Fastest shutter speed	1/15 s	1/15 s	1/500 s	1/1000 s

Table 541: Comparison of 1997 imaging technologies/products of leading sensor suppliers

O.4.2.1 Charge-Coupled Device (CCD)

A CCD is a photosensitive solid-state silicon-based imaging sensor (detector) implemented with large-scale integration technology based on MOS (Metal Oxide Semiconductor) capacitors that collect and transfer photon-generated charge. A MOS capacitor is a three-layer sandwich formed by positioning a metal electrode, insulated by a layer of silicon dioxide, onto a silicon substrate (buried channel). Typically, the device is built on a p-type substrate. An n-type region (about 1 μm in thickness) is formed on the surface.¹⁹²⁴⁾ The gate electrode consists of a thin silicon dioxide layer either on a metal surface or on a heavily doped polycrystalline silicon layer.

¹⁹²⁴⁾Note: CCD fabrication is based on **NMOS technology** because the surface layer consists of an n-type region.

The buried channel capacitor exhibits the following features:¹⁹²⁵⁾

- The ability to create a potential well in a local region beneath a single electrode
- The ability to modulate or control the potential under the gate
- The storage location (channel minimum) is positioned away from the silicon - silicon dioxide interface
- Low dark current makes it possible to store signal charge for long periods of time
- The charge that collects can be generated optically, injected electrically, or created by charged particles such as cosmic rays, protons, or high-energy photons
- The ability to move charge from a position beneath one electrode to a second neighboring electrode rapidly and with very low loss.

Image capture. Each CCD pixel absorbs a number of incident photons, converting their energy into an electrical charge which is trapped in the depletion region of the substrate. The isolated charge packets are transported by manipulating potential wells (place of minimum potential) within the substrate. CCD readout techniques employ clock-controlled circuits which transfer these charges to a matching grid of elements and shift all charges by one row at a time (shift register).

Figure 375: Schematic illustration of a buried MOS capacitor

Imaging arrays. Conceptually a CCD is a two-dimensional array of MOS capacitors (M columns by N rows) that collect and transfer photon-generated charge. An additional independent linear register (readout register) is placed next to the array with its charge transfer direction orthogonal to that in the array. This serial register is arranged so that there is a single pixel adjacent to each of the M columns, and is terminated in a charge-detection output amplifier. - Following an integration period, array readout involves simultaneous clocking of all rows of charge packets one pixel toward the serial register. The transfer process causes the bottom row to transfer into the serial register. The charge packets are then transferred along the serial register toward the output amplifier where they are detected. [The difference between a CCD and other charge-device technologies is that the charge from the CCD must be transferred down the parallel column and across the horizontal shift register to the amplifier, before it can be read out of the array.] The resulting data stream is a pixel-by-pixel, row-by-row representation of the image being detected on the CCD. - In a frame transfer configuration the detected image may first be transferred into an opaque temporary storage array by a proper clocking circuitry. From there it is shifted line by line into the serial readout register.¹⁹²⁶⁾

Figure 376: The CCD imaging array (back-illuminated frame transfer)

Figure 377: Schematic illustration of a CCD

An advantage of the CCD technology is that its readout scheme transfers the charge actually collected to the output amplifier. It means, there isn't any unwanted extraneous capacitance or resistance to degrade the signal integrity, the reason for its very low-noise behavior. Anti-blooming can be implemented by placing anti-blooming drains in the column stops adjacent to each pixel.

One of the limitations of conventional CCD structures are the polysilicon gate electrodes that are used to clock the charge down a column also obscure incident light - especially in the UV region of the spectrum. Back-illuminated operation overcomes this limitation by imaging through the thinned back surface of the CCD - away from the imaging electronics. Another limitation of the CCD scheme is that the charge must be transferred down a column before readout. If no shutter is used, there is a finite amount of time that each packet will integrate other parts of the scene while it is transferred from the active light sensitive region. This is often referred to as transfer smear. Frame transfer CCDs minimize this effect by using a storage region to protect the charge from incident radiation, they rely on a very fast transfer mode from the active to the storage region. Image smear decreases with the speed of the transfer mode.

In front-illuminated mode of operation, incident photons must pass through a passivation layer as well as the gate structure in order to generate signal electrons. Photons will be absorbed in these layers and not contribute to the signal. The QE (quantum efficiency) of front-illuminated CCDs is poor in the blue and UV regions due to the high absorption coef-

ficient for short wavelength photons in silicon. - First generation linear CCD arrays are usually front-illuminated devices.

In back-illuminated mode of operation, the silicon wafer is thinned to increase short wavelength QE. Light is incident on the exposed, thinned surface. The incident photons do not pass through the front surface electrodes and passivation layers. Rather, an enhancement layer at the back surface creates an electric field that forces photo-generated electrons toward the potential wells.

CCDs are manufactured from wafers. Silicon wafer sizes in 1980 were of 100 mm diameter; in 1990, wafers of 150 mm (6 inches) diameter were introduced. Current (1998) maximum wafer sizes of 200 mm diameter are a limiting factor for large CCD arrays. The year 2000 may see the introduction of 300 mm wafers in the program of major wafer manufacturers.

O.4.2.2 Charge-Injection Device (CID)

A photo-sensitive image sensor (detector) implemented in large-scale integration technology. Charge packets are typically measured by injecting them into a substrate or by shifting charge packets under an electrode to induce a voltage on the capacitance formed by the electrode and the substrate. A CID can be randomly addressed. The pixel structure is contiguous with maximum surface to capture incident light which is useful for sub-pixel measurements.

CID imagers have pixels constructed of the same basic structure of CCD imagers - MOS capacitor integrating site. The difference is how the collected photon-generated charge is being read. In a CID each addressable x-y photosite contains two coupled MOS-charge storage areas, referred to as photogates. Simultaneous selection of one or more rows and columns defines the coordinates of the pixels to be read out. Driving one photogate transfers charge to a second neighboring photogate within the same pixel. The charge is then read out. In most implementations, a single amplifier is located per row or per column. Therefore the charge remains intact to allow further integration or adaptive exposure control. The photosite sampling occurs by a row being selected and making the connection to the readout amplifier. Then, a column is biased to transfer the collected charge from the

column to the row at each pixel site. The collected charge at each pixel site remains at the pixel site during the readout operation. Only the pixel with its row connected to the output amplifier is read. The column can be rebiasd to return the charge into the column of any other pixel in the row to be read or any other row if selected to the output amplifier.

The benefits of the CID structure are: random access (CIDs can perform fast windowing of selected regions of interest), front side sensitive, non-blooming, radiation hard (CIDs have more than 100 times greater tolerance to ionizing particle radiation than CCDs), non-destructive read, and adaptive exposure control. The random access and radiation hardness features make the CID technology quite suitable for outward-looking sensors (in particular for astronomy applications).

The disadvantage of CID detectors, compared to CCD detectors, is noise due to the read-out method as described above. The charge collected at the pixel site is divided by the bus capacitance of the row, noise is introduced by the bus resistance. For this reason, CIDs have not been widely used for most applications.

Criterion	Eye	CCD	CMOS APS	Film
Spectral response	400-700 nm peaked at 555 nm	400-1000 nm smooth	400-1000 nm	300-700 nm
Peak quantum efficiency	<20%	>50%	>50%

O.4.2.3 CMOS/APS Detectors

The availability of the sub-micron semiconductor technology in the 1990s was needed to develop the CMOS/APS technology (the transistor sizes are now small enough to cover

¹⁹²⁷⁾Courtesy of Bart Dierickx of IMEC, Leuven, Belgium [presented at the IEEE Workshop on CCD&AIS (Ad-
vanced Imaging Sensors), June 4, 1997]. Note: Noise photons is defined as: noise photons = noise electrons /
(quantum efficiency x fill factor)

only about 75% of the imager area - allowing for radiation to get through a portion of the pixels). The method utilizes readout amplifiers at each pixel site (photosite), thereby eliminating the bus capacitance and bus resistance problems of a CID.

Because the CMOS/APS technology can be manufactured on conventional CMOS production lines, they offer the potential for significantly lower cost, they also offer the capability to be integrated with other functions such as timing logic and A/D conversion. The radiation hardness of CMOS/APS sensors is exceptionally good at nearly 1 Mrad. Typical CCD detectors have a comparatively low radiation hardness of approximately 10 krad.

O.4.3 Infrared Detection

Infrared radiation can be detected by its interaction with matter either through the process of direct photon absorption at the detector surface, or through the photon-to-photon exchange heating effect. In the latter case, the radiation is absorbed as heat, resulting in a temperature rise. The detectors measuring the change in resistance, are referred to as thermal detectors, or energy detectors, or square-law detectors. In the former case (photon absorption), the valence band (or impurity level) electrons in a bandgap semiconductor are elevated to the conduction band by direct photon absorption. The increase in conduction band electrons causes a current flow that can be measured. The devices measuring the direct photon absorption (and thereby generation electron-hole pairs) are referred to as photon detectors, or as quantum detectors, due to the quantum-mechanical interaction between the photons and the detector material. Note, the “Definitions” of chapter O.4.1 apply also to the infrared region.

Photodetector materials	Spectral Range (μm)	Comments
Si (silicon)	0.2 - 1.1 (UV, VNIR)	1.1 μm is the cut-off wavelength for detection of light imposed by the fundamental band-gap of Si
Ge	0.4 - 1.8	
HgCdTe (also referred to as MCT - mercury cadmium telluride)	1 - 20	MCTs are the most important material for IR detectors and arrays. MCT operates in photovoltaic mode. Recent advancements in LPE p-on-n back-side-illuminated detector technology have extended the cut-off wavelength to 17 μm
PtSi	3 - 5 (MWIR)	Schottky-barrier diode detector
InAs	1 - 3.8	
InSb (77K)	1 - 5.5 (SWIR, MWIR)	InSb operates in photovoltaic mode
HgZnTe		
QWIP	3 - 19	For low background, long wavelength applications

Table 543: Some detector materials for spectral ranges

Detector / Operating Temperature	300 K	190 K	80 K	1.5 - 60 K
PbS	3.0 μm	3.3 μm	3.6 μm	-
PbSe	4.4 μm	5.4 μm	6.5 μm	-
InSb	7.0 μm	6.1 μm	5.5 μm	5.0 μm
HgCdTe (PV mode)	1-3 μm	1-5 μm	3-12 μm	10-16 μm
HgCdTe (PC mode)	1-11 μm	3-11 μm	5-25 μm	12-25 μm
Extrinsic Si	-	-	-	8-32 μm
Extrinsic Ge	-	-	-	7-200 μm

Table 544: Detector spectral cutoff range for various detector materials

Table 544 summarizes the spectral response coverage of common IR detectors in four temperature ranges where 300 K refers to room temperature, 190 K is representative of a ther-

moelectric cooler, Freon-13, or dry ice; 80 K corresponds to the temperature of liquid nitrogen; 1.5 to 60 K refers to liquid Ne, H, or He. 1928) 1929) 1930) 1931)

A major drawback of IR photodetectors is the need for cooling to suppress thermal generation of free carriers resulting in noise. Hence, conventional IR semiconductor imagers use cryogenic or thermo-electric coolers, complex IR optics, and expensive sensor materials. Advances in micromachining and materials science have also lead to the development of uncooled infrared detectors for some applications.

Thermal detectors (active or passive) require cooling to increase sensitivity (this principle was first demonstrated in Germany during World War II). Infrared radiation is ‘thermal’ by nature, hence the detector is affected by the medium that is measured. As a rule of thumb, the longer the IR wavelength that is to be measured, the colder the detector must be. In the VNIR region the detector element temperatures rarely need to be below 200 K. From 1.1 - 17 μm , temperatures are typically in the range 50-80 K. The longer wavelengths of the microwave region usually demand temperatures below 20 K. (Note: The detectivity of a cooled detector is much higher than one operating at room temperature The noise contribution from background radiation at 300 K is several orders of magnitude higher than that of the 4 K surroundings of the detector).

Photon detectors are fundamentally limited by statistical fluctuations in the background and signal photon flux. To reach this fundamental limit, thermal fluctuation noise in the detector element must be reduced by cooling the detector. The detection of the longer wavelength (lower energy) photons requires more cooling to avoid performance degradation due to thermal noise.

O.4.3.1 Detector Arrays and Focal Plane Assemblies (FPAs)

Detector technology can influence some basic sensor design trade-offs, resulting in size and weight reductions. Increasing the number of detector elements can permit reductions in optical aperture size, until aperture size becomes governed by spatial resolution - and not by the optical collecting area required to achieve the requisite radiometric sensitivity. In essence, the availability of integrated high-density detector arrays allows designers to reduce the size of the optics to dimensions that are close to those set by the theoretical diffraction limit.

Technology now permits the design and production of integrated detector arrays that include first-level preamplification and multiplexing as part of the focal plane; this in turn permits simplification of the sensor’s other electronic subsystems.

Most conventional focal plane assemblies are built by using detector arrays (chips) with many detecting elements [in line array (pushbroom scanning) or area array (staring or scanning) operation mode]. These can be either monolithic (detector and signal processor in a single semiconductor crystal) or **hybrid** (detector and signal processor in separate elements).

The hybrid approach to imaging in the infrared region consists of coupling a silicon readout (CCD shift register or otherwise) to any one of the various types of IR photodetectors such as InSb, HgCdTe, etc. The silicon CCD acts as a signal processor (not as a detector). In direct-injection hybrid devices the photo-generated charge from a conventional infrared array is immediately transferred into a CCD shift register. Indirect injection devices employ a buffer stage between the photodetective elements and the CCD shift register, which may be a single MOSFET (Metal Oxide-Silicon Field Effect Transistor) or a number of off-chip

1931) Special Section: “Infrared Technology - Part 1,” Optical Engineering, January 1994, Vol. 33, No. 1

amplifiers. The entire hybrid structure is often called a “focal plane array” (FPA). Hence, infrared detector arrays are “sandwiched” structures whose layers are separated by an insulator, a grid of electrical connections in the form of tiny raised sections, referred to as “bumps.” At this point, it should be pointed out that infrared detectors are not based on the charge-coupling principle of the silicon CCD.

Two modes of operation are characteristic of monolithic infrared arrays: inversion mode and accumulation mode devices.

Inversion mode: These devices are constructed and operated like the basic silicon CCD, which is based on the generation of an inversion region at the insulator/semiconductor interface to which the photon-generated minority carriers migrate and are collected in potential wells (intrinsic mode operation).

Accumulation mode: This operation results from a proper polarity-gate voltage biasing that includes the same majority carriers at the semiconductor/insulator interface. The proper applied gate voltage is just the negative of that used for the more usual inversion mode devices. The accumulation mode enables extrinsic materials, whose photon-absorption cutoff wavelength is determined by the dopant impurity ionization levels, to be used for monolithic infrared CCDs.

