pulse repetition frequency	3 kHz (depends on the field of regard (FOR))	
Antenna gain	37 dB	33 dB
Antenna size	2.8 m x 6 m	
Polarization	VV or HH	
Quantization	complex 4 bit	
Swath width (H=400 km)	50 km	
Resolution in azimuth:	150 m (for satellite processing)	
Resolution in azimuth:	20 m (for ground processing)	
Range resolution:	100 m	

⁸⁶⁰⁾ I. V. Bragin, V. P. Sgibnew, et al., "Space-Based Remote Sensing Complexes," Proceedings of the 29th European Microwave Conference, Munich, Germany, Oct. 5-7, 1999, Vol. 2, pp. 388-390

Parameter	S-band SAR	L-band SAR
Look angle	35°	
Data rate	16 Mbit/s (ground processing)	16 Mbit/s (ground processing)
Data rate	2.56 Mbit/s (on-board processing)	2.56 Mbit/s (on-board processing)
Orbit repetition cycle	6 days (coverage)	
Operation mode	L- and S-band operate in parallel	

Table 230: Specification of SAR Travers parameters

3) PRIRODA optical equipment, consisting of ISTOK-1, MOS-A, MOS-B, MSU-SK, MSU-E, TV camera, Ozon-M, and a lidar ALISSA.

ISTOK-1 = IR Spectroradiometric System (sounder). The ISTOK-1 apparatus consists of the following modules:

- Opto-Mechanical Block (OMB),
- Electronic Block of the IR-Spectrometer system (EBS),
- The data processing block (digital processing of video data),
- The computer block (built in Rumania)

Objective: Measurement of atmospheric irradiation for different observation angles.

- Vertical temperature profiles of the atmosphere (up to 30 km with an accuracy of 4 - 5 K) and its CO₂ band radiation.
- Altitude profile of pressure and temperature (with 0.2 km resolution).
- Humidity profiles from the measurement of the water vapor band (6.3 μm)
- Measurement of ozone content in the 9.6 μm band
- Measurement of ocean surface temperature
- Atmospheric chemistry
- Study of convective processes in the atmosphere

The IR-spectrometer consists of two identical diffraction polychromatographs for the spectral ranges of 4 - 8 μm, and 8 - 16 μm.

- Number of spectral channels: 64
- Spectral resolution (bandwidth): 0.125 μm (4-8 μm region), 0.025 μm (8 - 16 μm region)
- Sensitivity: = 1 x 10 (W/cm/sr/m) for range 1; = 5 x 10 (W/cm/sr/m) for range 2
- Radiometric resolution: 14 bit
- Spatial resolution: 0.75 - 3 km (in flight direction)
- Look angles: -15° to 132° in orbit plane; 0° to 90° in azimuth plane
- Maximum rotation rate of instrument: 2.4 degrees/s
- Data rate: 10 kbit/s

MSU-SK = Optical Multispectral Scanner - moderate resolution. (heritage: from Meteor and Cosmos 1639, the sensor is being built by the Institute of Space Device Engineering, ISDE). MSU-SK measures in four channels of the visible spectrum: (0.5 to 0.6 μm, 0.6 to 0.7 μm, 0.7 to 0.8 μm, and 0.8 to 1.1 μm) with a resolution of about 120 m; MSU-SK also measures in the infrared spectrum (10.4 to 12.6 μm, TIR) with a resolution of about 400 m. The swath width is 320 km (at altitude of 400 km).

- Look angle = 39°
- SNR for channel 1 = 70
- SNR for channels 2-5 = 100
- Noise level for channel 5 = 0.5 K
- Range of radio temperatures for channel 5 = 210 - 320 K (TIR)
- Data rate for channels 1-4 = 2.56 Mbit/s
- Data rate for channel 5 = 1.28 Mbit/s

MSU-E = Optical Multispectral Scanner (electronic scanning, CCD technology, built by ISDE). Measures in three visible channels (0.5 to 0.6 μm, 0.6 to 0.7 μm, and 0.8 to 0.9 μm);

the resolution is 20 m; the average swath width is 2 x 27 km (two devices measure in parallel, one to each side of the ground track).

- Look angles: $\pm 32^\circ$ (the instrument may be pointed in the cross-range direction, thereby extending FOV to the Field of Regard (FOR))
- Radiometric resolution: 8 bit
- Data rate for each channel: 3.84 Mbit/s

Both scanners (MSU-SK and MSU-E) are operationally coupled (for instance: two channels may be switched on MSU-SK plus three channels on MSU-E).

MOS-P (Modular Optoelectronic Scanner - Priroda). MOS is a passive pushbroom imaging spectrometer of medium spatial resolution for the visible and near-infrared spectrum (VNIR) of 0.4 - 1.01 μm . It is a nadir-viewing instrument, built by DLR/ISST, Berlin, Germany. MOS is of MKS, and MKS-M heritage which were flown on Intercosmos-21, and the space stations Salyut-7 and MIR. Another version of MOS is flown on the ISRO mission IRS-P3.⁸⁶¹⁾

Parameter	MOS-A	MOS-B
Spectral range	755 - 768 nm	400 - 1010 nm
No. of channels	4	13
Spectral channels	756.7, 760.6, 763.5, 766.4 nm	408, 443, 485, 520, 570, 615, 650, 685, 750, 815, 870, 945, 1010 nm
Spectral resolution	1.4 nm	10 nm
Swath width (H = 400 km)	80 km	82 km
Spatial resolution	2.8 km	0.7 km
Quantization	12 bit	12 bit
Measurement range	0.1 - 40 W/cm ² / nm/sr	0.2 - 60 W/cm ² / nm/sr
Data rate	4 kbit/s	210 kbit/s

Table 231: Specification of some MOS-A and MOS-B parameters

Figure 143: Principle of the MOS-P electronic imaging spectrometer

Objective: Image generation of the Earth’s surface (surface-atmosphere interaction, ocean color, phytoplankton, regional and global distributions of aerosols and its links to gaseous

⁸⁶¹⁾ A. Neumann, “Spaceborne Imaging Spectrometers for Ocean Color Remote Sensing, MOS-Priroda and MOS-IRS,” DLR/ISST paper presented at the IOC Ocean Color Workshop, Victoria, BC, September 21-22, 1995

admixtures, spectral and spatial cloudiness characteristics, etc.) in the VNIR region. The sensor apparatus consists of two complementary instruments: MOS-A and MOS-B (see also Figure 143). MOS-A is a four-channel diffraction-scanner spectrometer, specialized for observing the atmosphere-ocean system in the O₂A absorption band around 760 nm. The objective is to estimate the aerosol optical thickness and stratospheric aerosols. - MOS-B is a 13-channel spectrometer in the range of 408 to 1010 nm. The center wavelengths of the channels are chosen with the objective for the quantitative retrieval of ocean and coastal zone parameters. They also provide a capability for vegetation signature determination (red edge) and estimation of H₂O (water vapor) content in the atmosphere from the NIR-measurements. An additional calibration mechanism permits the direct measurement of solar radiation.

TV Camera

Objective: surveying the region of measurement with 256 x 256 pixels of about 900 x 900 m edge. Spectral ranges: 0.4 - 0.75 μm , look angle = 15°, spatial resolution = 300 m.

Ozon-M = Sounder apparatus for the measurement of ozone concentration and other trace gas elements in the atmosphere. (Russian sensor, Organization: INTEGRAL).

ALISSA⁸⁶²⁾ = l'Atmosphere par LIdar Sur SAlout (French sensor. Note: ALISSA did not fly on Salyut). ALISSA is conceived as a simplified fixed frequency lidar, using Mie scattering to detect clouds and aerosols. The primary objective is to study the impact of altitude determination on the description of the cloud field provided by geostationary satellites. Operation is during orbital night to minimize the difficulty of accurate system alignment. The main characteristics of the sensor are as follows:

Emitter:

- Second harmonic of Nd-Yag lasers: $\lambda = 532 \text{ nm}$
- Energy pulse: 40 mJ
- Repetition rate: 50 Hz
- Natural divergence: 10^{-3} rad
- Divergence after collimator: 10^{-4} rad

Receiver:

- Cassegrain telescope of area $A = 0.12 \text{ m}^2$
- Field of view: 10^{-3} rad
- Filter bandwidth: 0.5 nm

Energy requirements: 3 kW. The signal is analyzed by a pulse counting system with a gate of 1 μs , which provides a height resolution of: $\Delta_z = 150 \text{ m}$. The integration of six consecutive pulses (to increase the SNR) gives a horizontal resolution along the satellite track of: $\Delta_{x,y} = 1 \text{ km}$. The pulse counting system has 512 channels of 1 μs , which can be adjusted at 2, 4, 8 μs .

Energy E_0 T^2 (window)	24 mJ 83%	40 mJ 83%	24 mJ 40%	40 mJ 40%
Cumulus	200	340	50	80
Cirrus ($\tau = 0.2$)	20	30	4	7
Boundary layer	5	8	1	2
Stratospheric aerosol ($R = 2$)	1	2	0.2	0.4

Table 232: Number of photoelectrons expected for six pulses

ALISSA science objectives:

- The cloud radiation problem: improving retrieval of large-scale cloud cover and cloud property data.

⁸⁶²⁾ M. L. Chanin, M. Desbois, A. Hauchecorne, "ALISSA a French Russian cooperation in the PRIRODA mission." Paper of CNRS - Service d'Aeronomie

- The cloud radiation problem: interpreting small-scale structures of cloud tops
- Measurement of tropospheric aerosols and the boundary layer.
- Stratospheric studies.

MIRIAM (MIR Infrared Atmospheric Measurements). MIRIAM is a sun occultation experiment for atmospheric trace gas spectroscopy. The instrument (German/Russian) was developed by the “Freie Universität, Berlin” (PI: R. Furrer) and by the St. Petersburg State University, St. Petersburg (PI: A. V. Poberovsky), Russia, using the FTIR (Fourier Transform Infrared) spectrometer technique (capable of sun radiation slant path IR absorption measurements during orbital sunsets) from satellites.^{863), 864)}

The objective of MIRIAM is to gather long-term datasets (vertical profiles) of various trace gases, like: O₃, N₂O, CO, CH₄, NO, SO₂, NO₂, HNO₃, HF, HCl, NH₃, OCS, HCN, CH₃Cl, C₂H₂, H₂O, HBr, ClO, HOCl, H₂O₂, OH, H₂CO, C₂H₆, etc.

The FTIR-spectrometer is mounted outside the PRIRODA module in a hermetic (N₂-pressurized) container. Solar radiation enters the spectrometer via an active suntracker and a telescope. The light passing the beamsplitter (potassium bromide) separates into two beams prior to entering the retro-reflector arrays. The amplified detector signal is noise-filtered before A/D conversion (14 bit resolution). Prior to Fourier transformation the signal biases are removed; the interferograms are apodized with a Hamming window.

Type of instrument	Fourier Michelson Interferometer
Design	rapid scan double pendulum with multi-pass capability due to retro-reflectors
Spectral range	2.5 - 20 µm (or 4000 - 500 cm ⁻¹ wavenumber range)
Spectral resolution	0.01 cm ⁻¹ , double sided, apodized
Vertical resolution	1 - 2 km
Bandwidth	ca. 4000 cm ⁻¹
Scan time	1 second
Detector type	CMT
Beamsplitter	KBr with Germanium coating
Mirrors	Zerodur with gold coating
Telescope	Cassegrain, 70 mm diameter, copper with gold coating
Spectrometer size	85 cm x 50 cm x 20 cm
Repeat coverage	2 months
Instrument mass	100 kg
Data points/spectra	max. 1,000,000

Table 233: Technical specification of MIRIAM

4) MOMS-2P (Modular Optoelectronic Multispectral/Stereo Scanner - 2 Priroda)

Mission context: MOMS-2P is a German imaging instrument on Priroda, a module of the Russian MIR space station. Part of the MOMS-2P instrument (the optical module, which is mounted on the outside of PRIRODA) was launched by a Progress M-31 launch vehicle on May 5, 1996 (docking of Progress at MIR on May 7, 1996). The Progress launch was a regular service flight to MIR, it was preceded by the PRIRODA launch on a Proton vehicle on April 23, 1996. MOMS-2P on Priroda is a modified MOMS-02 (of D2 Shuttle mission heritage, see J.13) instrument featuring an additional integrated navigation package (GPS receiver + Gyro), referred to as MOMSNAV (MOMS Navigation) for more accurate attitude and orbit determination, hence ground positioning of the data. MOMS-2P is a DLR instrument, sponsored by DARA, built by DASA/DSS and by Kayser Threde GmbH (MOMSNAV). Portions of the MOMS-2P (camera system) and the MOMSNAV package (two GPS

⁸⁶³⁾ R. Furrer, H. Rubin, M. Schaale, A. V. Poberovsky, A. V. Mironenkov, Y. M. Timofeyev, “MIRIAM - A Spaceborne Sun Occultation Experiment for Atmospheric Trace Gas Spectroscopy,” *GeoJournal* 32.1, January 1994, pp. 17-27

⁸⁶⁴⁾ “MIRIAM 1995-1998 MIR-Infrared Atmospheric Measurements - Untersuchung der Atmosphäre aus der Raumstation MIR,” Institut für Weltraumwissenschaften an der Freien Universität Berlin, 1994

antennas, two redundant gyro sensor blocks, one gyro electronics unit) are mounted onto the outside of the Priroda module. MOMS-2P is being operated from DLR/GSOC via ZUP, Moscow. ⁸⁶⁵⁾ ⁸⁶⁶⁾ ⁸⁶⁷⁾ ⁸⁶⁸⁾

MOMS-2P is a modular instrument with a total of five optical systems: three are dedicated for stereoscopic imagery, two are employed for multispectral imagery, one (central lens) is used for high-resolution data. Two linear CCD (Charge-Coupled Device) arrays are optically combined in the focal plane of the center lens in order to obtain a sufficiently wide swath. Along-track stereo imagery is obtained with the center lens (ch. 5) and two tilted (forward and backward) lenses (ch. 6 and ch.7). The focal length of the tilted lenses was chosen in such a way as to obtain an integral relationship between the ground pixel sizes seen by the center lens and the two tilted lenses; this ratio is 1:3. Each of two MS lenses (ch. 1,2,3,4) also optically combine two linear CCD arrays in the focal plane for a wider swath. Data quantization: 8 bit with seven gain steps [uncompressed for MS and stereo, 6 bit compressed for stereo and HR (High Resolution) data]. Each CCD array features 6000 elements (10 μ m per element).

Channel	Mode	Orientation	Bandwidth	Ground Pixel Size	IFOV	Swath Width	Focal Length
1	MS	nadir	449-511 nm	18 m x 18 m	45.45 μ rad	105/50 km	220 mm
2	MS	nadir	532-576 nm	18 m x 18 m	45.45 μ rad	105/50 km	220 mm
3	MS	nadir	645-677 nm	18 m x 18 m	45.45 μ rad	105/50 km	220 mm
4	MS	nadir	772-815 nm	18 m x 18 m	45.45 μ rad	105/50 km	220 mm
5 (PAN)	HR	nadir	512-765 nm	6 m x 6 m	15.15 μ rad	60/50 km	660 mm
6 (PAN)	Stereo	+ 21.4°	524-763 nm	18 m x 18 m	42.16 μ rad	105/50 km	237.2 mm
7 (PAN)	Stereo	-21.4°	524-763 nm	18 m x 18 m	42.16 μ rad	105/50 km	237.2 mm

Table 234: Performance parameters of MOMS-2P (400 km orbit)

MOMS-2P operations are limited by the data rate of the on-board tape recorder of 100 Mbit/s. It implies that all channels cannot be operated simultaneously. A set of four operational modes are defined combining different channels for various applications. Table 235 summarizes the four modes with the corresponding numbers of pixels per imaging line. The tape recorder allows a maximum tape capacity of 48 GByte corresponding to a recording time of 80 minutes for an average data rate of 10 MByte/s.

The MOMS-2P objectives cover applications in the fields of photogrammetry, land cover, geomorphology, ecology, basic research in the spectral signatures of rocks, soil, vegetation, etc. The following capabilities are provided:

- Three-line linear stereo imagery of high spatial resolution and pointing accuracy
- Along-track stereo capability in panchromatic or in defined multispectral (MS) modes
- Detection of surface materials by optimized position bands and detection of small-scale textures of the Earth's surface.

The MOMS-2P instrument is being operated by means of timelines stored onboard the Priroda module. Mission planning selects target areas for imaging along with all information required for execution. A set of four operation modes have been defined, combining different channels to be selected for various applications. The following modes are being operated during the mission:

⁸⁶⁶⁾ Protocol of the Meeting of Specialists of USSR and Germany on MOMS-2 for the PRIRODA Mission. DLR paper, May 1991

⁸⁶⁷⁾ D. Meißner, et. al., "The MOMS-2P Instrument and its Mission on Priroda/MIR Station," IAF-96-B.4.03, 47th International Astronautical Congress, Oct. 7-11, 1996, Beijing, China

⁸⁶⁸⁾ DASA Endbericht, "MOMS-02P auf Priroda/MIR," Doc. No. M2P-DAS-100-RP-001.0, Dec. 12, 1996

Mode/Channel	1	2	3	4	5a	5b	6	7	Swath (km)
Mode A/No. of pixels					4152	4152	2976	2976	50
Mode B/No. of pixels	5800	5800	5800	5800					105
Mode C/No. of pixels		3220	3220	3220	6000				36 (58)
Mode D/No. of pixels	5800			5800			5800	5800	105

Table 235: Operational modes of MOMS-2P

Mode A: Bands 5a, 5b, 6, and 7 allow for the calculation of three-band stereo models, i.e. high precision DTM (full stereo mode).

Mode B: Bands 1, 2, 3, and 4 in various combinations as color composites as well as digital data serve as base for thematic applications like classification relative to lithology, pedology, vegetation etc. (full spectral mode).

Mode C: Bands 2, 3, 4, and 5a fulfil the requirements for the generation of various standard image processing products by use of the three spectral bands, the additional application of the high resolution panchromatic band, and consideration of suitable algorithms (multi-spectral channel plus HR nadir channel).

Mode D: Makes use of 2 multispectral channels plus two stereo channels (channels 1,4,6,7). It permits DTM generation and thematic applications.

The MOMS-2P source data (along with housekeeping and navigation data) are recorded onto an on-board tape recorder and are transmitted to a ground receiving station (DFD Neustrelitz) during overpasses.

Other MOMS-2P observation restrictions are due to energy budget limitations of the MIR station and/or particular MIR orientations unsuitable for remote sensing.

MOMS-2P calibration:

Geometric calibration. Refers to the generation of exact object side angles for a precise photogrammetric three-dimensional reconstruction of the Earth's surface (considering all geometric scanner influences such as irregularities of the CCD arrays, bending of the focal planes, optical distortions, etc.).

Geometric inflight calibrations are performed on a set of precisely known ground targets in conjunction with navigation data (MOMSNAV). The Catalonia test site in Spain is being used (several times per month) during the commissioning phase.

Radiometric calibration. This method employs a set of ground targets with known spectral signatures.

Sun calibration. The cover of the MOMS-2P camera is coated on the inside with a diffuse reflecting coating. When opening the cover it can be locked at an angle of 20°. A sun calibration is performed by pointing this cover toward the sun. The measurements obtained are compared with data from inflight calibration for reasons of verification.

MOMSNAV (MOMS Navigation).⁸⁶⁹⁾ An integrated navigation package built by Kayser-Threde (Munich) with the objective to provide accurate location knowledge to MOMS-2P imagery. MOMSNAV is a DGPS-based navigation package consisting of the following elements: two GPS antennas, two redundant gyro sensor blocks, one gyro electronic unit, and an electronic box. The instrument provides navigation data which is used in post-processing in combination with the image data. MOMSNAV location knowledge accuracy of the imagery is ≤ 5 m horizontal (1σ), the relative attitude accuracy is ≤ 10 arcseconds (1σ). Instrument mass = 41 kg, power = 70 W (average).

Figure 144: Scheme of overlapping FOV's of PRIRODA sensors ⁸⁷⁰⁾

Data Distribution: Priroda has six on-board data recorders with a capacity 6 Gbit each. One recorder is used for the recording of SAR data, four recorders are used for all other data,

⁸⁷⁰⁾ IKAR-D, -P and MSU-SK with forward look angle (in flight direction) of 40° against nadir

one recorder is in reserve. PRIRODA sensor data are transmitted to two ground stations, one at RKK Energia in Obninsk, the other at DLR/DFD Neustrelitz, Germany. RKK Energia preprocesses all sensor data and provides all required ancillary data. The time delay for preprocessing is currently projected for about 1 week after data reception.

Agreements relating to data sharing have been concluded between IRE and its partners (the sensor providers and countries participating in the PRIRODA mission) who have primary access to all science data and ancillary information. MOS-OBSOR and MOMS-2P sensor data is being processed and archived by DLR/DFD Neustrelitz as the responsible data center for all German users. Thematic processing may be done at the user sites (SAR Travers data calibration is being planned at DLR in Oberpfaffenhofen). Data transfer from Moscow to Germany may be provided via suitable transportable storage media (Exabyte) or via Eutelsat satellite communication.

D.29 RADARSAT

The origin of Canada’s RADARSAT program resides in the necessity to monitor those parts of Canada that are covered with clouds and ice for large portions of the year.

D.29.1 RADARSAT-1

RADARSAT-1⁸⁷¹⁾ is a collaborative Canadian developed and operated (CSA = Canadian Space Agency) Earth observation satellite with a microwave (SAR) instrument. Launch: November 4, 1995. NASA is a major partner in the mission, providing launch services with a Delta II vehicle from Vandenberg AFB, in exchange NASA receives RADARSAT data at ASF, Fairbanks Alaska. The S/C prime contractor is Spar Aerospace Ltd. of Toronto, Ontario (Ball Aerospace & Technologies Corp. of Boulder, CO provided the spacecraft bus).⁸⁷²⁾

Field of application	Description
Agriculture and land cover monitoring	Measure of soil moisture, assess crop conditions, update land cover maps
Forestry (boreal and tropical)	Detect clear cuts, update forest inventories, map depletions, map forest fires, assess regeneration, monitor land use changes
Geology	Detect structural and lithologic features, assess geo-hazards (landslides), extract geomorphological information
Hydrology	Measure flood extent, improve hydrological modeling, assess flood damage
Coastal zones and oceans	Detect and track vessels, detect wind and wave spectra, detect mesoscale ocean features, monitor coastline changes
Cartography and land use	Update topologic maps, create digital elevation models, create land use and land cover maps

Table 238: Overview of some key RADARSAT applications

S/C characteristics: three-axis-stabilized with attitude sensors (horizon scanners, sun sensors and magnetometers), momentum wheels and yaw maneuver capability (the S/C uses a set of orthogonally mounted reaction wheels operating around a nominal momentum set point to achieve positive three axis control at all times); momentum desaturation is accomplished with magnetic torque rods. S/C pointing accuracy of 0.1°, pointing knowledge of 0.05°. S/C mass = 3200 kg, payload mass = 1500 kg; solar array power = 3.4 kW BOL (2.9 kW EOL); battery: 3 NiCd (48 Ah); TT&C link in S-band; fuel: 67 kg hydrazine (orbit adjustment and restitution); design life = 5 years.

871) R. K. Raney, A.P. Luscombe, E.J. Langham, S. Ahmed “RADARSAT,” reprint from Proceedings of the IEEE, Vol. 79, No. 6, June 1991
872) RADARSAT Annual Review 1997/98, CSA brochure, p. 19

Orbit: Near circular sun-synchronous dawn-dusk orbit at an altitude of 798 km; inclination = 98.6° , ascending node at 18:00 (6 PM equatorial crossing); period = 100.7 min; repeat cycle = 24 days (subcycles of 7 and 17 days); the dawn-dusk orbit has the following advantages:

- The platform is in near continuous solar illumination, providing equivalent opportunities for image acquisition during ascending and descending passes (energy consumption).
- A late equatorial crossing time reduces reception conflicts with other remote sensing satellites

Figure 145: The RADARSAT-1 S/C model and illustration of observation geometries

Sensor:

SAR (Multi-Mode instrument; observation in C-band (5.3 GHz, 5.6 cm wavelength, RF bandwidth: 11.6 MHz, 17.3 MHz, or 30.0 MHz; transmitter power: up to 5 kW), transmitting and receiving horizontally polarized radiation. Choice of three transmit pulses and selection of numerous beams permit a wide range of swath widths, incidence angles and

image resolutions. The SAR instrument can operate at a ‘high duty cycle’ capable of imaging for up to 28 minutes per orbit (orbital period of 101 minutes).

Special SAR design features: calibration, rapid data processing, a phased array antenna to provide controlled beam steering, and the first satellite implementation of a radar technique known as ScanSAR. The SAR antenna dimensions are: 1.5 m x 15 m (built by CAL Corp.). The antenna comprises one fixed and four deployable panels, each with 32 slotted waveguides fed by beam-forming networks which produce the varied coverage swaths of the radar.

ScanSAR is a technique permitting extended observation coverage (wider swath) on command. In this mode, rapid steering of the elevation beam pattern of the antenna is essential. Extended range coverage can be obtained by using a set of contiguous beams, enabling images to swath widths of up to 500 km. This is accomplished at no increase in mean data rate from the sensor, but at the cost of degraded resolution of the resulting image. The principle of ScanSAR is to share radar operational time between two or more separate sub-swaths in such a way as to obtain full image coverage of each.

Mode	Resolution m) [*] (Range x Azimuth)	Looks ^{**}	Swath Width (km)	Incidence Angle (°)
Standard	25 x 28	4	100	20 - 49
Wide (1)	48-30 x 28	4	165	20 - 31
Wide (2)	32-45 x 28	4	150	31 - 39
Fine Resolution	11-9 x 9	1	45	37 - 48
ScanSAR (N)	50 x 50	2-4	305	20 - 40
ScanSAR (W)	100 x 100	4-8	510	20 - 49
Extended (H)	22-19 x 28	4	75	50 - 60
Extended (L)	63-28 x 28	4	170	10 - 23

Table 239: RADARSAT imaging modes ⁸⁷³⁾

Data:

On-board recording capability of the total stream for up to 10 minutes (satellite outside of receiving station range). Downlink: two parallel X-band channels at 105 Mbit/s for real-time data and at 85 Mbit/s of recorded data. Ground stations: Prince Albert (Saskatchewan), Gatineau (Quebec), Fairbanks (Alaska). The RADARSAT-1 reception stations are compatible with ESA’s ERS series. Data distribution by RADARSAT International Ltd. (RSI) of Ottawa. RSI also distributes SPOT, Landsat, and JERS-1 data in Canada.

AMM (Antarctic Mapping Mission). During the period September 9-11, 1997, RADARSAT-1 underwent a successful maneuver to rotate its normally right-looking radar array into a left-looking attitude. This shift involved rotating the satellite by 180° in yaw. Although other missions do regular yaw maneuvers to reorient S/C, RADARSAT-1 was the first satellite to perform this maneuver to map the entire Antarctic continent, including the South Pole. Note: Complete coverage of Antarctica was not possible with existing or previous spaceborne sensors because of their orbit inclination and/or field of view capability. Almost 70% of the Earth’s fresh water is contained in the Antarctic region - changes in this enormous reservoir directly influence world sea levels and climate. The mapping of Antarctica began September 26 and lasted 18 days, followed by another yaw maneuver. Routine operations with the right-looking mode resumed November 4, 1997.

D.29.2 RADARSAT-2

RADARSAT-2 is a jointly-funded satellite mission of CSA (Canadian Space Agency) and MDA (MacDonald Dettwiler Associates Ltd. of Richmond, BC), representing a Canadian government/industry partnership in a commercial venture. In Feb. 1998, CSA awarded a

⁸⁷³⁾ * Nominal: range dependent and processor dependent; ** Nominal: ground range resolution varies with range

contract to MDA to build RADARSAT-2. The contract calls for MDA to develop, own and operate RADARSAT-2 and related infrastructure. CSA provides a fixed financial contribution to MDA (about 75%), in exchange for imagery allocation from the S/C to government agencies. Also, ORBIMAGE, an affiliate of Orbital Sciences Corporation, is a significant participant in this program as the exclusive distributor of RADARSAT-2 imagery to U.S. customers.^{874) 875) 876)}

US space policy, regulations related to the export of satellite and rocket technology as well as to the distribution of high-resolution imagery, caused CSA in January 2000 to cancel an existing satellite bus contract with OSC and to award a new contract to Alenia Aerospazio of Rome, Italy.

RADARSAT-2 is an advanced follow-on satellite mission of RADARSAT-1 with the objective to: a) continue Canada's RADARSAT program and to develop an Earth Observation satellite business through a private sector-led arrangement with the federal government, b) provide data continuity to RADARSAT-1 users and to offer data for new applications tailored to market needs..

Figure 146: Illustration of the RADARSAT-2 satellite

The S/C, consisting of a bus module and a payload module, is built by Alenia Aerospazio (based on PRIMA, a reconfigurable bus developed for the Italian Space Agency) with bus dimensions of 3.7 m (height) by 1.36 m (diameter). The phased array SAR antenna, built by EMS of Montreal, has 8192 radiating elements fed by 512 T/R modules. The overall antenna size is 15 m by 1.5 m. The S/C is three-axis stabilized. ACS (Attitude Control Subsystem) is using star trackers for precision pointing. Attitude knowledge is $\pm 0.03^\circ$, attitude control is $\pm 0.05^\circ$ (3 sigma in each axis). The GPS receiver provides real-time position knowledge of ± 60 m. Image location knowledge is < 300 m at downlink, and < 100 m for processed imagery. S/C mass at launch is 2600 kg., power of 915 W (two solar panels with dimensions: 3.73 m x 1.8 m, each), one Nickel-hydrogen battery with 89 Ah. The design life is seven years. RADARSAT-2 provides several new imaging modes, such as polarimetric imagery (retrieval of full vectorial polarization information), ultra-fine (3 m resolution) beams, in addition to preserving all RADARSAT-1 modes. A launch of RADARSAT-2 is planned for 2003.

Orbit: Sun-synchronous polar orbit, altitude = 798 km, inclination = 98.6° , period = 100.7 min (14 orbits/day), ascending node = 18:00 hrs, repeat cycle = 24 days. RADARSAT-2 is in the same orbit as RADARSAT-1, separated by 30 minutes (and having the same ground track and repeat cycle as RADARSAT-1). This facilitates proper ground station scheduling. In addition, the tandem flight configuration of RADARSAT-1 and -2 provides a wealth of interferometric applications.

Sensor complement:

SAR (Synthetic Aperture Radar). The SAR instrument specification is outlined in Tables 240 and 241 with the following functional capabilities:

- Operationally, the SAR instrument is identical to that of RADARSAT-1 (with regard to mission control, mission planning, and data collection and processing)
- Fully integrated into the RADARSAT-1 ground segment
- Supports tandem mission operations with RADARSAT-1
- All RADARSAT-1 image quality specifications are met or exceeded
- A 3 m ultra-fine resolution is provided
- A selectable incidence angle and the choice of **left- and right-looking imaging capability** is provided with the ability to maneuver the S/C on command. This feature offers much quicker revisit times for handling user requests.
- Provision of fully polarimetric imaging modes
- An increased downlink power permits the use of 3 m antenna dishes for ground receiving stations
- The encrypted downlink science data stream maintains service confidentiality
- The utilization of on-board GPS receivers offers real-time position knowledge within 60 m
- The functional exploitation of solid-state recording technology permits the provision of new customer services (selection of image scenes and receiving station)

Frequency	5.3 GHz, C-band (5.6 cm wavelength)
RF bandwidth	11.6, 17.3, 30 or 100 MHz
Transmitter power (peak)	1650 W (normal mode), 2280 W (ultra fine mode)
Antenna	Size: 15 m x 1.5 m; type: active phased array antenna
Antenna polarization	Simultaneous reception of two polarizations: H and V or LHC and RHC. Selectable transmission of one H, V, LHC or RHC polarization. Quad polarization beams allow dual transmit polarization and dual receive polarization.
Imaging mode delay time	10 ms
X-band downlink margin at 5° elevation	9 dB (allows 3 m receiving ground station antenna)
Data rate (max)	105 Mbit/s [recorded (encrypted) and realtime]

Table 240: SAR instrument parameters

	Beam modes	Nominal swath width	Incidence angles to left or right side	Nr. of looks	Spatial resolution (approx.)

	Ultra-fine narrow	10 km	30°-40°	1	3 m x 3 m

Table 241: SAR imaging modes of RADARSAT-2

Agreements between CSA and MDA make MDA the S/C owner and operator. The RADARSAT-2 ground segment is also owned and operated by MDA. This includes the re-use

of the existing RADARSAT-1 infrastructure where possible. CSA's investment will be recovered through the supply of imagery to a number of Canadian government agencies during the mission lifetime. RSI (as well as others) are a commercial distributors of imagery.

Data communication: An on-board recorder (capacity = 2 x 128 Gbit BOL and 100 Gbit EOL) provides recording of the source data outside of the receiving station range. Downlink of two parallel X-band channels at 105 Mbit/s for real-time data reception.

D.30 RADCAL (Radar Calibration Satellite)

A microsatellite built by CTA Space Systems of McLean, VA for the USAF under the Small Test and Small Launch Vehicle (ST&SLV) program. The satellite is hexagonal in shape with 762 mm diameter, it has a total mass of 87kg. It is passively stabilized to a nadir-pointing attitude by a gravity gradient boom and magnetic nutation dampers (magnetorquers and magnetometer). A prime objective is to provide space-based radar cross-sectional area calibration (via two C-band transponders) for more than 70 military and civilian radars operating in C-band (the S/C position is known to a fair degree of accuracy, thus allowing ground-based users to calibrate their systems by acquiring the RADCAL satellite and comparing their position with the "known" position). A further objective is to demonstrate spaceborne GPS-based attitude determination. RADCAL also carries a peak power tracker and a UHF Store and Forward payload. The design mission life is three years.

The S/C was launched on June 25, 1993 on a Scout launch vehicle from VAFB, CA. Mission design life is 1 year with a 3-5 year goal. The satellite transmits/receives at 306.775 MHz.⁸⁷⁷⁾
⁸⁷⁸⁾

Initial S/C operations were performed from SMC (USAF/Space & Missile Systems Center at Los Angeles AFB). Since November 1996 RADCAL is controlled from Kirtland AFB, NM (SMC/TEO).

Orbit: Near-circular polar orbit, altitude = 815 km x 765 km, inclination = 89.5°.

Sensor complement:

TANS Quadrex GPS receiver (Trimble Navigation). Objective: to demonstrate post processing attitude determination Two receivers (channels: 6+6, L1 C/A) were modified by Stanford University to measure the differential phase of GPS signals arriving at four micro-strip patch antennas mounted on the zenith face of the vehicle and canted outward 17.5°. The phase differences between each of three slaves and a master antenna are downloaded for post-processing.

SSPSR (Small Satellite Power System Regulator), built by PL. The objective is to test improved methods for battery charging.

D.31 RESURS-F

The Russian/CIS Resurs-F⁸⁷⁹⁾ (Resource-F, F1 and F2) satellite series is a photoreconnaissance S/C with short mission lifetimes, in the order of 14 to 30 days [built by TsSKB-Progress (Central Specialized Design Bureau Progress), Samara]. The on-board sensors are film cameras whose data (namely, the films) are recaptured after the end of each mission (Vos-

⁸⁷⁷⁾ L. M. Ward, P. Axelrad, "A Combined Filter for GPS-Based Attitude and Baseline Estimation," *Navigation: Journal of The Institute of Navigation*, Vol. 44, No. 2, Summer 1997, pp. 195-213

⁸⁷⁸⁾ L. M. Ward, P. Axelrad, "Spacecraft attitude estimation using GPS: Methodology and results for RADCAL,," *Navigating the 90s: Technology, Applications, and Policy*, Proceedings of The Institute of Navigation, National Technical Meeting, Anaheim, Calif., 18-20 January, The Institute of Navigation, Alexandria, Va., pp. 813-825.

tok-based film-return craft, the film camera systems are returned in small spherical descent capsules, which are reused an average of three times). The altitude of the orbit is changed during the mission from 400 km to 170 km.⁸⁸⁰⁾

Objective: Provision of high-resolution photographic images of the Earth's surface. Monitoring of natural resources, ecology studies, etc.

Basic Orbit:

F1: Near-circular polar orbit (non-sun-synchronous). Altitude = 275 km, inclination = 82.3° .

F2: Near-circular polar orbit (non-sun-synchronous). Altitude = 240 km, inclination = 82.3°

The Resurs-F1 S/C was space-tested in 1975-80, the Resurs F2 S/C in the period of 1989-90. The F1 typically flies missions of two weeks' duration (up to 11 days in standby mode) with three KFA-200 and 2 KFA-1000 cameras on-board. F2 undertakes 30 day missions in lower orbits using the MK-4 camera apparatus.

The S/C angular orientation is in an orbital coordinate system with an accuracy of $\pm 1.5^\circ$ for roll, pitch and yaw angles and $\pm 0.01^\circ/\text{s}$ for angular velocities. Both types of S/C are equipped with an orbit correction engine. The launch site for F1 and F2 is Plesetsk with a Soyuz launch vehicle. Launches of the Resurs-F series are carried out mainly in the spring and summer seasons. Annually between two or three F1 and one or two F2 S/C are launched, depending on user requirements.⁸⁸¹⁾

Since October 1990 the data products of the Resource-F series have been commercially distributed by State Center 'Priroda' (4b Str. Pervomajskaja, Moscow; in Germany by GAF = Gesellschaft für Angewandte Fernerkundung, in the US through Central Trading Systems, Fort Worth, Texas).

Figure 147: The Resurs-F2 S/C model

Sensor complement:

- **KFA-200** Camera System. Focal length = 200 mm, swath width = 0.9 altitude (245 km), duty cycle = 12%. KFA-200 provides images in three ranges: 0.5 - 0.6 μm , 0.6 - 0.7 μm ,

879) 'Sowjetisches kosmisches System zum Studium der Naturschätze der Erde und zur Umweltkontrolle - der heutige Stand und die Perspektiven für den Zeitraum 1991 -1995,' the paper is a translation of a presentation given by L. Dessinow of the USSR Academy of Sciences in 1989.

and 0.7 - 0.9 μm . The cameras provide synchronous images of the Earth surface in an image format size of 180 x 180 mm to a scale of 1 : 10⁶. Spatial resolution is between 25 and 30 m. These images provide very suitable correlation data for color synthesis in the-matic data products. The geometric properties of the images permit photogrammetric analysis. The precision of altitude determination (method of image triangulation) is in the order of 50 m.

- **KFA-1000** Camera System. Focal length = 1000 mm, swath width = 0.3 altitude (82 km for one camera), duty cycle = 12%. KFA-1000 provides spectro-zonal and panchromatic images. The concept employs a fan-like mounting configuration of two cameras (with a large focal length and wide format) in order to achieve an extra wide swath wide of 120 to 165 km. The film width is 300 mm. The scale of the images (focal length of 1000 mm) is 1 : 200 000 - 1 : 270 000, the resolution on ground (terrain) is 5 - 10 m. The total number of images of one film is about 1800. Spatial resolution = 8 - 10 m.

Table 244: Survey of Resurs-F series satellite launches in chronological order ⁸⁸³⁾ ⁸⁸⁴⁾

⁸⁸³⁾ Courtesy of E. L. Lukashevich of State Center Priroda, Moscow

⁸⁸⁴⁾ Note: For S/C No. 37 and (39), the orbit was changed from an altitude of 275 km (275 km) to an altitude of 355 km (180 km), respectively

D.32 RESURS-O

Resurs-O1⁸⁸⁵⁾ is an operational Russian/CIS satellite series (operator: NPO Planeta; S/C integrator: VNIIEM, Moscow). The objective is observing and monitoring natural resources (similar in function and objectives to the Landsat series). Operation of the Resource-O1 series was started in 1985 and is planned to continue at least until 2000 (and beyond). Applications: observation of the state of agricultural crops, assessment of hydrological conditions, forest and tundra fires, pollution monitoring.⁸⁸⁶⁾

Satellite	Launch Date	Orbit	Sensor Complement or payload	Remarks
Resurs-O1-1	Oct. 3, 1985 to Nov. 11, 1986	Perigee = 574 km Apogee = 663 km Inclination = 98°	MSU-E, MSU-SK, SAR-Travers	Analog sensor output and digital transmission
Resurs-O1-2	April 20, 1988 (operational until June 1, 1999)	Perigee = 620 km Apogee = 678 km Inclination = 98°	MSU-E, MSU-SK	Analog sensor output and digital transmission
Resurs-O1-3	November 4, 1994 Operational	Perigee = 660 km Apogee = 690 km Inclination = 98°	MSU-E, MSU-SK, RRA with SAFIR/R satellite	Analog sensor output and digital transmission
Resurs-O1-4	July 10, 1998 Operational	Sun-synchronous Altitude = 835 km Inclination = 98.7°	MSU-E1, MSU-SK1, MP-900B, RMK-2, ScaRaB, ISP-2, NINA, IRIS	Digital sensor output and digital transmission
Resurs-O1-5	2003	Sun-synchronous Altitude = 630 km Inclination = 98.7°	RLSBO, optical and microwave sensors	

Table 245: Overview of Resurs-O mission program

Orbit: sun-synchronous orbit, altitude = about 650 km, inclination = 98°, period = 97 minutes. Orientation accuracy = 6 arc/min along the velocity vector; service life = 2 (3) years, payload mass = 420 kg (Resurs-O1) series. Note: the Resurs and Meteor series S/C have the same platforms, they are being designed and built by VNIIEM, Moscow. Note 2: the Resurs-O-1 S/C and up have a higher orbit than the Resurs-O1-1 to -O1-3 series. Resurs-O1-4: Sun-synchronous orbit, altitude = 835 km, inclination = 98.7°. Communication: X-band downlink at 8192 MHz, data rate of 7.68 Mbit/s.