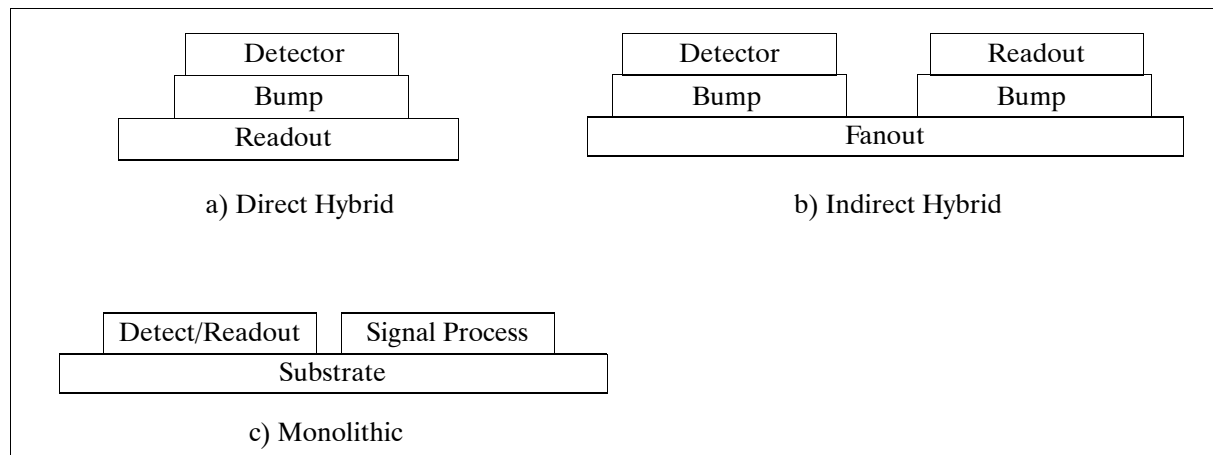

Figure 379: Some FPA detector readout architectures

The Schottky-barrier detection in monolithic infrared arrays is based on internal photoemission from metal/semiconductor Schottky barrier arrays onto a silicon substrate. Hot carriers are generated in the metal by absorption of photons with wavelengths greater than cutoff that penetrate through the semiconductor. The carriers with proper energy and momentum transit the contact barrier potential, they are emitted into the semiconductor, where they neutralize the fixed charges at the edge of the depletion region, induced by application of a reverse-bias voltage. Signal readout may be accomplished by a MOS transfer gate conversion of majority carriers to minority carriers required by the silicon CCD. Schottky barrier devices have a highly uniform responsivity across an array due to photo-detection in a metal film. However, they exhibit a relatively low photoemissive yield in comparison to other CCDs.

In the PtSi (Schottky-barrier) detector FPA, radiation is transmitted through the p-type silicon and is absorbed in the metal PtSi (not in the semiconductor), producing hot holes that are then emitted over the potential barrier into the silicon substrate, leaving the silicon charged negatively. The negative charge of silicide is transferred to a CCD by the direct charge injection method.

O.4.4 Radiation Detection Limits

Within the EMS (Electromagnetic Spectrum) the spectral radiance (i.e. energy per unit area and solid angle) varies considerably and with it the ability to detect (measure) radi-

ation. In general, photons are considerably more energetic at shorter wavelengths than at longer wavelengths.

The photon/frequency conversion relations in the EMS are:

1eV corresponds to 2.418×10^{14} Hz; or about $1.24 \mu\text{m}$

$E[\text{eV}] = \frac{1.24}{\lambda[\mu\text{m}]}$ photon energy related to wavelength ranges is shown in Table 545

Spectral region	Range of spectral region	Photon energy level range
UV (Ultraviolet)	0.01 - 0.38 μm	124 - 3.4 eV
VIS (Visible)	0.4 - 0.7 μm	3.1 - 1.8 eV
NIR (Near infrared)	0.7 - 1.3 μm	1.8 - 1 eV
SWIR (Short-Wave infrared)	1.3 - 3 μm	1 - 0.4 eV (or 400 meV)
MWIR (Mid-Wave infrared)	3 - 5 (or 6) μm	400 - 250 meV
TIR (Thermal infrared)	6 - 14 μm	200 - 90 meV
FIR (Far infrared) also referred to as SMMW (Sub- millimeter Wave) region	about 10 - 1000 μm (1 mm) 100 μm (3 THz) 200 μm 300 μm 500 μm 800 μm	124 - 1 meV 12 meV 6 meV 4 meV 2.5 meV 1.4 meV
MW (Microwave region)	1 mm - 1 m or (<300 GHz fre- quencies < 300 MHz)	1 meV - 1 μeV

Table 545: Photon energy levels within some defined regions of the EMS

Sensitivity of the detector is a measure of its ability to discriminate between small signal differences. Single photons can easily be detected by photomultipliers (PMT) in the visible and near-infrared range (also referred to as VNIR). This is so because of the relatively high energy level of single photons in these particular regions - the transformation from a single photon, striking a detector surface, to many electrons within the detector, works well within VNIR.

The same detection method does not work anymore for photons of longer wavelengths since the signals are too weak for detection. For instance, in the SMMW (Submillimeter-Wave) region, also referred to as FIR, the photon energy range is somewhere between 1-100 meV. For comparison, in the VIS region the photon energy is about a thousand times higher.

The FIR region is of great interest to spectroscopic research, because it covers the rotational spectra of molecules and vibrational spectra of solids, liquids, and gases. There are many applications in atmospheric research, astronomy and biochemistry.

Up to about the year 2000, most observation studies in the FIR region were hampered by the absence of sensitive detectors. So far, measurements in FIR have been made with either bolometers, which measure the total absorbed power, or heterodyne detectors, which use reference frequencies to mix the absorbed radiation down to lower, more readily managed frequencies. Neither approach comes close to the single-photon sensitivity, possible with photomultipliers in VNIR. Even with superconducting bolometers, the attainable sensitivities in FIR are far below the level of single-photon detection.

First experimental results of single-photon detection in FIR are reported by S. Komiyama et. al. in the wavelength range of 175-210 μm .^{1932) 1933) 1934)} This is done by using a SET (Single Electron Transistor), an element of nanotechnology, consisting of a semiconductor

¹⁹³²⁾ S. Komiyama, O. Astafiev, V. Antonov, T. Kutsuwa, H. Hirai, "A single-photon detector in the far-infrared range," Nature, Vol. 403, Jan. 27, 2000, pp. 405-407

quantum dot in a high magnetic field. The detection mechanism measures cyclotron resonance between two Landau levels (the Landau levels are narrow bands of allowed electronic states). Photon absorption can occur only when the photon energy equals the energy difference between the Landau levels. The sensitivity is a consequence of the measurement technique, in which one absorbed photon leads to a current of 10^6 - 10^{12} electrons through the quantum dot. By contrast, mechanisms of conventional detectors in single electron transistors produce only a few electrons per incident photons.

O.4.5 Acousto-Optic Devices

Acousto-optics is the science of the interaction of sound and light. Sound propagating through a solid or liquid creates compressions and rarefactions in the material that in turn pulls out color features from the light passing through it. This acousto-optic interaction has created a new optical filtering technology, referred to as AOTF (Acousto-Optic Tunable Filter), employed for spectral separation in imaging applications. One feature of AOTF is its electronically tunable center frequency. The center frequency is displaced by a change in sound frequency used to activate the filter. In this way, the AOTF sorts out radiation features emanating from an object. Since all objects have characteristic and distinctive optical signatures, an effective methodology exists for remote acquisition and identification applications.

Examples of acousto-optic devices include optical modulators, deflectors, scanners, Q-switches, isolators, spectrometers, and frequency shifters. These devices have many applications in high-speed laser printers, laser lithography, optical communications and computing, large-screen laser projectors, frequency shifting, particle inspection, optical spectrum analysis, signal processing, and radar, rangefinder, and target designation. ^{1935) 1936)}

Progress in acousto-optics has been stimulated by the development of growth methods for acousto-optic crystals and by new methods for fabricating piezoelectric transducers that can efficiently convert electrical energy into acoustic energy at frequencies ranging from a few tens of megahertz up to several Gigahertz. One promising development in acousto-optic devices is the recent commercial availability of acousto-optic tunable filters (AOTF). In these filters, the interaction between an ultrasonic wave and light in an acousto-optic crystal is used to spectrally filter the light. In operation, tunable filters resemble interference filters and can be used in applications that require a filter wheel, grating, or prism.

Principle of operation: The AOTF is based on acoustic diffractions of light in an anisotropic medium. The device consists of a piezoelectric transducer bonded to a birefringent crystal. When the transducer is excited by an applied RF signal, acoustic waves are generated in the medium. The propagating acoustic wave produces a periodic modulation of the index of refraction. This provides a moving phase grating that, under proper conditions, will diffract portions of an incident beam. For a fixed acoustic frequency, only a limited band of optical frequencies can satisfy the phase-matching condition and be cumulatively diffracted. As the RF frequency is changed, the center of optical passband is changed accordingly so that the phase-matching condition is maintained.

In a quartz collinear AOTF, the incident light, the diffracted filtered light and the acoustic wave all interact collinearly in a birefringent crystal. As a result of the acousto-optic interaction, part of the incident light beam within the filter spectral passband is coupled to the diffracted light beam. The polarization of the incident light beam is orthogonal to that of the diffracted light beam. Because of the zero-order beam and the diffracted beam are collinear, polarizers must be used to separate them.

¹⁹³⁵⁾ V. E. Pozhar, V. I. Pustovoi, "Acousto-optical spectrometers," Proceedings of the XIV International Conference on Geomagnetic Electronics and Electrodynamics, Section of Spin-Electronics, Moscow, Firsanovka, Nov. 13-16, 1998, Vol. 2, pp. 365-381

¹⁹³⁶⁾ http://www.brimrose.com/press_1.html

In a tellurium dioxide (TeO_2) non-collinear AOTF, the acoustic and optical waves propagate at quite different angles through the crystal. In this configuration, the zero-order and diffracted beam are physically separated, so that the filter can be operated without polarizers. Also, the two orthogonally polarized beams do not separate until they exit from the crystal, and the angle of diffracted beam is absent for the change in the first order with a change of wavelength. This implies that only a single fixed detector is necessary during a spectral scan.

Most AOTF devices are designed with two types of birefringent crystals depending upon operational wavelength. TeO_2 is preferred AOTF material because of its high acousto-optic figure of merit. The crystal, although useful in the visible and infrared region up to $4.5\text{ }\mu\text{m}$, is not suitable for ultraviolet applications due to its short-wavelength transmission cutoff at 350 nm . For ultraviolet spectroscopy, crystalline quartz is used.

Spectral imaging: Because of its large field-of-view angle and high spatial resolution ($>100\text{ lines/mm}$), an AOTF can also be used for spectral imaging applications. It can be used for acquiring spatial, spectral, and polarization information from fluorescent probes in biological cells, space and terrestrial observation, and image sensing. Spectral imaging at orthogonal polarizations can give the spectral properties and size distribution of gases and aerosols, in addition to revealing the nature of solid surfaces from their reflectance spectra.

The spectral resolution of the AOTF depends on the design of the AOTF and the wavelength, which is proportional to the wavelength squared (λ^2). This is quite different from a traditional grating system in which the spectral resolution is proportional to the wavelength.

For the collinear diffraction geometry, a 100% diffraction efficiency can be obtained corresponding to the full conversion of the incident wave energy into the only diffraction mode, having an orthogonal polarization. In quartz crystals, used in instruments with AO interaction length of 10 cm , the required acoustic power is a few Watt, and in TeO_2 with a length of 3 cm , it is much less than a Watt.¹⁹³⁷⁾

Since the cross-section sizes of collinear AO (Acousto-Optic) interaction are limited only by the sound beam diameter, the spatial aperture (pupil) of AOTF far exceeds the aperture of a slit on other spectral devices, e.g. gratings. A large AOTF aperture, both angular (up to dozens of degrees) and spatial (up to 1 cm^2) permits a large optical throughput. In a collinear diffraction, the interaction length is limited only by the dimensions of the crystal, this provides the high diffraction selectivity ($\Delta\lambda/\lambda$ is about 10^{-2} to 10^{-4}). The electronic control of the sound frequency makes fast AOTF spectrum tuning (10^{-5} to 10^{-6} s) possible.

Some AOS (Acousto-Optic Spectrometer) advantages. AOS offers some advantages when compared to the traditional optical instruments (such as the grating and Fourier-transform spectrometers). These are:

- High optical throughput due to the use of a bulk phase grating (having large cross-section sizes) produced in the crystal by the ultrasonic wave
- Rather high spectral resolution (in the order of $0.4\text{ }\text{\AA}$ in the UV spectral region)
- High SNR because the measurement technique based on amplitude modulation and synchronous demodulation. High SNR means also that rather weak optical signals can be measured.
- High-speed performance of the instrument. AOS tuning time from any spectral point to another arbitrary spectral point is only limited by the ultrasound transit time (about 10^{-5} s). The random spectral access is a unique feature that enables principally new and most general data collecting algorithms
- The use of an adaptive measurement mode implemented via optimum fitting of the instrument function to the spectral object and changing this function during the measurement process. It is useful for detection of unknown objects (mixtures)

¹⁹³⁷⁾S. E. Harris, R. W. Wallace, "Acousto-optic tunable filter," Journal of the Optical Society of America, Vol. 59, 1969, pp. 744-747

- High accuracy of the radiation intensity measurement (spectral brightness) due to exact analytical knowledge of the instrument apparatus function based on detailed mathematical analysis
- Absence of mechanical moving parts and insensitivity to vibrations, shocks and impacts
- Light mass and small size of the instrument, necessary for use of AOS in heavy exploitation conditions, e.g. on-board of aircraft and spacecraft
- One of the most important advantages of collinear AO systems is their ability to transmit color images of an object without any spatial distortions. This can be extremely useful in designing new imaging systems for the detection and identification of a variety of object monitoring.^{1938) 1939) 1940)}
- Low cost of commercial production. The cost of AOS devices is several times cheaper in comparison with conventional grating-based instruments.

Some AOS instrument applications are:

- Environment monitoring of the Earth surface (land and ocean) from spacecraft, aircraft and ship; measurement of minor gases in the atmosphere; monitoring of vegetation characteristics (projective factor and vegetation index); detection of sea water bio-productivity and pollution.
- Utilization in industrial/technological processes: automatic control of technological processes in microelectronics, quality output control, monitoring of hazardous gases discharged to the atmosphere and impurities released into waste waters; detection of organic chemicals inside industrial facilities.
- Monitoring of natural disasters and accidents: earthquakes, forest fires, volcanic eruptions, etc. Detection of technogenic catastrophes, including military activity.
- Attempts of forecasting of natural disasters. Investigation of volcanic activity, detection of earthquake precursors for different tectonic regions of land- and sea floors.
- Chemical spectral analysis, in particular Raman spectroscopy, fluorescence, transient processes spectroscopy.

O.4.6 Resolution (for Visible and Infrared Imagery)

The amount of data/information contained within an image depends in large part on the image resolution.¹⁹⁴¹⁾ Definitions of spatial, spectral and radiometric resolution are not unique. There are interdependencies between spatial, spectral, and radiometric resolutions for each remote sensor affecting the various compromises and trade-offs for particular applications.

Spatial (or Geometric) Resolution

Spatial resolution is the smallest unit of distance (usually a side length of a square area in an image) that can be discriminated by a sensor measurement of the target. Spatial resolution is a function of geometry (scale) between sensor and target for the instant of measurement. The image in a mechanical scanner setup is not formed at once over the swath width (as it would be the case in a camera setup), rather it is built up by a sequence of individual small images across the track (see scanners below). Each small image taken by the scanner represents an instant of measurement; hence it is the unit area of observation (actually a 'point') which is also referred to as 'the instantaneous field of view' (IFOV; note IFOV is a function of altitude, detector size, and focal length of the optical system). The output value of the sensor detector provides the value for one 'point' (smallest square area in an image), which is referred to as the picture element or simply pixel, in the overall image. Successive pixels in

¹⁹⁴¹⁾ *Manual of Remote Sensing*, Second Edition, American Society of Photogrammetry, 1983, pp. 20-26

the scan line are generated by data from successive positions. The advancement to the next scan line is achieved by the orbital motion of the satellite (or by a mirror tilt).

IFOV, the unit area of measurement of a scanner, may be given as an angle (in mradians or in degrees) or directly as a length (edge length of the spatial resolution). The IFOV is chosen depending on the type of application. For instance: observation of small-scale variations with relatively small-area coverage (in this case regional patterns may be difficult to characterize, because generalization is required of the high frequency information in such images), or large-scale variations with frequent large-area coverage (regional patterns may be readily observed, however, details may be averaged within a pixel, implying a loss of information). Sensor arrangements on-board Earth observation satellites are possible that provide specifically high and low resolution images. The high resolution images are used for regional coverage and detail, while the low resolution images offer large-area coverage as well as high temporal coverage for quick synoptic views of an area. The price of spatial resolution is paid with correspondingly high data rates, having direct consequences on the dimension of all follow-up processes (communications in the space and ground segments, processing, storage, and user access costs).

Naturally, there is a tendency and requirement for ever improving spatial resolutions. The Landsat-5 MSS sensor has a spatial resolution of 80 m, adequate for many land-based applications. The Landsat-5 TM sensor has a spatial resolution of 30 m. The Spot HRV sensor has a spatial resolution of 20 m (10 m panchromatic). The trend goes toward a 5 m spatial resolution.

Spectral Resolution

The spectral resolution of a dispersive remote sensing instrument is determined by the bandwidth of the channels used. High spectral resolution is achieved by narrow bandwidths which, collectively, are likely to provide a more accurate spectral signature for discrete objects than are broad bandwidths. A disadvantage of broad-band instruments is the tendency of increased system noise with bandwidth (low signal-to-noise ratio), lowering the system's radiometric resolution. This problem may be somewhat reduced if relatively long look times are used during imaging.

Radiometric Resolution

Radiometric resolution refers to the resolving power of a system in wavelength and energy. The limiting factor for a radiometric measurement is the signal-to-noise ratio (SNR) of the instrument receiver (see chapter O.7). Considering the effects of varying illumination, the radiometric dynamic range of a sensor is determined by the maximum radiance value that the sensor can experience for a given band.

A sensor does not have the capability to obtain measurements of reflectivity as a continuous function of wavelength for all pixels in an image obtained with a multispectral scanner. All that is obtainable are integrated (i.e. averaged) reflectivities over the wavelength bands used in the receiver.

On the output side of a sensor, the measurement is converted into a number of discrete digital levels in a process also referred to as 'quantization'. This secondary measurement effect of quantization (the primary effect is SNR) is sometimes referred to as 'radiometric resolution.' In this terminology, 10 bit radiometric resolution signifies that a detector's converted digital output signal may range from 0 to 1023 (or 1024 quantization levels). - Some applications do not require very high radiometric resolution (for instance sea surface temperature measurements), while other observations (in particular for vegetation, chlorophyll, etc.) require as many spectral channels as possible for good interpretation of the data.

O.4.7 SQUID Sensors in Magnetometry

SQUID (Superconducting Quantum Interference Device).¹⁹⁴²⁾ A new cryogenic particle detector type, based on SQUID technology, offers promising results in such applications as absolute magnetic field measurements. The SQUID technology provides the detection of magnetic signals with a sensitivity in the order of fT (femto Tesla or 10^{-15} T), making them the most sensitive detectors of magnetic signals so far. The overall SQUID measurement range stretches from about 500 nT to the fT level, thus providing a wide spectrum of application potential in such fields as geophysics, biomagnetism and nondestructive testing of materials. Note: the best sensitivity of fluxgate magnetometers is in the order of nT (nano Tesla). The HTS (High Temperature Superconductivity) technology (which started in the 1980s) is favoring the development of SQUID sensors.

A SQUID consists of a tiny superconducting ring (< 1 mm in diameter), which is interrupted by one or two Josephson junctions, they act as a “weak” superconductor. Only a small current (usually several microamps) can flow through such a weak link without dissipation. Above a certain current, the so-called critical current, a voltage drop develops across the junction. A magnetic flux through the SQUID, induced by an external magnetic field, alters the value of the critical current. Specifically, it changes the phase of the Cooper pair wave function across the junction(s).

In case of the so called DC (Direct Current) SQUID (a superconducting ring with two junctions), the variation in critical current with varying magnetic flux can be detected by simply passing a DC current through the SQUID. The value of the current is chosen to be slightly larger than the sum of the critical currents of the two Josephson junctions (the critical current of the SQUID). Then a DC voltage drop develops across the SQUID, which varies periodically with varying magnetic flux. The periodicity of this so-called flux-to-voltage transfer function of the SQUID is the flux quantum (about 2 fWb [femto Weber]). If the SQUID ring contains only a single junction (the so-called RF SQUID), it is usually coupled to a resonant LC circuit, which is driven by an RF current. The amplitude of the resulting RF voltage across this circuit oscillates with varying flux through the SQUID, similar to the DC voltage in case of the DC SQUID.

The principle governing the operation of SQUID devices is flux quantization in superconducting loops and the Josephson effect. The SQUID detector functions as a transducer whose output voltage is a periodic function of the magnetic flux. This periodic response is linearized using flux-locked loop electronics based on 100 kHz flux modulation and phase sensitive detection.

Although a SQUID primarily measures magnetic flux, it can measure all physical quantities which can be transformed into magnetic flux, like electrical currents, voltages or displacements. SQUIDs therefore play an essential role in countless applications, both in science as well as in industrial measurements.

O.5 Cryocooling Techniques

Space cryocoolers are miniature refrigerators designed to cool sensitive spacecraft components to cryogenic temperatures.¹⁹⁴³⁾ Cryogenic temperatures are necessary for the operation of many modern devices such as infrared detectors and focal planes, solid-state gamma-ray detectors, and a number of emerging superconducting technologies. Typical temperatures range from the boiling point of liquid Nitrogen at 77 K, down to near the boiling point of liquid Helium at 4 K.

¹⁹⁴²⁾ The SQUID was invented by James E. Zimmermann and Arnold Silver of the Scientific Laboratory of Ford Motor Co. in 1964

¹⁹⁴³⁾ http://www.jpl.nasa.gov/adv_tech/coolers/summary.htm

O.5.1 Stirling Cycle Cooler

A cycle named after Robert Stirling (1790 - 1878), a Scottish engineer. In this concept a confined volume of gas expands at high pressure and contracts at low pressure, thereby doing work on the surrounding environment. The expansion and contraction of the gas is driven by the absorption and rejection of heat at the engine's hot and cold heat exchanger. The Stirling cycle uses an air engine regenerator concept, having for its indicator diagram two isothermals and two lines of constant volume. The Stirling cycle can be applied as a heat engine cycle in which heat is accepted at a high temperature, rejected at a lower temperature, and net work or power is produced. Or the cycle can be applied as a refrigeration/heat pump cycle in which net work is done on the Stirling device and, heat is accepted at a low temperature and rejected at a higher temperature. If the useful heat is that which is accepted at the low temperature, then the device is being used as a refrigeration or cooling device. If the useful heat is that which is being rejected at the higher temperature, then the cycle is being used as a heating device. ^{1944) 1945)}

Most mechanical cryocoolers operated so far in space are based on the Stirling cycle concept. The Oxford cryocooler (developed at Oxford Instruments Plc. in Eynsham, UK) and the Ball Aerospace multi-stage Stirling cycle coolers are examples of Stirling cycle coolers.

O.5.2 Pulse Tube Cooler

A pulse tube cooler is a mechanical device for cryogenic cooling. It is a closed system that uses an oscillating pressure at one end (typically produced by a compressor) to generate an oscillating gas flow in the rest of the system. This gas flow (usually helium gas) can carry heat away from a low temperature point (cold heat exchanger) if the conditions are right. An orifice controlling the flow at the other end of the cooler can provide the right condition for cooling to occur. A single pulse tube cooler can cool from room temperature to 70-80 K and multi-stage systems can cool much lower. The amount of heat they can remove is only limited by their size and the power used to drive them. Their efficiency is comparable to other systems such as Stirling coolers. ^{1946) 1947)}

The principal benefits are greater reliability and lower cost compared to the Stirling cooler and an order of magnitude lower mass, lower cost, and longer life than the current state-of-the-art coolers. In 1994 TRW delivered its first pulse tube built under contract to the Air Force's Phillips Laboratory. The success of this cryocooler (1 W at 35 K with 200 W of input power) lead to TRW being selected to build a pulse tube cryocooler for the AIRS instrument of the Aqua spacecraft in the EOS program (planned launch in 2001). The TES (Tropospheric Emission Spectrometer) instrument of NASA/JPL (planned for launch on the Aura mission in late 2002) is another example of pulse-tube cryocooler technology. TES uses two coolers to cool two separate focal planes to 62 K. The two coolers are identical and are a variant of the TRW AIRS pulse-tube cooler, but configured with the pulse tube hard mounted to the compressor.

O.5.3 Hybrid Cryogenic System: CSE (Cryo System Experiment)

CSE was developed at Hughes Aircraft Co. and funded by NASA/JPL and successfully flown aboard the Shuttle Discovery (STS-63, February 3-11, 1995). The flight experiment validated and characterized the on-orbit performance of a hybrid cryogenic cooling system integrating two advanced cryogenic technologies: 1) a state-of-the-art Hughes ISSC (Improved Standard Spacecraft Cryocooler) 65 K long-life, low-vibration Stirling cooler, and 2) a Hughes experimental diode oxygen heat pipe (Note: a cryogenic diode heat pipe en-

¹⁹⁴⁴⁾ <http://www.grc.nasa.gov/WWW/tmsb/stirling.html>

¹⁹⁴⁵⁾ <http://www.oxford-instruments.com/>

¹⁹⁴⁶⁾ <http://irtek.arc.nasa.gov/WhatIsOPT.html>

¹⁹⁴⁷⁾ http://ranier.oact.hq.nasa.gov/Sensors_page/Cryo/CryoPT/CryoPTHist.html

ables large physical separation between the cryocooler and its thermal load, and provides on-off switching to limit reverse heat flow when the cooler is turned off).

The CSE cooler provided 1.2 W of cooling at 65 K and is the first U.S.-built long-life Stirling cooler to operate in space. Its thermal performance over the course of the eight-day mission equaled its thermal performance during ground testing.

The second important cryogenic component successfully demonstrated in the CSE flight was an oxygen diode heat pipe. The cryogenic heat pipe is designed to provide a high thermal conductance path between the cryocooler and its intended cryogenic load; the diode nature of the heat pipe has the ability to limit heat flow in the reverse direction when the cooler is turned off. In space, the heat pipe performance met and exceeded ground test measurements.

O.5.4 Optical Cooling

Optical cooling by fluorescence is an alternate and new concept in refrigeration that represents possible applications in small cryocooler technology, in particular for infrared devices and spectrometers. The technique was first demonstrated in the timeframe 1994-1995 at LANL (Los Alamos National Laboratory) using laser-induced cooling of a solid by net anti-Stokes fluorescence. ^{1948) 1949)}

The principle of fluorescent cooling makes use of anti-Stokes fluorescence, a phenomenon in which a substance that is excited by radiation at one wavelength fluoresces at a shorter wavelength. This results in more energy being radiated than is absorbed for each photon. Successful fluorescent cooling requires that a negligible fraction of the energy-level decays from the excited- to the ground-state groups occurs through non-radiative, heat-generating processes. Each fluorescent photon carries off, on average, thermal energy equal to the difference between the pump-photon and the mean fluorescent-photon energies.

A first-generation fluorescent cryocooler was designed at LANL utilizing a combination of diode lasers coupled with an ytterbium-fiber laser (ytterbium-doped ZBLANP) to efficiently produce pump radiation at the desired wavelength. The cooling element design employs an Yb^{3+} doped glass which has an exceedingly simple energy-level structure.

LASSOR (Los Alamos Solid-State Optical Refrigerator). ^{1950) 1951)} The objective is the design of a cooler capable to produce 0.5 W of cooling at 77 K with an efficiency comparable to that of small commercial mechanical cryocoolers. The first-generation fluorescent cryocooler design is based on a cooling element of Yb^{3+} -doped ZBLANP (a heavy metal fluoride glass containing zirconium, barium, lanthanum, aluminum, sodium, and lead). High-power diode lasers are used to produce an effective pump radiation at the required wavelength. An optical fiber carrying the pump radiation passes through the wall of the cryocooler vacuum chamber to a cylindrical block cooling element. Dielectric mirrors for reflecting the pump radiation are deposited on both ends of the cooling element. The pump radiation enters the cooling element through a small hole in one of the mirrors and is largely beamed along the axis of the cylinder. This light is repeatedly reflected between the dielectric mirrors and from the sides of the glass cylinder until it is entirely absorbed by Yb^{3+} ions. The ions subsequently fluoresce isotropically in a broad spectral band. Most of the fluorescent radiation escapes from the cooling element and is absorbed by the warm walls of the cooling chamber. The object to be cooled (cold finger) is mounted on one of the mirrors of the cool-

ing element and is thus shielded from the pump and fluorescent radiation. - A realistic mass estimate of such an instrument is in the order of 1 kg.

Some characteristics of the optical (solid-state) cooling technology are:

- No vibrations are produced by system operations (there are no moving parts)
- The system neither generates nor is it affected by electromagnetic interference
- Cooling temperatures of ≤ 77 K (from room temperature) can be achieved
- A conversion efficiency of about 0.5% is achieved (DC power to cooling power)
- An instrument mass of < 2 kg/W of cooling power is attainable
- Continuous operating life times of several years are possible

O.6 Imaging Spectrometers

The imaging spectrometer concept can be applied to the following spectral regions: VIS, NIR, SWIR and TIR (i.e. from about $0.4 \mu\text{m}$ to about $12 - 13 \mu\text{m}$). However, different optical components and detectors have to be used for the different regions. The collecting optics and an imaging slit are used to image one line (one pixel wide) across the swath on an intermediate focal plane. A dispersive element (grating or prism) is then used to spectrally disperse the 'line' signal into a series of lines, each corresponding to a spectral band (see Figure 380). A 2-D detector array is then used to measure the dispersed light. Thus, each array column will give the spectrum corresponding to one pixel. The whole process is repeated as the platform moves by the equivalent of one spatial resolution element along the track.¹⁹⁵²⁾

Imaging spectrometers allow the simultaneous acquisition of images in many contiguous, narrow spectral bands. Spaceborne sensors have relatively few and broad bands, while airborne sensors may have hundreds of narrow bands, the high spectral dimensionality of these airborne data enables the construction of laboratory-like spectra for each pixel in the scene (see Figure 361).

Figure 380: Collecting optics of an imaging spectrometer

¹⁹⁵²⁾ Ch. Elachi, "Earth Surface Sensing in the '90s," Progress in Imaging Sensors, Proc. ISPRS Symposium, Stuttgart, September 1-5, 1986, ESA SP-252, November 1986, pp. 1-9

Two approaches to the design of imaging spectrometers are in use. The whiskbroom approach includes an optomechanical fore-optics from which light is passed into a spectrometer, where it is dispersed and focused onto a linear detector array. This concept provides as many contiguous spectral bands as there are detector elements in the linear array. It is also possible to use 2-D (area) detectors instead of linear arrays in this configuration.

An alternate solution is the pushbroom approach using 2-D detector arrays at the focal plane of the spectrometer, thereby eliminating the need for the mechanical scanning device. In this arrangement, one dimension of the array corresponds to the cross-track pixel length while the spectral information is co-registered in the other direction.

The collecting optics of imaging spectrometers (2-D airborne devices), usually designed with many contiguous spectral and spatial bands, generates very high data volumes, which requires in turn very high-rate recording devices (sometimes in the order of 50-100 Mbit/s) for contiguous strip imagery acquisition. These recorders are usually very expensive, or not available at all for the intended application. In some cases a solution is provided by means of an interval acquisition technique employed by the sensor detector. The sensor abandons the concept of contiguous strip imagery in favor of discrete area or frame imagery. The data rate constraint at the recorder interface is circumvented in this way, because the next set of data frames is provided to the recorder at the instant when the previous set of frames was stored away.

O.7 Passive Radiometry (MW/MMW)

Radiometry is the measurement of microwave (MW) radiation generally considered to be in the wavelength region from about 1 mm to 1 m (the mm-wave region is a subregion of the microwave region and generally considered to be from 1mm to 10 mm wavelengths). Microwaves and mm-waves (MMW) have the known benefit of penetrating the Earth's atmosphere under conditions where visible and infrared waves display rather limited optical depth. The attenuation properties of the atmosphere have been a hindrance to the development of MMW scene imagers, while at the same time this attenuation has made it possible to sound the atmosphere. The MMW spectrum contains two principal gaseous absorbers: oxygen and water vapor. In addition to gaseous absorption, aerosols (solid and liquid) produce significant attenuation.