Sensor complement:⁸⁸⁷⁾

MSU-E = High-Resolution Multispectral Scanner with Electronic Scanning (for Resurs-O1-1 to O1-3). Three spectral ranges of 0.5 - 0.6 µm, 0.6 - 0.7 µm, 0.8 - 0.9 µm are provided. Spatial resolution = 45 m x 33 m; swath = 45 km (for one device), and 80 km for both devices (some overlapping), repeat cycle = 18 days. MSU-E has a look angle of ±32° (the instrument may be pointed in the cross-range direction thereby extending potential coverage to a 600 km wide strip (±300 km to each side of the S/C). The observation direction of the instrument can be set by ground commands in steps of 2°. The scan rate of MSU-E is 200 lines/s.

MSU-E1 (Note: Resurs-O-1 has a higher orbit than Resurs-O1-1 to -3). For Resurs-O-1 and up, there are changes with regard to: a) look angle of ±30°; and b) swath width = 60 km (for one instrument), the two MSU-E1 devices provide a total swath of 105 km. Otherwise same specification as for MSU-E.

MSU-SK = Multispectral Scanner of moderate resolution with a conical scanning device and a look angle of 39°. This gives the sensor the advantage that although it is a wide field

887) Information provided by B. Kutuza of IRE, Moscow, and translated by B. Zhukov of DLR, Oberpfaffenhofen

sensor, it produces constant resolution and viewing angle for all pixels, resulting in increased radiometric accuracy. Spectral bands (5): 0.5-0.6, 0.6-0.7, 0.7-0.8, 0.8-1.1, and 10.4 - 12.6 μm . Spatial resolution = 170m (in VIS) and 600 m (TIR). Swath = 600 km, potential repeat cycle = 3-5 days, orbit repeat cycle = 21 days. The scan rate is 50 lines/s in channels 1-4 and 12.5 lines/s in channel 5. The unusual scanner allows the MSU-SK instrument to have an absolute radiometric error of just 1%, a Signal-to-Noise Ratio (SNR) of 80 dB and a noise equivalent temperature of 0.5 K. Data quantization is at 8 bits. Instrument mass = 21kg. Downlink limitations: four out of five bands may be downlinked simultaneously.

Figure 148: The Resurs-O S/C model

MSU-SK1. Instrument for Resurs-O-1 and up. Spatial resolution = 210 m (VIS) and 700 km (TIR). Otherwise same specification as for MSU-SK. An additional spectral band (3.5 - 4.1 μm) was used for Resurs-O1-4 only.

ISP-2 (Izmeritel Solnechnoy Postoyannoy-2 - a Solar Constant Instrument). The objective is the measurement of the integral solar irradiation (solar constant) and of the shortwave reflected radiation of the Earth system. It is being used to complement the ScaRaB measurements. The ISP-2 radiometer consists of two channels with bolometer detectors:

- Solar constant channel: spectral band of 0.2 - 10.5 μm , FOV = 5°, accuracy of one measurement = 0.05%, accuracy of day-averaged measurements = 0.01%.
- Reflected radiation channel: spectral band of 0.3 - 3.0 μm , FOV = 60°, accuracy = 1%.

RMK-M (Radiation Measurement Control), of RMK-2 heritage flown on the Meteor-3 series satellites. Objectives: Registration of flux densities of protons in the 1-90 MeV and electrons in the 0.17-3.0 MeV energy regions. Measurement of galactic radiation with energies above 600 MeV.

NINA (New Instrument for Nuclear Analysis). NINA is a compact telescope, developed by INFN (Italian National Institute of Nuclear Physics) of Rome, Italy and MEPhI (Moscow Engineering and Physics Institute).⁸⁸⁸⁾ The objective is to measure fluxes of charged particles, in particular to detect cosmic ray nuclei of galactic, solar, or other origin from hydrogen to iron, between 10 and 200 MeV/n. The silicon detector telescope is composed of 16 X-Y planes, giving information on the energy of the crossing particle and its incident angle. Each of the 32 sensitive elements consists of two n-type silicon detectors, 60 mm x 60 mm, divided in 16 strips and connected to a supporting ceramic frame under lateral strips (1 and 16). Each couple of detector is glued orthogonal in order to provide X and Y independent view information. The thickness of the detector is $150 \pm 15 \mu\text{m}$ for the first plane, and $380 \pm 15 \mu\text{m}$ for the remaining 15 planes. The geometric factor of the instrument ranges from 8.6 cm² sr for low energy particles to 1 cm² sr for particles crossing the detector. The instrument mass is 40 kg, power = 40 W. - NINA was flown on RESURS-O1-4 only.

ScaRaB (Scanner for Radiation Budget), of CNES [France (CNES, LMD), Russia (Planeta, RKA), Germany (GKSS) are program partners]. See description under Meteor-3 series.

MP-900M TV Camera. The objective is the monitoring (imaging) of reflected radiation of the Earth's surface and atmosphere (clouds) in the VIS and NIR spectral regions. The spatial resolution of the imagery is 1.6 km x 1.8 km.

RESURS-O1-4 was launched from the Baikonur Cosmodrome on July 10, 1998. Secondary payloads on the Zenit-2 vehicle were: TMSat (also known as Thai-Phutt) of Thailand, the Israeli TechSat/Gurwin-II, WESTPAC of Australia, SAFIR-2 of OHB-System, Bremen, and the Chilean FASat-Bravo.

Parameter		Resurs-O1 Series
S/C mass	including payload mass	1900 kg
	payload mass alone	500 kg
Earth pointing accuracy		10 arc min
	along the velocity vector	30 arc min
Power supply	average per day	500 W
	peak value	1200 W
Power supply	voltage range	23-34 V
Lifetime		2 years

Table 246: Resurs-O1 series satellite characteristics

Note: Operations of RESURS-O1-4 continued until April 1999 when a communication failure disrupted all service.

D.33 ROCSat (Republic of China Satellite)

ROCSat is a satellite program of NSPO (National Space Program Office) of Taiwan. A major program objective was to provide a national (NSPO, industry, university, etc.) capability

⁸⁸⁸⁾ R. Sparvoli, et al., "Launch in orbit of the telescope NINA for cosmic ray observations: preliminary results," Proceedings of The Sixth Topical Seminar on 'Neutrino and Astro-Particle Physics,' Centro Studi 'I Cappuccini' in San Miniato al Toderco, Italy, May 17-21, 1999

and to create an infrastructure and environment for state-of-the-art space age technology and research.

D.33.1 ROCSat-1

The S/C, ROCSat-1, was developed/built by TRW (Space & Electronics Group) of Redondo Beach, CA, as a cooperative development project between TRW and NSPO, offering training capabilities and participation for NSPO engineers in S/C design, testing, and operation/control. The joint development effort started in June 1994. In May 1997, the S/C was returned to NSPO for integration and testing. Some satellite components (OBC, remote interface unit, filter/diplexer and S-band antenna, and solar panels) and instruments/experiments were developed at industry and institutes/facilities in the Republic of China (ROC).^{889) 890) 891) 892)}

The ROCSat-1 S/C structure (bus) is a hexahedron in shape and of modular design, accommodating payload growth. The hexahedron has a size of 2.1 m (height) x 1.1 m, the deployed vehicle has an overall length of 7.2 m. The S/C is three-axis stabilized with a reaction control subsystem module, providing pointing control of 0.5° , pointing knowledge of 0.1° and a stability of $0.01^\circ/\text{s}$. S/C dimensions: 1.10 m diameter and 2.1 m in height (hexahedron shape). Solar arrays of size 1.16 m x 2.46 m provide 450 W of power (645 W max). A reaction control module provides orbit trim capability. Total S/C mass is 402 kg (including propellant), the S/C design life is two years with a goal of 4 years. ROCSat-1 was launched Jan. 26, 1999 (UTC) from Cape Canaveral on an Athena-1 vehicle (Lockheed Martin). S/C operations and data processing are performed from NSPO facilities at Hsin-Chu City, there are two tracking stations at Chung-Li and Tainan, Taiwan.

Figure 149: Illustration of the ROCSat-1 spacecraft

RF communications are provided in S-band (uplink frequency = 2.039 GHz, downlink frequency = 2.215 GHz, bandwidth = ± 15 MHz, RHCP polarization, power = 6 W). The

uplink data rate is 2 kbit/s, the downlink data rate is 1.4 Mbit/s. On-board storage is provided for 2 Gbit of data.

Orbit: Circular orbit, altitude = 600 km, inclination = 35°, period = 96.7 min.

Sensor complement:

OCI (Ocean Color Imager), built by NEC Corp. of Japan. Objective: Collection of visible and near-infrared radiances over low latitude oceans. The science goals are: mapping of pigment distribution, study of marine productivity and the dynamics of meso-scale eddies, and estimation of influence of the atmospheric aerosols in remote sensing. The instrument is an all-refractive spectral radiometer designed to sense in six spectral bands (443 - 865 nm) with 800 m spatial resolution. Swath width = 700 km (FOV=60.4°).

Spectral bands	B1	B2	B3	B4	B5	B6
Center wave length (nm)	443	490	510	555	670	865
Tolerance (nm)	±3	±4	±4	±4	±4	±5
$\Delta\lambda$ (FWHM in nm) bandwidth	20	20	20	20	20	40
Minimum SNR at EOL	450	450	450	450	350	350
Instrument operating modes	FB, NI-A, NI-B, RGB, CA, SBY, OFF, SUV					
Instrument mass, power	15.2 kg, 33 W (peak), 18 W (standby)					
Date rate	655.5 kbit/s in mode FB via RS-422 (inclusive CCSDS overhead)					
Data quantization	12 bit					
Imaging method, detectors	Pushbroom scanning, linear CCD arrays with 1728 cells per line					
Pixels per band	896 pixels (832 double + 64 single cells)					
Absolute radiance accuracy	5% or better at BOL					
Integration time	115.8 ms					
Co-registration error (band 4)	Along-track: ≤ 0.65 IFOV; cross-track: ≤ 0.97 IFOV					
Instrument optics	Four telecentric dioptric systems (lens system)					
Polarization sensitivity	$\leq 2\%$					

Table 247: Parameters of the OCI instrument

IPEI (Ionospheric Plasma and Electrodynamics Instrument). Objective: Measurement of the Earth's upper atmosphere, in particular the ionospheric plasma and electrodynamic effects at 600 km altitudes to gain a better understanding of the ionospheric structure and effects on radio communications in the low and middle latitudes (up to 35°). IPEI is a cooperative project between the National Central University of ROC and the University of Texas at Dallas (UTD).

Instrument/Subsystem	RPA	IDM	IT
Measurement	Ion temperature and RAM velocity	Ion transverse velocity component	Total ion concentration
Sampling rate	Normal mode: 332/s Fast mode: 64/s	Normal mode: 32/s Fast mode: 1024/s	Normal mode: 32/s Fast mode: 1024/s
Envelope dimension	SEP: 19 cm x 47 cm x 41.9 cm; MEP: 12.8 cm x 27.9 cm x 13.9 cm		
Instrument mass, power	9.4 kg, 10 W		
FOV	45° x 45°		
Operating temperature	-10°C to about 40°C		
Date rate	Normal mode: 2.2 kbit/s; Fast mode: 53.38 kbit/s		
Duty cycle	Normal mode: 85%, Fast mode: 15%		

Table 248: Parameters of the IPEI instrument

ECP (Experimental Communication Payload), built by MTI (Microelectronic Technology Inc.) of ROC and NEC Corp. of Japan. ECP is a microwave instrument with the objective to conduct various low-altitude satellite communication experiments, in particular the collection of system characteristics and their relationship to different communication technologies (Ka-band telecommunications).

Antenna coverage	$\pm 65^\circ$ conic
Duty cycle (averaged)	8% of an orbital period
Bandwidth	27 MHz
Power consumption	Operating: 85 W peak, on-orbit power: 25 W
Frequencies	Uplink: 28.25 GHz, downlink: 18.45 GHz, beacon: 19.5 GHz
Instrument mass	18.53 kg
Volume	Transponder: 20 microwave boxes distributed in two sides of the payload adapter. Antennas: 25.4 cm diameter (transmit), 20.3 cm (receive)
Transmitter power	10 W (communication channel), 1.77 W (beacon signal)
Polarization	Transmit: LHCP; receive: RHCP

Table 249: Parameters of the ECP instrument

Figure 150: Illustration of the ROCsSat-1 payload

D.33.2 ROCsSat-2

ROCsSat-2 is an NSPO (Taiwan) Earth imaging satellite with the objective to collect high-resolution panchromatic (2 m) and multispectral (8 m) imagery for a great variety of applications such as in land use, agriculture and forestry, environmental monitoring, natural disaster evaluation, and in support of research interests, in particular with the ISUAL instrument. Daily image coverage of Taiwan and the surrounding region is required.

Background: A contract was signed in May 1999 between NSPO and DASA/DSS of Germany to build a high-resolution optical imaging satellite. However, the German government refused to give DASA an export licence for the S/C (the People's Republic of China was protesting the deal). The stalemate was resolved in Dec. 1999 when NSPO signed a new contract with MMS (now Astrium SAS of France). Quick approval of the export of ROCsSat-2 was provided by the French government.

The S/C bus is built by Astrium SAS of Vélizy, France, based on the Leostar 500 XO family. The S/C structure consists basically of a hexagonal body of 1.5 m side length. The satellite is three-axis stabilized. The upper deck of the platform carries the payload (RSI and ISUAL) and also part of AOCS (Attitude and Orbit Control Subsystem), namely the star sensors

and gyroscopes. The lower deck carries the four reaction wheels and the autonomous propulsion module. The fixed solar array uses GaAs cells and consists of two deployable flaps. The entire S/C architecture is designed in such a way as to provide a low roll inertia, a key factor for satellite agility and instrument line-of-sight stability. The design life is five years. A launch of ROCSat-2 is planned for 2003 (Taurus vehicle from OSC).^{893) 894)}

Figure 151: Illustration of ROCSat-2

S/C mass, power	712 kg, 693 W (EOL)
S/C pointing accuracy, knowledge	0.038°, 0.20°
RF communication S-band (TT&C function)	Data rate: 4 kbit/s uplink, 1.6 Mbit/s downlink
RF communication in X-band	Data rate: 120 Mbit/s in downlink
X-band modulation, polarization	NRZ-L, RHCP/LHCP (selectable)
X-band link margin at 20° elevation angle	>6 dB for clear sky
X-band station G/T at 20° elevation angle	>31.3 dB for clear sky
On-board data storage capability	42 Gbit

Table 250: Some performance parameters of ROCSat-2 spacecraft

Orbit: Sun-synchronous circular orbit, altitude = 891 km, inclination = 98.99°, the equatorial descending local time is between 9:45 to 10:00 AM (14 orbits/day).

The basic elements of the ROCSat-2 ground segment are the MMC (Multi Mission Center) and the XAS (X-band Acquisition System). MMC in turn consists of MOC (Mission Operations Center), MCC (Mission Control Center), SCC (Science Control Center), FDF (Flight Dynamics Facility), and GCN (Ground Communications Network). ROCSat-2 X-band imagery reception is also made available to third parties (international partners) with their own ground stations through cooperative agreements.

894) J. S. Chern, A. M. Wu, J. Ling, "Some Aspects of ROCSat-2 System Engineering," Proceedings of the 3rd International Symposium of IAA, Berlin, April 2-6, 2001, pp. 57-60

Sensor complement:

RSI (Remote Sensing Instrument), built by Astrium SAS. RSI is made up of the camera and IPU (Instrument Processing Unit). The camera itself consists of the optical sub-assembly, the primary structure, and the FPA (Focal Plane Assembly). The video electronics, sequencer, DC/DC converter, and compression cards comprise the IPU.

Spectral bands: Panchromatic band Four MS bands (nm)	460-890 nm (670 nm center) B1 = 460-520, B2 = 540-580, B3 = 630-680, B4 = 770-900 nm
Spatial resolution (GSD)	2 m for PAN, 8 m for MS imagery
Swath width	24 km
S/C body pointing capability, FOR (Field of Regard)	$\pm 45^\circ$ in the roll and pitch axis (providing a cross-track observation capability for disaster monitoring)
Optics, focal length, Aperture diameter	Cassegrain type optics with refractive corrector, 2896 mm, 600 mm
Detector types	CCD: TH 7834 for PAN, THX 31547 quad-linear CCD for MS
Integration time	0.308 ms for PAN, 1.232 ms for MS
Processing rate	10 Mpixel/s for PAN, 5 Mpixel/s for MS
Pixel quantization	12 bit
Data compression ratio	2.8 and 3.8 for PAN, 1.7 and 3.8 for MS
Instrument mass, power consumption	130 kg, 163 W for imaging, 78 W for standby

Table 251: Performance characteristics of RSI

ISUAL (Imager of Sprite Upper Atmospheric Lightning). ISUAL is a joint research program by NSPO, UCB (University of California at Berkeley), National Cheng Kung University, and Tohoku University. The objective is to observe the natural upward lightning discharge phenomenon toward the ionosphere on top of the troposphere.

The instrument consists of four elements: sprite imager, spectrophotometer, array photometer, and electronics package. The imager is a staring-type frame CCD camera, taking 180 frames/s with a resolution of 512 x 80 pixels in a FOV of $20^\circ \times 3.15^\circ$. ISUAL is operated in three modes: 1) the sprite continuous mode to take images with a sample rate of 100 Hz, 2) the sprite burst mode with a sample rate of 1000 Hz, and 3) the auroral mode at a constant rate of 1 sample/s. ISUAL monitoring occurs during each nightside pass. The source data are stored and compressed in a separate 128 MByte memory. The data are downlinked in S-band. The total data volume is about 1 Gbit/day.

An ISUAL observation sequence of sprites has the following performance characteristics:

- Pointing: Dip down to reduce range and limb view for large coverage
- Location: Storms
- Imager wavelength: N2 1st positive, 427.8 nm
- Photometer wavelength: UV bands, N2 2nd positive, 427.8 nm, N2 1st positive
- Spatial resolution: about 2 km
- Time resolution: 1-30 ms (programmable)
- Mode: Burst mode and sprite mode
- Sensitivity: SNR > 10 at 100 MR at 30 ms

An ISUAL observation sequence for a survey of aurora and airglow has the following performance characteristics:

- Pointing: Limb view; Location: All latitudes
- Imager wavelength: All wavelengths
- Photometer wavelength: All wavelengths
- Spatial resolution: about 2 km; Time resolution: 1 s (programmable)
- Mode: Continuous aurora mode
- Sensitivity: SNR > 10 at 10 kR

D.34 SAC-C (Satélite de Aplicaciones Científicas-C)

SAC-C is a cooperative Earth observation mission of Argentina, USA, Denmark, Brazil, Italy and France with CONAE and NASA as the main partners. CONAE provides the S/C bus and payload instrumentation, NASA provides launch services and a GPS flight receiver (BlackJack of JPL). INPE of Brazil is providing the system-level environmental testing facilities and its test support capabilities. The overall objective is to study the structure and dynamics of the Earth's surface, atmosphere, ionosphere and geomagnetic field. Specific science objectives are to:

- Provide multispectral images of the Earth in order to monitor the condition and dynamics of the terrestrial and marine biosphere and environment
- Develop and utilize new GPS-based techniques to globally measure atmospheric phenomena for the study of weather, seasonal, inter-annual and long-term climate change
- Enhance the understanding of the Earth's magnetic field and related sun-Earth interactions
- Measurement of the high-energy radiation environment, trapped particles intensities and energy distribution and correlation with degradation of electronic components.

A SAC-C launch on a Delta-2 launcher (secondary payload to EO-1) from VAFB took place on Nov. 21, 2000. ^{895) 896) 897)}

Figure 152: Illustration of the SAC-C spacecraft

The minisatellite structure has dimensions of 1.85 m x 1.68 m x 2.4 m with a total mass of 485 kg (payload = 104 kg, bus = 340.3 kg, fuel = 12.5 kg). The main body of the S/C features an aluminum structure. The antenna booms employ a CFRP (Carbon Fiber Reinforced Plastic) structure. Two fixed solar panels provide 360 W of EOL power (average power consumption of 221 W) and two redundant 12 Ah NiH batteries providing 100 W during eclipse phases of the orbit. The S/C is three-axis stabilized and nadir-pointing. The pointing accuracy required is 1.5° with a post-facto knowledge of 0.2° on three axis, the pointing stability is 0.1°/s. Attitude is maintained by two reactions wheels, three redundant torque rods, eight thrusters for orbit injection/maintenance (12.5 kg hydrazine), and a boom of 8 m in length; while attitude is measured by two partially redundant star trackers [referred to as ASC (Ad-

vanced Stellar Compass)], two redundant DGPS receivers, two horizon sensors, and a coarse sun sensor. All on-board communications are conducted via a Mil-STD-1553B bus. The S/C design life is 4 years.

Orbit: Sun-synchronous circular polar orbit, altitude = 705 km, inclination = 98.2°, equatorial crossing on descending node at 10:15 AM, repeat cycle = 16 days (with sub-cycles of 7 and 9 days).

RF communications: X-band and S-band data downlinks provide real-time and playback data transmissions. There are two S-band transmitters for MMRS low-resolution imagery transmission in real-time with a data rate of 0.9435 Mbit/s, recorder data are transmitted at 1.887 Mbit/s. In addition there are two X-band transmitters for high-resolution MMRS imagery at 3.774 Mbit/s. The on-board storage capacity is 768 Mbit. The spacecraft mission is operated by the CONAE Control Center at Cordoba, Argentina.

As of early 2001, the SAC-C spacecraft is part of a “morning constellation” train, a formation consisting of the NASA spacecraft Landsat-7, EO-1, Terra, and SAC-C (separation times are between 1-15 minutes). The objective is to explore new synoptic observational capabilities and to compare coincident imagery.

Sensor complement:

MMRS (Multispectral Medium Resolution Scanner). MMRS is provided by CONAE. Objective: Monitoring of agricultural production and the influence of climatic anomalies over agriculture and forestry. The instrument features a 5-band CCD linear array pushbroom imager. The swath width of the imagery is 360 km. There are two modes of operation: a high-resolution mode with a spatial resolution of 175 m, and a low-resolution mode of 350 m resolution (real-time transmission with low-resolution data).

Spectral bands (5) in nm	480-500, 540-560, 630-690, 795-835, 1550-1700
FOV (swath), IFOV (spatial resolution)	29.42° (or 360 km), 0.014° (or 175 m)
Optics system: effective focal length, f/number	40 mm, f/3.1
Data quantization	8 bits
Detectors	2048 x 4 silicon array (VNIR) , 2100 x 1 (SWIR)
Data compression	Onboard JPEG data compression at rates of 4:1 to 10:1
Co-registration of bands	±2 pixels (life time), ±0.25 pixel (one orbit)
Data rate (downlink transmission)	0.943 Mbit/s (low-rate mode) 3.3.774 Mbit/s (high-rate mode)
Instrument mass, power	22 kg, 25 W (peak)

Table 252: Technical characteristics of MMRS

Instrument pre-flight and on-orbit calibration of MMRS is provided. The on-board calibration system uses sunlight (in the south pole region of the orbit) for calibration. A cover mechanism in front of the instrument optics is partially opened for this purpose to reflect the sunlight into the optics and to perform a calibration.

HRTC (High-Resolution Technological Camera). A CONAE panchromatic instrument with the objective to acquire high-resolution imagery over portions of MMRS scenes to aid in the data analysis. HRTC has a spectral range from 400 - 900 nm, a spatial resolution of 35 m, and a swath width of 90 km. A scene size of HRTC is 90 km x 1150 km. Imagery of HRTC is regularly stored onto the on-board recorder prior to downlink transmission. Some instrument characteristics: the CCD detector array has 2592 pixels; data quantization = 8 bit; IFOF = 0.0027°; FOV = 7°; instrument mass = 8.5 kg; power = 10.5 W. HRTC has a mirror capable of cross-track pointing. The objective is to locate the HRTC swath of 90 km anywhere within the bounds of the MMRS observation of 360 km width.

HSC (High Sensitivity Camera). A small CCD imaging camera of CONAE with the objective to study a number of phenomena on the night pass of the orbit such as light intensities in

urban regions, lightning in thunder storms, forest fires, and polar auroras. HSC has a spectral range from 450 - 850 nm, a spatial resolution of 300 m, and a swath width of 700 km.

Ørsted-2 (Magnetic Mapping Payload). Primary objective: mapping of the Earth's magnetic field. DSRI (Danish Space Research Center) is providing the Ørsted-2 suite (of Ørsted heritage) sponsored by Denmark. Ørsted-2 consists of a deployable boom (8 m in length) mounted with a vector magnetometer and a star imager (0.5 arcseconds orientation), further included are the associated support electronics to control the sensors and the boom deployment, a power control unit and a command and data handling unit. A scalar helium magnetometer placed on the tip of the boom and associated support electronics from JPL completes the Ørsted-2 instrument package. The magnetic field measurements have a resolution of 1 nT at scalar and 2 nT at vector. - The overall objectives of Ørsted-2 are to perform highly accurate measurements of the Earth's magnetic field:

- To determine models of the main magnetic fields and its secular variation
 - To study the physical properties of the fluid core and the electrical conductivity of the mantle
 - To investigate the correlation between the geomagnetic fields and variations in the length of the day
 - To study the lithospheric structure and evolution
- To study the interaction between the Earth's magnetic field and the solar wind
 - Structure and variability of high-altitude fields and currents
 - Relationships between field-aligned and ionospheric currents in the cleft and cusp
 - External magnetic fields as functions of local time, season, and solar wind conditions
 - Ionospheric signatures of localized processes in the outer magnetosphere
 - Substorm processes.

IST (Italian Star Tracker). An ASI-funded technology demonstration instrument developed by Alenia Spazio.⁸⁹⁸⁾ The objective is to test a fully autonomous system for attitude determination using a star tracker. IST is able to provide in real-time the estimated attitude of the instrument boresight and its rotation rate, without any support from ground or other attitude sensors. IST is a prototype for a future multi-head system where a single EU (Electronic Unit) drives up to three Optical Heads (OH) to output absolute attitude and angular rate with high reliability and accuracy. - The prototype demonstrated accuracies in the order of a few arcsecs, continuity of operation, capability to recover from "lost in space" within a few seconds. The system is based upon a library of algorithms for autonomous attitude determination including reduced star catalogues, pattern recognition, estimation and self-calibration algorithms. IST is a single-head prototype composed of:

- One EU, developed by Laben, is based on an ERC32 chip-set processor. The CPU is based on the TEMIC ERC32 chip set (SPARC V, 32-bit RISC, 10 Mips) 12 MHz, 2 Mbyte RAM, and 512 kByte EEPROM. An STD-MIL-1553B external bus interface is provided.
- One OH (including baffle) of Alenia Difesa Officine Galileo. The optical system employs radiation hardened lenses (double Gauss modified), FOV = 8.23° x 10.96°, focal length = 46 mm, f/1.5 number, spectral range of 550-950 nm, CCD array of 288 x 384 pixels, a Peltier cooling system (3 stages), IFOV of 103 arcsec, integration time of 10 ms to 1 s (in 10 ms steps), data quantization of 16 bit (100 kHz), CCD readout time of 35 ms.
- The software package with attitude determination algorithms is developed by Alenia Spazio and EICAS Automazione.

IST provides as output the attitude quaternion and angular rate estimates with a frequency of 10 Hz. The average accuracy of the system, estimated after the first months of operation,

⁸⁹⁸⁾ Information provided by Andrea Bacchetta of Alenia Spazio, Torino, Italy

is: 12 arcsec (x axis), 4 arcsec (y axis), and 2 arcsec (z axis). The IST instrument mass is: 3 kg (EU) + 2.5 kg (OH) + 0.6 kg baffle, power of 19-26 W.

INES (Italian Navigation Experiment). INES is composed of two separate systems: the GPS Tensor receiver and LAGRANGE (Laben GNSS Receiver for Advanced Navigation, Geodesy, and Experiments) of Laben S. p. A. Vimodrone, Italy. Both instruments are funded by ASI.

- LAGRANGE is a 12-channel, dual GPS/GLONASS receiver that operates at L1 and L2 frequencies. It can provide raw data, including differential L1/L2 measurements that can be used for such applications as geodesy and atmospheric profiling. Navigation accuracies are 80 m for GPS and 10 m for GLONASS. Integrated Doppler precision, sampled at 1 Hz, is listed as 1 mm for GPS and GLONASS.
- The GPS Tensor unit is utilized by the SAC-C S/C as the primary AOCS sensor providing navigation and attitude solutions. The prime objective is to validate the attitude determination capabilities of the GPS Tensor instrument and to demonstrate new filtering techniques in combination with instrument solutions provided.

GOLPE (GPS Occultation and Passive reflection Experiment), a NASA/JPL instrument called BlackJack (see E.1) with the objective to observe ionospheric electron content, to provide atmospheric soundings permitting the derivation of atmospheric profiles of density, pressure, and temperature (refractive occultation monitoring), and to study GPS signals reflected from the Earth's surface.

The GPS receiver assembly of GOLPE consists of a multi-antenna system (four independent high gain antennas pointed in the zenith direction, in the fore and aft direction, and in the nadir direction, respectively). The zenith-pointing antenna is used for simultaneous tracking of GPS satellites. The receiver performs phase measurements of both GPS frequencies L1 and L2, and derives pseudoranges from these measurements for orbit determination.

- In limb radio-occultation monitoring the high gain and aft antennas receive the signals from the setting and rising satellites of the GPS constellation. This permits to determine atmospheric temperature and water vapor at about 500 occultations per day which are fairly uniformly distributed over the globe.
- The nadir pointing antenna is used to determine the utility of GPS signals reflected from Earth's surface to characterize the elevation and roughness of the Earth's surface for applications such as the determination of oceanic circulation and surface winds.
- The dual frequency capability of the instrument receiver permits the determination of ionospheric total electron content (TEC) along the direct, refracted and reflected ray paths, thereby providing data valuable for the tomographic determination of ionospheric structure.
- The ionospheric TEC measurements capability is an important complementary measurement to the Ørsted-2 (MMP) instrument data, thus permitting the derivation of parameters as: ionospheric and magnetospheric currents and conductivity.
- The data of GOLPE also help to improve the estimates of ionospheric delay which degrade the accuracy of single-frequency radar altimeters.

ICARE (Influence of Space Radiation on Advanced Components), a radiation monitoring instrument of CNES, France. The objectives are to support: ⁸⁹⁹⁾

- The improvement of risk estimation models for radiation effects on the latest generations of IC technologies
- Updates of environment models for radiation responsible for electronic component degradations and breakdowns
- Real-time monitoring of environmental conditions for preventive measures.

⁸⁹⁹⁾ Information provided by Robert Ecoffet of CNES

ICARE is composed of a set of radiation detectors (electrons, protons, ions) associated with a component test board. The radiation detectors are made of silicon fully depleted solid state detectors used in single and coincident mode. The on-board measurements consist in accumulating energy loss spectra in the junctions over a programmable accumulation period. The spectra are generated through signal amplitude classification using 8 bit A/D converters and resulting in 256 channels histograms. The reference levels of the discriminators and gain of the amplifiers are programmable to provide for possible on-board tuning optimization. The accumulation time for the spectra can be programmed from 4 to 256 s. - The component test board functions independently of the detector modes. It can be switched on or off in each mode. The purpose of this board is to measure single event effects rates and total dose parametric drifts on a set of advanced components. In its present version, the test processor is an AD2101 signal processor, single event test devices, commercial sub-micron 1 to 4 Mbit SRAMs, 16 to 64 Mbit DRAMs, and total dose test devices bipolar and CMOS operational amplifiers. The component test board is a separate module that is assembled on the main instrument box by 6 screws. The module can be changed from one mission to another. The instrument is also able to function if no module is connected. - An ICARE communication interface is available for dialog through a single RS-422 or a MIL STD 1553B bus interface. The component experiment module downloads its results in an asynchronous way when its result buffer is filled with a certain amount of results. ICARE has a mass of 2.4 kg, a size of 28 cm x 15.5 cm x 7.1 cm, and a power consumption of 3 W. The data rate is 2.6 kbit/s (max.).

WTE (Whale Tracker Experiment). A CONAE experiment (in cooperation with the Argentinean Secretariat of Natural Resources and Environment). The objective is to study the migration behavior of the Franca Australis Whale, to learn about its migration paths and to protect the species. WTE is in effect a regular data collection system consisting of two elements: a data collection module aboard the satellite and a number of data modules, the DCP (Data Collection Platforms) function, in the ground segment. A data module has been “installed” on a number of whales, each one containing a miniature GPS receiver to determine the whale location at any given time. In addition, the module contains two transducers to measure the water temperature and pressure. Communication with the space segment is provided by a transmitter and a data management unit. - The satellite module consists of a receiver to acquire the DCP data and the needed logic to handle the data.

DCS (Data Collection System). A “regular” CONAE-provided system (in addition to WTE) with the objective to collect data from user DCPs in the ground segment.

D.35 SEASAT

NASA/JPL Earth observation mission (built by Lockheed and Ball Aerospace Systems). Launch: June 27, 1978 (Atlas-Agena from Vandenberg AFB, CA); end of mission (abrupt power system failure in its 1,502 orbit) October 10, 1978. Mission duration: 70 days (data generation) of 106 operational days. The satellite utilized the Agena upper stage to provide satellite bus functions, including power, telemetry (S-band), attitude control, and command and control functions. A sensor package containing the mission’s five experiments was attached to the Agena, as were the experiments’ antenna systems. Seasat was three-axis stabilized using momentum wheels and horizon sensors. The vehicle was oriented with the SAR and other antennas remaining nadir pointing and the Agena rocket nozzle and solar panels zenith pointing. S/C size: 21 m length, 1.5 m diameter, total S/C mass=2290 kg.

Application: Ice and ocean monitoring (sea-surface winds, sea-surface temperatures, wave heights, internal waves, sea-ice features, ocean features, ocean topography, and the marine geoid), land use, geology, forestry, and mapping.

Orbit: Polar near circular orbit, 108° inclination, apogee = 799 km, perigee = 769 km, period = 101 minutes.

Sensor complement:

SAR (Synthetic Aperture Radar) in HH polarization, look angle = 20° ; pixel size = 25×25 m (spatial resolution on the surface at 4 looks); radiometric resolution = 5 bit raw data. Sensor transmission frequency: 1.275 GHz (L-band); wavelength = 23.5 cm; swath width = 100 km. Antenna: 1024-element phased array antenna of size 10.74 m \times 2.16 m; PRF = 1464 to 1640 Hz; pulse duration = 33.9 μ s; bandwidth (linear FM) = 19.077 MHz; transmitted peak power = 1 kW (nominal).^{900) 901) 902)}

Figure 153: The Seasat S/C model

The Seasat SAR sensor is regarded as the first imaging SAR system used in Earth orbit. A SAR antenna is mounted on the S/C with its boresight oriented at 20° from the vertical

direction (look angle), pointing to the right of the flight path. The antenna beamwidth measures 6.2° in elevation and 1° in azimuth. A footprint of 100 km x 15 km (3 dB contour) is provided (the swath extends from 240 km to 340 km to the right of the S/C ground track). The received radar echoes are downlinked in S-band (analog data link at 2.265 GHz) to a total of five ground receiving stations in real-time (no on-board recording capability) located at: Goldstone, CA, Fairbanks, AK, Merrit Island, FL, Shoe Cove, Newfoundland, and Oakhanger, UK.

SMMR (Scanning Multichannel Microwave Radiometer); Objectives: Monitoring sea surface temperatures, wind speeds, rain rate, atmospheric water content (mapping of columnar water vapor distribution over the global oceans) and ice conditions. SMMR is a multi-spectral, dual-polarization microwave radiometer observing at the following frequencies: 6.6 GHz (45.4 mm), 10.7 GHz (28 mm), 18.0 GHz (16.6 mm), 21.0 GHz (14.2 mm), and 37.0 GHz (8.1 mm). Six Dicke-type radiometers were utilized. Those operating at the four longest wavelengths measured alternate polarizations during successive scans of the antenna; the others operated continuously for each polarization. The antenna was a parabolic reflector offset from the nadir by 42° . Motion of the antenna reflector provided observations from within a conical volume along the ground track of the spacecraft. SMMR had a swath width of about 600 km and the spatial resolution ranged from about 22 km at 37 GHz to about 100 km at 6.6 GHz. The absolute accuracy of sea surface temperature obtained was 2 K with a relative accuracy of 0.5 K. The accuracy of the wind speed measurements was 2 m/s for winds ranging from 7 to about 50 m/s. An identical instrument was flown on Nimbus-7 (launch Oct. 24, 1978). ⁹⁰³⁾ ⁹⁰⁴⁾

ALT (Radar Altimeter). ⁹⁰⁵⁾ Heritage of S-193 flown on Skylab and ALT flown GEOS-3. Objective: Determination of sea surface profiles, currents, wind speeds and wave heights (first attempt to achieve 10 cm altitude precision from orbit). ALT was a Ku-band compressed pulse radar altimeter (first use of the full-deramp technique). With this new full-deramp technique no compression filter is required in the receiver. From SEASAT onwards, all altimeters have been using this technique, achieving a significant improvement in the resolution. Two of its unique features were a linear FM transmitter with a 320 MHz bandwidth, which yielded a 3.125 ns time-delay resolution, and microprocessor-implemented closed-loop range tracking, automatic gain control, and real-time estimation of significant wave height. This instrument flew the first microprocessor (8080-based controller/tracker) in space. The altimeter operated at 13.5 GHz using a 1-m parabolic antenna pointed at nadir and had a swath width which varied from 2.4 to 12 km, depending on sea state. The precision of the height measurement was 10 cm (rms). The estimate of significant wave height was accurate to 0.5 m or 10%, whichever was greater, the ocean backscatter coefficient had an accuracy of 1 dB.

In the SEASAT design the number of echo samples is increased (compared to GEOS-3). The samples are spaced 3.125 ns apart to encompass the anticipated spread in ocean return for wave heights up to 20 m. In this case waveforms sampling is implemented by a bank of filters with 312.5 kHz bandwidth and spacing. In contrast with previous designs, the samples are an integral part of the altitude tracking process and are used in such a way that the system adapts as a function of wave height to optimize tracker performances. The altitude tracking loop is closed in two parts: a coarse adjustment of the local oscillator pulse timing in 12.5 ns step, and a fine adjustment. - The ALT instrument was designed and built at JHU/APL.