A passive system is restricted to measuring the incoming radiation of a wave spectrum in question. Hence, a passive system is restrained to that portion of radiation that is emitted with a reasonable intensity from the observed objects (Earth surface, or atmospheric volume, or whatever).

Microwave radiation can directly measure the dielectric properties of the Earth's surface. Any changes in these properties directly affects the reflectivity or emissivity measured by the microwave system. The dielectric property of the Earth's surface layer is in turn strongly dependent on the surface moisture content. Hence, an analysis of the microwave data can be related to the moisture content of the soil surface layers. Microwave radiation interacts also with atmospheric water in its various states (gaseous, liquid, and solid) in distinctly different ways. This property can be used to study the water cycle and the energy balance of the Earth. For instance, microwave techniques are used to detect humidity, rain, and hail in the atmosphere, as well as soil moisture, snow, and permafrost on land. Over the ocean, microwave sensors are capable of measuring sea surface wind speed and direction, sea ice, and sea surface temperature and salinity.

In general, passive microwave radiometry is limited by its poor spatial resolution, which depends on range, on the wavelength of the radiation used, on the aperture of the antenna system, and on the SNR (Signal-to-Noise Ratio). The SNR is in turn influenced by the

strength of the signal produced by the target and by the temperature and sensitivity of the receiver.

The theoretical performance limit on radiometric sensitivity provides a useful framework for examining the interdependencies among performance and design parameters. Radiometric sensitivity, i.e. SNR, depends on the optical aperture area, the detector solid angle (spatial resolution), signal integration time, and spectral bandwidth (spectral resolution), among other parameters (this applies to any imaging device that receives electromagnetic energy). Improvements in either spatial or spectral resolution thus come at the expense of radiometric sensitivity unless these are offset by a larger aperture, better optical transmission, or increased integration time. Improvements in technology can influence the relative attractiveness of these alternatives. For example, effective integration time (and hence radiometric sensitivity) can be increased by adding more detectors and slowing the effective scan rate or by using additional detectors to take multiple samples of the same point in object space and coherently summing the outputs by employing TDI (Time Delay Integration). These strategies offer improved performance at the expense of added complexity in the detector arrays and associated signal processing electronics; on the other hand, technology improvements in these areas have made it possible to exploit such design strategies with relatively low cost and risk.¹⁹⁵³⁾

Passive sensors measuring radiation in the microwave spectrum have the advantage of collecting data during day and night cycles (measurement of emitted radiation rather than reflected solar radiation), the presence of cloud cover does not significantly degrade measurement accuracy. The spatial resolution of passive microwave sensors is fairly poor compared to VIS and IR sensors (longer wavelengths, by a factor of 100, and much lower intensity of microwave radiation results in poorer resolution); the advantage is global coverage capability. Passive microwave radiometry involves the detection of thermally generated microwave radiation. The characteristics of the received natural radiation, in terms of the variation in intensity, polarization, frequency and observation angle, is dependent on the nature of the surface being observed and on its emissivity. The spectrum of passive microwave radiometry is usually from 200 GHz - 1 GHz [or from 0.15 cm to 30 cm in wavelength; the newer planned sensors go to frequencies in the order of 600 GHz (0.5 mm wavelength)].

A passive microwave radiometer (or simply a 'radiometer') is different from traditional radar receivers (i. e. active microwave receivers) in two important respects. First, the input signal processed by a radar receiver may be coherent and nearly monochromatic, while secondly, natural radiation emitted by a surface (target or source) is phase-incoherent and extends over the entire electromagnetic spectrum. This means, it is noiselike in character and similar to the noise power generated by the receiver components.

The second difference relates to SNR at the receiver output. With the condition: $SNR \gg 1$, there is good confidence that the information can be extracted from the noise. However, the radiometric signal to be measured in a passive microwave receiver is usually much smaller than the receiver noise power. Radiometers are highly sensitive receivers that are configured to measure very small input levels with a high degree of precision. Several different configurations have been developed. Most of them use synchronous modulation at the input and demodulation at the output, and integrate the desired signal over as long a period of time as possible (integration time is set equal to the dwell time of the IFOV).

By inspection, optical wavelengths are about five orders of magnitude (10^5) shorter than microwaves; this implies that the resolution capability of an optical radiometer is inherently superior to the resolution of a microwave radiometer by about the same factor. For instance, the IFOV (spatial resolution) of an optical radiometer is of the order of tens of meters, compared to tens of kilometers for a microwave radiometer (for the same-size aperture and same orbital parameters). This means that the multiple-detector configurations

¹⁹⁵³⁾<http://www.nationalacademies.org/ssb/smallsatch3.htm>

employed in optical scanners are not feasible at microwave frequencies unless very large antenna structures (apertures) are used.

Radiometric imaging of a scene of interest is accomplished by scanning the main beam of the antenna. For a moving platform, scanning in the cross-track dimension is sufficient to produce an image. Both mechanical and electronic (beam-steering) scanning techniques are used in microwave radiometry. In mechanical scanning, the direction of the antenna beam is changed by mechanical rotation or angular movement of the radiating aperture of the antenna system. Alternatively, phased array antennas can be used to steer the direction of the antenna beam electronically (no mechanical motion in the scanning process).

Figure 381: Typical geometries of a conical scanning passive MW radiometer

In the 1970s, detector technology and signal processing electronics were less well developed than today; intelligent designs of that era minimized the number of detectors via the use of scanning mechanisms and relatively large optical apertures. Now that higher density detector arrays and sophisticated signal processing electronics are readily available, aperture size can be (and has been) significantly reduced for many classes of instruments. Still, for imaging sensors of relatively high spatial resolution, aperture diameter is clearly the dominant sizing parameter because diffraction-limited performance is a fundamental physical limit that is not amenable to technological improvement. Technology advances have nonetheless made it feasible to design radiometers whose performance is close to theoretical limits.

O.7.1 Radiometer Instruments

Two generic types of radiometers have evolved, profiling instruments (or sounders, also referred to as broadband radiometers), and surface imaging instruments (multichannel radiometers).

- 1) **Atmospheric sounders** provide information about vertical profiles of temperature and molecular constituent concentrations in the atmosphere by making measurements

near the molecular resonance frequencies (resonance method with nadir pointing). Another approach to atmospheric constituent monitoring is the limb sounding technique. This method can provide substantially improved sensitivities and vertical resolutions (profiles) over those of the nadir-looking instruments.

Sounders typically have broad beams to minimize spatial noise caused by atmospheric structure, the largest possible pre-detection bandwidths to minimize detection thresholds ($NE\Delta T$); they tend to accommodate short post-detection integration time dictated by the platform motion. Typical sounding systems yield beam footprints at nadir of 10 to 150 km.

The superheterodyning detection scheme, used by microwave radiometers, provides excellent frequency resolution which permits to resolve pressure broadened emission lines. In this case the limb-sounding instrument scans the atmospheric limb with a sufficiently narrow antenna beam (typically a few tens of a degree).

At the end of the 1990s there are four types of receiver technologies applied to microwave radiometers. These are: ¹⁹⁵⁴⁾

- HEMT (High Electron Mobility Transistor). HEMT receivers are available to frequencies of 110 GHz. The sensitivity depends on the operational temperature of the HEMT amplifier. For 300 K operational temperature, a noise temperature of about 50 times the quantum limit can be achieved.
- Schottky. Receivers are being built for frequencies from about 200 to 2500 GHz.
- SIS (Superconductor Insulator Superconductor). Receivers cover the frequency range from 100 to 1200 GHz. The upper frequency limit is given by the energy gap of the superconducting material; it is 700 GHz for Nb (Niobium) and 1200 GHz for NbTi. Since a SIS device can carry currents up to those of the superconducting gap, there is no fundamental limit to the bandwidth of the IF (Intermediate Frequency). A typical operational temperature of a SIS device is 4 K.
- HEB (Hot Electron Bolometer). In a bolometric detector the resistance is changed by heating due to the absorbed energy. Superconducting materials are most sensitive to this effect. Applications of two signals with different frequency modulate the resistance at an intermediate frequency (IF). Useful IF bandwidths require fast cooling and low heat capacity of the detector. In HEB this is done by diffusion of the hot electrons out of the detector. IF bandwidths of several GHz can be achieved with a HEB mixer. Conventional HEB devices require cooling down to 4 K for optimum performance. The newer HTS (High Temperature Superconductivity) HEB mixer is capable to operate at 77 K.

- 2) **Surface imaging sensors**, on the other hand, operate primarily at window frequencies, where atmospheric absorption is low and surface features can be imaged or measured quantitatively. For most of these surface features high spatial resolution is desirable (see also Ref.1956).

The nadir-viewing technique is employed for surface imaging. Radiometric measurements are affected to some extent by water vapor, clouds and rainfall. Hence, most surface sensing radiometers include frequency channels sensitive to atmospheric water vapor and liquid water, to measure global distributions of these parameters and to correct for their effects on the measurement of the surface parameters.

A radiometer system for microwave remote sensing typically consists of the following subsystems:

- An antenna and scan subsystem, which receives incoming radiation from specified beam-pointing directions

¹⁹⁵⁴⁾ P. Hartough, "Solar System Research with Microwaves," Proceedings of 32nd ESLAB Symposium on 'Remote Sensing Methodology for Earth Observation and Planetary Exploration,' ESA/ESTEC, Sept. 15-18, 1998 (SP-423 Dec. 1998), pp. 23-31

- A receiver subsystem (detectors plus the electronics subsystem) which frequency down-converts, amplifies, and detects the received signals in the assigned frequency bands
- A signal processor and housekeeping and control subsystem, which provides timing and sequencing signals for the antenna and radiometer subsystems, and performs digitizing and various other functions for the output of a digital data stream.

A radiometer responds to thermal radiation (noise-like signals) emitted and/or reflected from the atmosphere, the Earth's surface, or other bodies. Its output is expressed in terms of brightness temperature [$T_B(f)$], where $T_B(f)$ is a temperature at frequency f of a black body that produces an equivalent power. The values of T_B typically range between about 90 K over moderately reflective oceans reflecting the atmosphere and cold space (3 K), and about 305 K over highly emissive tropical forests. The change of very small temperatures (ΔT), measured by a radiometer, are expressed as: ¹⁹⁵⁵⁾

$$\Delta T = C (T_A + T_R) / (B \tau)^{1/2}$$

where C is a constant (typically 1 - 2), T_A is the equivalent antenna noise-temperature, T_R is the receiver noise-temperature, B is the prediction bandwidth, and τ is the post detection integration time.

Figure 382: Generalized radiometer receiver block diagram

A radiometer receiver subsystem is illustrated in Figure 382. All receiver components are at temperature $T_O = 300$ K, with individual gain “ G ” (loss “ L ”), and individual noise-temperature “ T ”. The radiometer’s hardware design challenge rests primarily with minimizing the receiver’s noise-temperature (T_R).

Many applications have become well established in the field of passive microwave radiometry, such as temperature sounding in operational meteorology, sea-ice mapping for navigation in the polar regions, measurements of ocean surface temperatures and surface wind speeds.

¹⁹⁵⁷⁾ "The Multi-Frequency Imaging Microwave Radiometer," Instrument Panel Report, ESA SP-1138, Aug. 1990

O.7.2 Aperture Synthesis in Radiometry

Long integration times were a considerable disadvantage of good-quality radiometer imagery in the early phases of spaceflight. This lack of performance resulted from the inherently weak signals of passive radiometry to be measured (and the lack of adequate technology). As a consequence, a considerable amount of radiometer development concentrated on improving and obtaining near real-time radiometric imaging. It requires the addressing of two overriding problems: **sensitivity** and **resolution**. Sensitivity implies a large total collecting area, while resolution demands a large aperture of an antenna. - Eventually, integration times were considerably reduced with the introduction of focal plane arrays and increased aperture sizes. Aperture synthesis improves on this technology by offering a parallel read-out scheme (simultaneous sampling), thereby eliminating the serial scanning requirement of the antenna beam. ¹⁹⁵⁸⁾

Aperture synthesis is a technique (pioneered in radio astronomy - with the luxury of long observation times) of generating high spatial resolution images by dividing the collection area of a telescope (or antenna) into smaller apertures spread out in a pattern covering several baselines. Specifically, the “sparse aperture” or the “partial aperture” technique can provide diffraction-limited performance that is comparable to that of a “filled aperture” - albeit at the expense of photon-collecting area and therefore, SNR. This may be a reasonable trade-off for systems in which resolution is more important than radiometric sensitivity. In microwave radiometry the concept employs an interferometric technique in which the product from antenna pairs is sampled as a function of pair spacing. Substantial reductions in the antenna aperture needed for a given spatial resolution can be achieved with this technique. However, the performance leap in resolution must be paid for with higher requirements for instrument precision sensing and stabilization. ESTAR (P.87) and MIRAS (P.132) are examples of airborne synthetic aperture microwave radiometers (both instruments operate in L-band).

The basic idea of aperture synthesis is to replace the conventional large aperture antenna of a radiometer with a thinned array of single small aperture antennas and to coherently correlate the input signals in pairs. The technique measures in parallel the normalized correlation function in the plane of the antenna array. For distant sources the spatial correlation function is proportional to the spatial Fourier transform of the source intensity distribution (Van-Cittert-Zernike theorem). The brightness temperature distribution is obtained by a Fourier inversion. - In such an aperture synthesis design, the resolution is determined by the transverse dimensions of the array, the sensitivity is that of a pencil-beam scanner with an area equal to the total area of the antennas.

O.8 Active Radiometry

An active instrument is restricted to wavelength ranges in which reasonable intensities of radiation must be generated by the remote sensing device in order to obtain a measurable return echo radiation (signal attenuation is minimized by choosing a suitable atmospheric “window,” see Figure 414).

An active microwave system can improve the ‘poor’ spatial resolution associated with a passive microwave system. An active microwave system measures not only the intensity of radiation, but also:

- The time taken for the emitted pulse of radiation to travel from the satellite to the ground and back.
- The Doppler shift in the frequency of the radiation echo as a result of relative motion of the satellite on the ground

¹⁹⁵⁸⁾A. R. Harvey, et al., “Optical up-conversion for passive millimeter-wave imaging,” Proceedings of SPIE, April 21-22, 1997, Orlando FL, Vol. 3064, pp. 98-109

- The polarization of the radiation (note: polarization can also be measured by passive devices)

O.8.1 Types of Radar Sensors

There are three general categories of radar sensors (i.e. active microwave instruments) that are flown on satellites, depending on the type of geophysical measurement, namely:¹⁹⁵⁹⁾

Altimeters

Altimeters are used for surface height measurement (distance) along the satellite track. They are used for land topographic mapping and for very high resolution (few cm) ocean topographic mapping (ocean circulation studies). This is achieved by very accurate measurement of the time delay for a radar pulse to propagate from the sensor to the surface and back. Scanning altimeters can provide topographic measurements across a wide swath, thus providing 'altimetric images.'

An accurate distance measurement (usually vertically down to the sea surface, i.e. nadir pointing) requires in turn very accurate knowledge of the satellite orbit. The size of the "footprint" of a radar altimeter pulse on the water surface is the area of the surface of the sea that contributes to the return pulse (echo) received by the altimeter.

Accurate measurements of the ocean surface mean level contribute to the detection and measurement of ocean currents, tides and storm surges, and to the accurate mapping of underwater features. Altimeters can also measure the surface wave height.

Scatterometers/Spectrometers

Scatterometers/spectrometers are used to measure very accurately surface reflectivity (back scatter) as a function of the frequency, polarization, and illumination direction of the sensing signal. They are used to characterize quantitatively the surface roughness. Spatial resolution is not of specific importance and is usually sacrificed at the expense of amplitude measurement accuracy. Scatterometry can be combined with high resolution imaging capability within the same sensor, leading to 'imaging scatterometry.'

Scatterometers use a complicated arrangement of radar beams (usually four which enables the determination of direction as well as of speed of the wind.

Imaging SARs (Synthetic Aperture Radars)

An imaging radar works very much like a flash camera in that it provides its own light to illuminate an area on the ground and take a snapshot picture, but at microwave wavelengths. A flash camera sends out a pulse of light (the flash) and records on film the light that is reflected back at it through the camera lens. Instead of a camera lens and film, an imaging radar uses an antenna and recorder (or tapes) to record its images. In a radar image, one can see only the radiation that was reflected back towards the radar antenna.¹⁹⁶⁰⁾

A typical radar (Radio Detection and Ranging) system measures the strength and round-trip time of the microwave signals that are emitted by a radar antenna and reflected off a distant surface or object (target area). The radar antenna alternately transmits and receives pulses at particular microwave wavelengths (in the range of 1 cm to 1 m, which corresponds to a frequency range of about 300 MHz to 30 GHz) and polarizations (waves polarized in a single vertical or horizontal plane). For an imaging radar system, about 1500 high-power pulses per second are transmitted toward the target or imaging area, with each pulse having a pulse duration (pulse width) of typically 10-50 microseconds (μ s). The pulse normally covers a small band of frequencies, centered on the frequency selected for the radar. Typical

¹⁹⁵⁹⁾ Ch. Elachi, "Spaceborne Radar Remote Sensing: Applications and Techniques," IEEE Press, 1988

¹⁹⁶⁰⁾ <http://southport.jpl.nasa.gov/desc/imagingradarv3.html> (courtesy of Anthony Freeman, JPL)

bandwidths for an imaging radar are in the range 10 to 200 MHz. At the Earth's surface, the energy in the radar pulse is scattered in all directions, with some reflected back toward the antenna.

This backscatter returns to the radar as a weaker radar echo and is received by the antenna in a specific polarization (horizontal or vertical, not necessarily the same as the transmitted pulse). These echoes are converted to digital data and passed to a data recorder for later processing and display as an image. Given that the radar pulse travels at the speed of light, it is relatively straightforward to use the measured time for the roundtrip of a particular pulse to calculate the distance or range to the reflecting object. The chosen pulse bandwidth determines the resolution in the range (cross-track) direction. Higher bandwidth means finer resolution in this dimension.

The length of the radar antenna determines the resolution in the azimuth (along-track) direction of the image: the longer the antenna, the finer the resolution in this dimension. Synthetic Aperture Radar (SAR) refers to a technique used to synthesize a very long antenna by combining signals (echoes) received by the radar as it moves along its flight track. Aperture means the opening used to collect the reflected energy that is used to form an image. In the case of a camera, this would be the shutter opening; for radar it is the antenna. A synthetic aperture is constructed by moving a real aperture or antenna through a series of positions along the flight track.

As the radar moves in its orbit, a pulse is transmitted at each position; the return echoes pass through the receiver and are recorded in an 'echo store.' Because the radar is moving relative to the ground, the returned echoes are Doppler-shifted (negatively as the radar approaches a target; positively as it moves away). Comparing the Doppler-shifted frequencies to a reference frequency allows many returned signals to be "focused" on a single point, effectively increasing the length of the antenna that is imaging that particular point. This focusing operation, commonly known as SAR processing, is now done digitally on fast computer systems. The objective in SAR processing is to correctly match the variation in Doppler frequency for each point in the image; this requires very precise knowledge of the relative motion between the platform and the imaged objects (which is the cause of the Doppler variation in the first place).

Because a SAR provides its own illumination (the radar pulses), it can image at any time of day or night, regardless of sun illumination. And because the radar wavelengths (microwaves) are much longer than those of visible or infrared light, SARs can also "see" through cloudy and dusty conditions that visible and infrared instruments cannot.

Imaging radars are used to acquire high resolution (from a few meters to cm range) large scale images of the surface. They are employed in the study of surface features such as geologic structures, ocean surface waves, polar ice cover, land use patterns. Conventional SAR systems are characterized by very high data rates, relatively large antennas, and large power requirements.

Hybrid radar sensors

Advanced imaging radar sensors simultaneously operate at a number of frequencies, in all polarization states. They are calibrated combining the imaging, scatterometry, and spectrometry functions. Stereo imagers and scanning radar altimeters are used to provide topographic maps over large swaths, thus combining the altimetry and imaging functions. Rain mapping radars use imaging, altimetry (sounding), and scatterometry functions to provide a calibrated three-dimensional volumetric image of rain regions, but at lower resolution than required with surface imagers or altimeters.

O.8.2 SAR Terminology and Definitions

An imaging radar system is generally arranged in a side-looking configuration.¹⁹⁶¹⁾ The radar antenna illuminates a surface strip (footprint) to one side of the nadir track. The side-looking configuration is necessary to eliminate right-left ambiguities from two symmetric equidistant points and to get better range resolution on the ground. As the platform moves in its orbit, a continuous strip of swath width is mapped in the along-track direction of the satellite. The look angle θ is the angle from the vertical to the center line of the radar beam direction (normal to the flight direction)

Actual imaging SARs use a series of pulses instead of a continuous signal. Each transmitted wave front hits the target surface at near range and sweeps across the swath to far range. The pulse bandwidth B determines the cross-track or range resolution. The echos are sensed coherently.

Figure 383: Characteristic geometry definitions for a side-looking imaging radar

SAR Antennas

In SAR observations the antenna beam casts an elliptical footprint on the ground surface with an effective rectangular aperture of typically 10 m in the along-track direction and 3 m in the cross-track direction (flat panel antenna). Multi-frequency observation requires the use of multi-frequency antennas. In this setup the along-track antenna dimension remains the same regardless of frequency while the cross-track dimension is approximately inversely proportional to frequency. Multi-polarization requires dual polarization antennas with good cross-polarization isolation. The use of electronic scanning (such as ScanSAR) provides flexibility in beam pointing and beam shape control for swath coverage.

SAR RF Electronics

The RF (Radio Frequency) portion of a SAR consists of signal generators, high power transmitters, low noise receivers, and the signal conditioning elements for amplification, filtering, and frequency conversion. Important RF features of a SAR instrument are: large dynamic range with good linearity and low noise floor, good amplitude and phase stability over time and temperature, and high power efficiency.

SAR Digital Electronics

The main functions provided by the digital electronics in SAR system are: radar configuration and timing control, radar signal digitization and processing, and radar system health telemetry generation. Advanced SARs perform in addition some digital processing to reduce the immense data rates.

SAR Images

Synthetic aperture radar images are acquired in an azimuth-range coordinate system; the sensor measures the Doppler history (time delay) of sequential wave fronts in the illuminated footprint. (Note: this is fundamentally different from VIS and IR imagery, which is acquired in an angle-angle coordinate system). The generation (reconstruction) of SAR imagery therefore involves an extensive amount of computation (with corrections applied for a number of effects) for the simple reason that the formation of each 'pixel' involves the combination of data from many thousands of echoes (i.e. synthetic array elements).

Most of the data handling in a SAR processor can be thought of as a correlation of the received signal with a two-dimensional reference function. The major processing step involves the accurate modeling of the SAR response to a point target and a continuous field of targets. Pixels as such exist only after the reconstruction of an image (representing the smallest distance unit that can be discriminated by computational methods) in their conventional raster pattern.

Range Resolution (across-track direction). The range resolution (X_r) corresponds to the minimum distance between two points on the surface which are separable. (B = bandwidth of signal (Hz); c = speed of light; θ = look angle)

$$X_r = c/(2B \sin \theta) \text{ (Ground range resolution for SAR)}$$

Azimuth Resolution (along-track direction).. The azimuth resolution (X_a) for a real aperture radar (non-SAR) corresponds to the two nearest separable points along the azimuth line, i.e. on a constant delay line. This is identical to the azimuth antenna footprint extension, because the echos returned from all the points along the line spanning that width are returned at the same time. (h = height above ground; λ = wavelength; L = antenna length)

$$X_a = h\lambda/(L \cos \theta); \text{ (for a real aperture radar)}$$

For a focussed SAR, however, X_a is independent of range.

$$X_a = L/2 \text{ (for a Synthetic Aperture Radar) one look highest azimuth resolution}$$

Hence, the spatial azimuth resolution of the SAR is not dependent on the altitude of the sensor. This can be explained by the fact that the imaging mechanism uses the Doppler shifts in the echo and the differential time delays between surface points, neither of which is a function of the distance between the sensor and the surface. Note: the altitude still plays a factor in the power requirements to acquire a detectable echo.

O.8.3 SAR Imaging Modes

In airborne SAR operations there are generally three common imaging modes for data collection; they are referred to as: stripmap, spotlight, and ScanSAR. Note: the stripmap and ScanSAR modes are also used in spaceborne applications. ^{1962) 1963) 1964)}

Figure 384: Illustration of common SAR imaging modes

- **Stripmap:** Antenna pointing is fixed relative to the flight line (usually normal to the flight line). The result is a moving antenna footprint that sweeps along a strip of terrain parallel to the path motion. The stripmap mode is normally used for the mapping of large areas (usually with coarse-resolution data).
- **Spotlight:** The sensor steers its antenna beam to continuously illuminate a specific (pre-determined) spot or terrain patch being imaged while the aircraft flies by in a straight line. The spotlight mode is a practical choice when the mission objective is to collect fine-resolution data from one or more localized areas. - The following attributes distinguish spotlight and stripmap modes. First, the spotlight mode offers finer azimuth resolution than that achievable in stripmap mode using the same physical antenna. Second, spotlight imagery provides the possibility of imaging a scene at multiple viewing angles during a single pass.
- **ScanSAR:** The sensor steers the antenna beam to illuminate a strip of terrain at any angle to the path of aircraft motion. The stripmap and spotlight modes are special cases of the ScanSAR mode.

O.8.4 Looks, Speckles and Radiometric Resolution of SAR Images

The number of neighboring pixels averaged in the processing of a SAR image is referred to as ‘the number of looks N’. This technique is used to improve the noisy appearance of a ra-

1962) W. G. Carrara, R. S. Goodman, R. M. Majewski, “Spotlight Synthetic Aperture Radar,” Artech House, Boston, 1995

1963) J. L. Walker, “Range-Doppler imaging of rotating objects,” IEEE Transactions of Aerospace and Electronic Systems, Vol. 16, 1980, pp. 23-52

1964) D. A. Ausherman, A. Kozma, J. L. Walker, H. M. Jones, E. C. Poggio, “Developments in Radar Imaging,” IEEE Transactions on Aerospace and Electronic Systems, Vol. 20, No. 4, July 1984, pp. 363-400

dar image. A noisy appearance results from the backscatter contributions of the many scattering points of the surface area. Two neighboring areas with the same backscatter cross section may be different in fine detail of the two surfaces, but otherwise homogeneous - the returned signals from the two areas will be different. There will be brightness variations in the resulting image from one resolution element to the next. This is referred to as 'speckle'.

The radiometric resolution in SAR images is mainly governed by the speckle phenomenon (coherent scattering) and not so much by the number of possible signal quantization steps. One way of describing radiometric resolution (Q) of a SAR image is by the signal-to-noise ratio. The radiometric resolution represents the logarithmic difference of two discernable backscatter coefficients which can be expressed in dB (neglecting thermal noise).

$$Q = 10 \log \left[1 + \frac{1}{\sqrt{N}} \right]$$

Small values of Q define good radiometric resolution. This is the case for higher values of N (looks). For $N=1 \rightarrow Q = 3 \text{ dB}$; $N=16 \rightarrow Q = 1 \text{ dB}$ (approximately).

O.8.5 Lidars (Laser-Based Remote Sensing)

Lidar = **L**ight **D**etection and **R**anging. Lidar refers to laser-based remote sensing, i.e. radar principle applied in the optical (and IR) regions of the electromagnetic spectrum (0.3 - 10 μm wavelength range, or a frequency range of about 1000 - 30 THz). This wave spectrum (shorter wavelengths than the microwave spectrum) implies and promises to be the next level of observation technology and of information interpretation (in the number of phenomena as well as in detail and accuracy, the targets can be much smaller), due to the use of a much finer scale of measurement. Lidars are based on the principle of a laser-light pulse being sent into the atmosphere to probe the distance, physical state, or chemical composition of the backscattering medium (atmospheric layers, etc.). Lidar is also a generic term for a variety of sensors operating on different concepts, like: ¹⁹⁶⁵⁾ ¹⁹⁶⁶⁾

Incoherent and Coherent Lidars

In general the same principles apply to lidars in the optical spectrum as to radars in the microwave region. A lidar is said to be 'incoherent' if only a portion of the backscattered signal, the amplitude information, is recovered and processed. A lidar is 'coherent' when amplitude and phase information is recovered (permitting a spectral analysis of all echoes). Most current lidars are of the incoherent type (to be able to handle the volume of data).

O.8.5.1 Backscatter Lidar

In this technique information on a remote target is derived from the manner in which the transmitted energy is backscattered, reflected or reradiated by the target. The technique offers data on the scattering and extinction coefficients of the various atmospheric layers such as extent, height distribution, and optical thickness of aerosol and cloud layers. A typical backscatter lidar is the Neodymium doped Yttrium Aluminum Garnet laser (or simply Nd:YAG laser at 1.064 μm wavelength).

A variety of incoherent detection backscatter intensity measurement techniques have been utilized to measure the atmosphere. These include:¹⁹⁶⁷⁾

- Direct time gated measurement of the molecular or aerosol laser backscatter intensity to measure particle concentrations

¹⁹⁶⁵⁾ H.Lutz, E. Armandillo, "Laser-Based Remote Sensing from Space," ESA Bulletin 66, May 1991, pp. 73

¹⁹⁶⁶⁾ R.T.H. Collis, P.B. Russell "Laser Applications in Remote Sensing," chapter 4 of 'Remote Sensing for Environmental Sciences,' Springer Verlag, 1976, pp. 110-146

¹⁹⁶⁷⁾ Special Issue on Laser Radar, Proceedings of the IEEE, Vol. 84, No. 2, Feb. 1996

- Differential attenuation measurement comparing the backscatter from the transmitter wavelength operating in an absorption band of the trace gas to that of a second transmitted wavelength not absorbed
- Raman shifted scattering where the radiated laser energy is transferred to a molecule which scatters the energy at a different wavelength than that of the original radiation
- Fluorescence where the atoms or molecules absorb the transmitted radiation and provide a detectable fluorescent emission. As an example, in time-resolved fluorescence spectroscopy, a UV laser beam excites a chemical being sensed; the emitted radiation at the chemical's characteristic wavelength gives a direct measure of the chemical's concentration.

O.8.5.2 Differential Absorption Lidar (DIAL)

In this path absorption technique information is derived relating to the path along which energy is transmitted or received by comparing the lidar echoes in a tuneable multiwavelength laser system (measurement of the differential ratios of the lidar returns with those of the transmitted ratios by tuning the laser wavelength to the specific absorption features of atmospheric trace constituents). The technique offers the capability to determine the densities of specific atmospheric constituents as well as water vapor and temperature profiles at better accuracies than obtainable with passive sounders.

O.8.5.3 Raman Lidar

The Raman Lidar technique involves detecting transmitted laser radiation which has been shifted in wavelength due to interaction with the scattering molecule. This wavelength shift, or Stokes shift, is equal in energy to a vibrational-rotational or rotational transition in the scattering molecule. The backscattered power of the wavelength shifted signal is proportional to the concentration of scattering molecules and inversely proportional to l^4 . Thus, the primary advantage of Raman Lidar of DIAL is that it offers a direct measure of species concentration or mixing ratio by comparing the Raman signal of the scatterer to the Raman signal of N_2 or O_2 .¹⁹⁶⁸⁾

However, Raman scattering is a very weak process and the signal can be two to four orders of magnitude weaker than the elastic backscattered signal. Also, the weak scattering cross section typically limits Raman lidar to nighttime measurements at ranges of less than 10 km. To increase the Raman signal and make daytime measurements, high power lidar systems have been developed to operate at wavelengths from 248.5 to 268.5 nm. Unfortunately at these wavelengths absorption by molecular oxygen and ozone can attenuate the transmitted beam and solar irradiance can obscure the backscattered Raman signal.