SASS = Seasat-A Scatterometer System

SASS (of S-193 heritage on Skylab) is a fan-beam dual-polarized Doppler scatterometer with the objective of radar backscatter measurements (sigma naught) over ocean surfaces for estimation of the wind field. Pulse transmit frequency of 14.599 GHz (Ku-band). SASS illuminated the sea surface with four fan-shaped beams (two orthogonal beams, each 500 km wide, on each side of the ground track). Doppler filters were used to discriminate resolution cells in the long dimension of the fan beam, resulting in 500 km swaths on either side of the satellite. The high wind swaths added an additional 250 km to each side. The spatial resolution was 50 km over a region of 200 to 700 km on either side of the spacecraft.⁹⁰⁶⁾

VIRR = Visible and Infrared Radiometer

VIRR is a supporting instrument on Seasat (of SR heritage on NOAA-1, G.13.1) with the objective to provide images of visual reflection and thermal infrared emission from oceanic, coastal, and atmospheric features that might aid in interpreting the data from the other Seasat sensors (also some quantitative measurements of SST and cloud top height). Scanning is accomplished by a rotating mirror mounted at 45° to the optical axis of the collecting telescope (scan angle = $\pm 51.2^\circ$). VIRR uses a 12.7 cm diameter Cassegrain-type telescope, focusing the radiation onto a field stop. A relay optical system transmits the radiation to a dichroic beamsplitter, which separates it into the visible and infrared wavelengths.⁹⁰⁷⁾

Parameter	Visible Channel	Infrared Channel
Spectral region	0.49 - 0.94 μm	10.5 - 12.5 μm
Resolution angular ground (nadir)	2.8 mrad 2.3 km	5.3 mrad 4.4 km
Sensitivity (NE Δ T)	Not applicable	4 K with a scene at 185 K 1 K with a scene at 300 K
Dynamic range	65 - 10,000 fL (scene brightness)	180-330 K (scene temperature)
Detector	silicon photovoltaic	thermistor bolometer
Scan rate	48 rpm	48 rpm

Table 253: VIRR instrument parameters

Laser Tracking Reflector. A device to support precision orbit determination for Seasat 1. Laser corner reflectors, composed of 96 fused silica 3.75 cm hexagonal corner cube retroreflectors, and ground-based laser systems were used to obtain precise satellite tracking information. The retroreflector array was configured as a single ring of cube corners 1.27 m in diameter. Sixteen of the cube corners were tilted away from the axis of the ring by an angle of 25° and the remaining 80 cubes by an angle of 50°. Because of the great distance of the array from the center of mass of the satellite, the range correction varied from 5.28 m at zenith to 3.08 m near the horizon. When illuminated by laser light pulses from the ground, each retroreflector cube in the array reflected the light pulses back to a telescope/receiver on the ground. A digital counter recorded the time of flight of the laser light pulses from the ground to the satellite and back to the ground. Range was determined from this time. NASA, USAF, SAO (Smithsonian Astrophysical Observatory) and foreign laser tracking stations tracked this satellite.

SAR Data:

Image size: 100 x 100 km (JPL); 100 x 75 km (DLR); four looks full digital image processing with 12.5 m pixel spacing; 8000 lines x 8000 pixels (JPL). Transmission frequency = 11.25 GHz (X-band); data rate = 110 Mbit/s.

Seasat provided global statistics on ocean mesoscale variability, detected strong currents, and showed the potential to detect the longer wavelengths of the circulation.

D.36 SMOS (Soil Moisture and Ocean Salinity)

SMOS is an approved ESA Explorer Opportunity mission, a technology demonstration minisatellite mission, in cooperation with CNES and CDTI (Center for Technological and Industrial Development) Madrid, Spain. 908) 909) 910) 911) 912) 913) 914)

As of June 2001 SMOS is undergoing phase A activities. The concept review took place in March 2001, and phase A will end in December 2001. The launch date is scheduled for 2005.

Figure 154: Illustration of the SMOS satellite

The main science objective of the SMOS mission is to demonstrate observations of SSS (Sea Surface Salinity) over oceans and SM (Soil Moisture) over land to advance climatologic, meteorologic, hydrologic, and oceanographic applications. Soil moisture is a key variable in the hydrologic cycle. Over land, water and energy fluxes at the surface/atmosphere interface are strongly dependent upon soil moisture. SM is an important variable for numerical weather and climate models as well as in surface hydrology and in vegetation monitoring.

915) 916) Knowledge of the global distribution of salt in the oceans and of its annual and inter-annual variability, is crucial for understanding the role of the ocean and the climate system. Ocean circulation is mainly driven by the momentum and heat fluxes through the atmosphere/ocean interface, it is dependent on water density gradients, which in turn can be traced by the observation of SSS and SST (Sea Surface Temperature).

Figure 155: SMOS baseline S/C after PCR (Preliminary Concept Review, April 2001)

Soil moisture can be retrieved from brightness temperature observations. Due to the large dielectric contrast between dry soil and water, the soil emissivity ϵ at a particular microwave frequency depends upon the moisture content. At L-band in particular, the sensitivity to soil moisture is very high, whereas sensitivity to atmospheric disturbances and surface roughness is minimal. - Mission requirements call for 1) a soil moisture accuracy of $0.04 \text{ m}^3/\text{m}^3$ (i.e. 4%) or better; 2) a spatial resolution of $<50 \text{ km}$, relevant for large-scale studies; and 3) a revisit time of 3-5 days. 917) 918)

For sea water, the dielectric constant is determined by the electrical conductivity and the microwave frequency. The ocean surface emissivity is a function of the dielectric constant and the state of the surface roughness. In principle it is possible to retrieve SSS from brightness temperature observations. - Mission requirements call for typical values to resolve specific phenomena:

- Barrier layer effects on the tropical Pacific heat flux: accuracy of 0.2 PSU (Practical Salinity Unit) 919), with a spatial resolution of $100 \text{ km} \times 100 \text{ km}$, and a revisit time of 30 days
- Halosteric adjustment of heat storage from the sea level: 0.2 PSU, a spatial resolution of $200 \text{ km} \times 200 \text{ km}$, and a repeat cycle of 7 days

919) Note: SSS is defined in practical salinity units ($1 \text{ PSU} = 0.1\%$) and ranges from 32 to 37 PSU

- North Atlantic thermohaline circulation: 0.1 PSU, a spatial resolution of 100 km x 100 km, and a repeat cycle of 30 days
- Surface freshwater flux balance: 0.1 PSU, a spatial resolution of 300 km x 300 km, and a revisit time of 30 days.

The SMOS satellite uses the Proteus bus developed by CNES and ASI (Alcatel Space Industries). This standard platform has been designed to accommodate a wide field of missions, orbits, attitudes, instruments, and launch vehicles. Proteus has simple, well defined interfaces. The platform architecture is generic. Adaptations are limited to minor changes in software modules and launch vehicle interface. The S/C bus is a box, nearly 1 m per side, with all the equipment units accommodated on four lateral panels and the lower plate. Electrical power is generated by two symmetric wing arrays covered with silicon cells which provide 619 W orbital average after 3 year mission (EOL). The power is distributed through a single non-regulated primary electrical bus (23/36 V) using a recurrent SPOT-4 NiCd battery. The S/C is three-axis stabilized. Typical pointing performance of better than 0.05° (3 sigma) is provided by control system with four reaction wheels and gyro-stellar attitude determination. Coarse sun sensor and magnetometers provide attitude measurement and magnetic torquers generate torque. In addition, two of the four reaction wheels are used to provide gyroscopic stiffness. The on-board command and data handling relies on a fully centralized architecture. The DHU (Data Handling Unit) performs most of the tasks through the central processor running the satellite software. It also supports the management of the communication links with all the satellite units either via discrete point-to-point lines or via a MIL-STD-1553B bus. The S/C bus is designed to operate in five distinct satellite modes: 1) normal operations mode, 2) safe hold mode, 3) star acquisition mode, 4) orbit correction mode with 2 thrusters, and 5) orbit correction mode with 4 thrusters. SMOS has a total mass of about 500 kg. The design life is three years with a goal of five years.

Orbit: Sun-synchronous polar orbit, altitude = 755 km, inclination = 98.43° , local equator crossing time at 6 AM on ascending node.

RF communications: An on-board solid-state recorder has a capacity of 2 Gbit for payload and TT&C data. Standard S-band communications are used.

Sensor complement:

The **SMOS** sensor is a dual polarized 2-D interferometer operating at L-band (1.41 GHz) and based on the MIRAS (Microwave Imaging Radiometer with Aperture Synthesis) concept. The design of the passive spaceborne instrument uses three coplanar arms consisting of an elementary antenna regularly spaced (0.875λ , maximum redundancy) in a Y-shaped configuration (also referred to as a sparsely populated antenna, a thinned array is substituted for a filled array). In this concept, an interferometric Fourier synthesis is applied to derive images from the correlations between each pair of antenna elements (small independent receivers) operating in the microwave region. The 2-D SMOS interferometer permits the brightness temperature to be measured simultaneously at different incidences, and at two polarizations. Moreover, the instrument records an entire scene instantaneously. As the S/C moves, a given point within the 2-D FOV is observed from different view angles. A series of independent measurements is obtained permitting the derivation of surface parameters with improved accuracy. The brightness temperature field of such a design is reconstructed with a resolution corresponding to the spacing between the outmost receivers.

The SMOS instrument, operating at L-band (1.4-1.427 GHz, or 21 cm wavelength), employs a Y-shaped antenna arrangement, consisting of three arms, separated at 120° . Every

antenna arm supports a row of evenly spaced receivers along its span. Each arm consists of three deployable segments. The total deployed arm length is 3.2 m, each providing 25 receivers, 18 are mounted on the deployable arm with six positioned on the hub (non-deployable part). The hub interfaces with the platform and houses some common equipment, such as a total power radiometer for absolute calibration. The instrument structure (modular design) uses CFRP (Carbon Fiber Reinforced Plastic) material for reasons of stiffness.

Background on L-band radiometry: Operating the radiometer in the L-band provides the maximum sensitivity of the emissivity to both SM (Soil Moisture) and OS (Ocean Salinity). However it implies antenna diameters of several meters in order to meet the spatial resolution requirement for SM mapping which, for the design of SMOS, has been set at 50 km. A large real-aperture antenna on a LEO satellite poses a number of practical difficulties. A problem also arises from the need to achieve global coverage of the Earth within three days, which implies a large instrument swath. Microwave imaging by aperture synthesis provides an effective alternative to more classical solutions like the use of mechanically or electrically steered antennas and of pushbroom instruments. This interferometric approach to microwave radiometry, inspired by the techniques developed in radio-astronomy over several decades, is based on the use of many small antenna/receiver units, geometrically arranged so as to sample the signal that would have been received by a real-aperture antenna. This sampling in the spatial domain, enabled by the use of multiple antenna elements, provides a scanning capability through a wide swath by means of (ground) signal processing only.

Background on main instrument characteristics: Each antenna/receiver unit is based on a patch antenna without dielectric substrate with about 70° half-power beamwidth, directivity of about 8 dB and provides both H and V polarizations with excellent cross-polarization characteristics (co-polarization/cross-polarization ratio > 25 dB). A single receiver chain per antenna element is available, so each unit can operate on either H or V polarization upon command from a control unit. In each receiver the antenna signal is filtered to the selected bandwidth (1404 to 1423 MHz, in a region of the spectrum reserved for passive measurements), amplified and finally sampled and converted to a 1-bit digital signal. The output data stream, combining both I and Q components and at a rate of about 130 Mbit/s, is transmitted to the correlator unit by means of an optical fibre link. Each element also receives (via a second optical fibre link) a centrally-generated reference clock signal in order to perform the frequency down-conversion and the sampling with phase coherence among all elements. An oversampling by a factor of about 2 with respect to the Nyquist criterion is achieved in each receiver, which improves the radiometric sensitivity. In the correlator unit, after conversion from optical to electrical signals, a massive bank of 1-bit/2-level correlators implemented in dedicated integrated circuits performs the cross-correlations between all signals. Horizontal and vertical polarization images are interlaced and the cross-correlation for each polarization is performed over a 0.3 s period. Up to 5 images are then averaged, so two images (one per polarization) are available every 3 s.

Each antenna arm provides 3×6 receivers with a polarization capability in H + V. The antenna features four balanced feeds to obtain a co/crosspolarized ratio > 25 dB over an angular extension of $\pm 30^\circ$; there is also an intermediate stage for E- and H-radiation pattern alignment. Each receiver outputs the I- and Q-digitized signals. Each receiver is furnished with a suitable filter to reject interference from adjacent bands and to shape the frequency response. A multiplexer converts the eight parallel I- and Q-level bit streams from each group of four receivers into a ten-bit serial data stream (quantization) which are fed into a central demultiplexer for serial/parallel conversion. The digital correlator, at the end of the processing chain, performs a complex correlation (at zero delay) between each pair of antenna elements of the interferometric array, resulting in the so-called “visibility function” at the spatial frequency defined by that particular antenna element baseline. The visibility function is ideally the Fourier transform of the brightness temperature of the scene, weighed by the element gain pattern, and recovered by the inverse Fourier transform. The output is the visibility map.

A calibration subsystem, consisting of a set of noise sources that are being fed into the receivers, corrects the phase and modulus errors of the receivers. The calibration frequency depends on the thermal gradient and the receiver behavior with the temperature. The operating temperature of MIRAS is kept within a range of 0 to 50°C.

A typical SMOS receiver includes the following elements:⁹²²⁾ 1) RF device (with an input switch, a filter and an amplifier), 2) a phase/quadrature frequency down converter, 3) two two-level quantizers and samplers. The RF bandwidth is limited to 1400-1427 MHz, the input RF filter band is fixed at 1404-1423 MHz (interference avoidance). The I (In-phase) and Q (Quadrature) outputs of all receivers are processed by a matrix of 1-bit digital correlators, located in the hub.

Parameter	Desired		Acceptable
	Soil Moisture (SM)	SSS (Sea Surface Salinity)	
Coverage	Global (separate)	Global	Global (separate)
Mission duration	3-5 years	3-5 years	3 years
Frequency	L-band	L + C-Band	L-band
Polarization	H + V	-	H + V
Spatial resolution	10 km	20 km	50 km
Revisit time	1-3 days	1-10 days	3 days
Radiometric accuracy	1 K	0.5 K	2 K
Radiometric sensitivity	1 K	0.25 K	3 K

Table 254: Science requirements for the SMOS instrument

The SMOS configuration provides a swath width of 934 km at an orbital altitude of 755 km, sufficient for a 3-day equatorial revisit time. The antenna boresight is tilted at an incidence angle of 33° in the forward along-track direction for nominal radiative flux observations. The instrument tilt maximizes the footprint area for a given resolution goal and antenna spacing ratio. The tilted antenna footprint is represented by the sum of the overlapping individual antenna receivers, each representing a pixel of a distorted hexagon shape with curved sides; all pixel projections are of various sizes and incidence angles. A snapshot brightness temperature map of the FOV is taken every 0.3 seconds with an average resolution of about 5 K over 200 K. Due to the platform motion in orbit, each pixel is measured several times with different spatial and radiometric resolutions and incidence angles. The minimum FOV along-track dimension is about 800 km, this corresponds to 380 snapshots at 0.3 s each. Ground data processing must account for all observation variations in size, shape, angles, overlapping conditions, weighing and averaging schemes, etc., resulting eventually in a brightness temperature map for each snapshot as well as for the accumulated and averaged along-track observation incidences within FOV. The repetitive measurement scheme of radiation, from varying footprints and incidences, has a similar summation effect on the retrieval of the overall signal, as a TDI (Time Delay Integration) scheme for an optical imager.

The overall instrument mass is 305 kg, power = 313 W. SMOS data processing requires the introduction of corrections due to atmospheric, ionospheric, and galactic effects over ocean surfaces. In addition, SSS retrieval requires a knowledge of sea surface temperature and sea roughness. For observations over land surfaces, knowledge of the surface temperature is needed with an accuracy of 2 K. These reference parameters have to be obtained from instruments of other missions.

D.37 SPOT (Système Pour l'Observation de la Terre)

The SPOT Earth observation system was designed by CNES (Centre National d'Etudes Spatiales) of France, and developed with the participation of Sweden (SNSB) and Belgium (OSTC). The manufacturers of spacecraft series are: MMS (Matra Marconi Space), Aero-spatiale, and Sodern of France. All SPOT launches were on Ariane from Kourou. The SPOT program was initiated by France in 1978, the SPOT S/C series services represent a major provider of long-term and high-resolution imagery for the world. The SPOT program evolved into a worldwide network for receiving and disseminating data. ^{923) 924) 925) 926)}

S/C	Launch	Sensor Complement	Comment
SPOT-1	Feb. 22, 1986	2 HRV	Tape recorder failed in Sept. 1986. Operational activities ceased at the end of 1990, SPOT-1 was reactivated on March 20, 1992). Stopped tracking on August 2, 1993. SPOT-1 was reactivated in March 1994.
SPOT-2	Jan. 22, 1990	2 HRV, DORIS	Tape recorder failed in 1991 and early 1993. Operational as of 2000
SPOT-3	Sep. 26, 1993	2HRV, POAM-II, DORIS	An ACS failure occurred (loss of Earth lock) on November 14, 1997, terminating the operational service life of SPOT-3.
SPOT-4	Mar. 24, 1998	2HRVIR, Vegetation, SILEX, PAS-TEC, POAM-3, DORIS	Second generation S/C featuring an additional service module for passenger payloads (5 year design life instead of 3)
SPOT-5	planned 2002	2 HRG, HRS, Vegetation,	

Table 255: Overview of SPOT series missions

The spacecraft is 3-axis stabilized with a pointing accuracy of 0.1° using three momentum wheels (unloaded by two magnetic coils). Attitude is sensed by digital Earth sensors (FOV of $2^\circ \times 2^\circ$). A single solar panel (8.14 m in length) generates power of 1 kW, three NiCd batteries provide 24 Ah for eclipse operations. A hydrazine propulsion system provides orbit maintenance (eight 15.6 N thrusters). Total S/C mass at launch = 1907 kg; payload mass = 790 kg; solar power = 1 kW; nominal design life time of SPOT-1,2,3 = 3 years; S/C dimensions: 2m x 2 m x 4.5 m (solar panel span of 8.14 m); on-board recorders with a capacity of 22 minutes. The S/C structure features the SPOT Mk1 bus for SPOT-1 to SPOT-3 satellites. The SPOT S/C are operated at CNES in Toulouse.

Application: Land use, agriculture, forestry, geology, cartography, regional planning, etc.

Orbit: Sun-synchronous polar orbit, altitude = 832 km, inclination = 98.7° , period = 101 minutes, repeat coverage = 26 days, 10:30 AM local time (descending) equator crossing. Duty cycle: daylight coverage only.

Data transmission: carrier frequency = 8.253 GHz (X-band downlink); data rate = 2 x 25 Mbit/s. A second downlink capability is by tracking beacon at 8.307 GHz.

Sensor complement:

HRV = Haute Resolution Visible (High-Resolution Visible Sensor), using pushbroom CCD detector technology (array of 4 x 1728 pixels). The HRV sensor operates in either of two modes, namely the Multispectral Mode (MS) and the Panchromatic Mode (P). Each SPOT payload consists of two identical HRV imaging instruments that are pointable in the

⁹²³⁾ CNES viewgraphs of 1991

⁹²⁴⁾ Jane's Spaceflight Directory 1988-89, Fourth Edition, pp. 22-23

⁹²⁵⁾ Note: SPOT-1 was retired from normal operations in Sept. 1990. Both of its recorders are defect. SPOT Image wants to reactivate SPOT-1 to meet increased demand for satellite imagery. See Space News Dec. 4, 1991, p. 4

⁹²⁶⁾ Note: The board of inquiry investigating the failure of SPOT-3 reported that the successive failure of three of the spacecraft's six gyroscopes caused the satellite to lose attitude control, ran out of power and then shut down within a period of hours.

cross-track direction up to 27° from nadir (each imager instrument is featuring its own tilting mirror for independent off-nadir pointing). This new capability dramatically improves the availability of data for a given area, and also enables (repeat pass) stereo imaging, a key feature for the establishment of digital elevation models.

Figure 156: The SPOT S/C model and its observation geometry bounds

Each HRV sensor consists of a telescope with a pointing mirror and in the focal plane a series of CCD detector arrays. Two IFOVs are available, 20 m in the MS bands and 10 m in panchromatic band. Each instrument covers a swath width of 60 km when vertically positioned (both instruments have a TFOV of 117 km, 3 km overlap, nadir pointing). The swath width is 80 km (each) when the instrument is angled 27° to the vertical. Measurement angle: $\pm 27^\circ$ from the vertical (in 45 steps). Radiation from the scene being viewed enters the HRV instrument via a plane mirror that is steerable by ground control. The viewing axis can thus be oriented as required in the plane perpendicular to the orbit. This off-nadir viewing capability covers a range of $\pm 27^\circ$ relative to the vertical (in 45 steps of 0.6° each). The pointing feature increases the revisit capability at intervals ranging from one to several days.

- **HRV Multispectral mode (MS)** three spectral bands (coregistered) : 500 - 590 nm, 610 - 680 nm, and 790 - 890 nm. Spatial resolution in MS = 20 m.
- **HRV panchromatic mode** (black and white images), spectral band: 510 - 730 nm, spatial resolution = 10 m.

The FOV = 4.13° in both modes with 3000 pixels per multispectral line and 6000 pixels per panchromatic line. With its side-viewing feature, the HRV instruments are capable of plotting contours by taking stereoscopic images, as well as imaging a particular location more frequently, without waiting for an overhead pass. - An on-board data compression scheme DPCM (Differential Pulse Code Modulation) is employed for the PAN data stream on the SPOT-3 and -4 missions.

Data: (commercial data distribution by SPOT-Image Corp. of Toulouse and of Reston VA)

- Image size: 60 x (60 - 85) km
- Image size: MS mode: (3000 - 4900 Lines) x (3000 - 5200 pixels)
- Image size: P mode: (6000 - 9800 Lines) x (6000 - 10400 pixels)

DORIS (on SPOT-2 as an experiment and prototype, later on SPOT-3, ff.). DORIS is a CNES-developed tracking system for the determination of precise orbits (see DORIS description under TOPEX/Poseidon, chapter E.21.1).

Table 256: Some of the SPOT series direct receiving stations around the world

D.37.1 SPOT-3

SPOT-3 was launched September 26, 1993. The S/C is equipped with 2 HRV imaging sensors + DORIS + POAM-II. The satellite entered safehold on November 14, 1996.

POAM-II = Polar Ozone and Aerosol Measurement (atmospheric chemistry experiment). The instrument was provided by the Naval Research Laboratory (NRL) of Washington, DC

(built by ThermoTrex Corp., San Diego, CA); it is sponsored by the Innovative Science and Technology Office of the Ballistic Missile Defense Organization (BMDO) and the Space Test Program of DoD. The objective is to measure vertical profiles of polar ozone, aerosols, water vapor, nitrogen dioxide, atmospheric density and temperature in the stratosphere and upper troposphere. The measurement technique is by solar occultation through the Earth's atmospheric limb at nine wavelengths from the UV to NIR. There are separate filtered optics for each of the nine channels, which are co-aligned with each other and the sun tracker. FOV = 0.01° by 0.75° (slit). Observation of the full width of the solar disk with a vertical resolution of 0.6 km (at the tangent point in the Earth's atmosphere). Instrument mass = 25 kg. ⁹²⁷⁾

Channel	Primary Measurement	Center Wavelength (nm)	Bandwidth at FWHM (nm)
1	Aerosols	353.0	5
2	NO ₂ off	442.0	2
3	NO ₂ on	448.3	2
4	O ₃	600.0	15
5	O ₂ on	760.8	2
6	O ₂ off	780.0	15
7	H ₂ O off	920.0	2
8	H ₂ O on	935.5	2
9	Aerosols	1059.0	10

Table 257: Spectral coverage of the POAM-II instrument

Parameter	Height Range (km)	Accuracy (%)
Aerosols	10 - 40	5 - 15
O ₃	10 - 60	5
H ₂ O	15 - 40	5 - 7
N ₂ O	20 - 40	5 - 10
Temperature	10 - 60	1 - 2

Table 258: POAM-II measurement capabilities

POAM-II observes 14 sunrise and 14 sunset events per day. The primary measurements are through the Earth's limb for each of the nine wavelengths as a function of tangent altitude. These measurements are inverted to yield vertical profiles of ozone, aerosols, nitrogen dioxide, water vapor, and oxygen.

The POAM data rate is 32.768 kbit/s. Downlinks are via a dedicated POAM antenna. The downlink is received by a network of ground stations operated by the US Air Force. Uplinks are part of the general SPOT uplinks. Once validated, the reduced data (transmittances) are archived in the BMDO's Background Data Center at NRL, and will be publicly available.

When NASA's TOMS instrument failed to provide operational service aboard Russia's Meteor-3-6 satellite after Dec. 27, 1994, POAM became the only operating US ozone sensor.

D.37.2 SPOT-4

The SPOT-4 S/C was taken out of storage and launched on March 24, 1998 on an Ariane-4 vehicle from Kourou. SPOT-4 is considered a 2nd generation satellite. The most important advance is the addition of the "Vegetation" instrument, with four spectral bands to allow continuous, worldwide crop monitoring. The data may be used for crop forecasts and environmental studies.

⁹²⁷⁾ R. M. Bevilacqua, et al., "Polar Stratospheric Studies with the Polar Ozone and Aerosol Measurement Experiment (POAM-II)," Proceedings of the American Meteorological Society, Eighth Conference on Atmospheric Radiation, January 23-28, 1994, Nashville, TN

The SPOT-4 S/C design differs from the earlier SPOT series (SPOT-1,2,3) in the following aspects: five years design lifetime instead of three; a new extended platform design (the SPOT-4 satellite bus (SPOT MK2, provided by MMS) and service module accommodates twice the payload of the SPOT 3 bus). The propulsion module consists of a frame made of aluminum bars and two capillary tanks holding 158 kg of hydrazine. Attitude is sensed by an inertial platform consisting of four rate gyros, two digital Earth sensors, and two digital sun sensors. The actuators employed are three magnetic-bearing reaction wheels, two magnetic torquers (to control the speed of the reaction wheels), and two types of hydrazine thrusters each producing a force of 3.5 N or 15 N. SPOT-4 offers increased on-board storage capacity (from 22 min to 40 min). In addition, a 10 Gbit solid-state memory was added to increase the overall onboard recording capability. S/C mass = 2755 kg; power = 2.2 kW; pointing accuracy $< 0.15^\circ$ (3σ).^{928) 929)}

Orbit: Sun-synchronous circular orbit, altitude = 820 km, inclination = 98.8° , repeat cycle of 26 days, period = 101.5 min, descending node at 10:30 AM (equatorial crossing time).

Sensor complement: Improvements: introduction of electronic sensor gains matching according to landscape type and season, thus ensuring greater dynamic range. In addition, the imaging instruments are no longer susceptible to glare or affected by the polarization of the incident light.

HRVIR (two units) = High-Resolution Visible and Infrared sensor (improved version of HRV). Spectral ranges: $B_1 = 0.50 - 0.59 \mu\text{m}$, $B_2 = 0.61 - 0.68 \mu\text{m}$, $B_3 = 0.79 - 0.89 \mu\text{m}$, SWIR = $1.58 - 1.75 \mu\text{m}$ (a supplementary band in the 20 m multispectral mode at $1.58 - 1.75 \mu\text{m}$ is provided). The panchromatic band ($0.51 - 0.73 \mu\text{m}$ of HRV on SPOT-1,-2,-3) has been replaced by band B_2 , enabling the 10 and 20 meter resolution data to be co-registered on-board the satellite instead of on the ground. Same pointing geometries and resolution capabilities as HRV. In addition, the two HRVIR sensors can be programmed for independent image acquisition (viewing directions of both sensors are independent). Both HRVIR instruments are protected against polarization or blinding by direct sunlight.

The main elements of HRVIR are: the telescope, the detection unit, the image processing electronics, and the viewing direction control mechanism. The telescope (catadioptric Schmidt telescope type) has a focal length of 1.08 m and an aperture of 3.5. The incoming beam is split into four spectral channels by a beam-splitter consisting of prisms and filters, then focused onto four rows of linear CCD detectors [one line of 6000 (PAN) and three lines of 3000 (MS) pixels, the four rows of detectors simultaneously generate four lines of “registered” pixels]. The SWIR band uses InGaAs/InP linear arrays developed specifically for the purpose. FOV = 4.13° corresponding to 60 km of ground coverage.

The entrance to each HRVIR features a strip-selection mirror enabling the viewing direction to be adjusted through $\pm 27^\circ$ about nadir. Adjustment is controlled by a stepper motor moving through increments of 0.3° . For each position, the viewing direction is accurate to within 200 m on the ground.

HRVIR calibration: The calibration system allows image signals to be corrected in two ways: (used at regular intervals to check and, if necessary, adjust the instrument response).

- In-band calibration (also referred to as CCD detector response normalization), the aim is to balance the response of the 3000 detectors in each band while the instrument views a perfectly uniform landscape
- Absolute calibration to measure the instrument’s dynamic responsivity by establishing a precise relationship between a perfectly stable external source (the sun) and the instrument’s output signal.

929) <http://spot4.cnes.fr/>

VEGETATION. An additional sensor for SPOT-4, called VEGETATION or **VMI** (Vegetation Monitoring Instrument), with a ground swath width of 2200 km, and a resolution close to 1 km [European project with the cooperation of the EC, France (CNES), Sweden (SNSB), Belgium (OSTC) and Italy (ASI), designed by Aerospatiale as the prime contractor and built by Sodern of Limeil-Brivannes], providing the capability of wide-area monitoring of the Earth's vegetation (VMI features advanced optics that allow perfect geometrical rectification of the pictures despite the wide swath width. The VMI optics virtually cancel the curvature of the Earth to provide directly usable geographical information). Calibration accuracy: interband and multitemporal = 3%, absolute = 5%; TFOV = 101° (swath width of about 2200 km); pixel size = 1.15 km at nadir; location accuracy < 0.5 km, local distortion < 0.3 pixel, collocation with HRVIR sensor data = 0.3 km for simultaneous acquisitions. Spatial coverage: about 90% of the equatorial regions are imaged each day (total daily imaging for latitudes > 35°).

The instrument collects radiation reflected by the earth's surface. Silicon linear detector arrays are used for spectral band B0 (blue), B2 (red) and B3 (near infrared), while InGaAs photodiodes (Thomson CSF) are used for the SWIR (Short Wave Infrared) band. Each array features 1728 individual CCD detectors. The output voltage signals are fed to a multiplexer (prior to this, SWIR voltages are adjusted for dark current values), then to a single analog to digital converter (ADC). All sensors are processed by a single high precision 11 bit ADC, thus completely by-passing the problem of electronic interband calibration.

The VEGETATION package is an independent add-on payload to the SPOT satellite [the package includes the sensor, a solid-state recorder (up to 97 minutes of imagery), an X- and L-band telemetry subsystem, and a computer]. The instrument design uses four cameras, one for each spectral band, each camera is covering the TFOV. VEGETATION payload parameters: mass = 152 kg, power = 200 W, instrument size = 0.7 m x 1 m x 1 m, data transmit frequencies in X-band (8153 MHz) at 3.4 Mbit/s, and L-band (1704 MHz), data rate of sensor (L-band) = 510 kbit/s. ^{930) 931) 932)}

Three spectral bands of VEGETATION (B2, B3 and SWIR) and HRVIR (Red, NIR, SWIR) are identical, they register perfectly allowing data to be interpreted at several scales. The combination of high and low spatial resolutions (of HRVIR and VEGETATION) provides a major contribution to the measurement of temporal changes over a few points or at certain time periods for a proper determination of the influence of the various kinds of ground cover. ⁹³³⁾

Channel	Spectral Range	Surface Reflection Range (albedo)	Radiometric Resolution NEAR	Optimized to detect
B0 (Blue)	0.43 - 0.47 µm	0.0 - 0.5	0.003	chlorophyll
B2 (Red)	0.61 - 0.68 µm	0.0 - 0.5	0.001 albedo ≤ 0.1 0.003 albedo of 0.5	vegetation
B3 (NIR)	0.78 - 0.89 µm	0.0 - 0.7	0.003	vegetation, atmospheric correction
SWIR	1.58 - 1.75 µm	0.0 - 0.7	0.003	vegetation, atmospheric correction

Table 259: Spectral parameters of the VEGETATION instrument

The VEGETATION processing center (CTIV) is at VITO (Vlaamse instelling voor technologisch onderzoek – Flemish institute for technological research), located in Mol, Belgium. The commercial distribution of VEGETATION products is provided on a global scale by SPOT Image (France), with CLEO (Belgium), SSC Satellitbild (Sweden) and Tele-spazio (Italy).

DORIS (Doppler Orbitography and Radiopositioning Integrated by Satellite), a satellite-based orbit determination and radiopositioning system, see E.21.1. The SPOT-4 DORIS package includes experimental software (DORIS/DIODE experiment) to determine the S/C position in real-time to within < 0.3 m on the radial component.

SILEX (Semiconductor Intersatellite Link Experiment), an ESA experiment built by MMS. SILEX consists of two optical terminals, namely PASTEL on board SPOT-4 (a LEO terminal) on the anti-Earth side of the SPOT platform, and OPALE mounted on ESA's geostationary satellite ARTEMIS (a GEO terminal). ARTEMIS is to be launched in early 2000. The ARTEMIS downlink to the ground segment link uses conventional radio transmission (Ka-band). The SILEX payload on SPOT-4 (namely PASTEL) has a mass of 160 kg, power = 150 W.^{934) 935)}

- **PASTEL** (PAssager SPOT de Télécommunication Laser). A joint ESA/CNES passenger demonstration experiment. PASTEL is a prototype high data-rate intersatellite transmission system based on laser technology. The objective is to transmit imaging data from SPOT-4 to ARTEMIS. The aim of the experiment is to validate the PASTEL concept design in an operational environment. PASTEL is a gimbal-mounted assembly consisting of a telescope, an optical bench with a fine pointing system, communication detectors with avalanche photodiodes, a thermal control system for precision temperature control, a two-axis gimbal mechanism, and the launch locking mechanisms needed during the launch phase. The telescope mirrors and main structural elements are made of Zerodur. The acquisition and tracking sensors use CCD detectors. The laser diodes are of the GaAlAs type. The SPOT-4 - ARTEMIS optical links operate at wavelengths of 830 nm. Data to be transmitted include: HRVIR image data, pseudo-noise (PN) code, PASTEL telemetry.
- **OPALE** (Optical Payload for Intersatellite Link Experiment) terminal, mounted on the geostationary satellite ARTEMIS (a GEO terminal).

Laser links have the potential to offer much higher transmission rates (up to 10 Gbit/s) than conventional radio links which are limited to rates of about 250 Mbit/s. Another advantage of laser links is that by their very nature, there can be no interference between optical and radio transmissions. The technical challenge of the technology demonstration involves alignment and stabilizing issues, it requires pointing errors of < 10 μ rad. This pointing accuracy is several orders of magnitude lower than open-loop pointing of a typical platform.

The divergence tolerance of the communication beam for the SILEX configuration is 8 μ rad (or about 0.00046°). PASTEL and OPALE use a dedicated acquisition sequence. Initially, both terminals (PASTEL and OPALE) coarsely point to each other. This is done when OPALE scans a wide-angle (750 μ rad) beacon beam in the direction of PASTEL. On illumination of PASTEL by the beacon beam, it rapidly corrects its line of sight and directs in turn a narrow communication beam towards OPALE. Similarly, OPALE detects the incoming PASTEL signal, aligns its line of sight, and transmits its narrow communication beam towards PASTEL. The two terminals then remain locked on each other in closed-loop tracking, permitting subsequent communication.

PASTEC. A technology demonstration passenger payload to study the orbital environment. PASTEC contains the following experiment packages (PASTEC mass = 50 kg, power = 50W):

- **CEDRE**: Contamination and degradation of thermal control coatings in space. The objective is to study the variation with time of the thermo-optical properties of thermal control coatings using a calorimetric method combined with contamination measurement using quartz-crystal microbalances.

935) A. F. Popescu, B. Furch, "Status of the European developments for laser intersatellite communications," SPIE, Vol. 1866, 1993, pp. 10-20

- **ERCOS:** Cosmic radiation experiment. The objective is to study the effects of heavy ion fluxes on VLSI electronic components.
- **ERDOS:** Radiation dosimetry experiment. The aim is to measure cumulative radiation doses with MOS dosimeters.
- **MEDY:** Measurement of satellite dynamics. The objective is to characterize the vibration environment during the launch phase
- **MicroMEDY:** The objective is the characterization of the in-flight microvibration environment.
- **SILLAGE:** Measurement of electrostatic potentials on the outside of the SPOT satellite which are due to the “wake” effect. The objective is to evaluate the behavior of the materials used and to gain insights into the electrostatic discharge hazard comparable with our current understanding of the corresponding phenomena affecting geostationary spacecraft.
- **THERME:** same aims as CEDRE, but highly simplified. The aim is to study the ageing of thermal control coatings depending on their exposure to solar and terrestrial radiation and on their orientation with respect to the satellite’s velocity vector (exposure to and effects of atomic oxygen) using a calorimetric method based on simplified sensors.

POAM-III (Polar Ozone and Aerosol Measurement).⁹³⁶⁾ POAM-III is an NRL instrument (now sponsored by ONR instead of BMDO as done before), an improved version of POAM-II flown on SPOT-3. The objective is the measurement of the vertical distribution of atmospheric ozone, water vapor, nitrogen dioxide, aerosol extinction, and temperature. Improvements were made in the electronic system that provides lower noise and more accurate measurements. POAM-III is a nine-channel photometer device with a light-weight and low-power design. The instrument mounts on the exterior of SPOT-4, has a size of 22 cm x 23 cm x 34 cm, and a mass of 13.9 kg. A PCEM (Primary Control and Electronics Module) with a mass of 11 kg is mounted inside the S/C. The optical head assembly of the outside instrument includes an azimuth-elevation gimbal mount to track the sun. The azimuth and elevation axes move the line-of-sight parallel and perpendicular to the Earth’s horizon. The range of elevation is from -10° to -35°, the range of azimuth motion is $\pm 173^\circ$ from a nominal zero position. - The measurement technique is by solar occultation through the Earth’s atmospheric limb at nine wavelengths from the UV to NIR. There are separate filtered optics for each of the nine channels, which are co-aligned with each other and the sun tracker. The new optical filters have a greater ability to withstand the space environment. The wavelengths and bandwidths of the science channels differ slightly from those in POAM-II and are given in Table 260.

Channel	Primary Measurement	Center Wavelength (nm)	Bandwidth at FWHM (nm)
1	Rayleigh scattering	353.4	9.7
2	NO ₂ present	439.6	2.1
3	NO ₂ absent	442.2	2.1
4	O ₃	603	17.7
5	O ₂ present	761.3	2.3
6	O ₂ absent, aerosol	779	10.2
7	H ₂ O absent, aerosol	922.4	2.6
8	H ₂ O present	935.9	2.6
9	Aerosol	1018	11.6

Table 260: Spectral coverage of the POAM-III instrument

Each of the nine wave bands is measured by a separate optical channel. An image of the sun is formed with a fused silica plano-convex lens having a clear aperture of 11 mm, a nominal focal length of 63 mm, and an f-number of f/5.7. The detectors are silicon photodiodes operated in photovoltaic mode (data quantization of 15 bits). The instrument tracks the sun as it

⁹³⁶⁾ R. L. Lucke, D. R. Korwan, et. al., “The Polar Ozone and Aerosol Measurement (POAM-III) instrument and early validation results,” *Journal of Geophysical Research*, Vol. 104, D15, Aug. 20, 1999, pp. 18,785 - 18,799

risers and sets through the atmosphere, using a four-cell sun tracker with a 1° FOV. For POAM-III, the 1° sensor is supplemented with a 10° sensor to accommodate initial acquisition.

POAM-III measurement extent in altitude ranges: Aerosols = 10-30 km; O_2 , O_3 = 10-60 km; H_2O = 10-40 km; NO_2 = 20-40 km.

D.37.3 SPOT-5

Background: In 1994 the SPOT-5 program was approved by the French government, consisting initially of two identical S/C in orbit and two new optical imagers for these S/C, called HRG (High Resolution Geometric) and HRS (High Resolution Stereoscopic) to provide a ground resolution of 5m.⁹³⁷⁾ In 1996, the SPOT-5 program was downsized (to one orbiting S/C) and redefined to improve the spatial resolution of the imagery below 5 m. As a result, an innovative image acquisition and processing scheme has been developed by CNES to obtain spatial resolutions of about 3 m from two 5 m images. In January 1999, a further functional improvement was introduced giving the HRS (High Resolution Stereoscopic) instrument a full stereoscopic capability. It was also decided to continue to fly the VEGETATION instrument. The SPOT-5 satellite program continues the partnerships of France (CNES), Belgium (OSTC) and Sweden (SNSB) as established at the beginning of the SPOT program.

Figure 157: The SPOT-5 S/C model

The overall mission objectives are:⁹³⁸⁾

- To provide image acquisition and service continuity consistent with previous SPOT satellites to satisfy the user investments. Hence, the same sun-synchronous orbit is used providing the existing functional instrument capabilities with a 26 day repeat cycle, the

⁹³⁷⁾ A. Ammar, A. Baudoin, D. Assemat, M. Arnaud, "The SPOT Programme, An Operational Earth Observation System," Proceedings 45th Congress of the International Astronautical Federation, October 9-14, 1994, Israel

⁹³⁸⁾ A. Baudoin, "The Current and Future SPOT Program," Proceedings of the ISPRS Joint Workshop 'Sensors and Mapping from Space 1999,' Sept. 27-30, 1999, Hannover, Germany

same off-track viewing capability of $\pm 27^\circ$ about nadir, the same spectral band selection, and the same 60 km double swath.