O.8.5.4 Doppler Wind Lidar (DWL)

This technique is based on the principle of measuring the Doppler shift of the light backscattered from aerosol particles transported by the wind (it is assumed that the suspended aerosol particles are moving at the same speed as the wind). The technique offers the capability to measure global wind fields from a spaceborne platform. Range resolution is obtained by dividing the return signal into sequential time intervals, this technique is referred to as range gating. The returned signal is Doppler shifted due to the motion of the platform (aircraft or spacecraft) and the line-of-sight (LOS) component of the wind. Scan techniques (with the telescope) and processing algorithms must be employed to obtain the desired wind field. - Most wind lidars are based on the carbon-dioxide (CO_2) gas laser. Such an instrument generally needs a highly coherent and powerful laser beam, combined with a complex receiver and Doppler processor.¹⁹⁶⁹⁾ Coherent detection of the Doppler shift of the lidar backscatter is an extremely sensitive technique, but it must operate in the near in-

¹⁹⁶⁸⁾ <http://daacdev1.stx.com/ELF/docs/PER/rall16.html>

¹⁹⁶⁹⁾ W. E. Baker, et al., "Lidar-Measured Winds from Space: A Key Component for Weather and Climate Prediction," BAMS, Vol. 76, No. 6, June 1995, pp. 869-888

frared, and consequently is dependent on atmospheric aerosols for backscatter. The free troposphere, from about 2 to 20 km in altitude, is particularly important for long-range energy transport, it is characterized by very low aerosol content; hence, it is very difficult to measure for coherent Doppler wind lidar.¹⁹⁷⁰⁾

Non-coherent, or “direct” detection of the wind speed Doppler shift, using optical interferometry, is an emerging and alternate approach to global measurements. Direct detection can employ the UV spectrum, where Rayleigh (molecular) backscatter is strong, thereby avoiding the dependence on atmospheric aerosols. In the “fringe imaging” technique, the lidar backscatter signal is passed through an interferometer (Fabry-Perot etalon), producing circular interference fringes. An imaging detector records the fringe images, and wind speed Doppler shifts are obtained from the measurement of small fringe displacements.

O.8.5.5 Ranging and Altimeter Lidar

Laser ranging and altimetry can provide accurate measurements of the distance from a reference height (i.e. the satellite orbital height) to precise locations on the Earth’s surface. It can improve understanding and knowledge of many processes and phenomena in such solid Earth Sciences such as geodesy, geodynamics, ice dynamics, land topography, and Earth resources. These observational requirements are met by different types of instruments in spaceborne applications:

- A laser ranging system for accurate point positioning in geodynamics.
This laser ranging concept from space could enhance the capabilities of the present ground-based satellite laser ranging systems (SLR’s) to such high-altitude satellites as LAGEOS or Starlette. A single-wavelength nanosecond pulse laser is sufficient for centimeter-level accuracy. Subcentimeter accuracies require a dual-wavelength picosecond laser to compensate for atmospheric propagation effects (beam refraction).
- A laser altimeter for altimetry measurements over land, oceans, and ice.¹⁹⁷¹⁾
Laser altimetry is the only way to obtain elevation data with centimeter-level vertical precision and horizontal resolution.
The laser altimeter, primarily for land and ice applications, is an extension of the backscattering lidar instrument. The main characteristics of a laser altimeter are: the small diffraction-limited footprint (proportional to the laser wavelength), which permits topographic mapping of ice sheets, terrain, forestry or waters with high spatial resolution; insensitivity to speckles, since direct detection can be successfully employed in a visible-wavelength laser; high single pulse measurement accuracy, since in principle no averaging is required; and the insensitivity of beam propagation to atmospheric water vapor.

Current (end of 1990s) lidar sensor technology is in an experimental state.¹⁹⁷²⁾ The first space lidar LITE (Lidar In-space Technology Experiment) of NASA/LaRC was flown on Shuttle (STS-64, Sept 9-20, 1994). On the US side space lidar programs such as LAWS (Lidar Atmospheric Wind Sounder) have been cancelled due to severe budget cuts in the EOS program. In Europe the ESA sensors ATLID (Atmospheric Lidar) and ALADIN (Atmospheric Laser and Doppler Instrument) are considered prime candidates as backscatter lidar and as Doppler wind lidar, respectively, for later missions in the ENVISAT series. ALISSA (France) is planned to be flown on PRIRODA.

O.8.5.6 Lidar Principle

In the principal radar-type or “lidar” applications of laser energy, the following basic elements make up the system:

1970) J. A. McKay, D. Rees, “Design of a Direct Detection Doppler Wind Lidar for Spaceflight,” European Symposium on Remote Sensing, Conference on Laser Radar Techniques (Ranging and Atmospheric Lidar) II, Barcelona, Spain, 21-24 Sept. 1998, SPIE, Vol. 3494, pp. 250-258

1971) “Topographic Science Working Group Report” to the Land Processes Branch, Earth Science and Applications Division, NASA Headquarters, 1988, p. 46

1972) “Lidar in Space,” in Optical Remote Sensing of the Atmosphere, 1990 Technical Digest Series of the Optical Society of America, Volume 4, pp. 67-70

- Laser transmitter
- Collector (receiving telescope) The telescope acts as an optical antenna (analogous to radar) with a corresponding detector system (heterodyne, etc.) in the focal plane.
- Electronics and data processing resources

The laser transmitter, which is the essence of the active lidar technique, provides all the energy available for the determination of the remote target's characteristics (including distance). By far the most effective approach in all forms of active lidar systems is the use of laser energy in high intensity pulsed form, although range information can also be derived from continuous wave (CW) transmissions. At present two somewhat different laser ranging methods are used:¹⁹⁷³⁾

- 1) the phase comparison technique using high-frequency modulation of one of the laser light's parameters (amplitude, polarization, wavelength, etc.)
- 2) the short pulse direct travel time measurement technique (delays are measured either by the 'single photon detection method,' or by the 'multiphotoelectron detection method').

The transmitted laser pulse from the lidar is propagated through the atmosphere and scattered, absorbed, or reflected by the various components of the atmosphere and surface (e.g. clouds, air molecules, aerosols, or the Earth's surface) at range R. Some portion of the scattered or reflected signal is directed back toward the lidar (receiving telescope) where it is detected. By measuring the intensity, polarization, and/or spectral properties of the return signal as a function of time (t), one can obtain information on the properties of the atmosphere.

The high degree of spatial coherence of laser energy makes it possible to achieve a good measure of directionality, and very narrow transmitted beams (typically less than a milliradian in angle) are used to achieve maximum concentration of energy and high resolution. Returned energy collected in the optical system of the receiver is converted to electrical signals by a photo detector. Due to the monochromaticity of laser energy, light of other wavelengths can readily be excluded from the detector by filters, thus reducing extraneous noise in the received signal.

Lidar Applications

- Lidar applications in atmospheric research:
Meteorology, climatology, boundary layer physics, pollution, visibility, radiative budget, atmospheric dynamics and chemistry (composition)
- Lidar applications in solid-Earth research:
Crustal movement, gravity field, Earth kinematics and terrain mapping; laser ranging will provide advances in precise orbit determination.

Lidar Observation Capabilities

Spaceborne lidars have the potential to observe directly or indirectly a number of atmospheric parameters, such as:

- Altitude (layer) measurements of features (such as cloud tops, planetary boundary layers, temperature inversions, subvisible cirrus clouds and aerosol particles, backscattering profiles and extinction coefficients,). This is the domain of backscatter lidars.
- Horizontal extent and density distribution of scattering layers (e.g. clouds and aerosols)
- Vertical humidity, temperature and pressure profiles throughout the depth of the atmosphere (depth-resolved measurements) and trace gas monitoring; the domain of the DIAL technique lidars.

¹⁹⁷³⁾J. Gaignebet, G. Lund, "The Potential of two Color Laser Ranging," in 'Radars and Lidars in Earth and Planetary Sciences,' International Symposium Sept. 2-4, 1991, ESA SP-328, pp. 123-127

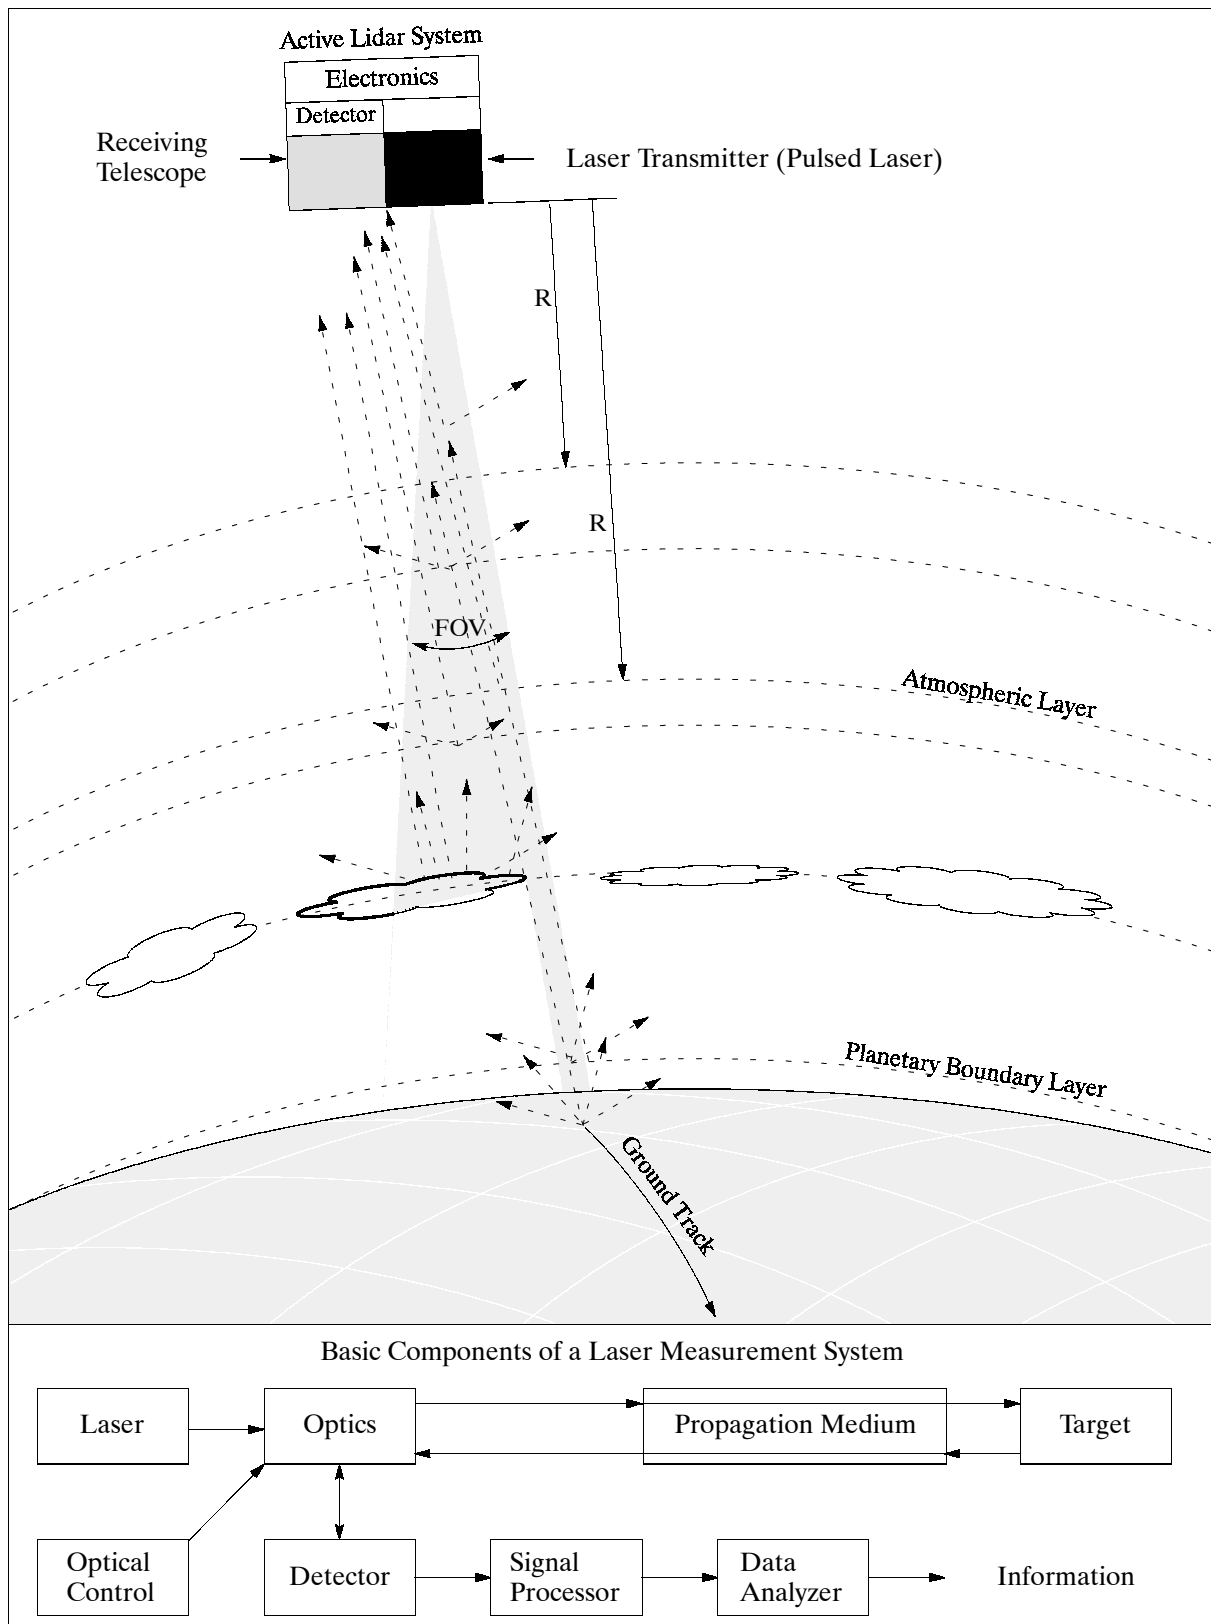

Figure 385: Spaceborne lidar and principle of backscattering lidar measurements

- Wind fields at many altitude layers, the domain of Doppler wind lidars (DWLs). A DWL is an active instrument which fires laser pulses towards the atmosphere and measures the Doppler shift of the collected return signal, backscattered at different levels (volume cells) in the atmosphere. The frequency shift results from the relative move-

ment of the scatter elements along the line-of-sight of the instrument. This movement relates to the mean wind observed in the volume cell.

Conceptually lidar measurements provide good vertical resolutions for altitude/height assignments of atmospheric features (the data is considered to be superior to that obtained by employing sounding or imaging techniques). Lidars are active instruments; as such they can operate during the day and night cycle of an orbit. A disadvantage: lidars cannot penetrate optically thick layers (e.g. clouds).

Lidar concepts proved operational for extended periods throughout the past decade in ground-based and airborne equipment.^{1974) 1975)}

O.9 Fourier Transform Spectrometer (FTS)

An optoelectronic (or optomechanical) instrument, usually for the infrared region of the spectrum, providing high spectral resolution and sensitivity for remote-sensing applications (Earth surface imaging, atmospheric soundings of temperature and water vapor versus altitude, environmental monitoring of trace-gas concentrations and distributions, pollutants, atmospheric process studies, characterization of optical backgrounds, etc.). The technique employs the mathematical concept of Fourier series analysis as a means of converting a detector signal output - referred to as the interferogram - into a form useful for spectral analysis. There are several ways in which the detector signal can be created from the incident radiation. The approach taken by the majority of FTS instruments is to use an interferometer (Michelson, Sagnac, etc.) and corresponding foreoptics (lenses) to create the interference pattern in such a way that each optical frequency is coded as a unique electrical signal output of the detector. The amplitude of each frequency is proportional to the incident radiation (see also chapter O.10 and Figure 387).