- To improve the spatial resolution of the imagery to < 3 m in the panchromatic band and to 10 m in the multispectral mode. The SWIR band imagery remains at 20 m.
- To offer in parallel a stereoscopic along-track observation capability (instead of the previously provided cross-track capability). The intend is to offer high-resolution imagery to be used for DEM (Digital Elevation Model) generation with an accuracy of 10 m.

The SPOT-5 satellite configuration takes advantage of the SPOT-4 bus design, using the extended platform design (SPOT MK2, provided by MMS) and service module accommodates twice the payload of the SPOT 3 bus. The ACS (Attitude Control Subsystem) provides a pointing accuracy of 0.05° and an attitude restitution of 6×10^{-5} radians. The S/C structure has dimensions of: 3.4 m x 3.1 m x 6 m (excluding the solar array). The S/C mass is 3000 kg, power = 2400 W (EOL), batteries = 4 x 40 Ah, design life = 5-7 years. A launch of SPOT-5 is planned for early 2002.

Orbit: Sun-synchronous circular orbit (identical to those of SPOT-1 to -4), altitude = 818-833 km, inclination = 98.7° , period = 101 min, equator crossing on descending node at 10:30 AM, repeat cycle = 26 days, revolutions/day = 14 5/26.

Sensor complement:

HRG (High Resolution Geometric), built by MMS of Vélizy, France to continue to improve the HRVIR service of SPOT-4. Two HRG instruments are provided in the conventional SPOT-series double-observation configuration, each with a FOV of 4.13° and the same cross-track pointing capabilities of $\pm 27^\circ$ as the HRVIR imager on SPOT-4. The observation coverage of each HRG is 60 km in the nadir direction and > 80 km in the oblique configuration (same two-swath coverage as before).

HRG features a new linear detector array configuration geometry for the panchromatic band using two parallel rows (i.e., a dual array) of 12000 silicon CCD detectors ($6.5 \mu\text{m}$ in size) for each instrument. The two PAN detector lines are offset in the focal plane in such a way as to provide coincident imagery of the same instantaneous cross-track area, each at a spatial resolution of 5 m. [Note: The dual array in the focal plane (offset by one half pixel in one direction and 3.5 pixels in the other to avoid overlapping) is sufficient to improve the sampling grid without doubling each array's acquisition rate. The new sampling concept is based on Shannon's theory of information which states that "the sampling frequency must be equal to or greater than twice the maximum signal frequency" to obtain clean images using interpolation.] The CCD integration time is within 0.75 ms for a dual-array observation in cross-track of 60 km in which the S/C is moving 5 m in the along-track direction.

Bands	Spectral range	SPOT-1,-2,-3	SPOT-4	SPOT-5	
		Spatial resolution		On-board	Supermode
PA-1 (PAN)	0.49-0.69 μm	10 m		5 m	3 m
PA-2 (PAN)	0.49-0.69 μm			5 m	(on-ground)
B0 (Blue)	0.43-0.47 μm		1 km		
B1 (Green)	0.49-0.61 μm	20 m	20 m	10 m	
B2 (Red)	0.61-0.68 μm	20 m	20 m	10 m	
B3 (NIR)	0.78-0.89 μm	20 m	20 m	10 m	
SWIR	1.58-1.75 μm		20 m	20 m	

Table 261: Overview of SPOT series spectral continuity and resolution improvement

Supermode: The term refers to an acquisition process, specific to the HRG instrument of SPOT-5, through which an image sampled at 2.5 m may be obtained from two 5 m resolution panchromatic images acquired simultaneously, keeping within the same borders as the two 5 m resolution images. It is possible to combine the two 5 m pixel image samples into four new slightly overlapping image samples of about 3 m pixel size. A specific image processing

software, developed by CNES is used to reconstruct the final image after three processing steps: interleaving, interpolation and restoration. This new type of image, simulated with all its geometric and radiometric characteristics, has been compared by several users to other types of digital images at different ground resolutions. These users (cartographers, urban planners, environmental experts, foresters, agronomists,) have concluded that the supermode resolution is about 3 m (between 2.5 m and 3.5 m depending on applications and analyzed features).⁹³⁹⁾

Figure 158: Supermode processing scheme

Figure 159: Illustration of the HRS instrument

HRS (High Resolution Stereoscopic), developed and built by MMS, sponsored by CNES and SPOT IMAGE. The objective is to provide large-area along-track stereoscopic imagery with good altimetric accuracy (5-10 m relative and 10-15 m absolute). Applications of the stereo imagery are seen in various fields such as map making and in the generation of DTMs (Digital Terrain Model) The panchromatic band (0.51-0.73 μm) of SPOT-1,-2,-3 is being re-introduced. Parallel observation of forward and aft swaths (120 km width) in the along-track direction at pointing angles of $\pm 20^\circ$. A spatial resolution of 10 m is provided in cross-track and 5 m (parallax direction) in along-track. The stereo acquisition mode can be sus-

⁹³⁹⁾ SPOT 5 brochure, "Supermode," of CNES and SPOT Image, May 1999

tained for scene lengths of up to 600 km. HRS uses the same CCD line detector design as for the HRG instrument.

Parameter	SPOT-1,-2,-3	SPOT-4	SPOT-5
Prime sensor	2 x HRV	2 x HRVIR	2 x HRG
Spectral bands PAN	PAN (0.51-0.73 μm) at 10 m resolution	PAN (0.61-0.68 μm) at 10 m resolution	PA-1 (0.49-0.69 μm), 5 m PA-2 (0.49-0.69 μm), 5 m

S/C size (main structure)	2 m x 2 m x 4.5 m	2 m x 2 m x 5.6 m	3.4 m x 3.1 m x 6 m
Solar panel span, power	8.14 m, 1 kW	8.032 m, 2.1 kW	2.40 kW
Detector line array (Si) (Si) (InGaAs/InP)	6000 PAN, 3000 MS	6000 PAN, 3000 MS (2 lines) 3000 SWIR (1 line)	12000 PAN (2 lines) 6000 MS (3 lines) 3000 SWIR (1 line)
Recording capability	2 x 22 min	2 x 40 min	2 x 40 min (+solid state)
On-board data compression technique	DPCM (3/4) for PAN data only	DPCM (3/4) MS and PAN	DCT
Data rate (X-band)	2 x 25 Mbit/s	50 Mbit/s	150 Mbit/s
X-band frequency	8.253 GHz	8.253 GHz	
Design life	3 years	5 years	5-7 years

Table 262: Overview of performance parameters of the SPOT family

VEGETATION-2. With some minor improvements regarding instrument operations, the VEGETATION-2 instrument is identical in its technical specification to VEGETATION flown on SPOT-4.

DORIS

Communication: SPOT-5 provides an on-board storage capacity of 90 Gbit in solid state memory. The data compression algorithm used is DCT (Discrete Cosine Transform).⁹⁴⁰⁾ Compression ratios of 3 are used. Downlink data transmission is in X-band.

D.38 SSR1 (Satelite de Sensoriamento Remoto)

SSR1 is Brazil's Remote Sensing Satellite (INPE). Objective: repetitive monitoring of Brazil through spaceborne imagery (in particular the Amazon rainforest). A launch is planned for the end of 2004.^{941) 942) 943) 944)}

A multi-mission platform (MMP) is being developed for the SSR program supporting a payload mass of up to 190 kg and power up to 180 W (80 W during eclipse phase of orbit). The S/C is three-axis stabilized using a star and a sun sensor for attitude measurement; momentum wheels and magnetic rods are used as actuators. The pointing accuracy <0.1° in several pointing modes (Earth, anti-Earth, inertial and sun). A GPS receiver provides on-board position data. SSR1 has a total mass of 290 kg. Nominal design life of 4 years.

944) "Satellite Launch to Advance Brazilian Space Program," Space News Aug. 31-Sept. 6, 1992, p. 43

Orbit: Circular equatorial LEO orbit; altitude = 905 km; inclination = 0°; the orbit provides a revisit rate < 2 hours with up to 5 useful passes during daylight.

Sensor complement:

WFI = Wide-field Imager (CCD Linear Array Camera)

Objective: medium resolution VIS/NIR/SWIR remote sensing (in particular over areas of extensive vegetation in the Amazon region). Operation of the camera is only considered over Brazil (direct sensor data transmission to the ground).

Spectral bands	B1	B2	B3	B4	B5	B6
Spectral region (µm)	0.440-0.505	0.530-0.575	0.650-0.680	0.845-0.885	0.895-0.990	3.4 - 4.2
Spatial resolution at nadir	100 m				300 m	600 m
Swath width	2200 km (from latitudes of 5° to -15°), or FOV = ±44°					
Data quantization	8 bits					

Table 263: Parameters of the WFI instrument

The MCC function will be performed at INPE over a single ground station located in Cuiabá (Brazil). Data will be pre-processed and retransmitted at Cuiabá. Sensor image data from SSR1 is in X-band and TT&C communications via S-band. SSR1 on-board storage capability of 5 Gbit. Data distribution to the user community is provided through a GEO communications satellite.

D.39 VCL (Vegetation Canopy Lidar Mission)

VCL is a NASA/GSFC minisatellite mission in the ESSP (Earth System Science Pathfinder) program (selected in the spring of 1997) with the overall objective to characterize the 3-D structure of land cover for ecosystem/climate modeling, monitoring, and prediction (mapping of biomass, height of vegetation layer, density profile of the vegetation layer). The principal long-term data source for landcover studies (in the horizontal plane) thus far has been that of AVHRR on the NOAA POES S/C series. The goals of the VCL mission, namely a quantitative description of landcover and global productivity, try to extend the quality of current monitoring capabilities with a new altimetric multi-beam measurement concept, yielding survey data on a finer scale than before (also in the vertical plane), with sufficient coverage and repetitive observation cycles. The new approach promises improved interpretation methods for parameter estimations and modeling.

- Significant improvement (5-10 fold over past system capabilities) in canopy height monitoring for better biomass estimation
- Significant improvement in surface coverage (2% of the tropical land surface)
- Direct estimation of degraded areas, areas of regrowth, and intact forests for quantifying biomass degradation
- Comprehensive assessment of structure and organization at landscape level for biodiversity studies
- Generation of an (almost) global reference grid of land topography. The dataset represents a network of closely-spaced topographic control points at 1 m accuracy.

The S/C structure (built and integrated by OSC, Dulles, VA) is comprised of two octagonal cylinders of 1.1 m max. diameter. The bus structure is based on the LeoStar design of OSC with three elements: core module, propulsion module, and separation system. The S/C structure consists of modular Al honeycomb plates with stringers; thermal control is provided by a passive radiation system with backup heaters; three-axis stabilization provides 23 arcsecond (3 sigma) pointing knowledge and 0.1° (3 sigma) attitude control; on-board hydrazine propulsion is feeding four 4.5 N thrusters with 45 kg propellant; power is provided

by GaAs solar arrays of 3.8 m² and 30 Ah NiH₂ batteries; S/C design life of two years; the S/C mass is 260 kg plus 133 kg of payload mass. On-board control and data handling (C&DH) uses a 80C186 based computer an S-band transponder and an X-band transmitter. Use of AstroNav GPS receivers. ^{945) 946)}

A launch of VCL, initially planned for Sept. 2001 on the Athena-1 vehicle from Kodiak Island, AK, is being re-planned as of mid-2001. There is also a reassessment of the science and the associated risk with the laser development. A new launch approval from NAS/HQ is required. ⁹⁴⁷⁾

Data and S/C communications: On-board data storage of 32 Gbit is provided; science data downlink in X-band at 28 Mbit/s; TT&C in S-band; data volume of 2.2 GByte/day compressed (5.5 GByte/day depacketized). Mission operations and data processing is performed at the University of Maryland at College Park, MD. Data distribution is provided through the EROS Data Center of USGS, Sioux Falls, SD.

Data products are gridded at two different spatial and temporal resolutions:

- Monthly products, gridded to 2 km x 2 km (level 2)
- Six-month products: Updated and accumulated level 2 data for a 2 km grid cell are gridded and released as level 3 products.

Orbit: Circular orbit, altitude = 390 - 410 km (the low orbit requires monthly reboosts to 410 km, using monopropellant hydrazine, to maintain the nominal orbital altitude of 400 km), inclination = 67°.

Sensor complement:

MBLA (Multi-Beam Laser Altimeter). MBLA [GSFC instrument of SLA (Shuttle Laser Altimeter, flown on STS-72, Jan. 11-20, 1996) and MOLA (Mars Orbiter Laser Altimeter) heritage; PI: R. Dubayah, University of Maryland] utilizes a pulsed laser radar (i.e. a lidar) system for continuous global remote sensing of tree canopy height ($< \pm 1\text{m}$), vertical distribution of intercepted surfaces in the canopy, and ground topography elevations ($< \pm 1\text{m}$). MBLA features five laser transmitters (arranged in a circular configuration) in a single altimeter instrument, a large receiver telescope (made of beryllium), a set of five detectors and laser-pulse analysis electronics, computer/data command electronics, and a pointing angle measuring system. Instrument power = 220 W; mass = 133 kg.

Lasers	3-5 Nd:YAG diode-pumped pulsed lasers, operating at 1064 nm wavelength
Laser pulse rate and energy	242 pps (land), 10 mJ per pulse
Laser pulse duration	5 ns
Telescope	0.9 m diameter f/1 parabolic mirror, 20 mrad TFOV, 0.3 mrad IFOV
Detectors	Silicon avalanche photodiodes
Waveform digitization	250 Msamples/s
Samples per waveform	10-200, average of 50
Swath width	8 km
Resolution	25 m (60 μrad) footprint diameter (at 400 km altitude)
Track spacing	2 km
Elevation accuracy	$< \pm 1\text{ m}$ in low slope terrain
Vegetation height accuracy	$< \pm 1\text{ m}$ limited by 100:1 pulse detection, dynamic range and cal/val
Data quantization	10 bits

Table 264: MBLA parameter specification

⁹⁴⁵⁾ R. Dubayah, B. Blair, J. Bufton, D. Clarke, et al., "The Vegetation Canopy Lidar Mission," presented at ASPRS, Washington, D.C., 1997

⁹⁴⁶⁾ <http://essp.gsfc.nasa.gov/vcl.html>

⁹⁴⁷⁾ Information provided by Nick Chrissotimos of NASA/GSFC

The active MBLA instrument employs the pulse time-of-flight measurement technique and a laser shape analysis. Spatial coverage in the cross-track direction is provided with multiple beams (5) arranged in a pentagon pattern, each beam traces a separate (almost contiguous) ground track, sufficient to characterize horizontal spatial variability and vertical height distributions. The footprint of each beam describes a circle of 25 m in diameter (60 μ rad FOV), adequate to resolve vegetation height and structure. Five parallel tracks (spaced at 2 km intervals across-track) of Earth surface coverage are simultaneously monitored, providing a (perforated) swath of 8 km as illustrated in Figure 160.

Figure 160: Typical MBLA lidar configuration/ground measurement pattern of beams

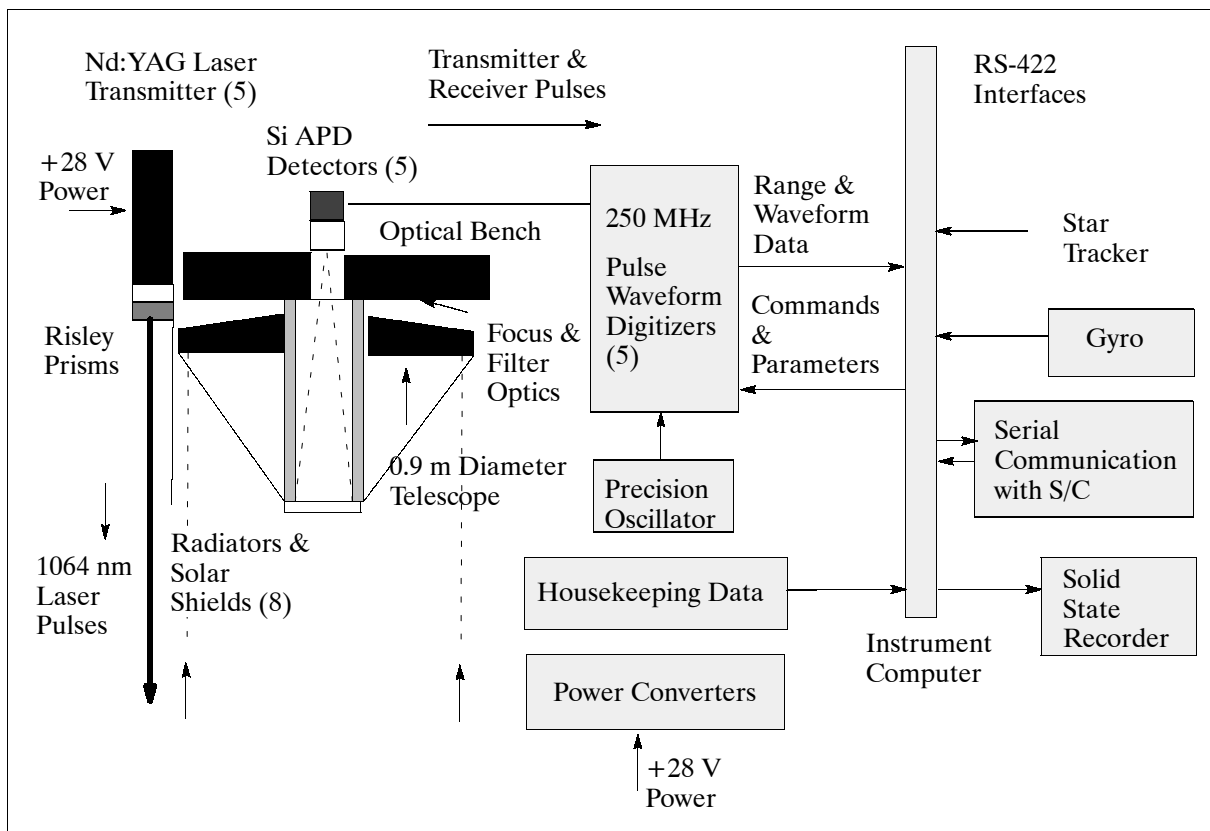

Figure 161: Schematic illustration of the MBLA instrument

MBLA makes simultaneous measurements of range by synchronous triggering of five laser pulse transmitters and detection with a single telescope that is staring at nadir and is equipped with multiple silicon avalanche detectors in its focal plane. Surface echoes from the five beams are digitized in the MBLA electronics at 250 Msamples/s.

Calibration. Calibration of ground height measurements requires on-orbit bias and drift retrievals. These are obtained through comparisons with results from the TOPEX/POSEIDON altimeter at ocean orbital crossover points between VCL and TOPEX/POSEIDON, as well as comparisons of VCL ocean altimetry with high resolution mean sea surface elevation maps.

RRA (Retro-Reflector Array). The corner cubes are made of the fused silica. Their performance is optimized at the green wavelength (532 nanometers). The corner cubes are symmetrically mounted on a hemispherical surface with one nadir-looking corner cube in the center, surrounded by an angled ring of eight corner cubes. The design is identical to the array used on the MSTI-2 Satellite.

D.40 UoSAT/SSTL Microsatellite Missions

The Center of Satellite Engineering (CSER) at the University of Surrey in Guildford, United Kingdom, has been pioneering the use of microsatellites in low Earth orbits (LEOs) since the late seventies. The numerous microsatellite missions so far are simple and low-cost designs featuring digital store-and-forward communications systems and services on a global scale. Communications payloads form the basis of communication links for both experimental and operational microsatellite missions and perform a range of missions from remote sensing data transfer and experimental data downlinks to remote site data collection and messaging. UoSAT stands for University of Surrey Satellites.^{948), 949)}

SSTL (Surrey Satellite Technology Limited) was formed in 1985 by the University of Surrey as a ‘technology transfer company’ in order to make its extensive research capability available to external organizations in an efficient and professional manner. Successful technology transfer and training programs have been conducted with numerous foreign government organizations.

S/C	Launch	Communications Payload and Objective	Uplink; Down-link
UoSAT-2	1984	First Store-& Forward (S&F) mission, 1200 baud AFSK, 128 kByte memory. - Amateur service	VHF; VHF/UHF
UoSAT-3 (OSCAR-14)	1990	S&F, 4 MByte file store, FSK digitally filtered, HealthNet/VITA. - Experimental	VHF; UHF
UoSAT-5 (OSCAR-17)	1991	S&F, 13 MByte file store, 9600 baud, FSK digitally filtered. - Amateur service	VHF; UHF
S-80/T	1992	S&F, 16 MByte file store, 9600 baud, FSK digitally filtered, transparent measurement transponder. - Experimental	VHF; UHF (WARC-92)
KITSAT-1 (OSCAR-23)	1992	S&F, 16 MByte file store, 9600 baud, FSK digitally filtered, DSP experiment using TMS320C25/C30, capability for adaptive modulation. - Amateur service	VHF; UHF
PoSAT-1	1993	S&F, 16 MByte file store, 9600/38400 baud, FSK digitally filtered, DSP experiment includes MSK downlink option and adaptive modulation. - Experimental	VHF; UHF
KITSAT-2	1993	S&F, 16 MByte file store, 9600 baud, FSK digitally filtered,	VHF; UHF
HealthSat-2	1993	S&F, 3x16 MByte file store, 9600/38400 baud, FSK digitally filtered, adaptive transmitter power under on-board computer control	VHF; UHF (WARC-92)
CERISE	1995	S&F, 9600/38400 baud, FSK digitally filtered,	VHF; UHF
FASat-Alfa	1995	S&F, 9.6/76.8 kbaud, FSK digitally filtered, DSP communications payload. Solid-state recorder at 256 MByte	VHF; UHF
FASat-Bravo	1998	S&F,	
TMSat	1998	S&F “email” communications,

Store & Forward (S&F) Communication.^{950), 951), 952)} The UoSAT-2 S/C carried the first digital S&F payload in orbit. Since then all further UoSAT/SSTL microsatellites have operated with S&F communication technique. A protocol suite called PACSAT was developed for this purpose. PACSAT uses packet radio techniques in the microsatellite system to transmit its data over the satellite RF link. Several layers of protocol are implemented in the PACSAT suite, at the lower level HDLC (High-Level Data Link Control) and X.25 provide the functions of packet multiplexing, error detection and ARQ (Automatic-Repeat Request) error correction. PACSAT is a point-to-multipoint protocol (broadcast); small ground terminals in the satellite footprint receive/send the data. The SSTL research aim in this area is to provide reliable service from distributed data collection terminals.

Aside from its many research and S/C-building activities, SSTL operates a command and control center in support of all its missions. The autonomous downlink data acquisition during a S/C pass includes housekeeping, experiment and point-to-point communications data.

The first UoSAT satellites were spin-stabilized and nadir-pointing S/C, employing attitude control by a combination of actuators: passive gravity-gradient boom, and 3-axis active magnetorquing system (switched currents under algorithmic computer control). Attitude is generally sensed by a combination of magnetometers (3-axis), horizon sensors, and/or sun sensors. The pointing accuracy is in the order of 2-3° rms.

SSTL microsatellite bus. The platform or bus is a modular tray design to exploit the technology upgrade opportunities presented by frequent missions (each launch represents in effect a new design configuration). The MicroBus was originally developed in 1988 and first flown on UoSAT-3 and -4 in 1990. The MicroBus platform is a boxlike structure (spin or three-axis stabilized) comprising service modules [such as: battery, solar power, communication (uplink/downlink, telemetry/telecommand), on-board computer (OBC), and attitude determination and control (ADCS)] and payload modules. All SSTL ADCS have been based on 3-axis magnetometers, computer-controlled 3-axis magneto-torquing, and by a gravity-gradient boom. Pointing accuracy was improved with the addition of sun sensors, horizon sensors, and star cameras.⁹⁵³⁾

SME). Objectives: Scientific and educational - investigation into low-cost microsatellite engineering techniques. S/C mass = 50 kg, power = 30 W peak.⁹⁵⁴⁾

Orbit: Sun-synchronous polar orbit, altitude = 534 km, inclination = 97.7°. The S/C re-entered the Earth's atmosphere on October 13, 1989 after eight years in orbit.

Sensors/Payload: CCD camera, Geiger-Müller radiation detectors, amateur radio communications, synthesized speech.

D.40.2 UoSAT-2

UoSAT-2^{955), 956)} was built by the University of Surrey within a 6-month period. Objective: proof-of-concept for LEO store-and-forward communications. UoSAT-2 was launched on March 1, 1984 (piggyback on the NASA payload Landsat-D' which became Landsat-5 in orbit), it is operating nominally as of 1/1996. S/C mass = 68 kg, power = 30 W peak (20 W orbit average).

Orbit: Sun-synchronous polar orbit, perigee = 655.7 km, apogee = 671.1 km, inclination = 97.98°

Spacecraft data is downlinked in VHF (145.825 MHz) at a rate of 1200 baud. In addition a secondary S-band beacon (2401.5 MHz) is operated with an output power of 180 mW. The S/C is operated by SSTL and is mainly providing amateur radio communication service.

Sensors/Payload: S&F (Store & Forward) communications, CCD camera, space dust detectors, amateur radio communications, synthesized speech.

The prototype CCD camera was based on a P8602 area-array CCD from EEV Ltd., array size: 384 x 288 pixels, 7 bit quantization; optics 4.8 mm, f/1.8.

D.40.3 UoSAT-3 (HealthSat-1)

UoSAT-3 was launched January 22, 1990 (piggyback on an Ariane flight V35 ASAP with SPOT-2 as primary payload), S/C mass = 50 kg, size: 650 x 300 x 300 mm, power = 35 W peak (25 W orbit average). The primary 80C186 on-board computer failed in May 1997. UoSAT-3 supports S&F communications for use by various humanitarian and medical groups around the world (VITA), in addition to its sensor operations. Sponsors: University of Surrey, Arianespace, VITA, AMSAT, RACAL.

Orbit: Sun-synchronous polar orbit, perigee = 784.4 km, apogee = 800.0 km, inclination = 98.58°

Sensor:

CREDO (Cosmic Radiation Environment and Dosimetry Experiment), of DRA. The objective is the monitoring of the near-Earth radiation environment. CREDO consists of two subexperiments: **CPE** (Cosmic Particle Experiment) and **TDE** = Total Dose Experiment (description under PoSAT). The **CPE** sensor is based around an array of large-area pin diodes (10 cm²) which are connected to a charge pulse height analyzer monitoring the linear energy transfer of particles as they pass through the diodes. CREDO instrument mass=2kg, power=0.5W, data=37.5 kByte/day.

D.40.4 UoSAT-4

UoSAT-4 was launched alongside UoSAT-3 (same mass, size, and power as UoSAT-3). UoSAT-4 carried technology demonstration payloads for ESA and DRA (Defense Research

Agency), Malvern, UK. After operating perfectly immediately following launch, communications were lost with UoSAT-4 and the mission had to be abandoned.

D.40.5 UoSAT-5

Objective:^{957), 958)} operational support for amateur satellite service, providing store-and-forward communications. Several space science and imaging experiments are supported in addition. S/C mass = 50 kg, size: 650 x 300 x 300 mm, power = 35 W peak (25 W orbit average). The S/C was topped by a 6 m antenna. UoSAT-5 was launched on July 17, 1991 (ASAP auxiliary payload to ERS-1 on Ariane flight V44). Nominal operations are conducted as of 1/1996.

Orbit: Sun-synchronous polar orbit, perigee = 763.7 km, apogee = 773.5 km, inclination = 98.42°

The S/C suffered a crash of its on-board computer system on January 29, 1995 (due to power problems). The S/C was diagnosed by ground control and returned to full operational state by February 1, 1995.

Sensors:

TDE = Total Dose Experiment (description under PoSAT)

EIS = Earth Imaging System (description under PoSAT). The images from UoSAT-5, KITSAT-1 and KITSAT-2 are freely available on amateur radio downlinks to suitably equipped and licensed radio amateurs.

SCTE = Solar Cell Technology Experiment. The experiment is designed to evaluate the effects of the space environment on 27 test samples of GaAs (Gallium Arsenide), Si (Silicon) and InP (Indium Phosphate) solar cells from a variety of manufacturers.

D.40.6 KITSAT-1 (Korea Institute of Technology Satellite)

A cooperative project between SSTL and KAIST (Korean Advanced Institute of Science and Technology) involving a S/C design based on the UoSAT platform (MicroBus) and concepts and a mission. On-the-job training of KAIST engineers at SSTL. A ground station was installed in South Korea (KAIST/SaTReC) for the purpose of tracking KITSAT S/C as well as to monitor other amateur satellites. S/C stabilization was realized with 3-axis magnetorquers and a gravity gradient boom. The KITSAT-1 S/C, the Korean name is Uribyul-1, (mass=46.6 kg) was launched August 10, 1992 on Ariane-4 ASAP (V.52, piggyback), along with Topex/Poseidon S/C as the prime payload. Nominal KITSAT-1 operations are conducted as of 6/1998.⁹⁵⁹⁾

Orbit: Circular orbit, perigee = 1302.5 km, apogee = 1327.8 km, inclination = 66.08°, period=111.9 minutes.

Sensors:

CRE = Cosmic Ray Experiment. CRE monitors the space radiation environment and its effects on S/C semiconductor electronics. CRE contains a PIN diode of 900 mm² and a multichannel analyzer capable of detecting energetic particles (5-600 MeV) with a wide range of linear energy transfer. The large number of channels and the fast response time of

the sensor allow CRE to build up the spectrum of observed energies of particles. CRE is the first UoSAT instrument to have its own built-in on-board compression software, enabling the system to carry out nearly 295,000 observations per day.

CEIS = CCD Earth Imaging System (of EIS heritage). Two video CCD imaging cameras with two optical assemblies. The cameras are aimed in the same direction but offer a different FOV. The wide angle camera (WAC) image has a ground resolution of 2 km and a FOV (68°) of 1500 km x 1050 km (NIR 810-900 nm filter; 4.8 mm focal length). The objective is to provide images with good contrast between land, sea, clouds, and ice or snow. - The narrow angle camera (NAC) has a ground resolution of 200 m and a FOV of about 150 km x 100 km (red 610 - 690 nm filter, 50 mm focal length). The cameras feature a monochromatic design with optical filters chosen to contrast ground properties, the NAC highlights variations in soil moisture content and vegetation density. An image is taken in a snapshot or staring mode (as opposed to a mechanically scanned pushbroom array) and is read from each CCD by a Transputer Data Processing Experiment (TDPE) and, after processing, provided to the On-Board Computer (OBC) and recorded. Camera sensor (both cameras): EEV CCD04-06 image sensor + chip set; 578 x 576 array (interleaved fields); anti-blooming and electronic integration control. Operational Earth imaging is performed on a scheduled snapshot basis.

DSPE = Digital Signal Processing Experiment. The DSPE consists of two Texas Instruments processors (C25 and C30 from TM320 series). The DSPE can be used as a programmable communications modem to modulate downlink data from, or uplink data to the OBC, thus enabling experiments with new modulation techniques to be optimized for LEO satellite mobile communications.

Communication: uplink = 9.6 kbit/s (FM) modulated FSK AX.25, 145.850 MHz, 145.900 MHz; downlink = 9.6 kbit/s FSK (FM) modulated AX.25, 435.175 MHz. In addition, **DSFCE** (Digital Store and Forward Communications Experiment).

D.40.7 S-80/T

A SSTL-built satellite under contract to Matra Marconi (France) for CNES. The S/C uses a standard ARIANE-4 compatible bus. The S-80/T satellite is a technology demonstrator for the S-80 LEO communications system. The objective is to evaluate the use of VHF frequencies for a full-scale LEO communications service (S-80) planned for the late 1990s. S-80/T measures in conjunction with a mobile ground station the effect of VHF spectrum noise and any signals interfering with the ability to communicate with a satellite in LEO. Frequencies: uplink=148 MHz, downlink=137 MHz. S/C mass= 50 kg, power = 35 W peak (25 orbit-average). The S/C was launched August 10, 1992 (along with KITSAT-1). SSTL provides S/C operations for CNES. Nominal operations as of 1/1996.

Orbit: Circular orbit, perigee = 1302.5 km, apogee = 1327.8 km, inclination = 66.08° , period=111.9 minutes.

D.40.8 HealthSat-2

A satellite built by SSTL for the SatelLife organization (VITA, Arlington, VA, USA) with the objective to provide inexpensive or free S&F communication links to doctors and health-workers beyond the reach of the global information infrastructure. HealthSAT-2 was launched on Ariane [along with six other microsatellites, among them: PoSAT-1, KITSAT-2, EyeSat, and ItamSat] September 26, 1993 as an auxiliary payload on the SPOT-3 launch from Kourou.

HealthSAT-2 is considered the operational successor to UoSAT-3, providing a second orbital element for the HealthNet and VITA networks.

Orbit: Sun-synchronous polar orbit, perigee = 792.5 km, apogee = 805.3 km, inclination = 98.64°

D.40.9 PoSAT-1 (Portuguese Satellite)

PoSAT^{960),961)} is Portugal's first satellite, built by a joint team of Portuguese and SSTL engineers at SSTL within a technology transfer program between UK and Portugal. The primary objective of the program is to stimulate a Portuguese space industry; the purpose of the PoSAT-1 mission is to generate a nucleus of engineers with first-hand space technology experience for Portugal's possible future satellite programs.

PoSAT-1 was launched from Kourou on Ariane, September 26, 1993 as an auxiliary payload on the SPOT-3 satellite. PoSAT-1 uses the modular UoSAT microsatellite platform. The S/C is stabilized by an Earth-pointing gravity boom and by a 3-axis magnetic torquing system. S/C mass = 50 kg, power = 20 W, downlink data rate = 9.6 or 38.4 kbit/s, VHF and UHF bands, ground receiving stations are in Portugal (Sintra) and the UK. S/C operation via Sintra station. The Portuguese S/C operator is 'Consortio PoSAT of LNETI (Laboratório Nacional de Engenharia e Tecnologia Industrial).' S/C design life = 5 years. On-board data recording capability of 32 MByte into solid-state memory. As of 1/1996 nominal operations are conducted.

Orbit: Sun-synchronous, perigee = 791.1 km, apogee = 805.4 km, inclination = 98.64°, period = 100.8 minutes.

Downlink frequencies: 145.975 or 145.925 MHz	Mode: JD 9.6 kbit/s FSK (primary or secondary)
Uplink frequencies: 435.075 or 535.050 MHz	Mode: JD 9.6 kbit/s FSK (primary or secondary)

Table 267: PoSAT-1 transponder frequencies

Sensor complement:

EIS = Earth Imaging System. Two video CCD imaging cameras with two optical assemblies. The cameras are aimed in the same direction but offer a different FOV. The wide angle camera (WAC) image has a ground resolution of 2 km and a FOV (68°) of 1500 km x 1050 km (NIR 810-900 nm filter; 4.8 mm focal length). The objective is to provide images with good contrast between land, sea, clouds, and ice or snow. - The narrow angle camera (NAC) has a ground resolution of 200 m and a FOV of about 150 km x 100 km (red 610 - 690 nm filter, 50 mm focal length). The cameras feature a monochromatic design with optical filters chosen to contrast ground properties, the NAC highlights variations in soil moisture content and vegetation density. An image is taken in a snapshot or staring mode (as opposed to a mechanically scanned pushbroom array) and is read from each CCD by a Transputer Data Processing Experiment (TDPE) and, after processing, provided to the On-Board Computer (OBC) and recorded. Camera sensor (both cameras): EEV CCD04-06 image sensor + chip set; 578 x 576 array (interleaved fields); anti-blooming and electronic integration control. Operational Earth imaging is performed on a scheduled snapshot basis.

SIS = Star Imaging System (attitude control). The sensor is based on the EIS camera but with suitable optics for imaging the faint light from stars. Spectral range: 400 - 1000 nm, the FOV is 10° x 7°, IFOV = 0.1° (in the Y-direction of the S/C). The star sensor image is analyzed by the TDPE and measurement data is returned to the OBC.

GPS Receiver (based on the Trimble TRANS-II 6-channel receiver). GPS data provides on-board position, velocity and time reference. The data is used by OBC to generate an orbital element set and to provide scheduling and synchronization to other on-board computers,

960) Information provided by J. Radbone of SSTL, University of Surrey, UK

961) "First PoSAT images," Space, Vol. 9, No. 9, December 1993, p. 6

and to allow ground stations equipped with a GPS receiver to experiment with applications for real-time DGPS. Posat is the first microsatellite to make use of a GPS receiver in orbit. It is the only satellite which has yet been able to autonomously determine its orbit through the processing of GPS data into orbital elements.

Satellite	EIS Camera configuration	Spectral Band	Orbit Altitude	Mean spatial resolution	Area of Image
UoSAT-5	single	600-615 nm	800 km	2 km	1500 x 1080 km
KITSAT-1	WAC NAC	810-890 nm 810-890 nm	1300 km	3.5 km 350 m	2550 x 1800 km 220 x 160 km
PoSAT-1	WAC NAC	810-890 nm 610-690 nm	800 km	2 km 200 m	1500 x 1050 km 150 x 100 km

Thai-Phutt	WAC NAC	810-890 nm 810-890 nm 610-690 nm 510-590 nm	800 km	2 km 100 m	1500 x 1050 km 100 x 100 km

Table 268: Versions of EIS video camera configurations on different spacecraft ⁹⁶²⁾

CRE = Cosmic Ray Experiment (description under KITSAT-1)

TDE = Total Dose Experiment. TDE is part of CRE, monitoring the total accumulated ionizing dose in a solid-state RADFET dosimeter. The larger memory devices in the computers are regularly ‘washed’ to detect and log Single Event Upset (SEU) information.

DSPE = Digital Signal Processing Experiment. The DSPE consists of two Texas Instruments processors (C25 and C30 from TM320 series). The DSPE can be used as a programmable communications modem to modulate downlink data from, or uplink data to the OBC, thus enabling experiments with new modulation techniques to be optimized for LEO satellite mobile communications.

D.40.10 KITSAT-2

KITSAT-2 was designed and built at KAIST/STRC in Korea. It was launched on Ariane-4 (along with PoSAT-1 and HealthSAT-2), September 26, 1993 as an auxiliary payload on the SPOT-3 launch from Kourou. For a description, see chapter D.19.1.

D.40.11 CERISE

CERISE (Caracterisation de l’Environnement Radioelectrique par un Instrument Spatial Embarque) was procured by the French Ministry of Defense (DME) through its prime contractor Alcatel Espace of France, and built by SSTL. Objective: characterization of the Earth’s radio environment. CERISE was launched on July 7, 1995 [Ariane ASAP, secondary payload to Helios-1A (a French military photo-surveillance S/C), flight number 75]. S/C mass = 50 kg, size: 650 x 300 x 300 mm, power = 35 W peak (25 W orbit average). The CERISE payload is classified (designed to eavesdrop on weak high-frequency communications).

On July 24, 1996, the CERISE S/C collided with a piece of debris (a suitcase-sized piece of an old Ariane rocket), cutting in half the 6 m long stabilizing boom of CERISE.⁹⁶³⁾ French ground controllers regained control over the satellite following the collision.

⁹⁶²⁾ M. Fouquet, A. Brewer, “The Role of Microsatellites for Earth Observation, Eight years of orbital experience at the University of Surrey,” in *Small Satellites for Remote Sensing*, Proceedings of Space Congress, Bremen, Germany, May 24-25, 1995, pp. 133-144

Orbit: Sun-synchronous polar orbit, altitude = 657.5 km x 680.3 km, inclination = 98.07°.

Figure 162: Typical UoSAT S/C models

D.40.12 FASat-Alfa (Fuerza Aerea Satellite - Alfa)

A microsatellite of Chile designed and built within one year under a Technology Transfer Program between the Chilean Air Force (FACH = Fuerza Aerea de Chile) and SSTL. The primary goal of the program is to obtain for Chile the basic scientific and technological experience required to continue with more advanced steps. Specific objectives of the FASat-Alfa mission are to create a group of engineers with aerospace experience and to operate the Mission Control Station (ECM-Santiago) in Chile.