The simultaneous observation of a wide spectral range is a way of increasing the signal bandwidth, an SNR (Signal-to-Noise Ratio) advantage occurs when compared to dispersive systems which observe one wavelength at a time. The result is a 'multiplex or Fellgett advantage' of FTS instruments (note: the term 'multiplexing' has its origin from the fact that each optical frequency is converted to a corresponding electrical frequency by 'frequency-division multiplexing'). The advantage is particularly noticeable for low-energy conditions or where scale expansion is required to bring out very weak signals.

In early interferometry times (1960s and 1970s) the challenge was in computer processing power converting the interferogram into a spectrum by a Fourier transform. In the meantime there have been considerable advances in FFT (Fast Fourier Transform) methods. In the mid-1990s FTS technology has become a viable concept for a variety of airborne and spaceborne applications because of the availability of increased computational power, better data processing algorithms, and transmission/recording capacities sufficient to handle large data volumes.

The functionality of an FTS (like a Michelson interferometer) is governed by the displacement of the movable mirror, which modulates the radiant intensity $I(\lambda)$ as a function of mirror distance (the pattern obtained is the sum of a collection of monochromatic interference patterns, each with its own amplitude)¹⁹⁷⁶⁾. The intensity distribution captured by the detector (array) is referred to as the 'interferogram' (representing the sum of all modulated waves). The interferogram is not directly usable; it requires a Fourier transformation to ob-

1974) H. Lutz, E. Armandillo, "Laser Sounding from Space," Report of the ESA Technology Working Group on Space Laser Sounding and Ranging, esa SP-1108, Jan. 1989

1975) P. Betout, D. Burrige, Ch. Werner, "Doppler Lidar Working Group Report," esa SP-1112, June 1989

1976) Note: For every position of the moving mirror, the radiation that reaches the detector is the sum of components of different amplitudes and different frequencies, and for each frequency there is a different phase difference causing the various states of interference. This is the interferogram (or interference pattern) - a sum of sine waves with different amplitudes.

tain the spectrum. An interferogram value (measurement) of the broadband radiation may be taken at each instant of maximum stroke distance of the movable mirror. - The spectral resolution of an FTS instrument is governed by the optical path length (the mirror position at zero distance is generally referred to as the 'zero path difference;' the spectral distribution becomes more detailed with growing mirror distance). All spectral elements are simultaneously present. A long stroke provides generally high resolutions. A key requirement of Michelson interferometry is to assure constant parallelism of the moving mirror surface during translation.¹⁹⁷⁷⁾

Figure 386: Conceptual diagram of a Michelson interferometer

The spectral range of an FTS system is mainly governed by the detector system design. If a wide spectrum is to be analyzed, then the detector system design must conform to the detector material limitations for the individual spectral regions. Low energy conditions may in addition require active cooling of the detectors for the infrared region.

A comparison of FTS instrument technology with that of a dispersive spectrometer brings out the following points:¹⁹⁷⁸⁾

- The throughput of an FTS can be orders of magnitude greater than that of a dispersive spectrometer.
- The spectral resolution of an FTS is usually much better than that of a dispersive spectrometer; it is in fact constant across the spectrum.
- The frequency coverage of an FTS can be very large, 10:1 is routine. Dispersive spectrometers rarely cover more than 2:1.

Tables 17 and 18 give a chronological introduction of airborne and spaceborne FTS instruments, respectively.

O.10 Interferometry

Interferometry is the technology of combining radiation (visible light or microwave signals) from spatially distributed telescopes or antennas to measure distances with high precision. Radio astronomy turned first to interferometry to improve both spatial resolution and sensitivity. Astronomers combined the radiation received from many single telescopes into such systems as VLA (Very Large Array) and VLBA (Very Long Baseline Array). Interferometry allows us to use the virtual size of the array (of apertures) to achieve the desired degree of spatial resolution.

1) Spatially separated collecting apertures

¹⁹⁷⁷⁾Courtesy of P. Haschberger, DLR

¹⁹⁷⁸⁾R. Beer, "Remote Sensing by Fourier Transform Spectrometry," John Wiley & Sons, New York 1992, Chapter 4.1.5

An interferometer is an observational instrument that combines the output of a collection of spatially distributed “small” collecting apertures to synthesize the performance of a single larger aperture. The achievable resolution depends on the maximum distance separating any two apertures in the instrument. An interferometer using two small apertures (e.g. 10 cm diameter) separated by a baseline of 100 m offers a resolution ten times that of a 10 m diameter single aperture.

2) Single filled collecting aperture

The resolving power in a single filled aperture scales with the aperture diameter. The technique determines the relative phase of two (or more) wave fronts as a function of spatial location by observing interference fringes. Radiation is split into two or more beams which traverse different path lengths. The beams are reflected by mirrors and recombined for interference analysis. - Interferometers are used for the precise measurement of wavelengths, spectral fine structure, indices of refraction, and very small linear displacements (for instance to measure the angular width of sources, or to determine the angular position of sources, etc.).

Figure 387: Illustration of some interferometer concepts

The design of interferometric instruments has a long history. The most important are listed.

- **Michelson interferometer** (Albert Abraham Michelson, US physicist, 1852-1931)¹⁹⁷⁹) Incident radiation from source *S* is partly reflected and partly transmitted by a beam splitter to two mirrors. Both mirrors reflect the radiation back to the beam splitter, where interference occurs. In Fourier spectrometry one of the mirrors is movable.
- **Mach-Zehnder interferometer.** Variation of Michelson-type - incident radiation moves in only one direction with the use of two beam splitters. A test object is traversed only once.

- **Fabry-Perot interferometer** (Ch. Fabry, French physicist, 1867-1945). A multibeam interferometer consisting of two parallel glass plates that are coated with highly reflecting and partially transparent films on their inner surfaces. A radiation source S from a spectrometer generates multiple reflections between the two surfaces, producing concentric interference rings.
- **Sagnac interferometer**. (Sagnac, French physicist, 1869-1928). A variation of the Michelson interferometer. A triangle-path or common-path interferometer: the two beams emerging from the beamsplitter, one in reflectance and one in transmission, follow the same path in opposite directions. These two beams, observed beyond the interferometer, form two images of an input source.

O.10.1 Radar Interferometry

Interferometric measurements are not only performed in the optical and infrared regions, but also in the microwave region of the electromagnetic spectrum. For instance, conventional SAR image mapping of the Earth's surface suffers from poor height resolution to distinguish terrain features.

Background: In a conventional (single antenna) synthetic aperture radar, images are acquired in an azimuth-range (i.e., along-track - cross-track) coordinate system. Two principles are applied to achieve a high spatial resolution in the illuminated footprint. In the azimuth direction, a synthetic aperture is generated through the coherent addition of the radar echo. In the cross-track direction, however, the Doppler history (time delay) of sequential wave fronts is determined. The latter technique of time delay measurements leads to ambiguities, because two points with equal distance in the instantaneous footprint, but with different position and elevation, cannot be separated since their echoes are received simultaneously at the SAR antenna.

Single-pass SAR interferometry, on the other hand, employs two antennas, separated by the baseline. This 3-D observation geometry, similar in function to stereoscopic observation, is able to resolve the surface position ambiguities through slightly different delay times. In stereoscopic analysis, the parallax is determined through direct distance measurements. However, single-pass SAR interferometry employs signal coherence and phase difference measurements of both antennas to resolve the position ambiguities.

- 1) Cross-track SAR interferometry. The technique in either single-pass or two-pass (multi-pass) mode is the most widely used configuration.

The problem of terrain feature detection (elevations) is either overcome with a single-pass interferometric SAR using a dual-antenna system whose elements are positioned at a distance from each other (the so-called baseline), or by a regular (single antenna in monostatic mode) SAR instrument that covers the same ground swath a second time, possibly in a repetitive pass; the latter technique is also referred to as 'two-pass or repeat-pass interferometry' (the term "pursuit dual monostatic mode interferometry" is also used).

- Two-pass interferometry (use of a single antenna SAR system; however, the SAR platform must pass the same terrain in the same direction along a trajectory parallel to the first one). The interferometric image is obtained in post-processing by superposition of

1979) Albert A. Michelson is regarded as the father of interferometry. He is the first American who received the Nobel Prize in physics in 1907. In 1881, Albert A. Michelson did an experiment to try to detect a difference in the speed of light in two different directions: parallel to, and perpendicular to, the motion of the Earth around the sun. However, to his dismay, he found no difference. In 1887, Michelson repeated the measurement with Edward Morley. As they turned their apparatus (an interferometer), there was no measurable difference between the speed of light in the two directions. The Michelson-Morley experiment was an attempt to detect the velocity of the Earth with respect to a hypothetical luminiferous ether, a medium in space proposed to carry light waves. The experiment led eventually to the deduction that the motion of the Earth through space has no effect on the velocity of light and that the absolute motion of the Earth is not measurable. This null result seriously discredited the ether theories and ultimately led to the proposal by Albert Einstein in 1905 that the speed of light is a universal constant.

both scenes (or multiple scenes) and by calculating the phase differences from slightly different viewing angles to obtain the surface elevation geometries in a rather tedious process. The image of two or more superimposed scenes is referred to as an ‘interferogram.’ - The concept of two-pass interferometry was first demonstrated with an airborne SAR (C/X-SAR) in 1991.

An extension of the two-pass interferometry technique is the so-called “differential SAR interferometry or **exact repeat-pass interferometry**.” It is used to detect very small elevation changes (in the order of one cm or less) while preserving the same ground range resolution and swath width as that of a conventional SAR interferometer. The basic idea is to use one antenna flown twice over the same scene. If the second flight exactly duplicates the trace of the first, the time dependent phase changes can be measured. There would be no phase changes between the images at all unless there was a physical change in the scene, such as ground swelling and buckling in fault zones, residual displacements from seismic events, etc. If the two passes are made from flight tracks that are separated, it is no longer possible to distinguish surface changes from the parallax caused by topography. However, a third image made at some other baseline may be used to remove the topography and to leave only the surface changes. ¹⁹⁸⁰⁾

- Single pass interferometry. The interferometric SAR technique (referred to as **IFSAR** or **INSAR**), on the other hand, generates the interferogram in a single pass (dual antenna configuration) by relating the signals from both antennas in such a way that signal phase differences can be detected (the phase difference indicates the angle of arrival of the echo for each resolution cell in the SAR image). Across-track or along-track dual-antenna configurational directions or modes are possible in this context. - There are many key factors in producing accurate IFSAR maps, including accurate motion compensation, accurate baseline length and attitude measurement, phase-preserving SAR processing, 2-D phase unwrapping, and measurement of the absolute phase difference. - First airborne IFSAR (TOPSAR) was flown in 1994. The first spaceborne IFSARs, namely C-RADAR and X-RADAR on SRTM, are planned for launch in 1999.
- 2) Along-track SAR interferometry. It offers the capability to detect the motion of the illuminated targets. One application is the measurement of ocean surface currents. The SAR system must use two antennas, spaced along the radar velocity direction. The signals from each antenna are separately processed into two images, where the phase difference between the images is calculated. The phase difference of a resolution element is proportional to the radial distance moved by the resolution element in the time required for the rear antenna to move to the position formerly occupied by the forward antenna. - Early along-track SAR interferometry measurement demonstrations of ocean surface currents were conducted by JPL (in the time frame 1985-86) with an L-band SAR system aboard a NASA Convair-990 aircraft. In this configuration, one antenna was mounted near the rear cabin door, the other near the front, forming a baseline of 18.5 m (both antennas were pointing in the flight direction with separate, closely matched receiver channels). ¹⁹⁸¹⁾

It should be pointed out that motion-sensing SAR systems (using two or more antenna systems aligned with the platform flight vector) provide the capability of detecting and/or measuring the radial component of velocity within the observed scene. Potential applications of motion sensing include such wide fields as oceanography, air traffic monitoring, land vehicle monitoring (detection of traffic jams on major highways), etc. ¹⁹⁸²⁾

O.10.2 VLBI (Very Long Baseline Interferometry)

VLBI is a geometric (triangulation) technique, originally introduced in the field of astronomy (1960s), which measures the time difference between the arrival of radio signals, emitted from a distant source (mostly a quasar), at two or more widely-separated antennas (up to an Earth diameter and more). A precision synchronization of a ground-based VLBI-network of antennas permits the measurement of time differences to a few picoseconds. This in turn determines the relative positions of the antennas in the VLBI-network to a few millimeters, and the angular quasar position to fractions of a milliarcsecond. The high-resolution VLBI measurement technique has found many applications in Earth-based sciences, in particular geodesy.

VLBI is unique in its ability to define an inertial reference frame and to measure the Earth's orientation in this frame. Since the antennas are fixed to the Earth, their locations track the instantaneous orientation of the Earth in the inertial reference frame. Relative changes in the antenna locations from a series of measurements indicate tectonic plate motion, regional deformation, and local uplift or subsidence.¹⁹⁸³⁾

Between 1979 and 1991 NASA's Crustal Dynamics Project (CDP) adopted the VLBI and SLR (Satellite Laser Ranging) techniques into a network of ground-based stations. This was followed by the Space Geodesy Program (SPG) with a substantial increase in sites through international cooperation. GPS techniques have also become part of SGP (the VLBI technique can be applied to GPS signals, in which case relative carrier phase measurements can be obtained without knowledge of either P-code or C/A-code). Of course, GPS receivers can also take advantage of the coded information for determining point or relative positions. - Sustained VLBI measurements (in one-day sessions) provide three-dimensional point positions; this data permits an estimation of velocities.

The VLBI technology offers also solutions for highly-accurate satellite position measurements using a ground-based network. The concept employs delta-differential one-way ranging (delta DOR) which fixes the spacecraft direction angle relative to that of a quasar. Accuracies of 30 nrad may be achieved. This relative positioning is useful only if the absolute position of the quasar is known to a similar level of accuracy.

Starting in 1997, NASA/JPL is defining the Space Interferometry Mission (SIM) to be launched in 2004. The SIM spacecraft will fly an optical interferometer (utilizing multiple telescopes) in a circular sun-synchronous orbit. The main objective is to improve angular measurement precision by two orders of magnitude - down to the level of a few microarcseconds. The technological challenges of such a mission are considerable.

O.11 Spatial Heterodyne Spectroscopy (SHS)

Interferometric spectroscopic instruments offer sensitivities typically 100 times those of conventional grating spectroscopic instruments of similar size in many applications. In 1990, Fred Roesler and John Harlander at the Department of Physics of the University of Wisconsin at Madison conceived and developed an unusual and novel interference spectroscopic technique called Spatial Heterodyne Spectroscopy (SHS).^{1984) 1985) 1986)} It is an interferometric Fourier transform technique, but unlike conventional Fourier transform spectroscopy (FTS) it requires no moving parts for obtaining a spectrum. Moreover it can

¹⁹⁸³⁾ <http://lupus.gsfc.nasa.gov/brochure/bintro.html>

¹⁹⁸⁴⁾ J. M. Harlander, "Spatial Heterodyne Spectroscopy, Interferometric Performance at any Wavelength without Scanning," Ph.D. Thesis, University of Wisconsin-Madison, 1991

¹⁹⁸⁵⁾ J. Harlander, R. J. Reynolds, F. L. Roesler, "Spatial Heterodyne Spectroscopy for the Exploration of Diffuse Interstellar Emission Lines at Far-Ultraviolet Wavelengths," *The Astrophysical Journal*, Vol. 396, 1992, pp. 730-740

¹⁹⁸⁶⁾ Note: The invention was patented (US patent No 5059027, issued Oct. 22, 1991), the patent was assigned to the Wisconsin Alumni Research Foundation.

be field-widened without moving parts to provide additional gains of typically 100. As a result of these gains, the SHS instrument can be made small and still achieve a level of performance equal or superior to grating instruments of practical dimensions. At the same time it avoids many of the mechanical problems associated with conventional field-widened FTS techniques.