FASat uses the proven modular UoSAT bus design; the S/C is stabilized by an Earth-pointing gravity boom and by a three-axis magneto-torquing system. First introduction of a yaw-axis reaction wheel into the micro bus to provide a nadir-pointing non-spinning platform. The FASat structure consists of 11 module trays including the battery box. Eight of the module trays are used for the platform systems, three module trays for payloads. S/C mass = 50 kg, power = 35W peak (25 W orbit-average).

A launch (secondary payload to SICH-1) was performed August 31, 1995 on a Russian Cyclone (Tsyklon) vehicle. **Unfortunately, the separation mechanism to release the microsatellite from SICH-1 failed to operate.** This implied non-operation (or hibernation) for FASat-Alfa. Some time after the launch, FACH and SSTL have declared the spacecraft to be lost. The SICH-1 S/C is able to perform its observation functions unharmed with the FASat S/C permanently attached to it.

A replica, FASat-Bravo, is under construction at SSTL as of 1996 for a launch in 1998.

Orbit: Sun-synchronous near-circular orbit, perigee=651 km, apogee=682 km, inclination = 82.5°, period = 98.7 minutes.

Sensor complement:

EIS = Earth Imaging System (description under D.40.9).

WAC		NAC	
Number of active pixels	568 x 560	Number of active pixels	568 x 560
Focal lens length	4.8 mm	Focal lens length	75 mm
FOV	102 x 73°, 1150 x 850 km	FOV	6.5 x 4.8°, 74 x 55 km

Table 269: Some parameters of the EIS camera system for FASat orbit

OLME = Ozone Layer Monitoring Experiment. The instrument consists of two UV cameras, one operating with CCD detectors, the other with UV photodiodes. The objective is ozone layer monitoring by measuring the backscattered UV solar radiation in frequency bands of 308 - 318 nm and 385 - 395 nm (total column ozone measurements). The measurements of OLME are in particular dedicated to overflights of the antarctic and sub-antarctic regions of Chile (correlations with ground-based observations of the UV radiometric network). The UV cameras use the EEV CCD02 (384 x 576 pixels) in the same circuit as the EIS cameras.

Parameter	Value	Parameter	Value
Number of active pixels	378 x 560	Focal lens length	12.5 mm
FOV	39° x 29° (450 x 330 km)	Resolution at nadir	0.1 x 0.05° (1.2 x 0.6 km)
Mean resolution (nadir)	0.9 km		

Table 270: Parameters of the OLME UV cameras

DTE = Data Transfer Experiment (S&F mode operation). The instrument consists of two redundant receivers and a redundant DSP (Digital Signal Processing) unit. The objective of DTE is to provide the space segment infrastructure (hardware, interfaces, firmware and software) to allow a variety of communication experiments of the following nature: a) uplink experiments, b) duplex/two-way experiments, c) data collection, d) data transfer (collection and distribution), e) downlink experiments, f) data distribution, g) technology demonstration, h) enhanced modulation/data rates/small terminals.

GPS Receiver. GPS data provides on-board position, velocity and time reference (Trimble TANS II with LEO firmware). Generation of Keplerian elements using a 32-bit transputer system (see description under PoSAT).

SSDRE = Solid-State Data Recorder Experiment. Provision of 256 MByte of RAM memory to all systems of the S/C (SSDRE was built by Lockheed Martin of Nashua, NH). The recorder is a highly integrated processing unit able to communicate with the host system, to manage storage operations and to perform internal diagnostic functions.

EdEx = Educational Experiment. EdEx is intended to promote direct participation in space by Chilean schools to communicate with the FASat S/C. EdEx in turn uses DTE to generate telemetry signals that can be received by low-cost receivers and a PC. DSP chips with the DTE produce digitized voice data that may be received by simple receivers. EdEx takes place on a scheduled basis. The curricular benefit for the students arises from the following activities:

- S/C tracking (learning of some basic orbital parameters)
- Handling of satellite communications (telemetry reception)
- FASat satellite telemetry analysis (in particular those parameters related to electric and thermodynamic parameters).

Data: The RF system consists of two redundant transmitters, three receivers and the associated modulators/demodulators. Downlink data rates are between 9.6 to 76.8 kbit/s to a single ground station in Chile. MSC-Santiago (Mission Control Station - Santiago at the Los Cerrillos Air Force Base) is in charge of controlling all aspects of satellite operations.

D.40.13 FASat-Bravo (Fuerza Aerea Satellite - Bravo)

FASat-Bravo is the second Chilean microsatellite in orbit, built under a technology transfer program between the Chilean Air Force (FACH = Fuerza Aerea de Chile) and SSTL. The program's primary objective is that of acquiring the basic scientific and technological experience required to take more advanced steps. The mission includes the same sensors/experiments as those of FASat-Alfa.

FASat-Bravo was launched successfully as a secondary payload (along with Thai-Phutt, TechSat/Gurwin-II, WESTPAC, and SAFIR-2 - and RESURS-O1-4 as primary payload) from the Baikonur Cosmodrome on a Zenit-2 launcher on July 10, 1998.

Orbit: Sun-synchronous circular orbit, altitude = 830 km, inclination = 98°.

Sensor complement: see FASat-Alfa description.

D.40.14 UoSAT-12

UoSAT-12 is an SSTL-funded proof-of-concept (technology) mission in low-cost minisatellite engineering techniques. Invited collaborative payloads are from NTU (Nanyang Technological University) in Singapore and from ESA. The design of a new standard minisatellite platform, MiniBus, started in 1996. The objective is to demonstrate and qualify the new MiniBus platform to fly an Earth observation package and to qualify new technology for flight on subsequent missions.

General MiniBus characteristics:

The MiniBus structure is essentially cylindrical with a height of about 1 m and a diameter of 0.6 m, supporting a payload mass of 50 to 150 kg. Payloads can either be carried in one or more standard SSTL MiniBus modules in the Module Stacks, or in the large payload frame with aperture access to the Earth-facing facet. Payloads for Earth observation can be carried directly on the nadir pointing Earth frame, and space-facing payloads are accommodated on the zenith-facing facet. The thrust bearing column of the minibus consists of three stacks of Surrey's standard microsatellite module trays. The stacks (340 mm x 340 mm x 500 mm) are joined around a triangular central void and placed on a honeycomb panel of about 1.1 m diameter. ^{964) 965)}

The OCS (Orbit Control and Determination System) comprises a GPS receiver, and a cold gas thruster system. Both are also an integral part of ADCS (Attitude Control and Determination System). The ADCS actuators include: two Surrey momentum wheels, one Ithaco momentum wheel, cold-gas jets, magnetorquers, and a gravity gradient boom. The sensors include: three three-axis magnetometers, four two-axis analog sun sensors, a GPS receiver (SGR-20) and two star cameras, a Servo Earth sensor and an Ultra magnetometer and a solid-state gyro. The three-axis control system maintains Earth pointing to an accuracy of 0.5°, with an experimental target of 0.1°, for Earth observation payloads and communication antennas. The ADCS can be operated in momentum-biased mode, zero momentum mode, or in gravity-gradient mode (for EOL mission extension). ADCS and OCS are supported by an attitude control processor, which can be run on any of the four primary on-

964) J. Ward, M. Sweeting, "First In-Orbit Results from the UoSAT-12 Minisatellite," Proceedings of 13th Annual AIAA/USU Conferences on Small Satellites, Logan, Utah, Aug. 23-26, 1999, SSC-99-I-2

965) W. Sun, M. N. Sweeting, "In-Orbit Results from UoSAT-12 Earth Observation Minisatellite Mission," Proceedings of the 3rd International Symposium of IAA, Berlin, April, 2-6, 2001, pp. 79-82

board processors. Additionally, UoSAT-12 carries an electric propulsion system, a 90 W resistojet producing 93 mN of thrust, which uses nitrous oxide as its working fluid. ^{966) 967)}

The power system comprises a set of nine deployed solar panels and battery charge regulators, three 6Ah battery packs, a centralized power switching system, and a distributed power conditioning system. Power is distributed and switched via an unregulated 28V bus. The solar panels employ highly efficient GaAs cells, supplying an orbit average power of 150 W to the platform. Panels are deployed at an angle depending on the orbit and power profile required for the mission. In order to provide prolonged battery cycle life, NiCd cells are used in the 18Ah battery.

Figure 163: The UoSAT-12 minisatellite

Communication: UoSAT-12 carries five uplink receivers. Three are 10 kbit/s FSK channels in the VHF-band. Two are L-band receivers integrated in the Merlion 1 Mbit/s transponder. The communication system employs VHF and UHF uplinks and downlinks for standard telemetry and telecommand. These also provide the standard S&F (Store and Forward) digital transponder service. An S-band 1Mbit/s downlink supports payloads that generate large amounts of data, such as Earth Observation payloads. The three UHF downlinks support 9.6 and 38.4 kbit/s with CPFSK modulation. The dual redundant S-band downlink provides 1Mbit/s BPSK modulation, with optional Viterbi encoding.

Telemetry and telecommand is implemented as a distributed system based on a microcontroller with ISO-11898 CAN (Controlled Area Network) support. Each payload and bus system contains one or more nodes, each of which is implemented using a CAN microcontroller. The network is dual redundant and DC isolated. The TT&C master is implemented in software, and its function is to collect, format and downlink telemetry and issue telecommands, either direct or programmed. The TT&C master would nominally be the primary on-board-computer, however this architecture allows any other computer, and indeed any of the nodes to perform this function.

UoSAT-12 was launched April 21, 1999 by a Russian launcher, Dnepr, of Kosmotras International Space Co., Moscow, from the Baikonur Cosmodrome, Kazakhstan. S/C mass = 325 kg. The launch was the first commercial mission for the former Soviet Union's arsenal of SS-18 Satan missiles (all of which have to be destroyed or used for peaceful purposes under the START arms reduction treaty). The Dnepr vehicle was created in 1997 under an agreement between the Russian and Ukrainian space agencies.

Orbit: Circular orbit, altitude = 650 km, inclination = 64.57°.

Sensor/payload complement of UoSAT-12

The payload imaging systems include high-performance processor modules to provide autonomous image assessment and compression. The processing units are based on the Inmos T805 transputer and are an integral part to the operation of the imaging instruments (they manage all aspects of the imagers including scheduling, image capture, analysis preprocessing and compression). The compression algorithm used is AMPBTC (Adaptive Moment-Preserving Block Truncation Coding), achieving compression ratios up to 4:1. Although the compression is relatively modest, the AMPBTC routine preserves fine detail more faithfully than for instance JPEG.

WAC (Wide Angle Camera). The instrument is of UoSAT-5 and PoSAT-1 heritage under the name of EIS (Earth Imaging System). An extremely wide angle lens is used (4.8 mm focal length) to offer wide coverage. The camera is fitted with an optical filter giving NIR sensitivity and providing strong contrast between land, sea and cloud. The WAC instrument often serves as a spotter camera to assist in locating scenery from the other cameras.

SHC (Surrey High-resolution Camera). SHC uses COTS (Commercial Off-The-Shelf) components. The panchromatic instrument features a Kodak-built silicon CCD detector of size: 1024 x 1024 pixels and a Leica lens with an aperture of 560 mm (f/8). The footprint is 10 km x 10 km per image (step-and stare operation of a 2-D detector array). The camera can also be programmed to capture a sequence of images, thus allowing long swaths of imagery to be collected. The mass of SHC is 10 kg.

Camera	Spectral Band	Orbit	Mean Resolution	Coverage (Image Size)
WAC	810–890 nm	650 km	975 m	1000 x 1000 km
SHC	Panchromatic	650 km	10 m	10 x 10 km
MSI-0	Bands 1,2,3,4 & 8	650 km	32.5 m	33 x 33 km
MSI-1	Bands 1,2,3,4 & 8	650 km	32.5 m	33 x 33 km
Star0	400-1000 nm	650 km	0.02°	20° x 15° (FOV)
Star1	400-1000 nm	650 km	0.02°	20° x 15° (FOV)

Table 271: Parameters of UoSAT-12 camera systems

MSI (Multispectral Imager). There are two MSI instruments (MSI-0 and MSI-1) on-board working in tandem and angled in the cross-track direction (3°) to provide a combined coverage of 60 km (cross-track) x 30 km (along-track). Each imager has a 2-D CCD silicon detector of size 1024 x 1024 pixels and a lens of 180 mm aperture (f/3.4). The spatial resolution is 32.5 m. The MSI instruments use rotating filter wheels to image in four spectral bands (0.45 - 0.52; 0.52 - 0.60; 0.63 - 0.69; and 0.76 - 0.90 µm), identical to bands 1-4 of Landsat's TM (Thematic Mapper). The transputer support of MSI makes it possible to image contiguous swaths or to support step-and-stare observations. The mass of each MSI instrument is 3 kg.

Star cameras (Star0 and Star1). There are two star cameras aboard acting as precision attitude sensors. The FOV of one camera is 20° x 15° to ensure coverage of enough stars, the other camera has a FOV of 10° x 7° providing a fine resolution. The optics for the star cameras are: f/0.85 25 mm and f/1.0 50 mm, respectively. Both cameras use CCD detectors. In order to operate under very low light conditions, such techniques as long integration times

(up to a second), reduced output noise bandwidth, a non-linear transfer function, and low-noise amplification are used to obtain usable signals from faint stars.

The spacecraft imagers have been performing excellently, their success has been the return of spectacular 10m resolution panchromatic and 32m multispectral images from orbit demonstrating “a breakthrough in the order of magnitude reduction in cost for high resolution space imagery.”

SGR (Space GPS Receiver). SGR-20 is an ESA-funded instrument in partnership with SSTL. The objective is to provide an experimental test-bed for GPS orbit and attitude determination. The SSTL design uses a MITEL chip set and an ARM60 RISC processor (32 bit). Radiation tolerance is implemented through an EDAC (Error Detection And Correction) memory and a latch-up protected power switch. SGR is a 24-channel instrument, it features five GPS antennas, four of which can be used simultaneously to track GPS signals. The carrier phase of L1 signals are observed at each of the four antennas. One antenna is sufficient for orbit determination. With the signals from the multiple antennas it is possible to determine the S/C attitude by measuring phase differences and applying interferometric techniques.⁹⁶⁸⁾

EPS (Electric Propulsion System). EPS is an experimental resistojet electric propulsion system. Water on nitrous oxide is super-heated over a resistive heater element, the resulting hot gas is expelled through a nozzle to produce low-level thrust at moderate specific impulse. The thruster provides a thrust of 93 mN, using 90 W of input power, the Isp is 1250 m/s. A total Δv of 10.4 m/s is provided by a 2-liter tank of self-pressurized nitrous oxide.

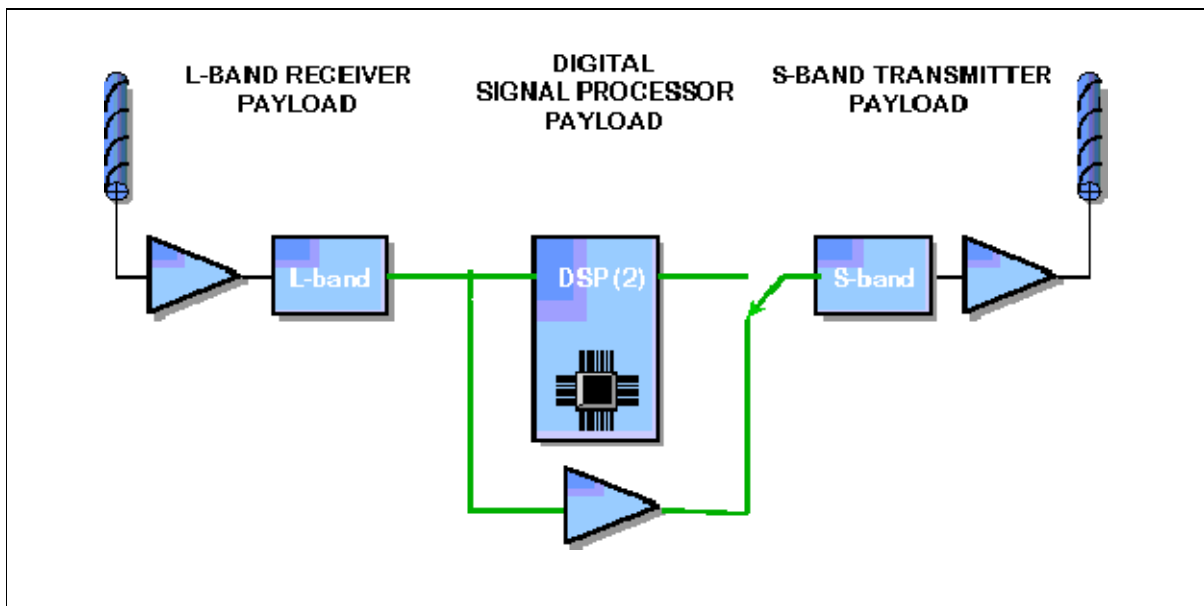

Figure 164: The Merlion L-band to S-band transponder

Merlion Communications Package of NTU (Nanyang Technological University), Singapore in cooperation with SSTL. The objective is to demonstrate a new communications technology (radio amateur L/S-band transponder) for LEO systems to improve coverage in particular for equatorial regions. A later constellation of several suitably phased satellites in such an orbit can provide continuous coverage for the lower latitude regions. The use of L-band and S-band amateur frequencies is to stimulate more extensive use of these bands (by experimenting with various access schemes and operating modes). A ground station at

⁹⁶⁸⁾ S. Purivigraipong, M. J. Unwin, Y. Hashida, “Demonstrating GPS Attitude Determination from UoS-12 Flight Data,” ION-2000, Salt Lake City, UT, Sept. 19-22, 2000, pp. 2625-2633

NTU is testing these schemes. The payload combines an analog and digital regenerative transponder with L-band uplink and S-band downlink.⁹⁶⁹⁾

Downlink: The frequency-agile digital S-band downlink is used for high-speed data transfer and performs a variety of communication experiments. It is capable of low rate spread spectrum communications, and has Viterbi coding options to investigate its performance in the highly dynamic LEO environment. The downlink is also used to perform link characterization at these frequencies. The modulation scheme is NRZ-L/BPSK at 256 kbit/s, 512 kbit/s and 1 Mbit/s with square root raised cosine shaping. The data is processed via various scramblers and encoders. Data is scrambled using a standard V.35 scrambler, or via a programmable 32-bit universal scrambler. A 1/2 rate Viterbi encoder ($k=7$, $G1=171$, $G2=133$) is also included, and a spread spectrum mode permits experimentation with lower data rates for smaller ground stations while keeping the chip rate at 1Mbit/s. The downlink power is 7W.

Uplink: The digital uplink consists of a frequency-agile L-band 9600 bit/s FSK receiver. Both IF outputs and baseband outputs are presented to a TI C31 Digital Signal Processor, for modulation and coding experiments. The frequency scanning functions and variable bandwidth IF filtering permit the receiver to be used in conjunction with the DSP for narrow band channel characterization and transponder measurements. In conjunction with the on-board-computers, the digital uplink and downlink system can be configured into a high rate S&F transponder.

The satellite antennas are shaped in such a way as to provide equal power flux density across the satellite footprint. Quadrifilar helices are employed with downlink LHCP and uplink RHCP.

D.40.15 TMSat (Thai-Microsatellite)

TMSat, also known as Thai-Phutt, is the result of a two-year in-depth collaborative technology transfer program (focusing on the construction and launch of TMSat) between the UK and Thailand. TMSat is also the name of a company, namely of TSC (Thai Satellite Communication) and of MUT (Mahanakorn University of Technology), both of Bangkok, Thailand. MUT and TSC are investing in TMSat in order to develop satellite technology in Thailand. The TMSat application objectives are in the fields of Earth observation and store-forward communications.⁹⁷⁰⁾

The S/C platform is based on the latest version of the 'Micro-Bus' of SSTL, a boxlike three-axis stabilized (Earth-pointing) structure with gravity boom. The bus consists of a series of identical module trays stacked one on top of the other to form a body, onto which solar panels and instruments are mounted. The ADCS (Attitude Determination and Control Subsystem) module controls the alignment of S/C in the Earth-pointing direction. Magnetometers measure the Earth's magnetic field vector, they are used together with sun sensors for achieving the attitude information. A S/W package (using estimation theory and robust control theory) provides for proper attitude determination and control (attitude is maintained within 1° of nadir and determined within 0.001°). Magnetorquers and a momentum wheel are applied as actuators. Power is provided by four body-mounted GaAs panels (35 V, 1 A). Batteries are used to provide power during eclipse phases. There are 10 NiCd commercial cylindrical cells with F size cells with a capacity of 7Ah. The S/C mass is 50 kg.

TMSat was launched successfully as a secondary payload (along with FASat-Bravo, TechSat/Gurwin-II, and SAFIR-2 - and RESURS-O1-4 as primary payload) from the Baikonur Cosmodrome on a Zenit-2 launcher on July 10, 1998.

⁹⁷⁰⁾ <http://www.ee.surrey.ac.uk/CSER/UOSAT/missions/tmsat/info/index.html>

Communication: 1) uplink: three redundant receivers and four monopole antennas, three demodulators (CPFSK). VHF uplink frequency, UHF downlink frequency, downlink data rate at 9.6 kbit/s, FSK modulation. 2) downlink: two redundant transmitters, four monopole antennas, two modulators (CPFSK). UHF downlink frequency, downlink data rates of 9.6 kbit/s and 38.4 kbit/s (data).

Orbit: Sun-synchronous circular orbit, altitude = 835 km, inclination = 98°.

Sensor complement:

EIS = Earth Imaging System. EIS consists of two basic elements:

- **WAC** (Wide Angle Camera), a CCD sensor made by EEV Ltd. with an active imaging pixel array of 568 x 560 (same as for FASAT-Bravo). WAC is fitted with an ultra wide angle lens (focal length 4.8 mm) to provide a coverage area of 1500 km x 1050 km at a mean resolution of 2 km. The camera is fitted with a near-IR optical filter (810-890 nm) to provide strong contrast between land, sea and clouds. The camera is recording light from the sun, reflected off the Earth's surface and atmosphere. A WAC image is 330 kByte in volume.
- **NAC** (Narrow Angle Camera). The camera design is a new development for the TMSat mission and uses a 1020 x 1020 pixel CCD sensor manufactured by Eastman-Kodak. The three NACs are electrically identical, as are the lenses (75 mm focal length) used to provide 100 m resolution for an 835 km orbit. The cameras employ 2-D CCD arrays with digitized data of 8 bits, offering 100 km swath widths and a capability to collect images contiguously along the flight path. The images are in three spectral bands (red, green and VNIR) providing information on Earth resources, land use, and effects of natural disasters. Each NAC image is 1 MByte in volume.

WAC		NAC	
Spectral range	810 - 890 nm (VNIR)	Spectral range, NAC0 NAC1 NAC2	810 - 890 nm (VNIR) 610 - 690 nm (red) 510 - 590 nm (green)
Number of active pixels	568 x 560	Number of active pixels	1020 x 1020
Focal lens length	4.8 mm	Focal lens length	75 mm
FOV	102° x 73°, or 1500 km x 1050 km	FOV	6.5° x 6.5°, or 100 km x 100 km
IFOV (nadir)	0.18 x 0.13°, 2.0 x 1.5 km	IFOV (nadir)	0.085° x 0.085°, 100 m

Table 272: Some parameters of the EIS camera system for the TMSat orbit

CMOS Video Camera with APS (Active Pixel Sensor) technology.

CCD detector array	382 x 287 pixels
Spatial resolution, FOV	400 m, 10.5° x 7.8°
Ground coverage	150 km x 110 km
Spectral range	350 - 750 nm (VIS range)
Lens	25 mm, f/8

Instrument power	200 mA at 5V = 1W continuous operation
Instrument data storage	4 MByte (= 30 images)

Table 273: Parameters of the CMOS Video Camera

DSPE = Digital Signal Processing Experiment. The objective is to provide a programmable DSP capability to perform any communication and signal processing experiments. The

DSPE consists of two Texas Instruments processors (TM320 series). The system is equipped with 128kbyte program memory with Error Detection and Correction (EDAC). Also 1MB of unprotected data memory is provided. The design permits a number of experiments to be conducted via DSPE which can be summarized as follows:

- Real-time voice communication
- Experimental digital modem design
- In orbit signal analysis
- A scanning receiver
- Digital voice broadcaster
- etc.

GPS Receiver. The objective is to provide: a) a real-time clock to synchronize the satellite and ground station, b) information of the satellite position which is used by the ground station to determine the microsatellite orbit.

D.40.16 SNAP (Surrey Nanosatellite Applications Program)

A program of SSTL and CSER (started in 1998) with the objective to develop a modular, multi-mission nanosatellite bus (mass range of 1-10 kg), to demonstrate the use of miniature electrical and mechanical COTS (Commercial-Off-The-Shelf) product technologies in space and their use as autonomous robots for observing orbiting space vehicles. SSTL intends to market SNAP-type satellites commercially. Future applications of nanosatellites are seen in remote inspection of satellites and monitoring of deployment systems in orbit, and carrying small space science instruments requiring measurements with spatial diversity. 971) 972) 973)

D.40.17 SNAP-1

SNAP-1 was designed and built as a low-cost research mission by a joint academic-commercial team at the Surrey Space Center and at SSTL, funded entirely by SSTL. The objective of SNAP-1 is to demonstrate the feasibility of a standardized modular nanosatellite bus.

- Provide a test-bed for novel microelectronic technologies - in particular a new GPS navigation system, APS camera technologies and RISC processors. The intent is to use SNAP-1 as a “remote inspector demonstrator.”
- Provide experimental data and imagery to the radio-amateur/amateur-scientific communities
- Provide a vehicle for the education and training of students in spacecraft engineering at undergraduate and post-graduate level
- The SNAP program is also intended to demonstrate the feasibility of using clusters of low-cost satellites that can fly in formation and conduct multipoint remote sensing.

The SNAP-1 nanosatellite is three-axis stabilized by a momentum wheel and magnetorquers as actuators; the S/C attitude is sensed by a three-axis magnetometer and sun sensors. A GPS receiver (model: SGR-05 of SSTL) is used for autonomous orbit determination (on-board navigation parameters and timing). The SGR-05 performs differential orbit determinations in conjunction with Tsinghua-1. The S/C bus features a modular design based on a tray structure (up to three trays). A micro-propulsion system (liquified gas) is used for orbit maneuvers (rendezvous with other S/C). Four body-mounted solar cells provide an average power of 6.5 W each. SNAP-1 has 4 W of average orbit power and 9.1 W of peak power. A six cell NiCd battery provides eclipse-phase energy of 1.4 Ah. The S/C mass is 6.5 kg (the all up mass is 8.3 kg with about 1.8 kg for the attach fitting for mating onto the carrying vehicle).

971) Data sheets provided by Craig Underwood of SSTL

973) A. Cropp, “The SNAP-1 NanoSat Project at Surrey - A New Generation of Satellites,” Proceedings of the 49th IAF Congress, Melbourne, Australia, Sept. 1998

S/C mass	6.5 kg (1.2 kg of payload mass)
S/C size	175 mm x 200 mm (diameter) hexagonal prism
Solar panels	Each panel 7 x 8 cells (40 mm x 40 mm GaAs)
S/C power	2.5 W at 5.0 V regulated, 6 cell NiCd (an advanced form of NiCd)
RF communications	VHF uplink, 750 mW, S-band downlink
On-board data handling	Asynchronous uplink (9.6 kbit/s), downlink (76.8 or 38.4 kbit/s selectable)
Data rate	Uplink: 9600 bit/s, FSK modulated Downlink: 38.4 kbit/s nominal, 76.8 kbit/s max; BPSK & QPSK modulation, convolutional encoding on QPSK
On-Board Computer (OBC)	A 32-bit StrongARM OBC includes 16 MB FLASH and 4 MB of EDAC protected code memory. CAN-bus on-board data handling network
ADCS	Navigation, magnetometer, sun sensors, magnetorquers. GPS receiver accuracy <15 m. Attitude is estimated using a Kalman filter
Payloads	- SRG-05 based on the Orion GPS receiver of MITEL Semiconductors, - APS camera (referred to as MVS)

Table 274: Specification of the SNAP-1 satellite

The launch of SNAP-1, along with Tsinghua-1 of China (a microsatellite of 50 kg mass) as secondary payloads, took place on June 28, 2000 on a Russian Cosmos-3M launcher from the Plesetsk Cosmodrome. The primary payload on this launch was Nadezhda, a Russian S&RSAT (Search & Rescue Satellite) of COSPAS.

Communication: SNAP-1 carries a VHF receiver and an S-band downlink transmitter, as well as an intersatellite link, a UHF receiver, tuned to the downlink frequency of Tsinghua-1 (when within range, data can be transmitted from Tsinghua-1 to SNAP-1). The SNAP-1 S-band data rate is 38.4 kbit/s nominal or 76.8 kbit/s maximum. The S-band modulation is BPSK or QPSK (selectable), the convolutional encoding on QPSK is selectable. The uplink data rate is 9.6 kbit/s with FSK modulation. The mass of the S-band transmitter is 0.5 kg, the size is: 120 mm x 160 mm x 20 mm; DC power of 5.2 V @ 670 mA (330 mA idle).^{974) 975)}

Orbit: Sun-synchronous orbit, 700 km altitude, inclination=98°, period about 98.7 minutes.

Instrument complement:

MVS (Machine Vision System). The objective of MVS is to enable SNAP-1 to act as a remote inspector. The intent is to obtain imagery of TV-quality of other S/C in the local vicinity of SNAP-1 and to relay this information to the ground. MVS, a CMOS video system with APS (Active Pixel Sensor) technology, consists of the following components:^{976) 977) 978)}

- Three wide-angle CMOS cameras, each with a 350 x 288 pixel detector, and each with a 90° FOV to cover an arc of 270°
- A single narrow-angle camera (350 x 288 pixels) co-aligned with the center wide-angle camera providing the capability of finer feature inspection
- Video digitizer circuitry to convert the composite camera video output into digital data
- A recording capability of 8 Mbit of 70 ns SRAM for code and image storage
- A processor of the type StrongARM 1100 (220 MHz) for video/image compression. The processor may also being used for optical navigation functions in support of target tracking or automated optical docking.
- A CAN (Control Area Network) bus interface for communication with the spacecraft.

MVS features a software digitizer design due to the lack of implementation time (six months from project start to launch). The video signals of the cameras are fed into an ADC

(Analog Digital Converter) and recorded. The MVS processor scans the digital representation and extracts the video data. - MVS has performed to specifications. The images captured in flight show in detail the complete deployment sequence of both the SNAP-1 and the Tsinghua-1 satellites.

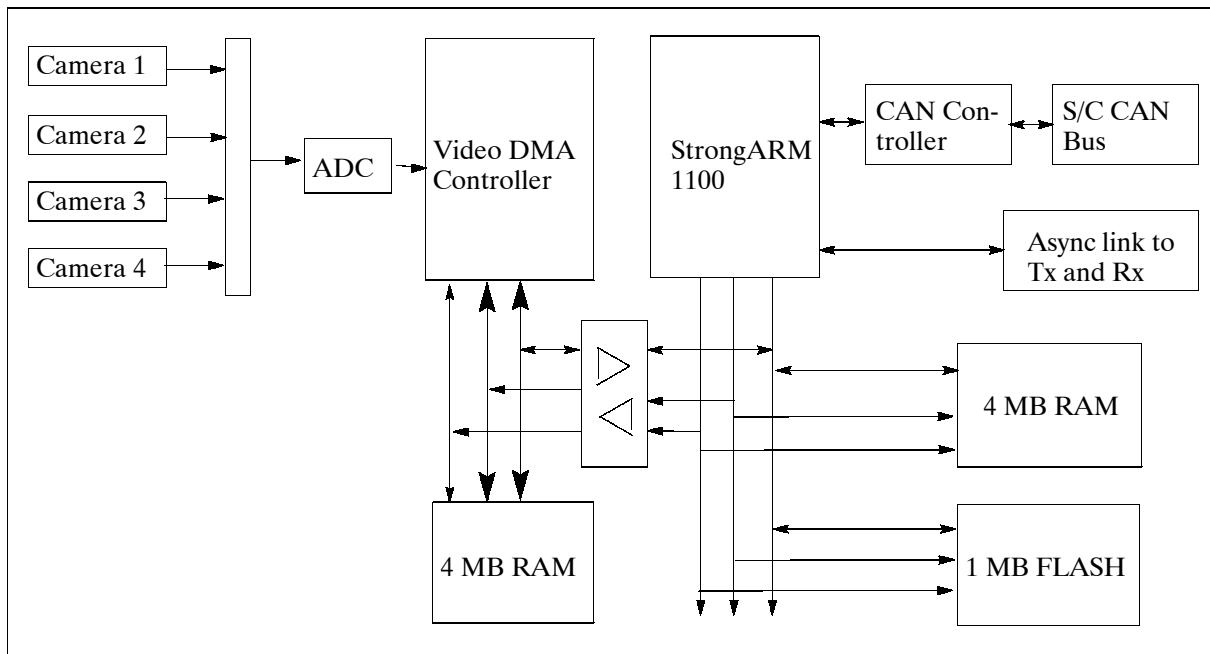

Figure 165: Schematic layout of the MVS

MPS (Micro-Propulsion System). ⁹⁷⁹⁾ MPS is an SSTL-funded technology development with the objective to demonstrate the capability of SNAP-1 as an inspection vehicle (rendezvous with Tsinghua-1). The MPS is a stand-alone instrument consisting of three boxes and interconnected in such a way as to form a triangular structure (140 mm side length). The thruster selected is a cold gas system from Polyflex Aerospace Ltd. with a maximum thrust of 100 mN at a chamber pressure of 4 bar (minimum impulse of < 1 mNs). It utilizes butane as propellant, operating in a cold gas mode. The propellant (32.6 grams) is stored in a formed titanium tube (coiled tube of 1.1 m in length with a volume of 65 cm³). The thruster valve is a solenoid-operated valve. The drive electronics are operated from a microcontroller, deriving its commands and feedback telemetry via a CAN (Control Area Network) interface. The microcontroller also controls the manifold heater, which ensures that the propellant is vaporized. MPS is rated as a 30 mN thruster with a Δv capacity of 3 m/s.

Initially, the propulsion system was also intended to be used to maneuver SNAP-1 to rendezvous with Tsinghua-1 of the University of Beijing (sometime in Nov. 2000). However, the rendezvous did not occur in November. Still, MPS demonstrated the new nanosatellite's unique capability for controlled orbital maneuvers using its miniature propulsion system.

SNAP-1 and Tsinghua-1 were both released from the Cosmos launcher in different directions specifically to avoid the possibility of accidental re-contact. SNAP-1 ended up in an orbit about 2 km below that of Tsinghua-1 and, being relatively light (6.5kg), suffered more from the effects of atmospheric drag than the much heavier (50 kg) Tsinghua-1 microsatellite. ⁹⁸⁰⁾ This meant that, relative to Tsinghua-1, SNAP-1 dropped in altitude more quickly. This was exacerbated by a very active sun (at solar maximum), causing the atmospheric den-

⁹⁷⁹⁾ D. Gibbon, J. Ward, N. Kay, "The Design, Development and Testing of a Propulsion System for the SNAP-1 Nanosatellite," Proceedings of the 14th Annual AIAA/USU Conference on Small Satellites, Logan, UT, Aug. 21-24, 2000

⁹⁸⁰⁾ Information provided by Craig Underwood of SSTL, Surrey, UK

sity at 700 km to be higher than normal. SSTL measurements showed that on average, SNAP-1 was falling about 10 m per day with respect to Tsinghua-1.

Thus MPS was used firstly to demonstrate orbit control (the primary objective) by maintaining its altitude by overcoming the relative atmospheric drag effects, and then also to climb back up to an altitude about 1 km higher than that of Tsinghua-1. Most of the propellant was used for this climb in December 2000. In this period Tsinghua-1 separated from SNAP-1 by more than 10,000 km along their orbital tracks. Once SNAP-1 was higher than Tsinghua-1, the along-track gap began to close. In January 2001, SNAP-1 was about 300 m higher than Tsinghua-1 with the gap closing.

SGR-05 (Space GPS Receiver-05).⁹⁸¹⁾ The instrument is essentially based on the Orion GPS GP2000 applications receiver of MITEL Semiconductors. SGR-05 comprises solely the core GPS engine (no features of the SGR-10/20 series). It uses a single antenna with 12 channels. The features of EDAC protection, CAN-bus support, and telemetry and command capability were disengaged in the trimmed-down version.

D.40.18 Tsinghua-1

Tsinghua-1 is a microsatellite of Tsinghua University, developed and built in a joint venture between SSTL of Guildford, Surrey, UK, and Tsinghua University in Beijing, China. The TSRC (Tsinghua Space Research Center) was set up in Oct. 1998 with the goal to integrate all space research activities at Tsinghua University and to provide a means and facilities for S/C building. The joint-venture company in Beijing is referred to as T-SSSC (Tsinghua-Surrey Small Satellite Company). The cooperative program is to develop and build microsatellites (Tsinghua-1) and nanosatellites (THNS-1) and to provide integrated training in small satellite design.^{982) 983) 984)}

Tsinghua-1 is a demonstrator microsatellite in the 50 kg class of size: 35 cm x 35 cm x 64 cm. The overall objective is to provide daily high-resolution imaging for disaster monitoring and mitigation on a worldwide scale. A further goal of Tsinghua-1 is to conduct communications research in LEO. The design uses standard platform modules or trays to carry the subsystems and payload. The three payload modules include the GPS receiver, Transputer, and DSP/DTE (Digital Signal Processing/Data Transfer Experiment) unit. The cameras and wheels are accommodated in the Earth Observation Compartment. Two GPS antennas are accommodated on the space facing side of the S/C..

Attitude control	Magnetorquer-assisted gravity gradient, 3-axis reaction wheels and 3 magnetorquers	$\pm 0.3^\circ$ roll/pitch, nadir pointing $\pm 0.3^\circ$ in yaw axis pointing accuracy: $\pm 15^\circ$ roll nadir
Solar panels	GaAs, about 35 W/panel (BOL)	Four fixed body-mounted panels
Batteries	7 Ah NiCd	
OBC	80C186+16 MByte, 80C386+64 MByte	Primary and secondary OBC
On-board data	9.6 kbit/s serial bus; High-speed CAN bus	Single network Dual network
Communication links	9.6 kbit/s VHF uplink 9.6 - 38.4 kbit/s UHF downlink	3 single cha. RCV, 2 synthesized RCV 2 synthesized transmitters

Table 275: Some parameters of the Tsinghua-1 S/C

The S/C is three-axis stabilized using a combination of passive (gravity-gradient boom) and active (magnetorquers, reaction wheels) actuator elements. The platform is nadir pointing.

Attitude is sensed by sun sensors and a magnetometer. The body-pointing platform has the capability to perform fast slew maneuvers within $\pm 15^\circ$ about the roll axis (or $\pm 180^\circ$ about the yaw axis). An off-nadir pointing configuration can be sustained for up to half an orbit.

A launch of Tsinghua-1 as a secondary payload to Nadezhda, a Russian S&RSAT (Search & Rescue Satellite) of COSPAS, took place on June 28, 2000 on a Russian Cosmos-3M launcher from the Plesetsk Cosmodrome.

Orbit: Sun-synchronous circular orbit, altitude = 700 km, inclination = 98° .

Sensor complement:

MEIS (Multispectral Earth Imaging System). The objective is to acquire multispectral Earth surface imagery with a spatial resolution of 50 m. The MEIS camera assembly consists of two cameras mounted at an angle of 15° from nadir so that the yaw angle can be selected to offer the required off-pointing angle of $\pm 15^\circ$ from nadir. The image swath is 80 km, each camera can collect four images contiguously along the flight path.

Imaging detector array	1024 x 1024 pixels, Kodak KAI-1001 non-interlaced sensor
Optics	Color-corrected Nikon lenses with 150 mm aperture
GSD (Ground Sampling Distance)	50 m x 50 m (resolution)
Swath width	400 km
Spectral bands (selectable in μm)	0.5 - 0.59 (green), 0.61 - 0.69 (red)) 0.81 - 0.89 (NIR)
Exposure control	Electronic integration time & gain (1000:1)
Radiometric resolution	8 bit - video digitization is synchronized with pixel stream producing 8-bit quantization (9 bit linearity)
SNR	>35 dB at 100% (about 2000:1)
Image raw data size	1 MByte per spectral band and per frame
Image compression	Scene-dependent compression ratios of 3:1 to 5:1 using AMPBTC (Adaptive Moment-Preserving Block Truncation Coding)
On-board processing	2 x T805 20 MHz Transputers + 32 MByte SRAM
On-board data storage	Up to 150 compressed multispectral images

Table 276: Specification of the MEIS instrument

D.40.19 TiungSat

TiungSat-1 (Tiung is the name of a small bird in Malaysia) is an SSTL-built (Surrey, UK) microsatellite for the Malaysian government (developed through a collaborative program of technology transfer and in-depth training). A team of eight Malaysian engineers from ATSB (Astronautic Technology SB) of Kuala Lumpur completed the construction during 1998. ATSB was established for this purpose and is wholly owned by the government of Malaysia. The overall objective is to generate a cadre of trained personnel in Malaysia to establish a national capability for sophisticated microsatellite and minisatellite design and fabrication for a variety of commercial and scientific research applications. The TiungSat-1 specific applications are in the following fields: ⁹⁸⁵⁾ ⁹⁸⁶⁾

- Collection of imagery for environmental and meteorological use
- Digital S&F (Store & Forward) communications
- Technology demonstration
- Space science
- Amateur radio access

The TiungSat-1 S/C structure comprises eleven module trays used to house the electronics for the bus and payload systems. The box-like spacecraft has a size of 690 mm x 366 mm x 366mm; it is three-axis stabilized using a gravity-gradient boom, two 3-axis magnetorquers,

⁹⁸⁵⁾ <http://www.atmsb.com.my/>

⁹⁸⁶⁾ TiungSat-1 data sheet of SSTL provided by Craig Underwood

and a momentum wheel. Attitude is sensed by two 3-axis magnetometers and by two-axis analog sun sensors. In addition, there are UED (Underneath Earth Detector) and SOD (Sun Overhead Detector). The pointing knowledge is $\pm 1^\circ$ in roll and pitch and $\pm 3^\circ$ in yaw (3 sigma values). The S/C power is 35 W per panel, provided by four surface-mounted GaAs solar panels and by a 10-cell NiCd battery (7 Ah). The power subsystem provides regulated voltage supplies at +5V and ± 10 V along with an unregulated supply which fluctuates between 12-14 V. Autonomous functions, safe modes and data are handled by two OBCs (On-Board Computer), OBC-186 and OBC-386. The on-board data storage capacity is 1 Gbit. The S/C mass is 50 kg (platform = 35 kg, payload = 15 kg). The design life is three years.

TiungSat-1 was launched Sept. 26, 2000 on a Dnepr-1 vehicle (the other payloads were: SaudiSat-1A/-1B of SISR (Saudi Institute for Space Research), UniSat of the University of Rome, and MegSat-1 of the MegSat Space Division of "Gruppo Meggiorin," Brescia, Italy) from the Baikonur Cosmodrome.

RF communications: TiungSat uses conventional AMSAT frequencies, thereby giving amateur radio operators access to its data (imagery and communication capabilities). The uplink is in VHF-band with a data rate of 9.6 kbit/s; three receivers are used: Rx1 operates at 144.46 MHz, Rx2 and Rx3 operate at 145.86 145.925 MHz, selectable. The downlink is dual-redundant in UHF-band (435 to 438 MHz range with 437.300, 437.325, 437.350, 437.375 MHz, selectable) with data rates of 9.6 and 38.4 kbit/s. An error-protected digital packet communications protocol is used. All spacecraft operations are performed at ATSB in Kuala Lumpur.

Orbit: Circular orbit, altitude = 642 km, inclination = 64.54° , period = 97.43 minutes.

Sensor/experiment complement:

MSEIS (Multi-Spectral Earth Imaging System). MSEIS is a NAC (Narrow Angle Camera) system of three cameras (green, red and near-infrared) in parallel, each with a 75 mm focal length optic and 100 mm aperture diameter. The NAC system provides a 70 m ground spatial resolution in three spectral bands: 510-590 nm, 610-690 nm and 810-890 nm (green, red, and near infrared). A 2-D CCD staring array detector with 1024 x 1024 pixels is used providing snapshot imagery of scene size 70 km x 70 km. Up to four contiguous images can be collected along the flight path. The data are digitized to 8 bits radiometric resolution (256 levels).

MEIS (Metrological Earth Imaging System). MEIS is a single-band WAC (Wide Angle Camera) system with 4.8 mm focal length optics. It provides NIR imagery (810-890 nm) with a 1.2 km spatial resolution. The CCD area array detector has a size of 1024 x 1024 elements (pixels) for snapshot observations. Data are quantized to 8 bits radiometric resolution. An image has the size of 1200 km x 1200 km.

S&F (Digital Store & Forward Communications). The subsystem provides global, frequency-agile, communications for any form of digitized data: e-mail, voice-mail, scientific data exchange, fax, imagery, or even Internet mail for remote regions. The low cost and direct access offered by the TiungSat-1 microsatellite in orbit also makes it ideal for use by scientists, engineers and students based in institutes, universities and even schools throughout the world. - **DSPE** (Digital Signal Processing Experiment). The DSPE consists of a TM320C31 low power DSP suitable for special or general purpose signal processing tasks on LEO satellites. The VHF scanner operates in the 140-150 MHz range. A built-in FSK decoder is used. The system is capable to detect signals from a pre-set signal strength threshold within selected band. DSP can be used for processing audio transmission for re-broadcast.

CEDEX (Cosmic Ray Energy Deposition Experiment). The objective of CEDEX is to characterize the TiungSat-1 orbit radiation environment in terms of the observed particle LET (Linear Energy Transfer) spectrum at the spacecraft. The primary sensor consists of a

30mm x 30mm PIN diode detector 300 microns in depth, housed in a separate screened aluminium unit mounted on the CEDEX module box (three area PIN-diode detectors are mounted in a "telescopic" arrangement; hence, information pertaining to directions of the energy particles detected can be derived.). This is connected to a charge amplifier and a pulse-shaping circuit which, in turn, are connected to an event-driven, hardware-logic controlled pulse-height multi-channel analyzer. CEDEX is controlled autonomously by a CAN-microcontroller with its own data-storage RAM and built-in data-compression software. This sends data to an internal CAN-controller which formats and sends them on to the primary OBC via the spacecraft's CAN (Controlled Area Network) bus. CEDEX is a multichannel analyzer with 512 channels and a 0.5 pC (picocoulomb) charge resolution. The instrument charge range is between 0.2 -24 pC, equivalent to a normal incidence particle LET range of about 60 - 7500 MeV cm² g⁻¹ (200,000 particles/s).

The CEDEX data obtained are comparable directly with such instruments as CREDO-II flown on STRV-1c (launch Nov. 16, 2000) and CRE (Cosmic Ray Experiment) flown on Kit-Sat-1 (launch Aug. 10, 1992) and PoSat-1 (launch Sept. 26, 1993).

Experimental Microsatellite GPS, an SSTL/ESA collaboration. An advanced 12-channel GPS receiver with two GPS patch antennas is installed for several objectives: 1) on-board generation of Keplerian orbital elements (NORAD experiment, this was first performed on PoSat), 2) on-board navigation, attitude, and timing services, and 3) refractive sounding of the ionosphere. The instrument is primarily used for orbit and position determination and for precise on-board timing services. In parallel, the instrument is also employed for refractive ionospheric monitoring. The TEC (Total Electron Content) occultation observations of the instrument provide slant range measurements which can be converted into vertical profiles.

Part E Geodynamic/Earth-System Missions

E.1 CHAMP (Challenging Minisatellite Payload)

CHAMP is a German BMBF-funded geophysical minisatellite mission of GFZ (GeoForschungsZentrum, Potsdam, Germany) in cooperation with DLR. The satellite was built by the German space industry with the intent to foster high-tech capabilities especially in the East-German space industry. The S/C prime contractor is DJO (Jena Optronik GmbH) in Jena, a daughter of DASA (now Astrium). The overall science objectives are in the following fields of investigation:

- Global long- to medium-wavelength recovery of the static and time variable earth gravity field from orbit perturbation analyses for use in geophysics (solid Earth), geodesy (reference surface), and oceanography (ocean currents and climate), supported by a feasibility test of GPS altimetry for ocean and ice surface monitoring
- Global Earth magnetic field recovery (solid Earth and solar-terrestrial physics)
- Atmosphere/ionosphere sounding by GPS radio occultation with applications in weather forecasting, navigation, space weather, and global climate change.

Figure 166: Front view of the CHAMP spacecraft

The structure of the satellite (FLEXBUS of Astrium GmbH) features a trapezoidal body with overall dimensions of 4.3 m length x 0.75 m height x 1.6 m/0.4 m width at base/top. A boom of 4 m length accommodates the magnetometry assembly (the boom is nominally pointed into the flight direction). The S/C is three-axis stabilized (Earth pointing) with three magnetorquers and cold gas propulsion for attitude and orbit change maneuvers; attitude control is $< 2^\circ$, attitude knowledge is provided by two star sensors on the boom and on the body, respectively, each one with two sensor heads (0.01° orientation accuracy), the star sensor instrument is referred to as ASC (Advanced Stellar Compass) and is manufactured by DTU, Denmark [dual-head CCD (hot), Quad A/D (2 cold) and single DPU]; S/C design life = five years; total S/C mass = 522 kg (including 30 kg of propellant); payload mass = 32 kg; S/C power = 150 W (50 W for payload) provided by a solar array of 6.9 m^2 in size; in addition there are 10 cells of NiH_2 batteries (16 Ah) for night phase operations. Passive thermal control is provided by paints and multi-layer insulation. A S/C launch took place on July 15, 2000 from Plesetsk on a Russian Cosmos-3M launcher (along with the MITA satellite of ASI, Italy).

CESS (Coarse Earth-Sun Sensor). An Astrium-developed patented attitude package consisting of six single sensor heads arranged on the S/C in such a way that an omnidirectional and unobstructed view to space is given. Each head features two equally sized optical surfaces of different properties in the spectral ranges (the IR absorptance is the same but the VIS absorptance is different). Thermistors serve as detectors. The hardware configuration permits to take temperature measurements driven by the Earth and sun illumination. The measurements are weighted, averaged, and extrapolated to steady-state equilibrium temperatures. An algorithm derives overall heat flux based on the input temperatures and corrects for albedo. The output is a computed Earth vector and a computed sun vector in the S/C coordinate system. CESS pointing performance is within 6° for sun vector knowledge and within 15° for Earth vector knowledge. On CHAMP, CESS serves as a low-cost and low-mass demonstration package. The intent of the CESS design is to permit future S/C to fall back on a safe attitude control in case of a failure or degraded service of components of the regular attitude control system. CESS offers also its services for initial acquisition and coarse pointing in general.⁹⁸⁷⁾

Data: On-board storage capacity of 1 Gbit. All data links are in S-band using BPSK modulation. Spacecraft science data are received by the DLR/DFD station in Neustrelitz (downlink frequency of 2.28 GHz at a data rate of 1 Mbit/s). S/C operations are provided at DLR/GSOC in Oberpfaffenhofen via the Weilheim station (TT&C data in S-band; uplink at 2.093 GHz and 4 kbit/s; downlink at 2.28 GHz and 32 kbit/s).^{988), 989) 990) 991)}

Initial orbit: perigee = 418 km, apogee = 474 km (the orbit is decaying to about 300 km at end of the design life of five years), inclination = 87.275°.

Sensor complement:

BlackJack (GPS Flight Receiver), a new generation instrument of TRSR (TurboRogue Space Receiver) and of GPS/MET heritage, first flown on SRTM. BlackJack is being provided and built by NASA/JPL. Objectives: a) BlackJack is a dual-frequency GPS receiver system for precise (cm accuracy range) orbit determination and continuous coverage; b) The instrument observes in parallel ionospheric electron content, and provides atmospheric soundings permitting the derivation of atmospheric vertical profiles of density, pressure, temperature (of water vapor) and ionospheric electron density profiles (refractive occultation monitoring); c) Experimental use of the GPS signals reflected from the ocean's surface for altimetric measurements.

The LEO CHAMP S/C and the MEO GPS satellite-constellation establish a so called high-low satellite-to-satellite (SST) link for the BlackJack instrument.

BlackJack features a new DSP (Data Signal Processor) ASIC, capable of tracking 12 GPS signals at once; there are four ASICs in each receiver so the instrument can track up to 48 signals in parallel, in any mode (C/A, P, or codeless). Two new ASIC capabilities (among several) are: 1) a patented new enhanced “quasi-codeless” tracking of L2, providing a measurement error comparable to that achieved by the TRSR instrument with P-code tracking, and 2) special software for atmospheric occultation and ocean reflection applications. This particular BlackJack implementation is the first 4-antenna version. The BlackJack receiver system consists of the RPA (Receiver/Processor Assembly) containing the RF down-converter sections, an internal bus and the cold-redundant baseband processor cards, the RF

coaxial cables to the 4 antennas and the antennas itself. The RPA antennas are pointed: in the zenith direction, two in the aft direction, and in the nadir direction. The zenith-pointing antenna is used for simultaneous tracking of up to twelve GPS satellites to derive CHAMP's trajectory. The receiver performs phase measurements of both GPS frequencies L1 and L2, and code pseudoranges. The GPS output is the complete navigation solution, i.e., position, velocity and time for use in on-board orbit prediction and attitude control, in addition to the direct phase and pseudorange measurements from GPS-LEO satellite-to-satellite tracking which are used for precise offline orbit restitution. The receiver has the following measurement modes: ⁹⁹²⁾ ⁹⁹³⁾

- Tracking mode (default), 0.1 Hz
- Occultation mode: in this mode the receiver software schedules every 50 Hz tracking of setting occultations of up to four GPS satellites
- Altimetry mode: in this mode the nadir antenna collects specular reflections of GPS signals from the surface of the oceans.

The BlackJack aft antennas are used for limb sounding. High resolution atmospheric soundings can be retrieved when the radio path between the LEO GPS receiver and one GPS satellite traverses the Earth's atmosphere. This occultation technique employs dual frequency carrier-phase observations of retarded signals (atmospheric path delays) which permit the derivation of atmospheric profiles of density, pressure, and temperature (or water vapor) in an altitude range from 85 km to the ground. All observables are sampled 50 times per second. In parallel to limb sounding a non-occulted GPS satellite is tracked, which allows correction of system inherent biases. Ionospheric occultation is performed with 1 Hz samples.

A nadir-pointing antenna is used experimentally to receive specular reflections of the GPS signals from the ocean's surface. In this case, the receiver does not track the direct GPS signals, but instead performs an "open-loop" sampling of the GPS spectrum for later analysis on the ground. Therefore, any and all reflected GPS signals that happen to be present in sampled spectrum are being captured, though that may not generally be more than one or two. The sample rate for this operations mode is about 100 samples/s, or about the same as in occultation mode. Knowing both the position of CHAMP and the transmitting GPS satellite, it is possible to derive the precise position of the S/C with respect to the ocean's surface and thus to gain information about its topology.

Computed position in telemetry (navigation solution)	< 60 m
Time calibration accuracy	< 1 μ s from GPS time (resolution 0.1 ns)
Dual-frequency range and integrated carrier for POD (Precise Orbit Determination) at a 1s interval:	
Phase (ionosphere-free)	< 0.2 cm
Range (ionosphere-free)	< 30 cm
Dual-frequency integrated carrier phase and amplitude for atmospheric occultation:	
Phase (ionosphere-free)	< 0.05 cm
Range (ionosphere-free)	< 50 cm
Limb-sounding observables (prior to atmospheric de-focusing):	
L1 carrier phase	< 0.05 cm (1 s)
L2 carrier phase	< 0.15 cm (1 s)

Table 277: Performance characteristics of BlackJack

The BlackJack data rate is between 0.4 - 17 kbit/s, depending on occultation events (0, 1, or 2 occultations); the mean data rate is 2.5 kbit/s, which amounts to about 27 MByte/day.

STAR (Space Three-axis Accelerometer for Research mission), an accelerometer system provided by CNES and developed by ONERA, France. The objective is to measure all non-

⁹⁹²⁾ Information provided by T. P. Yunck of NASA/JPL

⁹⁹³⁾ T. Meehan, C. Duncan, et al., "GPS On A Chip - An Advanced GPS Receiver for Spacecraft," Proceedings of the ION GPS-97 Conference, Sept. 16-19, 1997, Kansas City, MO, pp. 1509-1517

gravitational accelerations of the satellite (drag, solar and Earth radiation pressure) in order to determine the Earth's gravity field from purely gravitational orbit perturbations (orbit from BlackJack). The accelerometer measurement principle is based on electrostatic suspension of a proof-mass in a cage. Instantaneous position of the proof-mass is measured by three capacitive sensors which permit a determination of the acceleration vector. The instrument has a dynamic range of $\pm 10^{-4} \text{ ms}^{-2}$, a resolution of better than $\pm 3 \times 10^{-9} \text{ ms}^{-2}$, and a frequency range of 10^{-1} to 10^{-4} Hz . The STAR instrument is positioned at the center of gravity of CHAMP to minimize the influence of measurement disturbances due to rotational accelerations and gravity gradients. STAR is also connected to a star sensor (ASC of DTU, Denmark) with two heads to provide the accelerometer's axes orientation. The accelerometer proof-mass is positioned at the center of gravity of CHAMP.⁹⁹⁴⁾

LRR (Laser Retro Reflector), developed at GFZ. A passive optical device for accurate satellite tracking from ground laser ranging stations of the SLR network. LRR consists of four cube corner prisms to reflect short laser pulses back to the transmitting SLR ground station. Laser pulses from the ground typically have durations of 35 - 100 picoseconds, providing a single-shot range accuracy of 1 to 2 cm without any ambiguities. LRR data are used for a) precise orbit determination in connection with BlackJack for gravity field recovery, b) calibration of the on-board BlackJack system, and c) technological experiments such as two-color ranging to achieve millimeter ranging accuracies.

MIAS (Magnetometer Instrument Assembly System). A boom-mounted package consisting of an Overhauser scalar magnetometer (OVM, built by LETI, France), two fluxgate vector magnetometers (FGM), and two star imagers to provide attitude information for FGM (FGM and the two star sensors are built by DTU, Denmark).

The measurement method of OVM is based on proton Larmor precession in a weak magnetic field (the Larmor frequency's being directly proportional to the magnetic field permits the derivation of the absolute total Earth magnetic field intensity). The absolute intensity is used for calibrating the FGM observations. OVM measurement range = 16,000 - 64,000 nT, resolution = 0.1 nT, absolute accuracy = 0.5 nT, sampling rate = 1 Hz.

The measurement principle of FGM is based on 'vector feedback geometry' (three sets of coaxial coils are mounted equidistant on the surface of a 9 cm diameter sphere, with the three sets orthogonal to each other - the coil currents are a measure of the three magnetic field components). Two FGMs are located on the boom, 60 cm apart, permitting simultaneous measurement of both FGMs in a 'gradiometer' arrangement. The FGMs have a measurement range of $\pm 64,000 \text{ nT}$ and a resolution of 1 to 2 nT. The sampling rates are at 32 Hz (both sensors active) or 64 Hz (one sensor active), corresponding to spatial resolutions of about 200 or 100 m, respectively. - The FGMs are rigidly mounted on an optical bench also housing two star sensors.

ASC (Advanced Stellar Compass), designed and built by DTU (Technical University of Denmark in Lyngby). The objective is to provide an attitude reference instrument with a precision of a few arcseconds aboard the satellite (to measure the magnetic field with a vector precision of a fraction of a nT). The design of this star imager is based on a new development presently flown on the Ørsted satellite. On CHAMP, there are two ASC systems, each consisting of two Camera Head Units (CHU) and a common Data Processing Unit (DPU). One ASC is part of the magnetometry optical bench unit on the boom, the other provides high precision attitude information for the instruments fixed to the S/C body. Additionally the ASCs serve as sensors for the satellite attitude control system. The ASC is a fully autonomous system that directly outputs the attitude quaternions in a preselectable coordinate system.

ASC measurement principle: An image of the stars within the FOV is acquired by integrating the light focused onto a photosensitive CCD array. The pattern is serially read out, digi-

⁹⁹⁴⁾ P. Touboul, B. Foulon, G. M. LeClerc, "STAR, The Accelerometer of the Geodesic Mission CHAMP," Proceedings of the 49th IAF Congress, Melbourne, Australia, Sept. 28 - Oct. 2, 1998, IAF-98-B.3.07

tized and fed to a microprocessor. The digital image is then sifted for stars brighter than $m_V = 6$ and corrected for lens distortions resulting in a list of calculated star centroids with sub-pixel precision. The determined star centroids are subsequently matched against real star positions derived from an on-board HIPPARCOS star catalog. The star attitude which fits best the observed pattern is the output result. For further improvement of the attitude solution a GPS updated orbit model is maintained to correct for astronomical aberration and also the epoch of star constellation is taken into account.

The ASC on the boom provides the high attitude precision needed for the magnetic field vector measurements. The ASC on the spacecraft body provides attitude data primarily for the STAR and DIDM instruments. This information is also required for the proper reduction of the GPS data, laser ranging data and for attitude control.

Attitude determination precision	4 arcsec (3 sigma, BOL)
FOV (Field of View)	18.4° x 13.4°
Sampling rates	1 Hz (nominal), 0.5 Hz, 2 Hz
Magnetometer moment CHU	10 ⁻⁵ A/m ²
Power	8 W
Mass: CHU, DPU	0.20 kg (excluding baffles), 0.80 kg
Dimensions: CHU, DPU	50 mm x 50 mm x 45 mm, 100 mm x 100 mm x 100 mm

Table 278: Performance characteristics of ASC

DIDM (Digital Ion Drift Meter, the instrument is provided by AFRL, Hanscom Air Force Base, Bedford, MA). DIDM is an enhanced version of the first DIDM instrument, flown on STP-4 (Space Test Program-4) with a launch in Oct. 1997. DIDM on CHAMP includes a charge collecting plate to account for spacecraft charging. The objective of DIDM is to measure the Earth's electric field parallel to the magnetic field (in-situ measurements of the ion distribution and its moments within the ionosphere). DIDM measures magnitude and direction of the incoming ion flux. The electric field is derived from the relationship between electric field, measured ion drift velocity and measured magnetic field strength.

Note: SSI/ES (Special Sensor Ionospheric Plasma Drift/Scintillation) instruments have been flown on DMSP series satellites for a long period of time (20 years) to monitor the space plasma. These instruments rely on analog technology and older electronics. As a result they have limited dynamic range, are physically large and heavy, and have significant power requirements. The follow-on US meteorological satellite program (NPOESS), which will replace DMSP in the first decade of the 21st century, requires higher resolution, sensitivity, accuracy, and dynamic range for its plasma measurement devices. The goal is for a next generation DIDM instrument to be the standard drift meter aboard the NPOESS spacecraft series.⁹⁹⁵⁾

DIDM utilizes miniaturized state-of-the-art detector components and on-board digital signal processing. The instrument consists of two side-by-side ion detectors (MCP type) arranged within one unit of 2.2 kg mass. Both apertures are facing the S/C ram direction. Both detectors can measure the normal and perpendicular velocity components of incident ions. Ions entering through a pinhole aperture fall into a Retarding Potential Analyzer (RPA) cup. Those ions with energies higher than a certain threshold potential are electrostatically focused onto charge multiplying microchannel plates (MCPs) and high-resolution wedge and strip charge detecting anodes. The images created by these impacting ions on the anode are digitally processed on-board to reconstruct the full 3-D ion velocity vector.

A **PLP** (Planar Langmuir Probe) is operated in combination with DIDM. This device provides auxiliary data needed to interpret the ion drift measurements. Quantities that can be derived from the PLP sweeps are S/C potential, electron temperature, and density. The

⁹⁹⁵⁾ <http://www.vsbs.plh.af.mil/projects/didm/didm.html>

PLP voltage is swept for 1 s every 15 seconds typically between ± 2.5 V in 32 steps. A selectable bias voltage can be added to account for the S/C potential. By interpreting the measured current/voltage characteristic the plasma parameters are being determined. The S/C floating potential is measured during the remaining 14 seconds of the measuring cycle.

Direct measurements	Ion density: $10^2 - 10^6$ ions/cm ³ Ion resolution: <1° direction, <130 m/s in speed Ion energy: 0 - 32 eV
Indirect measurements	Ion drift velocity: 0 - 6 km/s, Electric field resolution: <4 mV/m Ion temperature: 200 - 55 000 K
Sample rates DM (Digital Meter) mode RPA (Retarding Potential Analyzer) mode PLP (Planar Langmuir Probe) mode	0, 1, 2, 4, 8, 16 Hz 0, 8, 16 Hz 0, 1/15 Hz
Instrument data rates	5 kbit/s (peak), 1 kbit/s (nominal)
Power, mass, dimensions	5 W, 2.2 kg, 153 mm x 150 mm x 109 mm

Table 279: DIDM instrument parameters

E.2 CryoSat

CryoSat is the first Earth Explorer Opportunity Mission in ESA's Living Planet Program to be launched in 2003/4. CryoSat is a radar altimetry mission dedicated to observations of the polar regions. The science objectives are to determine variations in the thickness of Arctic sea ice and elevation changes of ice sheets, ice caps and glaciers that ring the Arctic Ocean. Sea ice plays a central role in Arctic climate. The CryoSat mission is to further knowledge of the wider role of the Earth's cryosphere and its effect on the sea level. The CryoSat mission was proposed by Duncan Wingham of the University College London and an international science team. Duncan Wingham is also the mission PI. A mission duration of three years is planned. ^{996) 997)}

Figure 167: Illustration of the CryoSat spacecraft

⁹⁹⁶⁾ D. J. Wingham, "The first of ESA's Opportunity Missions: CryoSat," ESA Earth Observer Quarterly, No 63, Sept. 1999, pp. 21-24
⁹⁹⁷⁾ <http://www.estec.esa.nl/explorer/cryosat/>

The CryoSat spacecraft is being built by Astrium GmbH of Friedrichshafen, Germany, as prime contractor. The spacecraft structure consists of a long rectangular main platform body, surmounted by fixed solar arrays in the form of a tent. The two SIRAL instrument antenna dishes are mounted on a separate rigid bench in the forward section of the S/C. In addition, a dedicated SIRAL radiator is mounted at the nose tip. A slight nose-down attitude of the S/C is chosen to ensure minimum attitude correction due to gravity-gradient disturbances. The S/C has a total length of 4.6 m and a width of 2.34 m. The S/C mass is 628 kg, the design life is 3 years.

The AOCS (Attitude Orbit and Control Subsystem) comprises the following elements:

- A cold gas system for attitude control and orbit transfer and maintenance maneuvers, 16 attitude control thrusters (10 mN) and 4 orbit control thrusters (40 mN). Nitrogen is used as propellant (132 l tank).
- A set of 3 magnetometers for compensation of environmental torques
- A set of three star tracker heads (also a part of the payload) providing autonomous inertial attitude determination for the spacecraft. The multiple configuration makes the sensor system one-failure tolerant, except for the rare occurrence of simultaneous sun and moon blinding of two heads, to which the system software is tolerant. Consequently, two camera heads are operated in parallel at all times. The star tracker attitude serves also as reference for determining the orientation of the SIRAL interferometric baseline.
- Real-time DORIS measurements of satellite position, velocity and time
- CESS (Coarse Earth-Sun Sensor). Provides attitude measurements with respect to the sun and Earth for initial acquisition and coarse pointing
- A set of three-axis magnetometers are used for magnetorquer control and as rate sensors.

The CDMU (Control and Data Management Unit), consisting of a processor and a hardware-based fault detection system, handles all on-board command and control functions including telecommand decoding and the AOCS processing functions. A MIL-STD-1553B communications bus is used as payload interface (for SIRAL and DORIS). The on-board solid-state memory has a capacity of 126 Gbit. S/C power of 414 W is provided by fixed solar panels (GaAs cells). Lithium-ion batteries are used for operations support during eclipse phases.

Orbit: Non sun-synchronous circular orbit, altitude = 720 km, inclination = 92°. Ground track repeat cycles are of 1 year duration with subcycles of one month. This configuration allows a sufficient coverage for the polar regions. The CryoSat mission requirements include:

- An orbit of 92° inclination. Since this orbit is not sun-synchronous, it results in a nodal rotation period, through all mean local solar times, of about 8 months
- An orbit change is required during the mission with the objective to visit twice a validation orbit, approximately 6 km lower in altitude than the science phase orbit
- The payload must be operated in various modes, as a function of geographical region, such that the orbital operations, and data sets collected, on successive orbits are dissimilar
- The payload utilization demands very precise orbit and attitude restitution. Minimum operations of three years are required.

RF communication: The S-band link is used for all TT&C communications. The X-band downlink provides a payload transfer rate of 100 Mbit/s.

The CryoSat mission will be operated at ESA/ESOC. The Kiruna ground station in Sweden functions as the prime command and data acquisition facility. The payload data segment (data processing, archiving and distribution) function is also located at the Kiruna station.

Sensor complement:

SIRAL (SAR Interferometer Radar Altimeter) designed and developed by ASI (Alcatel Space Industries), France. The objective is to observe ice sheet interiors, the ice sheet margins, for sea ice and other topography. The SIRAL design features two receiving antennas forming an interferometer in the cross-track direction. In addition, the return signal in along-track direction is processed to construct a synthetic aperture for enhanced ground resolution. The instrument is a Ku-band radar altimeter which uses the full-deramp range compression technique of conventional altimeters. However, it introduces two features that make it different from previous spaceborne altimeter implementations: ⁹⁹⁸⁾ ⁹⁹⁹⁾

- 1) The instrument has two antennas (including pulse-to-pulse phase coherence) and two receive chains, permitting an interferometric mode of operation
- 2) SIRAL operates at high PRF (Pulse Repetition Frequency), ensuring coherent along-track sampling for aperture synthesis (PRF > Doppler bandwidth)

The instrument consists of three major subsystems, two of these are in discrete electronic boxes:

- DPU (Digital Processing Unit), it serves all digital altimeter functions, including the digital chirp generation, the full sequencing functions of the altimeter, and the receive and processing functions of the echo
- RFU (Radio Frequency Unit). It contains all analog IF and RF electronics and a solid-state power amplifier with an RF peak power of 25 W.

The antenna subsystem consists of two Cassegrain antennas, mounted side-by-side and forming the interferometric cross-track. Both antennas are identical; one is used to transmit and receive, whereas the other antenna is used to receive echoes. The primary super-elliptic reflectors are about 1.1 m x 1.2 m in size. They are supported by a composite sandwich plate. A high thermoelastic stability is needed to meet the interferometric instrument performance. The new features of SIRAL have been demonstrated with the airborne D2P (Delay/Doppler Phase-monopulse Radar) of JHU/APL.

Parameter	Value
RF frequency	13.575 GHz (Ku-band)
Pulse bandwidth	320 MHz, (40 MHz for tracking only in SARIn)
PRF (Pulse Repetition Frequency)	1.97 kHz in LRM, 17.8 kHz in SAR and in SARIn
Pulse duration	51 μ s
Timing	Regular PRF in LRM, burst mode in SAR/SARIn
Samples/pulse	128 in LRM and SAR, 512 in SARIn
RF peak power	25 W
Antenna size	2 reflectors 1.2 m x 1.1 m, side-by-side
Antenna beamwidth	1° x 1.2° (cross-track)
Antenna footprint	15 km
Range resolution	About 45 cm
Along-track resolution	250 m (SAR/SARIn)
Data rate	60 kbit/s for LRM, 12 Mbit/s in SAR, 2 x 12 Mbit/s in SARIn
Mass (with antennas)	60 kg non-redundant, 90 kg redundant
Instrument power	100 W LRM, 135 W for SAR/SARIn

Table 280: SIRAL key instrument parameters

The science requirements demand of CryoSat to measure variations in ice thickness of perennial sea and land ice fields to the limit allowed by natural variability, on spatial scales

⁹⁹⁸⁾ L. Rey, P. de Chateau-Thierry, L. Phalippou, C. Mavrocordatos, R. Francis, "SIRAL, a High Spatial Resolution Radar Altimeter for the CryoSat Mission," Proceedings of IGARSS 2001, Sydney, Australia, July 9-13, 2001

⁹⁹⁹⁾ L. Phalippou, L. Rey, P. de Chateau-Thierry, "Overview of the Performances and Tracking Design of the SIRAL Altimeter for the CryoSat Mission," Proceedings of IGARSS 2001, Sydney, Australia, July 9-13, 2001

varying over three orders of magnitude. The natural variability of sea and land ice depends on fluctuations in the supply of mass by the atmosphere and ocean, and snow and ice density. The precisions of the measurements are expressed in terms of cm of yearly ice equivalent thickness variations. These are:

- Arctic sea-ice: 1.6 cm/year vertical measurement accuracy at 10^5 km^2 scale (equivalent to 300 km x 300 km cells). Temporal sampling: 1 month
- Land ice (small scale): 3.3 cm/year at 10^4 km^2 (equivalent to 100 km x 100 km cells). Temporal sampling : 1 year
- Land-ice (large scale): 0.17 cm/year over $13.8 \times 10^6 \text{ km}^2$ (about the area of Antarctica). Temporal sampling: 1 year.

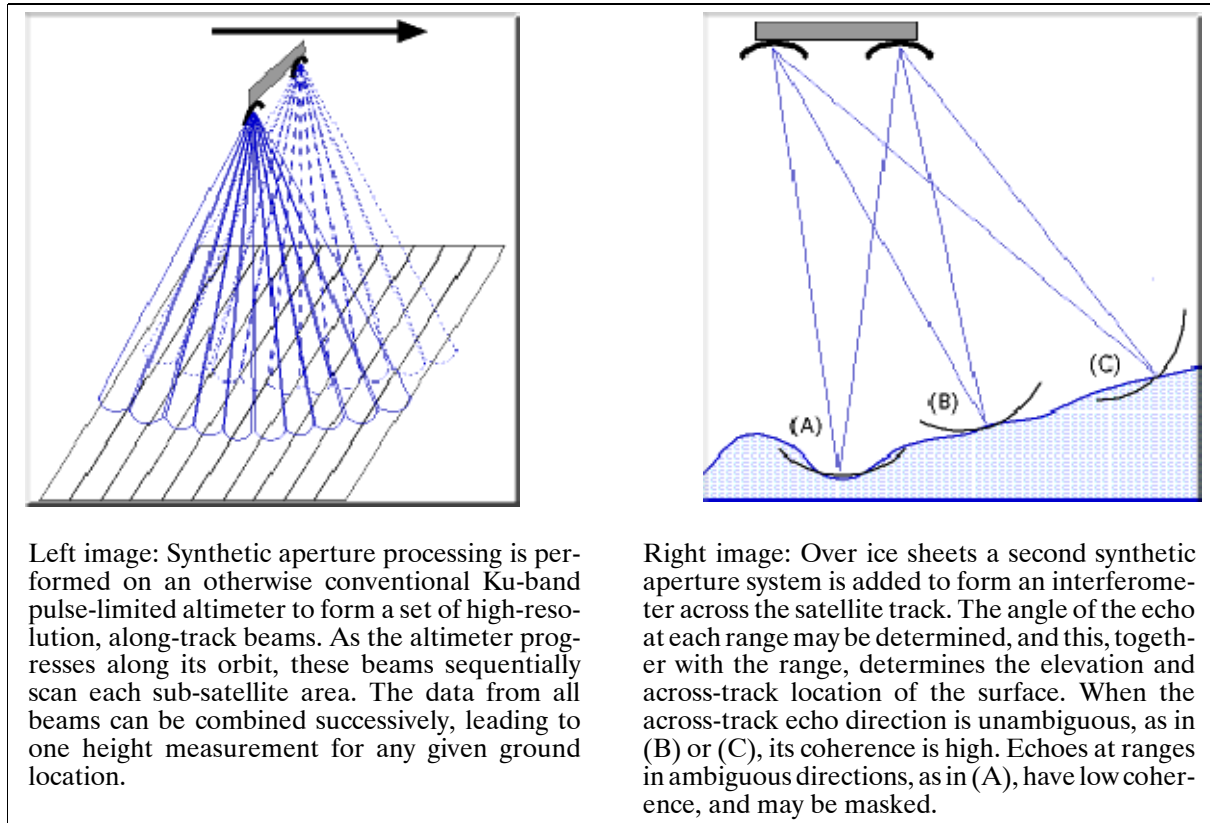

Figure 168: SAR observation principle of SIRAL

SIRAL operations: SIRAL provides the following operational modes for different observational support types. The complex waveform data stream from the CryoSat altimeter requires a sophisticated processing scheme in particular for exploiting the synthetic aperture and interferometry techniques over ocean and ice surfaces.

- LRM (Low Resolution Mode) operation support: LRM uses a single receive channel and low PRF for conventional pulse-limited operation for ice sheet interiors/open oceans. The transmitted pulse length and the transmitted bandwidth are set to the same value as that for Envisat in a similar mode (51 s, 320 MHz). The PRF is kept constant over the orbit at a value around 2 kHz to ensure the decorrelation of received echoes. The averaging for tracking and ground processing is performed after the FFT (Fast Fourier Transform).

The LRM mode is useful over surfaces where the topography is homogeneous, at least as large as the antenna footprint of about 15 km. The altimeter echoes have a predictable shape and the mean surface level of this area can be derived by an appropriate model.

- SAR (Synthetic Aperture Radar) support mode: SAR uses a single channel and a high PRF. Closed burst timing is employed to ensure a high along-track resolution. The PRF

is chosen higher than the Doppler bandwidth over the half-power beamwidth to avoid aliasing in the ground processing of the data (the PRF is about 10 times higher than that of LRM to ensure coherence between the echoes of successive pulses). Bursts of 64 pulses at a PRF of 18.5 kHz with a burst repetition frequency of 85 Hz are transmitted.

In the SAR mode, the resolution of the radar is improved in the along-track direction. This is achieved by exploiting the Doppler properties of the echoes as they cross the antenna beamwidth. The result is equivalent to decomposing the main antenna beam into a set of 64 narrower synthetic beams in the along-track direction. The footprints of the different sub-beams over a flat surface are adjacent rectangular areas, about 250 m wide in along-track and as large as the antenna's cross-track footprint (up to 15 km). Hence, a larger number of independent measurements are available over a given area; this property is used to enhance the accuracy of the measurements over sea ice. The echoes are transmitted to the ground segment in the time domain, prior to any averaging. Hence, the data rate in SAR mode is significantly higher than that for LRM.

- **SARIn (SAR Interferometric) support mode.** This mode is used mainly over ice sheet margins with high surface slopes. Both receive channels are operating simultaneously at high PRF to ensure the availability of a high cross-track resolution used for ice sheet margins and coastal areas (accurate determination of the arrival direction of the echoes in along-track and in cross-track). This is needed to derive the height of the surface from the range measurement of the radar. Narrow-band tracking pulses, transmitted in-between successive wide-band measurement bursts are used in this range-tracking concept to cope with abrupt height variations.

In the SARIn mode, the addition of the interferometric feature to the SAR further improves the echo localization capabilities, as the cross-track direction angle of the echoes can be determined. This is achieved by comparing the phase of one receive channel with respect to the other.

Parameter / Mode of Operation	LRM	SAR	SARIn
Receive chain	1	1	2
Samples per echo	128	128	512
Range window	60 m	60 m	240 m
Bandwidth	350 MHz	350 MHz	350 MHz
PRF	1970 Hz	17.8 kHz	17.8 kHz
Tx pulse length	51 μ s	51 μ s	51 μ s
Useful echo length	44.8 μ s	44.8 μ s	44.8 μ s
Burst length	N/A	51 μ s	51 μ s
Pulses/burst	N/A	64	64
Burst repetition interval	N/A	11.7 ms	46.7 ms
Azimuth looks (46.7 ms)	92	240	60
Tracking pulse bandwidth	350 MHz	350 MHz	40 MHz
Samples per tracking echo	128	128	128
Size of tracking window	60 m	60 m	480 m
Averaged tracking pulses (46.7 ms)	92	32	24
Data rate	51 kbit/s	12 Mbit/s	2 x 12 Mbit/s
Power	100 W	135 W	130 W
Mass (non redundant)	62 kg		

Table 281: Summary of instrument parameters for operational mode support

The innovative technical features of SIRAL are:

- The capability to operate in all measurement modes
- Digital chirp generation with pulse to pulse coherence for Doppler processing
- Solid State Power Amplifier (SSPA) in Ku band with high performance (25 W),

- Dual antennas forming an interferometer, mounted on an optical bench together with star-tracker heads, ensuring the accurate knowledge and stability of the interferometric baseline orientation
- Two receive chains matched together with very low distortions.

The novel feature of SIRAL, as compared with conventional altimeters, is the capability to locate a resolution cell in the 3 dimensional space. The SIRAL concept is based on a Ku-band nadir-looking radar which can be operated in the conventional mode over oceans. Over terrain (ice or land) the “advanced mode” uses Doppler filtering for the enhancement of the along-track resolution. A second antenna and receiving channel provides a second take of the scene which is used for surface height retrieval as it is usually done with SAR interferometry.

DORIS (Doppler Orbitography and Radiopositioning Integration by Satellite). DORIS is an uplink radio frequency tracking system based on the Doppler principle. The CNES instrument provides accurate measurements for a precise orbit determination. Knowledge of the orbit is essential for exploitation of the altimeter data and the overall performance. The onboard receiver measures the Doppler shift of uplink beacons in two frequencies (2.03625 GHz for Doppler measurement and 401.25 MHz for the ionospheric correction) which are transmitted continuously by the ground stations. One measurement is used to determine the radial velocity between spacecraft and beacon, the other to eliminate errors due to ionospheric propagation delays. The 401.25 MHz frequency is also used for measurements of time-tagging and auxiliary data transmission. The DORIS instrument comprises:

- A fixed omni-directional dual-frequency antenna
- A receiver performing the Doppler measurements every ten seconds. The nominal mode of operation is an autonomously programmed mode in which the receiver tracks the beacon signals according to information provided by the navigation software (DIODE) based on an on-board table of beacon data.
- An USO (Ultra Stable Oscillator) delivering the reference frequency with a stability of 5×10^{-13} over a period of 10 to 100 s.

The mass of DORIS is 15 kg (including the antenna of 160 mm diameter). The instrument requires 20 W of power, the data rate is 4 kbit/s.

The following DORIS services are used for CryoSat operations:

- Real-time orbit determination for spacecraft attitude and orbit control (on-board)
- Provision of a precise time reference based on TAI (International Atomic Time); in addition a precise 10 MHz reference signal is used (on-board)
- Provision of on-ground POD (Precise Orbit Determination) and ionospheric modeling.

LRR (Laser Retroreflector). The objective is to use LRR as an additional tool and backup for precise orbit determination with the aid of the international laser tracking network. LRR is accommodated in the nadir plate of the spacecraft, suitable for range measurements above 20° elevation angles at all azimuths.

E.3 EGS (Experimental Geodetic Satellite, Ajisai)

Japanese (NASDA) geodetic mission. Launch: Aug. 12, 1986 from Tanegashima Space Center with the H-1 launch vehicle. The primary objective was performance confirmation of the H-1 launch vehicle. Objectives of EGS: provision of long-range geodetic applications aimed at rectifying Japan’s domestic geodetic triangular network, determining the exact position of many Japanese islands and establishing Japan’s geodetic point of origin.

EGS is a passive spherical satellite of 2.15 m diameter and a mass of 685.2 kg, carrying 318 mirrors and 120 laser reflector assemblies (1436 corner cube reflectors) for precise satellite

laser ranging (SLR) measurements from ground-based laser ranging stations. The reflectors and mirrors on the satellite sphere reflect laser beams back to the source, regardless of the angle of incidence (solid Earth studies, crustal movements, plate tectonics). The reflection of solar light is used to determine the direction to the satellite from an observation site.

The body of the satellite is a hollow sphere made of glass-fiber-reinforced plastics. The surface is covered with corner cube reflectors (CCR's) and solar light reflectors. Twelve CCR's form a set of laser reflectors (LR's), and 120 LR's are distributed almost uniformly over the surface. The remaining surface is covered with 318 solar reflectors. The base of the mirrors is made of an aluminum alloy and the surface has a protective coating of silicon oxide.¹⁰⁰⁰⁾

Orbit: circular orbit with an altitude of 1500 km, inclination = 50°, period = 116 minutes.

Observation method of EGS: The basic concept for geodetic use of the EGS is to simultaneously determine directions through photography and measure distances by laser ranging. The principle is to determine the relative geodetic location of two observation sites by simultaneously measuring the distance and direction to the EGS at a known station (named the base station) and an unknown station (primary station) of which the precise geodetic location is unknown. The distance from a site to the EGS is measured by SLR. To determine the location of a number of unknown stations around the base station, at least one Transportable SLR (TSLR) is used.

The laser ranging surveys are conducted by the 'Geophysical Survey Institute' of the Ministry of Construction, and the 'Hydrography Department of the Maritime Safety Agency', Ministry of Transport.

E.4 ETALON

ETALON ("standard") = Soviet Geodynamical Satellites. ETALON-1 was launched on January 10, 1989 from Baikonur together with two GLONASS satellites. (ETALON-1 is also known as Cosmos-1989). ETALON-2 (identical S/C) was launched on May 31, 1989.

Orbits (ETALON-1 and -2): Near-circular orbit, altitude = 19130 km, eccentricity = 0.00068, inclination = 64.8°, nodal period = 10874.7 days (29.8 years), perigee period = 94402.9 days (258.6 years), one revolution period = 675 min (11.25 h)¹⁰⁰¹⁾

Features of ETALON S/C.

Shape = sphere with a diameter of 1.294 m, mass = 1415 kg, laser reflectors = 2140, distance from the geometrical center to the plane of probable reflection = 558 mm.

Objectives: ETALON is a passive satellite system dedicated entirely to laser ranging [see also LAGEOS (E.15)]. Solid Earth studies: geodynamic processes, development of high-accuracy global references, long-period disturbances, geopotential modelling, etc.

Three laser stations in Russia (at Ternopol, Yevpatoria, and Maydanak) provide laser ranging services. In addition, a network of 10 sites outside Russia are performing ranging measurements. GFZ of Potsdam, Germany, is the data collection and distribution center for ETALON laser measurements in Europe.

E.5 GEO-IK

GEO-IK¹⁰⁰²⁾ = Space Geodetic Complex. A Russian S/C for Solid Earth Research, launched May 30, 1988. Builder and operator of GEO-IK S/C is NPO PM, Krasnojarsk.

1000) M. Sasaki, H. Hashimoto, "Launch and Observation of the Experimental Geodetic Satellite of Japan", IEEE Transactions on Geoscience and Remote Sensing, Volume 25, No. 5, Sept. 1987

1001) S.K. Tatevian, A.N. Zakharov, "The Geodynamical Satellite ETALON," CSTG Bulletin No. 11, Title: New Satellite Missions for Solid Earth Studies, 1989, pp. 3-9

Each mission is planned for an operational life of 5 years. More GEO-IK satellites were launched in 1989 (Aug. 28), 1990 and 1994 (Nov. 29).

Orbit: Near-circular orbit, altitude = 1500 km, inclination = 74° , period = 116 minutes.

The satellite is equipped with a Doppler transmitter, a flashlight system and laser corner reflectors. The S/C is oriented with the long axis toward the Earth's mass center, stabilization is realized towards the orbital axis.

The frequency range of the Doppler transmitter is 150 and 400 MHz

Objectives: geodetic measurements (geodetic connection of islands, development and control of local geodetic networks, improvement of general ellipsoid parameters, connection of initial geodetic dates, etc.). The scientific program is carried out by the Astronomical Council of the Russian Academy of Sciences.

The geodetic complex GEO-IK consists of the satellite itself, the ground-based tracking sites, and the S/C control center.

E.6 GEOS (GEOstationary Satellite)

The GEOS¹⁰⁰³) missions (1 and 2) of ESA were reference spacecraft for IMS (International Magnetosphere Study, 1976-79). GEOS was designed for GEO operations to study the particles, fields and plasmas of the Earth's magnetosphere.

E.6.1 GEOS-1

GEOS-1 mission (ESA). Launch April 20, 1977 by Delta vehicle from Cape Canaveral, FL (a booster/separation problem meant that geostationary orbit could not be achieved). The S/C performed measurements in this orbit for 14 months.

The S/C structure consisted of a cylindrical bus, 132 cm high and 164.5 cm in diameter, equipped with several booms. The S/C was spin-stabilized. An apogee kick motor, with 269 kg of propellant, was used for injection into GEO. Six 15 N thrusters provided reaction control. Attitude was measured by sun and Earth sensors and an accelerometer. Surface-mounted solar cells provided energy of > 110 W (BOL). S/C mass = 574 kg. S/C integration by British Aircraft Corporation as prime contractor.¹⁰⁰⁴)

Orbit: GEOS-1 was left in a GTO orbit due to a stage 2/3 separation problem; apogee of 38,475 km, perigee of 2683 km, inclination of 26.6° .

Application: Detailed study of the magnetosphere's radial distribution of plasma, particles and waves (in conjunction with ground-based observations in Scandinavia, Iceland, Antarctica, and Alaska). Magnetospheric transport phenomena.

Sensors: ¹⁰⁰⁵) (simultaneous waves and particle experiments along with electric and magnetic fields and total plasma density).

- **S 300** = Search Coil Magnetometer (CRPE, France; ESTEC; Danish Space Research Institute). Objectives: study of magnetospheric wave phenomena in both electric and magnetic domains; measurement of AC magnetic fields up to 30 kHz; DC/AC electric fields and plasma resonances up to 80 kHz; mutual and self-impedance

¹⁰⁰⁴) "More than Thirty Years of Pioneering Space Activities," ESA publication BR-142, 1999, compiled by Andrew Wilson, pp. 46-49

¹⁰⁰⁵) GEOS - Projects under Development, ESA Report to COSPAR, Jan. 1977, pp. 112-123

- **S 302** = 2 Electrostatic Analyzers (Mullard Space Science Lab, UK). Objectives: measurement of thermal plasma (electron, protons) up to 500 eV.
- **S 303** = Combined Electrostatic and Magnetic Analyzer (University of Bern; MPI, Garching). Objectives: measurement of the composition (1-140 amu) and energy spectra of ions up to 16 keV.
- **S 310** = 10 Electrostatic Analyzers (Kiruna Geophysical Observatory, Sweden). Objectives: measurement of the pitch-angle distribution of electrons and protons in the 0.2-20 keV energy range.
- **S 321** = Magnetic Deflection System followed by Solid-state Detectors (MPI, Lindau). Objectives: measurement of the pitch-angle distribution for electrons (20-300 keV) and protons (20 keV - 3 MeV).
- **S 329** = Tracing of Electron Beam over one or more gyrations (MPI Garching). Objectives: measurement of DC electric field grad $|\mathbf{B}|$.
- **S 331** = Fluxgate Magnetometer (CNR, Frascati, Italy and NASA/GSFC). Objectives: measurement of the three components of the DC and ULF magnetic field. The instrument was boom-mounted.

The GEOS-1/-2 were the first S/C anywhere to carry a totally conductive coating - even over their solar panels. An electron beam experiment and a pair of probes, 40 m apart, provided independent measurements of the electric field surrounding the S/C. The S/C surface-treatment technology was confirmed.

Data: Transmission rate of 100 kbit/s (continuously at a frequency of 2299.5 MHz, no on-board data storage) containing high-speed data (wide-band analog and correlator data from the wave experiment), and low-speed data, consisting of low-frequency data from the wave experiment and the data from all other experiments. Uplink at 149.48 MHz.

E.6.2 GEOS-2

The GEOS-2 satellite (ESA) carried the same payload (sensor complement) as GEOS-1 and is regarded a replacement for GEOS-1 (GEOS-2 was originally considered as backup). GEOS-2 was launched July 14, 1978 from Cape Canaveral. Orbit: 25,640 km perigee, 35,592 km apogee at 0.77° inclination, positioned at 37° East (initially).

Objective: Measurement of fluctuations in the magnetic field which are picked up by small antennas (about 25 cm). GEOS-2 had six antennas to measure the three components of the field in two frequency bands.¹⁰⁰⁶⁾

GEOS-2 provided two years of data, was placed in hibernation for eight months, then revived for eight months in 1981 to support the EISCAT program of upper atmosphere motion measurements. GEOS-2 remained in use until the end of 1983. Periodic monitoring support (1984) of the chemical releases of the AMPTE mission.

E.7 GEOS

The NASA mission initiative of three S/C was of a study nature to test tracking system behavior experimentally and to unify the world's tracking datums to the 5-10 m level of uncertainty with respect to the geocenter. In this context the GEOS acronym has two definitions, 1) Geodetic Earth Orbiting Satellite, and 2) Geodynamics Experimental Ocean Satellite.

E.7.1 GEOS-1 (Geodetic Earth Orbiting Satellite)

S/C launch Nov. 6, 1965 on a Delta vehicle from Cape Canaveral, FL. The GEOS 1 S/C (also known as Explorer 29) was a gravity-gradient-stabilized, solar-cell powered satellite (387 kg

¹⁰⁰⁶⁾“GEOS,” Interavia Space Directory 1992-93, pp. 155-156

of on-orbit mass), designed exclusively for geodetic studies. It was the first successful active spacecraft of the National Geodetic Satellite Program. Instrumentation included 1) four optical beacons, 2) laser reflectors, 3) a radio range transponder, 4) Doppler beacons, and 5) a range and range rate transponder. These were designed to operate simultaneously to fulfill the objectives of locating observation points (geodetic control stations) in a three dimensional Earth center-of-mass coordinate system within 10 m of accuracy, of defining the structure of the Earth's irregular gravitational field and refining the locations and magnitudes of the large gravity anomalies, and of comparing results of the various systems on-board the spacecraft to determine the most accurate and reliable system. Acquisition and recording of data were the responsibility of the GSFC Spaceflight Tracking and Data Network (STDN). Ten major observing networks were used.

Orbit: Elliptical orbit, perigee = 1113 km, apogee = 2275 km, inclination = 59.4°, eccentricity = 0.07193, period = 120.3 minutes.

Sensor complement:

Optical Beacon System. The optical beacon system, used for geometric geodesy, consisted of four xenon 670 W (1580 candle-second/flash) flash tubes housed in reflectors. These tubes were programmed to flash sequentially in a series of five or seven flashes at times when they could be optically observed from Earth. Observations were made by STDN and SPECT MOTS 1 m and 0.6 m cameras, SAO (Smithsonian Astrophysical Observatory) Baker-Nunn and geodetic 0.9 m cameras, USAF PC 1000 cameras, and U.S. C&GS (Coastal and Geodetic Survey) BC-4 cameras. Telescopic cameras at three or more stations simultaneously photographed the flashes against the star background. Satellite position and angle of elevation from each station could then be determined by using star charts as guides. If two of the three stations had known positions, the coordinates of the third could be calculated by triangulation. The instrument operated satisfactorily from November 18, 1965, to December 1, 1966, when command capability was lost.

Laser Tracking Reflector. Laser corner reflectors composed of fused quartz cubes with silvered reflecting surfaces, were used for determining the spacecraft's range and angle. The 322 cubes were mounted on fiberglass panels on the bottom rim of the spacecraft and provided a total reflecting area of 0.18 m². The reflectors conserved the narrow beamwidth of incoming light and reflected a maximum signal to the ground, almost exactly to where it originated. About 50% of the light which struck the prism area at a 90° angle was reflected within a beam of 20 arcseconds. Reflected light received by ground telescopes was amplified by a photomultiplier tube that converted the optical impulse to an electrical signal. The time for the beam to return to the Earth was recorded by a digital counter. The reflected laser pulse was also photographed against the stellar background. Total time traveled by the light pulses was also considered in the optical laser tracking system.

Radio Doppler System. The Doppler technique of timing and measuring the frequency shift of radio transmissions from a moving S/C was used to help establish the structure of the Earth's gravitational field to an accuracy of about five parts in 100 million. Three transmitters were operated on frequencies of 162, 324, 972 MHz. Timing markers (bursts of 60° phase modulation) of 0.3 s duration once each minute were carried by the 162 and 324 MHz transmitters. Synchronization of the markers was to an accuracy of 0.4 ms. The system began operating during November 1965. The 972 MHz Doppler operated until January 14, 1967, when an intermittent command system response caused a permanent turn-off. The two lower frequency beacons operated continuously until December 1967, when operations became intermittent and progressively weaker. Operations were terminated on Jan. 15, 1968.

SECOR (Sequential Collation of Range). The system operated by the Army Map Service (AMS) was used for the S/C radio range system. A 3.6 kg transponder received and retransmitted ground radio signals (421 MHz receiver and 224.5 and 449.0 MHz transmitter).

Ground-based equipment included phase-modulated transmitters, range-data receivers, and electronic phase-meters. The transponder provided valuable ranging data for four US SECOR stations to make possible inter-comparison tests from December 29, 1965, to May 1, 1966. Inter-datum and inter-island ties were completed from Tokyo to Hawaii using data from SECOR tracking stations and other geodetic observations made between May 24, 1966, and February 8, 1967. The transponder failed on February 8, 1967.

Radio Range/Rate System. Objective: Measurement of range and the radial velocity of the S/C by making phase shift and Doppler measurements. The onboard transponder, which operated on 2271 (receiver) and 1705 MHz (transmitter), and a conical antenna were the spacecraft components of the NASA/GSFC Range and Range/Rate System. The antenna, mounted on the Earth-facing portion of the S/C, could receive and transmit data. Its beam width was 150° . Data received from this instrument by three S-band stations were used to augment other geodetic data and to provide a comparison of this system with others used in tracking the S/C. The command system failure occurred on December 1, 1966.

Minitrack System. The minitrack interferometer tracking system (136 MHz) was used in combination with the NASA Range and Range/Rate System to establish the GEOS 1 orbit. Raw data from the two systems were used for early orbit determinations and routine orbit updating. Minitrack acquired 16,271 data points (station axis crossings). The Minitrack stations also participated in mutual visibility events that involved tracking with other stations for tracking system intercomparison experiments. The system operated nominally from Nov. 6, 1965, until January 14, 1967.

E.7.2 GEOS-2 (Geodetic Earth Orbiting Satellite)

The S/C launch was on Jan. 11, 1968 on a Delta vehicle from VAFB, CA (also known as Explorer 36). Objectives: optimization of optical station visibility periods and provision of complementary data for inclination-dependent terms established by GEOS 1 gravimetric studies. A gravity-gradient-stabilized, solar-cell-powered S/C (469 kg of on-orbit mass) that carried electronic and geodetic instrumentation. The geodetic instrumentation systems included 1) four optical beacons, 2) two C-band radar transponders, 3) a passive radar reflector, 4) a sequential collation of range radio range transponder, 5) a range and range rate transponder, 6) laser reflectors, and 7) Doppler beacons. Non-geodetic systems included a laser detector and a Minitrack interferometer beacon. The S/C was placed into a retrograde orbit to accomplish these objectives. Operational problems occurred in the main power system, optical beacon flash system, and the spacecraft clock, and adjustments in scheduling resulted in nominal operations.

Orbit: Elliptical polar retrograde orbit, perigee = 1082 km, apogee = 1570 km, inclination = 105.8° , eccentricity = 0.03165, period = 112 minutes.

Sensor complement:

Optical Beacon System. Identical system as flown on GEOS-1. Data were obtained until Jan. 31, 1970.

Laser Tracking Reflector. Identical system as flown on GEOS-1.

Radio Doppler System. Identical system as flown on GEOS-1. The US Navy Doppler Tracking Network (TRANET) monitored the spacecraft for Doppler data. Observations made from three or more known stations allowed deduction of orbital parameters.

SECOR (Sequential Collation of Range). Identical system as flown on GEOS-1. The range measurements were made by measuring the phase shift of the ranging sidetones that modulated the CW carrier. By using trilateration techniques, the unknown position of one of the four stations could be accurately determined.

Radio Range/Rate System. Identical system as flown on GEOS-1. The system is also known under the name of GRARR (Goddard Range and Range Rate).

C-band Radar Transponder. The system was used for experimental range radar calibration and data recording to determine the accuracy of the system for geometric and gravimetric investigations. For redundancy, two transponders, each operating on 5690 MHz (receiver) and 765 MHz (transmitter) were carried on the S/C. One transponder had a 5 ms interval time delay, and the other had a near-zero internal delay that allowed for real-time identification by the C-band participants. The transponders were operated on a select-call basis to conserve S/C power. A C-band passive reflector was used in conjunction with the transponders for precise calibration of the internal time delay and to provide passive C-band tracking capabilities.

Minitrack System. Identical system as flown on GEOS-1.

Precipitating Electron Detector. The instrument consisted of an electrostatic deflection device and channeltron detector intended to measure electrons in the energy range 2 - 10 keV.

Magnetometer. The instrument consisted of a uniaxial fluxgate magnetometer oriented perpendicular to the orbital plane. Although the principal function of the magnetometer was to serve as an attitude sensor, a very limited amount of scientifically useful data on fluctuations in the range 0.03 to 3.0 cps were obtained through use of a filter.

E.7.3 GEOS-3 (Geodynamics Experimental Ocean Satellite)

GEOS-3 is a NASA mission.¹⁰⁰⁷⁾ Launch: April 9, 1975 with a Thor-Delta launch vehicle from VAFB, CA. Operation of satellite for over 3 1/2 years. The S/C structure was an octahedron, topped by a truncated pyramid, with a parabolic reflector for a radar altimeter on the flat bottom side. A metal ribbon boom with end mass extended upward approximately 6.1 m from the top of the pyramid. Passive laser retroreflector cubes were mounted in a ring around the parabolic reflector with the normal vector from each cube facing 45 deg outward from the direction of the Earth. A turnstile antenna for VHF and UHF frequencies and separate antennae for Earth-viewing 324 MHz Doppler, C-band, and S-band transponders were mounted separately on flat surfaces next to the parabolic reflector. The dimension across the flats of the octahedron was 1.22 m, the spacecraft was 1.11 m high. S/C on-orbit mass = 340 kg.

Mission objectives were to perform a satellite altimetry experiment in orbit, to support further the calibration and position determination of NASA and other agency C-band radar systems, and to perform a satellite-to-satellite tracking experiment with the ATS-6 spacecraft using an S-band transponder system. This system was also used for periodic GEOS-3 telemetry data relay through ATS-6, to support further the intercomparison of tracking systems, to investigate the solid Earth dynamic phenomena through precision laser tracking, to refine further orbit determination techniques and determine inter-datum ties and gravity models, and to support the calibration and position determination of NASA Spaceflight Tracking and Data Network (STDN) S-band tracking stations.

Orbit: Near-circular polar retrograde orbit, apogee = 858 km, perigee = 818 km, inclination = 115°, period = 101.82 minutes.

Application: Determination of oceanographic and geophysical parameters, satellite altimetry. Estimation of significant wave height. Geometric, gravimetric and other geodetic investigations. First estimations of surface wind speeds with altimeter data. Provision of the first comprehensive data set for most areas of the world's oceans.

Sensor complement:

ALT (Radar Altimeter). Multimode radar system with two distinct data-gathering modes (global and intensive). The global mode used a long pulse with two altimetric readings per

¹⁰⁰⁷⁾H.R. Stanley, "The GEOS 3 Project," Journal of Geophysical Research, July 30, 1979, pp. 3779-3783

second, while the intensive mode used a short pulse with six readings per second. Both modes operated at 13.9 GHz frequency, used a parabolic antenna, had a maximum range acquisition time of 6 s, and had an altitude granularity of plus or minus 0.2 m. First radar altimeter to provide sea surface height measurements (50 cm range precision in the global mode and 20 cm in the intensive mode). This radar altimeter was of S-193 heritage on Skylab; however, with improved accuracy and the ability to operate over extended areas for greater periods of time, thereby providing the capability of examining the Earth over longer arcs and observing extensive ocean areas.

Laser Tracking Reflector (JHU/APL) consisting of a spaceborne laser retroreflector subsystem and ground-based laser-ranging systems (provision of precision satellite-ranging data). The laser reflector system consists of 264 quartz cube corner reflectors mounted on a 45° conic frustum. When illuminated by a laser light pulse from the ground, each retroreflector cube in the array reflected the light ray back to a special telescope receiver on the ground. The reflected light was picked up by the telescope, and the optical impulses converted to an electrical signal. A digital counter recorded the time when the light beam was returned to the ground. The total travel time of the light pulses, from ground to satellite and back to the ground, measured the distance to the satellite, thus forming the basis of the satellite optical laser system. The following observational systems acquired the necessary data: NASA/Wallops Laser Ranging Systems, SAO (Smithsonian Astrophysical Observatory) Laser Ranging Systems, GSFC Laser Ranging Systems, and other national and international laser stations.

Doppler System GEOS-3 (US Navy) of GEOS-1 heritage, consisting of two spaceborne transmitters and ground Doppler receiving stations. The dual frequencies (162 and 324 MHz) were coherently related and utilized in conjunction with ground Doppler receiving stations to obtain precision satellite range-rate data. The dual frequencies were generated by a highly stable oscillator driving two frequency multipliers. Both frequencies were used simultaneously to provide comparison data of the effect of the ionosphere on the signals. Observations made from three or more known stations allowed deduction of orbital parameters. Data rate = 15.6 kbit/s or 1.56 kbit/s.

S-Band Tracking System. The transponder subsystem consisted of a single-channel transponder, a power amplifier, a diplexer, and an Earth-viewing and ATS-viewing antenna system. The transponder operated in the following three modes: 1) satellite-to-satellite tracking, 2) direct unified S-band (ground-station tracking of GEOS-3), and 3) direct GRARR (Goddard Range and Range Rate) ground-station tracking of GEOS-3.

C-band Radar Transponder. Identical to the system on GEOS-2.

Satellite-to-Satellite Tracking (SST). The experiment consisted of 1) the ground-based ATS ranging system, 2) the wideband communication transponder on the ATS-6 geosynchronous spacecraft, and 3) the ranging transponder on the LEO satellite. ¹⁰⁰⁸⁾

E.8 GEOSAT (Geodetic/Geophysical Satellite)

US Navy Altimeter Mission.^{1009),1010)} Mission control, data handling and processing, archiving and distribution at JHU/APL, Navy and NOAA. The S/C was launched on March 12, 1985 on an Atlas-E vehicle from VAFB, CA. GEOSAT consisted of two mission phases. The first was the classified Geodetic Mission (GM); mission duration = 18 months (until Sept. 1986). The second mission phase is known as the 'Exact Repeat Mission' (ERM),

¹⁰⁰⁸⁾ P. Argentiero, et al., "Results of GEOS 3/ATS-6 Satellite-to-Satellite Tracking Orbit Determination Experiment," *Journal of Geophysical Research*, Vol. 84, No. B8, pp. 3921–3925, 1979.

¹⁰⁰⁹⁾ "The Navy GEOSAT Mission: An Overview," Johns Hopkins APL Technical Digest, Volume 8, No. 2, 1987

¹⁰¹⁰⁾ "The Navy GEOSAT Mission Radar Altimeter Satellite Program," in *Monitoring Earth's Ocean, Land, and Atmosphere from Space*, Volume 97, 1985 AIAA, pp. 440-463

which was unclassified; it started Oct. 1, 1986 and ended in January 1990. APL was the prime contractor for the S/C and radar altimeter and provided S/C operations.

Objectives: Provision of a dense global grid of altimeter data for Navy use in the areas of geodesy (Earth's gravitational models), the study of fronts and eddies, winds, waves and ice topography, physical oceanography in the 'Exact Repeat Mission.'

Orbit:

1. GM mission: Sun-synchronous polar orbit, inclination = 108.1° , apogee = 814 km, perigee = 757 km, period = 100.6 minutes. Orbit of nonrepeating ground tracks in order to obtain a densely sampled map of the marine geoid.

2. ERM mission: Starting Nov. 8, 1986 the orbit was changed to an exact repeat cycle of 17.05 days for the observation of geodetic parameters of the oceans. ERM continued until January 1990, when the mission was terminated due to the degradation of the altimeter's output power.

The basic structure of the GEOSAT is similar to the GEOS-3 satellite: The design consists of a conical structure below the core for the structural attachment of the velocity control system. The GEOSAT attitude control subsystem (gravity gradient stabilization) was designed to point the radar altimeter to within 1° of nadir 98% of the time. The system components were a 6 m scissors boom with 45 kg end mass, redundant momentum wheels for roll and yaw stiffness, and pitch and roll attitude control thrusters. Attitude sensing was provided through the use of three digital sun-attitude detectors and a three-axis vector magnetometer. Spacecraft command was accomplished via a VHF uplink from the APL ground station. The telemetry subsystem consisted of two S-band transmitters, two tape recorders, and two encryption units. The GEOSAT was equipped with two dual-track high-density tape recorders (Odetics) that independently recorded the 10.205 kbps telemetry stream and played it back at 833 kbps for transmission to the ground. S/C mass = 635 kg.¹⁰¹¹⁾

Sensor:

Radar Altimeter. (mass = 86.5 kg, power = 125 W). Frequency = 13.5 GHz; range precision = 5 cm. Range measurement between satellite and subsatellite point (at nadir) of the orbit with high measurement precision. Orbit determination with a two-frequency Doppler Tracking System (TRANET). The altimeter's two main subsystems are the RF section and a signal processor. The RF section consists of a 5 cm thick honeycomb panel with various subsystems attached to one surface and a parabolic dish attached to the opposite surface. The signal system generates a linear FM (chirp) pulse waveform for transmission by a traveling wave tube 20 W amplifier. The on-orbit dry mass of the S/C is 635 kg.¹⁰¹²⁾

Data:¹⁰¹³⁾

On-board recording up to 12 hours. S-band downlink to APL tracking facility.

Data products: Raw data were processed into Geophysical Data Records (GDRs) by APL and NOAA. The GDRs include height data derived from average echoes at a rate of 10 Hz, and mean height values at 1 Hz (every 6.7 km on the surface). Although the primary objective of the Geosat mission was to operate over oceans, echoes were also collected over ice and land surfaces.

NOAA/NODC in Washington, DC provides Geosat data of the ERM period on CD-ROM (Geosat altimeter crossover differences) as of Dec. 1992.

E.9 GFO-1 (Geosat Follow-On Program)

A US Navy spacecraft, designed and built by Ball Aerospace Corp. of Boulder, CO. The objective of the GFO program is to provide operational altimetry data for the US Navy. The S/C structure consists of a conductive graphite composite; three-axis stabilized; attitude knowledge is derived from horizon scanners; sun sensors for yaw knowledge; attitude control accuracy is 0.25° (3σ); location knowledge by redundant GPS receivers with an rms accuracy of 10 cm (radial component); a Doppler beacon transmitter is also carried to support orbit determination. A hydrazine propulsion system for orbit maintenance. S/C mass = 340 kg; power = 319 W; design life = 8 years; on-board recorder of 384 Mbit capacity; the S/C is 2.56 m in length and 0.78 m in diameter. The launch of GFO-1 took place on Feb. 10, 1998 on a Taurus launcher from Vandenberg Air Force Base, CA.¹⁰¹⁴⁾

Areas of application: The altimetry data from the GFO program will be used to obtain ocean topography measurements which can be used to derive the location of fronts, eddies, and current data. This information is pivotal for the development of global structure models.

Orbit: Non-sun-synchronous polar orbit providing an exact repeat ground track; inclination = 108° ; perigee = 775 km, apogee = 878 km repeat period = 101.4 minutes.

Figure 169: The GFO-1 S/C Model

Sensor complement:

- **RA** = Radar Altimeter. Frequency = 13.5 GHz ; range precision ≤ 3.5 cm. Range measurement between satellite and subsatellite point (at nadir) of the orbit with high measurement precision (performance equivalent to GEOSAT altimeter). RA consists of the following modules: RF unit, digital unit, solid-state power amplifier, T/R switch, combined RA/WVR feed horn, and integrated antenna. RA measures continuously along the subtrack with an approximately 2 km pulse-limited footprint. On-board calibration of radar cross section and height. Instrument mass = 24.7 kg; power = 75.5 W; data rate = 8 kbit/s.

¹⁰¹⁴⁾Information provided by B. Barry of Ball Aerospace, Boulder, CO, and by Ch. Kilgus of JHU/APL

- **WVR** = Water Vapor Radiometer. Measurement of the water vapor content along the altimeter pulse path. A two-channel instrument (22 and 37 GHz) that provides water vapor time corrections for the altimeter. The instrument consists of the electronics module, power supply, cold horns, combined RA/WVR feed horn and integrated antenna. WVR data rate = 160 bit/s.
- **GPS** = Global Positioning System. Redundant GPS receiver systems referred to as **TRSR** (TurboRogue Space Receiver) are used for precision orbit determination.

Data:

S-band downlink at 16 kbit/s (direct) and 512 kbit/s in dump mode to ground receiving stations. All data links to/from GFO-1 are encrypted. The science data will be made available to the general user community through NOAA. Mission operations by NAVSOC (Naval Satellite Operations Center) with ground stations at Prospect Harbor, ME, and Laguna Peak, CA.

E.10 GFZ-1 (GeoForschungsZentrum-1 Geodesy Satellite)

GFZ-1 is a German (GFZ Potsdam) geodesy mission (passive satellite) with the objective to improve knowledge of the Earth's gravity field. Kayser-Threde GmbH of Munich is the GFZ general contractor for the design and construction of the satellite as well as for the arrangement of a MIR launch by RKK Energia. GFZ-1 has a mass of 20 kg and a diameter of 215 mm. The launch of GFZ-1 was April 9, 1995; insertion of GFZ-1 into its own orbit: April 19, 1995. - GFZ-1 reentered the atmosphere in June 1999. The last track by a German ground station occurred on June 23, 1999 at an orbital altitude of 121 km.

Figure 170: Illustration of the GFZ-1 S/C model

The small GFZ-1 satellite is of spherical shape whose outer surface is covered with 60 laser (corner cube) reflectors. The low Earth orbits of GFZ-1 was selected for high-accuracy determination of the Earth's gravity field.¹⁰¹⁵⁾

Orbit: Near-circular orbit, eccentricity < 0.01 , altitude 400 km (initial orbit of MIR) to about 150 km (end of mission), inclination = 51.6° , mission life > 3 years. The low-altitude and slowly decaying orbit is chosen for high-sensitivity response in the Earth's gravity field. As such, GFZ-1 is the lowest orbiting geodynamics satellite in its class.

The precise orbit of GFZ-1 is determined by laser ranging (cm range accuracy). GFZ operates its own SLR (Satellite Laser Ranging) station in Potsdam and supports a further station at Santiago de Cuba (in cooperation with Centro Nacional de Investigaciones Sismológicas). The international SLR community, comprising a worldwide network of about 30 SLR stations, is invited to track GFZ-1.

E.11 GOCE (Gravity field and steady-state Ocean Circulation Explorer)

GOCE is a combined SGG (Satellite Gravity Gradiometry) and SST (Satellite-to-Satellite Tracking) mission. It was selected as a core mission in the ESA Earth Explorer Program (selected at the Granada meeting Oct. 12-14, 1999). The mission objectives are to determine the stationary gravity field - geoid and gravity anomalies with high accuracy (1 cm of geoid heights and 1 mgal) at spatial grid resolutions of 100 km over the Earth's surface. The GOCE mission serves to support the following multi-disciplinary science objectives:¹⁰¹⁶⁾¹⁰¹⁷⁾¹⁰¹⁸⁾

- To provide a new understanding of the physics of the Earth's interior including geodynamics associated with the lithosphere, mantle composition and rheology, uplifting and subduction processes
- To permit, for the first time, a precise estimate of the marine geoid, needed for the quantitative determination, in combination with satellite altimetry, of absolute ocean circulation and transport of mass
- To estimate the thickness of the polar ice sheets through a combination of bedrock topography, derived from space gravity, and ice sheet surface elevation (from altimetry)
- To provide a high-accuracy global height reference system for datum connection. This may serve as a reference surface for the study of topographic processes, including the evolution of ice sheets and land surface topography.¹⁰¹⁹⁾¹⁰²⁰⁾

The overall mission objective is to obtain measurements with high spatial resolution and high accuracy (homogeneous accuracy) such that global and regional models of the (static) Earth's gravity field and of the geoid (the equipotential surface of the Earth's gravity field potential) can be deduced with unprecedented precision. Knowledge of the Earth's gravity field allows for exact orbit determination of satellites with regard to a unique reference plane, the geoid. This is then directly related to topics such as high-accurate point positioning using satellite techniques and mapping of ocean and land surfaces. A second argument to determine the Earth's gravity field is related to Earth sciences: To better understand processes that take place within the Earth's interior, and on and above its surface. Knowledge of the geoid allows for studies of the solid Earth's mass distribution, interpretation of sea-level changes, ocean water flows/ocean heat transport and related with these, climate studies- and predictions.

Figure 171: Schematic illustration of the GOCE S/C (structural and payload elements)

Application	Accuracy		Spatial Resolution half wavelength
	Geoid (cm)	Gravity (mgal)	
Solid Earth:			
- Lithosphere and upper mantle density structure		1-2	100 km
- Continental lithosphere		1-2	50-100 km
• Sedimentary basins		1-2	20-100 km
• Rifts		1-2	100-500 km
• Tectonic motions		1	100 km
• Seismic hazards		0.5-1	100-200 km
Ocean lithosphere & interaction with asthenosphere			
Oceanography:			
- Short scale	1-2		100 km
	0.2		200 km
- Basin scale	0.1 (approx.)		1000 km
Ice sheets:			
- Rock basement		1-5	50-100 km
- Ice vertical movements	2		100-1000 km
Geodesy:			
- Levelling by GPS	1		100-1000 km
- Unification of worldwide height systems	1		100-20000 km
- Inertial navigation system		1-5 (approx.)	100-1000 km
- Orbits (1 cm radial orbit error for altimetric satellites)	1-3 (approx.)		100-1000 km
Sea-level change	Many of the above applications, with their specific requirements, are relevant to sea-level studies		

Table 282: Measurement requirements in terms of geoid height and gravity anomaly accuracies

The GOCE satellite will be built by a consortium led by Alenia Spazio of Italy as the prime contractor, Astrium GmbH is responsible for the platform. The S/C structure consists of a long slender (octagonal) prism, with a cross sectional area of 0.9 m^2 (featuring total symmetry to minimize disturbances, there are no deployable appendages) and a length of about 4.5 m. Within the structure there are several platforms upon which the payload modules are mounted, and which subdivide the platform into 3 modules for ease of integration. The lower module contains AOCS/DFACS (Attitude and Orbit Control System/ Drag-Free and Attitude Control System), and Ion Thruster including the Xenon tank. The central module houses the the EGG assembly and its electronics. In fact, the EGG assembly is located close to the center of mass of the S/C (and will stay within 10 cm of the center of mass throughout the S/C lifetime). The upper module contains the electrical equipment, data-handling and radio-frequency equipment, and a nitrogen gas tank. Electric power of 1 kW EOL is gener-

ated by fixed body-mounted solar arrays (about 5.0 m^2) with GaAs cells. NiCd batteries of 25 Ah provide energy storage. The S/C thermal design and control is based on passive insulation and radiation techniques. The S/C has a launch mass of about 1000 kg, including up to 125 kg of propellant.

The key element of the on-board AOCS/DFACS system is the drag-free attitude and orbit control. The DFACS is designed to compensate for the effects which atmospheric drag forces and torques have upon the gradiometer measurements using ion thrusters and micro-thrusters. The total error budget for the gradiometer is of the order of $4 \text{ mEHZ}^{-1/2}$ (Note: $1 \text{ E} = 1 \text{ Eötvös} = 10^{-9} \text{ s}^{-2}$, a unit of gravity gradient). S/C attitude control is provided with an absolute pointing accuracy of 0.38 mrad. Attitude is sensed by a sun sensor, a three-axis magnetometer, a star sensor plus SSTI (Satellite to Satellite Tracking Instrument) and EGG. Two 20 mN RF ion thrusters and four pods of four 1 mN cold gas proportional thrusters are used as actuators.

A conventional data handling system is used on-board, based on the MIL-1553B bus, an ERC 32 processor, and 2.5 Gbit data storage. S/C communications are in S-band (two coherent S-band transponders, two antennas and a radio frequency distribution unit, 1 W RF power) with data rates of 2 kbit/s in the uplink and up to 850 kbit/s in the downlink. The ground receiving station (TT&C) is Kiruna. Mission operations and control of GOCE are at ESOC.

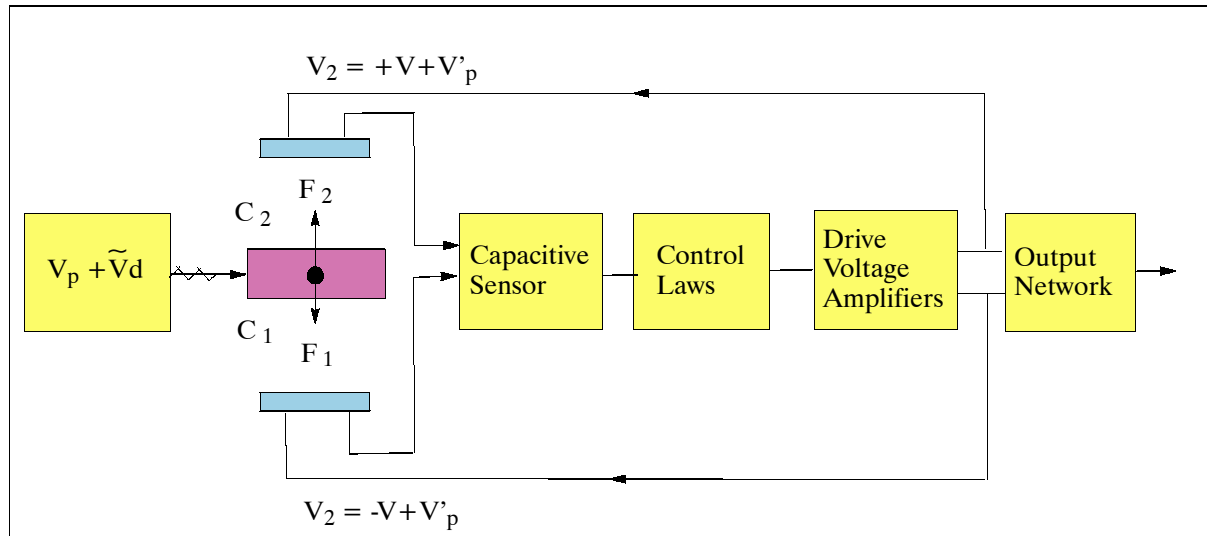

Figure 172: Single accelerometer control loop for proof mass position and feedback to AOCS/DFACS

A nominal mission duration of 20 months is planned. A Rockot-class launch vehicle from Plesetsk, Russia is planned as a reference launcher. The expected launch date is 2005.

Orbit: Sun-synchronous low Earth orbit, altitude = 250 km, inclination = 96.5° , equatorial crossing at 6:00 hours (dawn-dusk orbit) or 18:00 hours (dusk-dawn orbit) at the ascending node. Global coverage outside the polar caps is reached after about 30-40 days.

Sensor complement:

Technical concept: Satellite gradiometry is the measurement of acceleration differences between the test masses of an ensemble of accelerometers inside a satellite. The measured signal is the difference in gravitational acceleration inside the spacecraft, where the gravitational signal reflects the pull of the Earth's varying gravity field (caused by varying masses of mountains and valleys, ocean ridges and trenches, subduction zones and mantle inhomogeneities, etc.). The measured signals correspond to the second derivatives of the gravitational potential. - The gradiometer measurements are supplemented by SST (Satellite-to Satellite Tracking) measurements.

The two core instruments are SSTI and EGG. SSTI incorporates a geodetic GPS/GLO-NASS receiver for high-low tracking between the satellites of the two navigation constellations, and the low-flying GOCE spacecraft, referred to as SST-hl. The EGG is a three axis satellite gravity gradiometer (SGG). The gradiometer principle is based upon differential accelerometry. Drag and attitude control together with some fundamental properties of gradiometry - allow the separation of the gravitational signal from non-gravitational satellite skin forces and angular motion. Time variable effects of eigen-gravitation will be kept below the instrument noise level. The SSTI allows the retrieval of the long wavelength terms of the gravity field, while the EGG function is devoted to the medium and short wavelength terms. The instruments overlap in the low frequency range, around 0.005 Hz.

From the measurement principle point of view, the GOCE mission concept is unique by meeting four fundamental criteria for gravity field missions, namely:

- Uninterrupted tracking in three spatial dimensions
- Continuous compensation of the effect of non-gravitational forces
- Selection of a low orbital altitude for a strong gravity signal
- Counteracting of the gravity field attenuation at altitude

EGG (Electrostatic Gravity Gradiometer). The main objective of EGG is to measure the three components of the gravity-gradient tensor (i.e. gradiometer data). The EGG instrument, designed and developed at ONERA and to be built at Alcatel, is based on an ambient temperature, closed loop, capacitive accelerometer concept. EGG is a three-axis gradiometer consisting of 3 pairs of three-axis servo-controlled capacitive accelerometers on an ultra-stable carbon-carbon structure. The thermal control (passive with heaters) provides 10 mK stability during 200 s. The performance is better than $4 \text{ mEHZ}^{-1/2}$ (or $4 \times 10^{-13} \text{ g Hz}^{-1/2}$). The EGG assembly has a mass of 150 kg and requires up to 75 W of electric power.

The principle of operation of the EGG is based on the measurement of the forces needed to maintain a proof mass at the center of a cage. A six degree of freedom servo-controlled electrostatic suspension provides control of the proof mass in terms of translation and rotation. A pair of identical accelerometers, mounted on the ultra-stable structure, 50 cm apart, form a “gradiometer arm.” The difference measured between accelerations measured by each of the two accelerometers, in the direction joining them, is the basic gradiometric datum (differential measurement), while half the sum is proportional to the externally induced perturbing drag acceleration (common mode measurement). Three identical arms are mounted orthogonal to one another and, the axes so defined are nominally aligned to the along-track, cross-track and vertical directions. The three differential accelerations provide direct, independent measurements: not only of the diagonal gravity components, but also of the perturbing linear and angular accelerations.

Design bandwidth (MBW)	5×10^{-3} to 10^{-1} Hz
Baseline length	0.5 m
Sensitivity (detection noise)	
Measurement bandwidth (MBW)	$< 10^{-12} \text{ m s}^{-2} \text{ Hz}^{-1/2}$
Extended bandwidth (10^{-5} to 1 Hz)	$< 10^{-10} \text{ m s}^{-2} \text{ Hz}^{-1/2}$
Proof-mass positioning error	$6 \times 10^{-8} \text{ m Hz}^{-1/2}$
Absolute / relative scale factors	$10^{-3} / 10^{-5}$
Absolute / relative misalignment	$10^{-3} \text{ rad} / 10^{-5} \text{ rad}$

Table 283: EGG performance parameters

In-orbit calibration of EGG: Calibration involves carefully planned coordination with S/C maneuvers and feedback from the gradiometer to the AOCS.. Such calibrations will be repeated, to check parameter stability with respect to thermal drifts and fluctuations. The objective of in-orbit calibration is to enhance the level of balancing to 10^{-5} in both scale-factor matching and alignment.

SSTI (Satellite to Satellite Tracking Instrument). The objective is to provide the SST-hl (Satellite-to-Satellite Tracking - high/low) contribution to the gravity field recovery, by the simultaneous tracking of up to 12 GPS/GLONASS satellite signals. In addition, SSTI provides data for precise orbit determination; it is also used for real-time on-board navigation and attitude-reference-frame determination. The instrument has a 12-channel dual-frequency receiver with a codeless tracking capability. It processes, demodulates and decodes the signals from GPS and GLONASS satellites, received through a hemispherical antenna pointing in the zenith direction. The frequency bands L1 and L2 signals are used to allow the compensation of ionospheric delays by ground post-processing. Each channel of SSTI receives either GPS or GLONASS signals and provides the following measurements: C/A (coarse acquisition) pseudo range (L1), L1 and L2 carrier phase, P1 and P2 code pseudo range (L1 and L2), L1-L2 differential carrier phase and P1-P2 differential pseudo range. In addition, SSTI provides the following capabilities:

- Position and velocity measurements from GPS (GLONASS optional) and corresponding UTC time
- One pulse per second output synchronized with GPS time
- Measurement time-tagging with respect to instrument internal time
- Redundant communication interface
- The ability to turn off unused measurement channels for power saving.

The carrier phase noise is better than 1 mm. The receiver mass is about 15 kg with a peak power demand of <40 W.

SREM (Standard Radiation Environment Monitor). The objective is to provide radiation environment measurements. Since the EGG instrument of the primary payload is sensitive to electrical charging, SREM data can be used to correlate its measurements with encountered electron and proton fluxes. The SREM instrument of ESA/ESTEC has already flown on the DERA mission STRV-1c (Space Technology Research Vehicle-1c). The SREM detector unit features two heads, each with a 20° half-cone FOV. The electronics unit comprises three particle detectors for electron and proton spectroscopy (measurement error <1%), cosmic-ray events counting and radiation-dose measurements. SREM has a mass of 2.6 kg and a power demand of 2.6 W.

LRR (Laser Retro Reflector). LRR provides a supplementary data set of range observations (satellite laser ranging by the SLR ground network) as backup for precise orbit determination post-processing. The LRR is a corner-cube array capable of reflecting laser pulses back along the incident light path. LRR has a total mass of 2.5 kg.

RITA (Radio-Frequency Ion Thruster Assembly). RITA consists of a quartz discharge chamber around which an RF field coil is wrapped, which induces the internal ionizing electric field. Separate Xenon propellant flows feed the discharge chamber and a hollow-cathode neutralizer. A positive voltage on the screen grid attracts electrons into the discharge chamber from the neutralizer plasma, to initiate the discharge. A flat triple-grid system is used to extract the ion beam, with the thruster grid at +1200 V, the acceleration grid at -500 V, and a grounded deceleration grid. To minimize erosion, the acceleration grid is made from graphite. The RITA system on GOCE is operated in the drag control range; it goes from 100 W for 1 mN to 500 W for 12 mN. The 20 mN required for orbit reboost require 625 W of power input. The total mass of RITA is about 60 kg. See also Figure 400 in O.14.2.

The RITA system was already test-flown on the EURECA-1 mission (launch July 31, 1992 - retrieval July 1, 1993). The ARTEMIS data relay satellite of ESA (launch in 2001), also employs a RITA propulsion system.

GOCE/GRACE (Gravity Recovery And Climate Experiment) mission comparison:

The GRACE mission (launch in 2001) complements GOCE by providing extremely high precision gravity measurements (an order of magnitude better than GOCE) at half-wave-

lengths exceeding 250 km. The advantage of GRACE data analysis is to recover temporal variations of the gravity field at these relatively longer spatial scales. The high resolution and accurate gravity field derived from GOCE in the 80 - 250 km half-wavelength range may also help to de-alias the shorter wavelengths of the gravity field of the GRACE analysis. A combination of the GRACE and GOCE results will permit construction of a gravity field model of the required precision on all relevant spatial scales.

- GRACE: Designed to measure the time variability of the gravity field at a low spatial resolution at the Earth’s surface (typical values for half lambda are 1000 - 200 km).
- GOCE: Designed to measure the static gravity field at a high spatial resolution at the Earth’s surface (typical values for half lambda are 200 - 80 km).

	1/2 wavelength =1000 km	1/2 wavelength =260 km	1/2 wavelength =133 km	1/2 wavelength =80 km
GRACE	<0.001 cm	= 0.15 cm	= 15 cm	unmeasurable
GOCE	= 0.04 cm	=0.15 cm	= 0.8 cm	= 10 cm

Table 284: GRACE/GOCE performance in terms of cumulative geoid error at various spatial scales

E.12 GP-B (Gravity Probe B - Relativity Mission)

A NASA gravitational physics mission, under development at Stanford University (PI: C. W. F. Everitt; Stanford is building the experiment apparatus, Lockheed Martin the S/C and payload). The objective is to provide two extremely precise new tests of Einstein’s general theory of relativity by means of observations on gyroscopes in Earth orbit. The experiment will check, very precisely, tiny changes in the directions of spin of four gyroscopes contained in an Earth-orbiting polar satellite. The gyroscopes will be so free of disturbances that they will provide an almost perfect space-time reference system. They will measure how space and time are warped by the presence of the Earth, and, more profoundly, how the Earth’s rotation drags space-time around with it. These effects, though small for the Earth, have far-reaching implications for the nature of matter and the structure of the Universe.^{1021), 1022)} Since GP-B is a “controlled physics experiment” it required many years of challenging work and sophistication in technology. ^{1023) 1024) 1025) 1026)}

The S/C is spin stabilized (0.1 to 1 rpm) using proportional helium thrusters (drag-free control). Attitude measurements are provided with a cryogenic science telescope and control gyros for angular rates. The attitude reference platforms are mounted on the stable graphite rings of the dewar. Each platform has a star tracker and a rate gyro providing the information to orient the S/C initially to acquire the guide star with the science telescope, and to maintain accurate pointing during 45 minutes of occultation of the guide star by the Earth during each orbit. One star sensor provides roll information (<1 arcsec). The pointing control < 20 milliarcseconds rms. The S/C structure has a length of about 6 m, total mass = 3,000 kg, power = 500 W, design life = 3 years. A launch of GP-B is scheduled for May 2002 on a Delta-2 vehicle from VAFB.

The S/C has an on-board solid-state recorder of 1.9 Gbit capacity. There are two communication links, a direct downlink via S-band at 2.5 Mbit/s, and a TDRS MA (Multiple Ac-

cess) link at 1.032 kbit/s (return) and 250 bit/s (forward). GP-B will be operated from Stanford University.

Orbit: Polar circular orbit, altitude = 640 km, inclination = 90° , period about 90 minutes, eccentricity $e = 0.00134$, the orbit plane is aligned with the guide star direction.

Figure 173: The GP-B S/C model

Background: ¹⁰²⁷⁾ Gravity Probe A (GP-A) was launched on June 18, 1976 on a Scout-D launch vehicle from Wallops Island, VA. The probe attained a ballistic (sub-orbital) flight path with an apogee of 10,000 km. The principal payload was an atomic hydrogen-maser oscillator system with the objective to measure directly the effect of the gravitational potential on the frequency of a proper clock, a hydrogen maser. The objective of the experiment was to determine whether time progressed at a different rate in conditions where gravity is weaker. Hence, the sub-orbital clock tests included the Shapiro time delay experiment and redshift experiments. During this short trip, GP-A transmitted accurate measurements of slight changes in the clock's rate in lower gravity. The analysis of the GP-A experimental data verified a portion of Einstein's gravitation and relativity theories which are referred to as the "Principle of Equivalence."

GP-B background: A gyroscope orbiting the Earth experiences two distinct space-time processes – namely the Frame-Dragging effect and the Geodetic Effect (orthogonal effects) – gradually changing its direction of spin.

- Frame Dragging: A rotating massive body drags space and time around with it. A gyroscope orbiting Earth tends to tilt away from the plane of its orbit because the Earth is dragging it.
- Geodetic Effect: According to Einstein's General Theory of Relativity, space and time in the vicinity of a massive body is distorted. For a gyroscope orbiting near the Earth, this distortion leads to a tilting of the gyroscope's spin axis in the plane of the orbit. This effect is predicted by general relativity theory to be 150 times larger than the frame dragging.

¹⁰²⁷⁾ R. F. C. Vessot, M. W. Levine, "A Test of the Equivalence Principle Using a Space-Borne Clock," *General Relativity and Gravitation*, Vol. 10, No. 3, 1979, pp. 181-204

Figure 174: Relativistic precessions of an orbiting gyroscope

In late 1959, these concepts were independently conceived and formulated by the physicists, Leonard Schiff of Stanford University and George Pugh of DoD. According to calculations by L. Schiff, the frame-dragging effect (rotation of space-time) should turn the gyroscope with the Earth through an angle of 42 milliarcseconds in a time period of one year. G. Pugh provided a complete error analysis of a possible experiment. In particular, he suggested for the first time the far-reaching concept of a drag-free (or drag-compensated) satellite.¹⁰²⁸⁾ The GP-B project evolved eventually from these early thoughts. - GP-B will measure this frame-dragging effect to a precision of $\leq 1\%$.

According to Einstein, a second, much larger change in spin direction, the geodetic effect, follows from the gyroscope's motion through this space-time curvature. The predicted effect for a gyroscope is a rotation in the orbit-plane of 6,600 milliarcseconds per year – quite a large angle by relativistic standards (see Figure 174). GP-B will measure this change to 1 part in 10,000 or better.

The measurement of Schiff's two effects demands much more than placing a gyroscope in a satellite. Six distinct technical requirements have to be simultaneously satisfied:

- 1) A drift-free gyroscope: a gyroscope having an absolute drift-rate (i.e. change in spin direction from non-relativistic disturbances) of $< 10^{-11}$ degrees/hour. This is six orders of magnitude (10^6) better than the best inertial navigation gyros available.
- 2) A gyro readout: a method for determining the changes in spin angle to 0.1 milliarcsecond without disturbing the gyroscope.
- 3) A stable reference: a means (telescope and mechanical structure) of referring the gyro readout to the guide star.
- 4) A trustworthy guide star: a bright, properly located star whose motion with respect to inertial space is known.
- 5) A technique for separating relativity effects: an orbit and a data processing method that together allow the frame-dragging and geodetic effects to be separated.
- 6) A credible calibration scheme: a scheme of in-flight calibration tests to ensure that the gyroscopes – and the entire instrument – are free of errors that might masquerade as relativity signals.

All six prerequisites are met by GP-B.

¹⁰²⁸⁾ Note: The first drag-free satellite to fly a completely gravitational orbit was Triad-1 of the US Navy, built by JHU/APL and launched Sept. 2, 1972. The development of the drag-free system on Triad-1 is a direct flight experiment of George Pugh's proposal.

E.12.1 Mechanical Systems

Two mechanical systems, essential to the success of the relativity measurement, are decidedly unusual: 1) a set of seven mass-trim mechanisms is used to balance and align the principal axis of the spacecraft, and 2) the use of helium proportional thrusters.^{1029) 1030)}

Mass trim mechanisms. Each mass trim mechanism consists of a 20 kg mass mounted in a closed rectangular box; they are adjusted in position by a lead screw driven by a stepper motor. These mechanisms have been subject to a very extensive qualification program. Four of the masses are mounted transversely to move the axis of rotation laterally until it coincides with the line through the center of the gyroscopes to within 0.8 mm. The other three masses are mounted parallel to the S/C axis, they adjust the direction of the principal axis of inertia. Trimming is performed intermittently as the helium is depleted (this occurs probably a few times during the course of a year).

Helium proportional thrusters for attitude and translational control: In most S/C with gas-jet attitude control systems, constraints on gas consumption set by mass dictate the use of on-off valves that are fired only on demand. To apply this method to GP-B with its very fine pointing requirement of ± 20 milli-arcseconds would take a space-qualified valve capable of reseating perfectly hundreds of millions of times; this is obviously a severe reliability problem. Fortunately there is a solution. Already on board is a supply of gas that must be vented, namely the helium boil-off from the dewar. By directing this gas continuously through pairs of opposed nozzles operated as “proportional thrusters,” one obtains a control system that is at once smoother and mechanically more reliable than the conventional kind. This design was proposed by Stanford graduate students (J. S. Bull, J.-H. Chen, P. Wiktorski and Y. Jafry) and eventually further developed and built by Lockheed Martin.

S/C control is maintained in all three support modes, namely pointing, drag-free, and roll, using signals derived from:

- The science telescope
- Either of two science gyroscopes operated drag-free
- Conventional rate-gyroscopes mounted on the spacecraft

The signals are updated from a ‘star-blipper’ picking up a band of stars spread over the heavens at an angle to the roll axis. The pointing accuracy is better than 10 milli-arcsec, the residual cross-track average acceleration is measured to better than 10^{-12} g, and the roll rate to about 1 part in 10^5 . The translational controller is designed to force the center of rotation of the S/C into coincidence with the line through the gyro centers. The mass trim mechanism brings it within 0.8 mm; the translational controller brings it to 50 μ m, that is, to within the limit to which the gyros are aligned. - The spacecraft has 16 helium thrusters mounted on fixed struts, and extending from the S/C, with geometrical and internal redundancies such that any four systems can be allowed to fail with no loss of control performance.

Note, acceleration levels on satellites at the GP-B altitude (of 640 km) with normal mass/area ratios are typically of the order of 10^{-8} g. In GP-B, as a drag-free spacecraft rolling about the common axis of the gyroscopes, the mean cross-track acceleration will be below 10^{-12} g.

E.12.2 Experiment Payload

The GP-B payload is a ‘thermos bottle’ in space. The science payload consists of a superfluid (2,400 l) helium dewar, within which a high-vacuum probe is installed, containing the SIA (Science Instrument Assembly), made up of a Quartz Block Assembly (QBA), which is op-

1029) C. W. F. Everitt, S. Buchman, D. B. DeBra, G. M. Keiser, J. M. Lockhart, B. Muhlfelder, B. W. Parkinson, J. P. Turneure, “Gravity Probe B: Countdown to Launch,” NASA contract NAS8-39225 paper, 2000

1030) G. M. Reynolds, R. H. Vassar, R. T. Parmley, et al., “Payload and Spacecraft Technology for GP-B,” *Advances in Space Research*, Vol. 25, No 6, 2000, pp. 1193-1197

tically contacted to a fused quartz Cassegrainian telescope. The QBA consists of four gyroscopes and a drag-free proof mass sensor mounted in a precision-machined fused-quartz block. The spin axes of the four gyroscopes are aligned parallel to the line of sight to the guide star. The SIA is maintained at a stable temperature of 1.8 K which provides necessary stability of the precision alignment between the gyroscopes and the telescope.¹⁰³¹⁾

Each gyroscope (with the world's roundest sphere) is a 38 mm diameter sphere of homogeneous fused quartz with a uniform superconducting layer of niobium (Nb) coated on its surface. The coating thickness is 1.25 μm . The gyroscope is assembled inside a housing composed of two halves also made of fused quartz. Each housing half has three pairs of electrodes for electrostatic suspension of the gyroscope and raised support lands around each electrode to prevent electrical contact (when not suspended) between the gyroscope and the electrodes. In addition, the readout half has a thin-film Nb pickup loop located on its parting plane; the spin-up half has a spin-up channel with an inlet and an outlet for He gas spin-up of the gyroscope.

Figure 175: Gravity Probe B experiment payload¹⁰³²⁾

The four gyroscopes are aligned parallel to the telescope axis, two spinning clockwise and two counterclockwise, each gyroscope measuring both relativity effects. The difference in spin direction does not change the predicted effects; it does provide one of the many validation checks on the experiment. The gyroscopes are electrostatically suspended and then spun up to about 100 Hz by means of a helium gas at a temperature of 6.5 K. They are then evacuated to a pressure of $\leq 10^{-11}$ torr which, in conjunction with the averaging effect of rolling the S/C about the line-of-sight to the guide star, sufficiently minimizes torques due to differential gas damping. The proof mass sensor controls thrusters which compensate for the effects of residual drag on the S/C, and achieves an average acceleration at the gyroscopes of $\leq 10^{-11}$ g.

1031) S. Buchman, C. W. F. Everitt, B. Parkinson, et al., Gyroscopes and Charge Control for the Relativity Mission Gravity Probe B," *Advances in Space research*, Vol. 25, No 6, 2000, pp. 1181-1184

1032) Note: PODS = Passive Orbital Disconnect Struts

Two characteristics of the superconducting Nb play important roles in the performance of the gyroscope. First, the Nb coating makes an ideal equipotential surface for the electrostatic suspension; secondly, the London ¹⁰³³⁾ magnetic dipole moment provides a means to readout the direction of the gyro spin axis. Note: The spinning superconducting rotor develops a magnetic ‘London moment’ whose north-south axis exactly coincides with the rotor’s spin axis. This direction is measured by a magnetometer of extreme sensitivity, known as the SQUID (Superconducting Quantum Interference Device), coupled to a superconducting loop on the gyro housing. The SQUID has the capability to detect a field change of 5×10^{-14} Gauss within a few days, which corresponds to a gyro tilt of 0.1 milliarcseconds.

The gyroscope spin directions are related via a quartz block to the telescope viewing the guide star. Like the rest of the instrument, the telescope is made of fused quartz. Its aperture (i.e. primary mirror diameter) is 14.2 cm, length = 35.5 cm, folded optics design, Cassegrainian-type, focal length = 3.70 m.

Within the dewar, surrounding the probe, is a shield formed of superconducting lead bags (foil) which almost completely excludes the Earth’s magnetic field. Thus, the gyroscopes operate: a) at low temperature, b) at low pressure, c) in a low magnetic field, and d) in the low gravity of space.

The spin of the spacecraft is needed to average out potential error sources in GP-B (drifts in the telescope readout, Newtonian drift torques on the gyroscopes, etc.). Thus, the spin offers an important symmetry effect in the overall measurement concept.

The SIA is enclosed in a cylindrical cryogenic vacuum tube, 0.3 m in diameter and 2.4 m in length. The inside of the dewar vessel contains 2400 l of superfluid helium. The dewar, which maintains cryogenic temperatures on orbit for 18 months, serves as the main structural element of the S/C. The boil-off gas from the dewar, vented through proportional thrusters, provides thrust for attitude, translational and roll control of the S/C.

Magnetic shielding (DC and AC) is an essential feature of the experiment. For the London moment readout to work, the field trapped in the gyro rotor during cooling through its superconducting transition temperature must be below the value of 3×10^{-10} T (this is well below the limit achievable by conventional ferromagnetic shields). Equally important is to eliminate the AC disturbances from external magnetic fields such as the Earth’s. The required AC shielding factor is 10^{12} . These requirements are met by surrounding the instrument with a nested series of conventional and superconducting magnetic shields.

E.13 GRACE (Gravity Recovery And Climate Experiment)

An international cooperative US-German dual-minisatellite SST (Satellite-to-Satellite Tracking) mission with the overall objective to obtain long-term data with unprecedented accuracy for global (high-resolution) models of the mean and the time-variable components of the Earth’s gravity field (a new model of the Earth’s gravity field every 30 days for five years). GRACE is also part of NASA’s ESSP (Earth System Science Pathfinder) program. Some science objectives are: ¹⁰³⁴⁾ ¹⁰³⁵⁾ ¹⁰³⁶⁾

- To enable a better understanding of ocean surface currents and ocean heat transport
- To measure changes in the sea-floor pressure
- To study ocean mass changes
- To measure the mass balance of ice sheets and glaciers

¹⁰³³⁾ When a superconductor like niobium spins, it generates a magnetic field effect known as the ‘London moment,’ after physicist Fritz London (1900-1954).

¹⁰³⁴⁾ C. W. Hughes, C. Wunsch, V. Zlotnicki, “Satellite Peers through the Oceans from Space,” EOS Transmissions of AGU, Vol. 81, No. 7, Feb. 15, 2000, p. 68

¹⁰³⁵⁾ <http://www.csr.utexas.edu/grace/>

¹⁰³⁶⁾ <http://essp.gsfc.nasa.gov/grace/>

- To monitor changes in the storage of water and snow on the continents

The mission concept makes use of measurements of the inter-satellite range and its derivatives between two co-planar satellites (in low-altitude and polar orbits), using a microwave tracking system. The orbits of the two separately flying S/C are perturbed differently in the Earth's gravity field, leading to inter-satellite range variations. In addition, each S/C carries a GPS receiver of geodetic quality and high-accuracy accelerometers to enable accurate orbit determination, spatial registration of gravity data and the estimation of gravity field models. The fluctuations in the strength of the Earth's gravity field reflect in turn changes in the distribution of mass in the ocean, atmosphere, and solid Earth, and in the storage of water, snow, and ice on land. Since ocean bottom pressure represents a column integral of the mass of the atmosphere plus ocean, this measurement technique permits the deduction of ocean bottom pressure changes from space.

The GRACE mission is led by B. Tapley (PI) of the University of Texas at Austin and by Ch. Reigber (Co-PI) of GFZ, Potsdam. NASA/JPL leads the S/C development in partnership with DASA/DSS (Dornier Satellitensysteme) and SS/L (Space Systems/Loral). DSS provides major elements of two flight satellites based on the existing CHAMP S/C. SS/L provides the attitude control system, microwave instrument electronics and system and environmental testing. DLR/GSOC performs mission operations with tracking stations at Weilheim and Neustrelitz. Science data distribution/processing is managed in a cooperative approach by JPL and UTA/CSR (University of Texas at Austin/Center for Space Research) in the US and GFZ in Germany. Germany provides also the Eurockot launch vehicle.

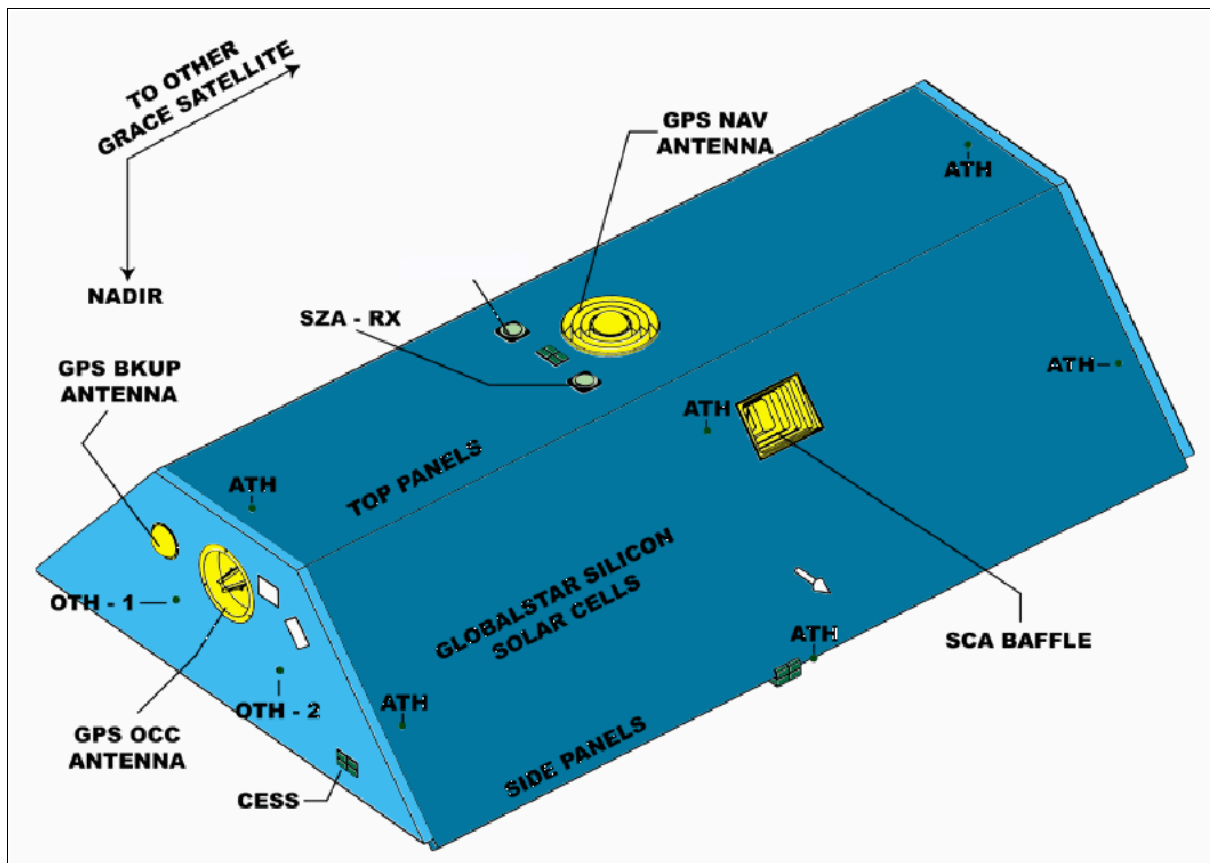

Figure 176: The GRACE S/C model

Both S/C structures are of identical design. The shape of each satellite is trapezoidal in cross section, based on the FLEXBUS design of DSS (length = 3122mm, height = 720 mm, bottom width = 1942 mm, top width = 693 mm). Each Earth-pointing S/C is three-axis stabilized by AOCS (Attitude and Orbit Control System) consisting of sensors, actuators and software. The sensors include CESS (Coarse Earth Sun Sensor) for omni-directional,

coarse attitude measurement in the initial acquisition, survival and stand-by modes of the satellite. The high precision sensors are SCA (Star Camera Assembly) of ASC heritage (flown on Ørsted), and the BlackJack (GPS Flight Receiver), see description under E.1. An IMU (Inertial Measurement Unit) provides 3-axis rate information in survival modes. A boom-mounted Förster magnetometer provides additional rate information. The actuators include a cold gas system (with 12 attitude control thrusters and two orbit control thrusters, each rated at 40 mN) and three magnetorquers. Each S/C has a mass of 432 kg (science payload = 40 kg, fuel = 34 kg); the S/C power is 150-210 W (science payload = 75 W). The top and side panels of each S/C are covered with strings of silicon solar cells; NiH batteries with 16 Ah provide power storage. The S/C design life is five years.

A dual-launch on an Eurockot vehicle is planned from Plesetsk, Russia, for Nov. 2001. The re-ignitable third stage, BREEZE, is used to place both satellites in the same nominal orbit.

Orbit: Circular polar co-planar orbit (non-repeat ground track); the initial altitude is 485 km at launch (near a solar maximum), decaying to about 300 km (near a solar minimum) after five years; inclination = 89° . The two satellites in tandem formation are loosely controlled, they are separated at distances between 170 to 270 km apart.

Figure 177: Bottom view of GRACE

Communications: The TT&C activities are carried out using a pyro-deployed S-band receive and transmit antenna, mounted on a nadir-facing deployable boom. A backup zenith receive antennae and a backup nadir transmit antenna (SZA-Tx), along with the appropriate RF electronics assembly, complete the telemetry and telecommand subsystem. The daily science data volume is about 50 MByte, including gravity data and GPS occultation data. CCSDS protocols are used for all data communication. The S-band frequencies for the two satellite system are:

- Downlink: 2211.0 MHz for satellite 1 and 2260.8 MHz for satellite 2. Modulation: BPSK/NRZ is modulated onto the subcarrier which is PM modulated onto the uplink carrier. The data rate is 32 kbit/s for real-time data and 1 Mbit/s for dump data.
- Uplink: 2051.0 MHz for satellite 1 and 2073.5 MHz for satellite 2. Modulation: BPSK/NRZ.

Sensor/payload complement:

The science instruments are mounted on a CFRP (Carbon Fiber Reinforced Plastic) bench in the S/C interior, as are the fuel tanks and the batteries and other satellite subsystems.

The **SIS** (Science Instrument System) includes all elements of the inter-satellite ranging system, the GPS receivers required for precision orbit determination and occultation experiments, and associated sensors such as SCA. SIS also coordinates the integration activities of all sensors, assuring their compatibility with each other and the satellite.

KBR (K-Band Ranging) instrument assembly of JPL. KBR is the key science instrument of the GRACE mission. The objective is ultra-precise satellite-to-satellite tracking (SST) in low-low orbit. Variations in the gravity field cause the range between the two satellites to vary. The relative range is measured by KBR (a microwave link which is integrated with a GPS receiver). The measured range variations are corrected for non-gravitational effects by SuperSTAR. KBR consists of the following elements: USO (Ultra Stable Oscillator), the microwave assembly, the horn, and IPU (Instrument Processing Unit).

USO (of JHU/APL) serves as the frequency reference. The microwave assembly, or sampler, is used for up-converting the reference frequency to 24 and 32 GHz; down-converting the received phase from the other satellite; and for amplifying and mixing the received and the reference carrier phase. The horn is used to transmit and receive the carrier phase between the satellites. The IPU is used for sampling and digital signal processing of not only the K-Band carrier phase signal, but also the signals received by the GPS antenna and the star cameras. Each satellite transmits carrier phase to the other at two frequencies, allowing for ionospheric corrections. The transmit and receive frequencies are offset from each other by 0.5 MHz in the 24 GHz channel, and by 0.67 MHz in the 32 GHz channel. This shifts the down-converted signal away from DC, enabling more accurate measurements of the phase. The 10 Hz samples of phase change at the two frequencies are downlinked from each satellite, where the appropriately decimated linear combination of the sum of the phase measurements at each frequency gives an ionosphere-corrected measurement of the range change between the satellites.

SuperSTAR (Super Space Three-axis Accelerometer for Research mission) of ONERA, France (of STAR heritage on CHAMP, with a resolution a factor 10 higher than that on CHAMP). The objective is the measurement of non-gravitational accelerations (drag, solar and Earth radiation pressure) acting on the S/C. SuperSTAR is mounted at the CG (Center of Gravity) of the satellite. SuperSTAR consists of the following elements: SU (Sensor Unit, EEU (Electromagnetic Exciting Unit), ICU (Interface Control Unit), and a harness. SU consists of a metallic proof mass, suspended inside an electrode cage of gold-coated silica. The proof mass motion is servo-controlled using capacitive sensors, and is a measure of the non-gravitational accelerations acting on the satellite. The mass and electrode cage core is enclosed by a sole plate and a housing in which vacuum is maintained using a getter. The SU vacuum unit is surrounded by analog electronics. The EEU is used to deliver a 10 mg acceleration, and is used only in case of an SU start-up problem. The ICU supplies power to the SU and EEU, and operates the accelerometer through a micro-controller board.

SCA (Star Camera Assembly). The objective is the precise measurement of satellite attitude. SCA consists actually of two DTU (Technical University of Denmark) star camera assemblies, each with a FOV of $18^\circ \times 16^\circ$. Both assemblies are rigidly attached to the accelerometer, and view the sky at a 45° angle with respect to the zenith, on the port and star-board sides. The SCA is used for both: science as well as AOCS; the two assemblies provide

the primary precise attitude determination for each satellite. The baffles are used to avoid the degradation due to solar heating.

LRA (Laser Corner-cube Reflector Assembly), provided by GFZ. LRA is mounted on the underside of the spacecraft to permit orbit verification from terrestrial laser tracking networks.

BlackJack (GPS Flight Receiver), a new generation instrument of TRSR (TurboRogue Space Receiver) heritage, provided by JPL (see description under E.1). The objective is to use the GPS instrument for navigation (precise orbit determination) and radio-occultation (refractive occultation monitoring) applications. BlackJack features three antennas, the main zenith crossed dipole antenna is used to collect the navigation data. In addition, a backup crossed dipole antenna and one helix antenna on the aft panel are used for back-up navigation and atmospheric occultation data collection, respectively. This system is capable of simultaneously tracking up to 24 dual frequency signals. In addition, this system provides digital signal processing functions for the KBR and SCA instruments as well.

E.14 Jason-1 (Joint Altimetry Satellite Oceanography Network)

Jason¹⁰³⁷⁾ 1038) is the name of a joint CNES/NASA oceanography mission series with the objective to monitor global ocean circulation, discover the tie between the oceans and atmosphere, improve global climate predictions, and to monitor events such as El Niño conditions and ocean eddies. The oceanography mission series is considered a cornerstone of GCOS (Global Ocean Observing System). The Jason-1 satellite carries a radar altimeter, a follow-on mission to the TOPEX/Poseidon mission. Jason-1 is planned to be launched on a Delta-2 7920 vehicle from VAFB in Dec. 2001 (along with TIMED).¹⁰³⁹⁾ 1040) 1041) 1042)

Figure 178: Illustration of the Jason S/C

1037) Jason-1 is named after the mythological hero who led the Argonauts on the adventurous and hazardous search for the Golden Fleece which they found and returned. "Jason" symbolizes both the hard-fought quest for a worthy goal and civilization's fascination with the ocean and its mysteries.

The Jason S/C uses the Proteus minisatellite bus, a multimission platform of CNES/Alcatel Space Industries (partnership). The overall architecture uses redundancy by sharing two half satellites, each under the control of one data handling unit. The satellite consists of the payload module (which accommodates the various instruments) and the Proteus platform, a boxlike structure of 1 m side lengths, which provides on-board services. The hydrazine propellant system uses a 28 l tank with 4 x 1 N thrusters (propulsion is only used for orbit acquisition and maintenance). A WFOV star tracker for attitude sensing is located on the payload module to minimize attitude errors. The normal in-orbit attitude control is based on a gyro-stellar concept. Four reaction wheels are used as actuators (they are desaturated using magneto-torquers). Power (450 W) is provided by two solar panels (silicon cells). Power is distributed by a non-regulated primary electrical bus, using a single battery (40 Ah NiCd). S/C mass = 490 kg (245 kg bus dry mass), the S/C bus size is: 954 mm x 954 mm x 1000 mm, the payload module size is: 954 mm x 954 mm x 1218 mm, design life = five years, data storage capacity of 2 Gbit (EOL), pointing accuracy = 0.035° . Communication: downlink rate at 650 kbit/s (S-band, QPSK modulation), uplink at 4 kbit/s (S-band). The CCSDS communication protocol standard is used.

The Jason-1 S/C is monitored and controlled from CNES in Toulouse up to the end of the assessment phase (30/50 days). Then the POCC (Project Operation Control Center) of JPL takes over. The baseline ground network includes stations at Aussaguel (France), Fairbanks (AK, Poker Flats location), and at Wallops Island, VA. In addition, the Altimetric and Orbital Topography Mission Center (SSALTO), located in Toulouse and the Jason Science Data System at JPL in Pasadena, form the mission ground segment.

Orbit: Circular non-sun-synchronous orbit; 1336 km altitude (2 hour period), inclination = 66° , 9.9-day repeat orbits (127 revolutions), ground track repeatability = ± 1 km cross-track at the equator. The plan is to fly Jason-1 and Topex/Poseidon along identical orbital tracks (about a minute apart) to perform cross calibration. Topex/Poseidon was launched August 10, 1992 and is now well beyond its design life of five years.