SHS provides the first practical approach to extend interference spectroscopy into the FUV (Far Ultraviolet, 1200-2000 Å) spectral range. The technique appears to be offering high-resolution spaceborne spectroscopy applications in astronomy (detection of faint interstellar emission lines, study of the dynamics of hot interstellar gases) as well as in Earth observation. Examples in this field include the measurement of vertical density profiles of the hydroxyl (OH) radical in the middle atmosphere (30-100 km), study of the distribution of aerosols in the mesosphere, and to investigate the role of OH in the photochemistry of water vapor and ozone in the presence of aerosols in the mesosphere.

Figure 388: Schematic diagram of the SHS configuration

In the basic SHS design, Fizeau fringes of wavenumber-dependent spatial frequency are produced by a modified Michelson interferometer in which the return mirrors are replaced by conventional blazed diffraction gratings (see Figure 388 part a). The fringes are recorded on a position sensitive detector and Fourier-transformed to recover the spectral content of the source. Zero spatial frequency corresponds to the Littrow wavenumber of the gratings, which can be chosen by adjustment of the interferometer. Since zero spatial frequency corresponds to a finite wavenumber, SHS measures differences between the source and alignment wavelengths, and high resolution spectra over a limited spectral range can be recovered.

ered with modest requirements on the spatial resolution of the detector. In this process, no element is mechanically scanned.

The resolving power of an SHS design is equal to the theoretical resolving power of the dispersive (i.e. grating) system while the field of view of the system is characteristic of interferometric spectrometers (conventional Michelson and Fabry-Perot). The interferometric field of view gives SHS systems a 100-fold gain in sensitivity for diffuse source spectroscopy over diffraction grating spectrometers of the same size and resolving power. Furthermore, field widening techniques can be applied to SHS systems which enable SHS to view even larger fields of view. Gains associated with field widening are typically two orders of magnitude in solid angle over conventional interferometers (10^4 larger than diffraction grating spectrometers).

Field widening is accomplished by inserting prisms into the arms of the interferometer (see Figure 388 part b). The prism apex angles are chosen so that from a geometrical optics point of view the gratings appear coincident. The geometrical path difference in the system is then near zero for a wide range of input angles and the system behaves much like a conventional Michelson interferometer at zero path difference. Aberrations introduced by the prisms ultimately limit the field of view, but not before large gains can be achieved in many applications.

The SHS optical system is similar to the Twyman-Green interferometer that is often used for optical testing of surfaces. In the SHS system, diffraction gratings replace the test and reference surfaces of the Twyman-Green; hence grating figure errors, if present, distort the Fizeau fringe pattern. Such fringe distortions degrade the instrumental profile and reduce the signal-to-noise ratio in the recovered spectrum. However SHS fringe distortions for monochromatic light provide a measure of the grating figure errors that can be used in software to correct broadband interferograms without loss in signal-to-noise ratio.

Fringe distortions resulting from figure errors and index inhomogeneities in the beamsplitter and field widening prisms can be corrected if these elements are of good quality over the area sampled by one spatial resolution element on the detector. In the SHS system, these elements are nearly focused on the detector; hence the area that is sampled at each detector pixel is relatively small. This is to be contrasted with conventional interferometers where a single channel detector collects light over the full aperture of the critical optical components. Figure errors in conventional interferometers will result in a reduction in the contrast of the fringes and a reduced signal-to-noise ratio in the recovered spectrum.

Due to the heterodyne nature of SHS interferograms, figure errors distort the individual (carrier) fringes to a greater extent than the envelope (visibility) of the fringes. The envelope provides physical information on the spectral line shape; so therefore, a correction technique is needed which corrects the carrier fringes without distorting their envelope.

The optical concepts that lead to the predicted high performance for the SHS were also demonstrated and validated by Harlander and Roesler in various field tests.

NRL (Naval Research Laboratory) in Washington, DC has been cooperating with UWM (University of Wisconsin-Madison) for the last years to develop an instrument. A first implementation of the SHS concept is realized in SHIMMER (Spatial Heterodyne Imager for Mesospheric Radicals). The instrument is planned to be flown on Shuttle in 2002.

O.12 Orbital Concepts and Terminology in Remote Sensing

Ascending node. Point where a satellite orbit crosses the equator from south to north. The 'descending node' refers to an equator crossing from north to south.

Fictitious mean sun. An imaginary body in the equator plane with mean tropical motion of the sun. The concept is needed to define mean solar time [and in this respect the universal time (UT) and UTC (Universal Time Coordinated) respectively].

Local time. Defines the angle in the equator plane between the local meridian (of the place or the region of interest on the Earth's surface, for instance, a subsatellite point) and the fictitious mean sun. The local time is shown in Figure 389. The equator plane is subdivided into 24 hours (one period of rotation or one full day), with the morning period to the left of the local noon (fictitious mean sun position) and the afternoon period to the right of local noon.

Mean solar time. A measure of time based conceptually on the diurnal motion of the fictitious mean sun, under the assumption that the Earth's rate of rotation is constant.

Inclination (I) is defined as the angle between the Earth's equatorial plane and the satellite's orbital plane [which is for most inclinations slowly variable and always passes through the center of mass (the Earth)]. The different orbital periods of the Earth and the satellite provide longitudinal precession for successive orbits. An inclination angle of 30° means for instance that the observation area of the satellite is bounded by $\pm 30^\circ$ latitude (tropical region). An inclination of 0° (or near 0°) refers to an equatorial orbit. **Polar orbits** have an inclination near 90° . For this case the Earth's rotation provides successive swaths of observation with every orbit. If we consider about 14.5 satellite orbits per day, then the instrument FOV must be about 25° for contiguous global coverage.

Mean motion. Refers to the average speed of a satellite in its orbital plane (units are usually given in revolutions per day). Satellites in circular orbits travel at constant speed. Satellites in non-circular (elliptical) orbits move faster when closer to Earth, and slower when they are farther away.

Nutation (Latin: nutare, “to nod”). Refers to the short-period oscillations in the motion of the pole of rotation of a freely rotating body which is subjected to a torque from external gravitational forces (the British astronomer James Bradley announced his discovery of nutation in 1748). In the case of the Earth, it is a small irregularity in the precession of the equinoxes. Nutation superimposes a small (wobbling) oscillation, with a period of 18.6 years upon the very slow motion of precession [nutation in longitude (of the ecliptic) with an amplitude of 17.2 arcsec, and a nutation in the obliquity of the ecliptic with an amplitude of 9.2 arcsec]. The cause of nutation lies mainly in the fact that the plane of the moon's orbit around the Earth is tilted by $\sim 5^\circ$ from the plane of the Earth's orbit around the sun (the ecliptic). The moon's orbital plane precesses around the Earth in 18.6 years, and the effect of the moon on the precession of the equinoxes varies with this same period.

Precession. A phenomenon associated with the action of a gyroscope or a spinning top, it consists of a comparatively slow rotation (gyration) of the axis of rotation of a spinning body about a line intersecting the spin axis and describing a cone, caused by the application of a torque (e.g. external gravitational forces), and tending to change the direction of the rotation axis. It is a motion continuously at right angles to the plane of the torque producing it. The smooth, slow circling of a spinning top is precession, the uneven wobbling is nutation.

Precession of the equinoxes. A slow westward motion of the equinoctial points along the ecliptic (the Earth's orbital plane) caused by the gravitational influence of the sun and the

moon acting on the Earth's equatorial bulge in connection with its diurnal rotation (the planets exert an influence as well, but to a much lesser extent). Precession is the slow, top-like oscillation of the spinning Earth, with a period of about 26,000 years.

Prograde orbit (or direct orbit). A satellite orbit with an inclination of $< 90^\circ$ (note: most satellite orbits are 'prograde'). For an Earth-orbiting satellite the tropical motion of the equator crossings (or nodal points) of successive orbits is from east to west, i.e., in the opposite direction of Earth rotation.

Retrograde orbit. A satellite orbit with an inclination $> 90^\circ$. For satellite (circular or elliptical) orbits the tropical motion (of the nodal points) of successive orbits is from west to east, in the same direction of Earth rotation. All sun-synchronous orbits are retrograde orbits. For geosynchronous transfer orbits (which are 'prograde' from an inertial point of view) the apparent motion of the satellite is retrograde in the vicinity of the apogee; this is due to the smaller satellite velocity with respect to the Earth's rotation.

Right ascension of ascending node. Refers to the angle in the equatorial plane which is measured from the vernal equinox to the ascending node. Note, the inertial coordinate representation (of right ascension and declination) provides simply one angle (right ascension) for the orbital plane of the spacecraft which is inertial.

Precise orbit determination. Refers to the analysis of satellite tracking data (of various sources, such as: altimeter, GPS, SLR, Doppler, etc.) in order to model the position (or ephemeris) of the satellite at a given moment.

Tropical motion. Motion of a body (planet or satellite) related to the vernal equinox which is the intersection point of the Earth's equator with the ecliptic.

O.12.1 Sun-synchronous Orbit

An orbit is said to be sun-synchronous if the orbit precession of the satellite compensates for the Earth's revolution around the sun (about 0.9856° per day)¹⁹⁸⁷. The daily node rotation of 0.9856° is eastward such that the angle between the orbital plane and the sun remains constant. For near-Earth satellite orbits (altitude < 1300 km) sun-synchronous orbits are polar orbits at an orbital inclination and altitude such that a satellite passes over a given site always at the same local time. The orbital nodes maintain a near constant solar time. The satellite always crosses the equatorial plane at the same local time [from an equator crossing to the next equator crossing (one orbital period), the Earth has rotated exactly as far as to make the local time of day the same]. This means that the sun position (lighting conditions) is always the same (within certain limits) for a repeat observation of any given site (consistent sensor-target-sun relationships). Sun-synchronous orbits may be placed so as to see points of the Earth at anywhere from local sunrise/sunset to local noon; due to this they are often referred to as 'morning' (AM) or 'afternoon' (PM) orbits. - There are advantages and disadvantages to the measurement at constant sun-angle depending on the application. Varying sun angles may be important for geologists to reveal subtle structural details not visible at higher sun angles.

There are two limiting cases for sun-synchronous orbits, depending on the choice of local time for the ascending nodal equator crossings:

- 1) A dawn/dusk orbit with ascending nodal equator crossings at 6 AM or 6 PM local time. For both cases the satellite orbital plane is perpendicular to the mean sunlight direction. This means the satellite orbit is normally sunlit, but always close and parallel to the terminator plane.

¹⁹⁸⁷) Note: The daily rotation of the orbital satellite plane (with respect to the equatorial plane) is identical to the mean motion of the fictitious sun around the Earth - which in turn is identical to the mean motion of the Earth around the sun. The effect of the rotation of the orbital satellite plane is due to the oblateness of the Earth.

- 2) A full-sun / full-shadow orbit with ascending nodal equator crossings at local 12 AM (noontime or 12:00 hours) or at local midnight (0:00 hours). For both cases the mean sun direction is in the orbital plane. This means that about 60% of the orbit is in full sunlight and the other portion is in full shadow of the sun. The choice of the 12 AM ascending orbit provides first a sunlight phase followed by a shadow phase, while the midnight orbit reverses these phases.

All other choices of ascending nodal equator crossings at specific local times are positioned between these two limiting cases for sun-synchronous orbits.

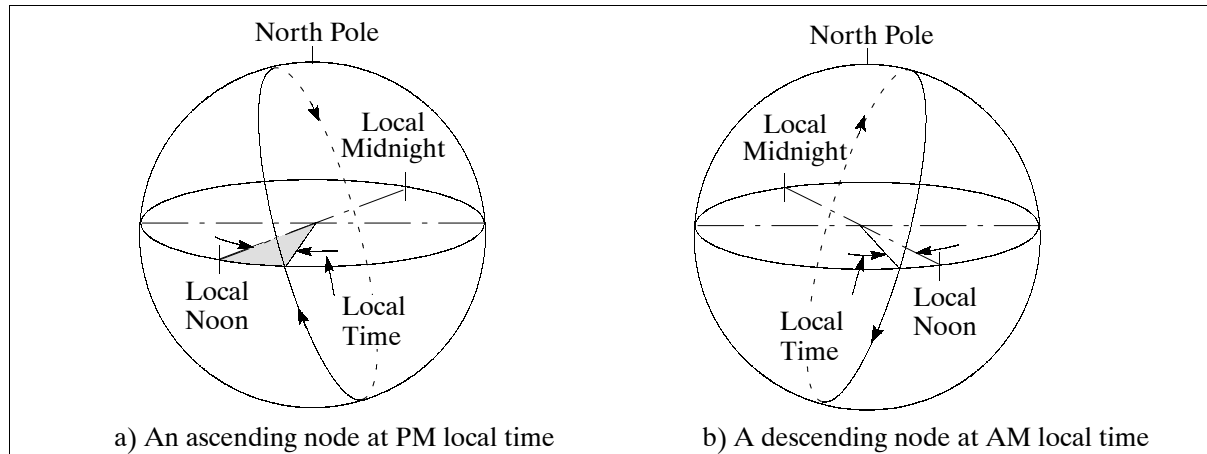

Figure 389: Examples of relative orientation of sun-synchronous orbits with local time

O.12.2 Geosynchronous Orbit

An orbit in which the satellite's orbital period is identical to the orbital period of the Earth. Thus, a geosynchronous satellite has the Kepler period of one sidereal day, which is equal to 23 hours, 56 minutes, and 4.09 seconds (or 1436.07 minutes). The semi-major axis of such a geosynchronous orbit is 42,164.182 km from the center of the Earth (or approximately 35,786 km above the Earth's surface). Two limiting cases of the geosynchronous orbits are of particular interest:¹⁹⁸⁸⁾

- 1) Inclination = 0° . A geosynchronous orbit with zero inclination is conventionally referred to as **geostationary** or **GEO**. The ideal geostationary orbit is circular, its orbital plane coincides with the equator plane, and its orbital period is one sidereal day (23 hours, 56 minutes, 4 seconds). In practice, the orbits have a small eccentricity and inclination as a consequence of perturbations. Each satellite in GEO is usually assigned a longitude/latitude box, within which it has to stay, typically to within $\pm 0.1^\circ$ for direct-TV communication satellites. - The subsatellite point of a zero-inclination orbit remains ideally "stationary" over a particular meridian at the Earth's equator. Perturbations to the orbit of a satellite [due to a) anomalies in the Earth's gravity field, b) gravitational effects of the sun and moon, c) solar radiation pressure] are normally counteracted by the process of 'station-keeping'.
- 2) Inclination $\neq 0^\circ$ [IGSO (Inclined Geosynchronous Orbit)]. A geosynchronous satellite with an inclination different from zero is not "stationary" when observed from the Earth. The subsatellite track described by such a constellation is referred to as 'lemniscate,' meaning 'the locus of the foot of the perpendicular from the center of a conic on its tangent'. The subsatellite-track projection onto the Earth's surface describes a path

as outlined by the number 8 in the period of one day. An inclination of 60° causes a latitudinal displacement of $\pm 60^\circ$ during one orbital period (just as is the case for any non-geosynchronous orbit). However, the subsatellite-track projection (i.e. the Figure 8) of an inclined geosynchronous orbit has the property of remaining stationary over a particular meridian. Hence, there is no longitudinal precession for successive geosynchronous orbits. An inspection of the subsatellite track reveals zero longitudinal precession at the equator and increasing precession or regression with increasing latitude.

In general, a geosynchronous orbit is not necessarily a circular Earth orbit, but may also be defined as an elliptical HEO orbit. This can be done as long as the semi-major axis is 42,164 km and the orbital period is equal to a sidereal day. An example of such a geosynchronous HEO mission is ISO (Infrared Space Observatory) of ESA with a launch on Nov. 17, 1995. The orbit parameters of ISO are: perigee = 1,000 km, apogee = 70,500 km, inclination = 5.25° , eccentricity = 0.825, period = sidereal day.

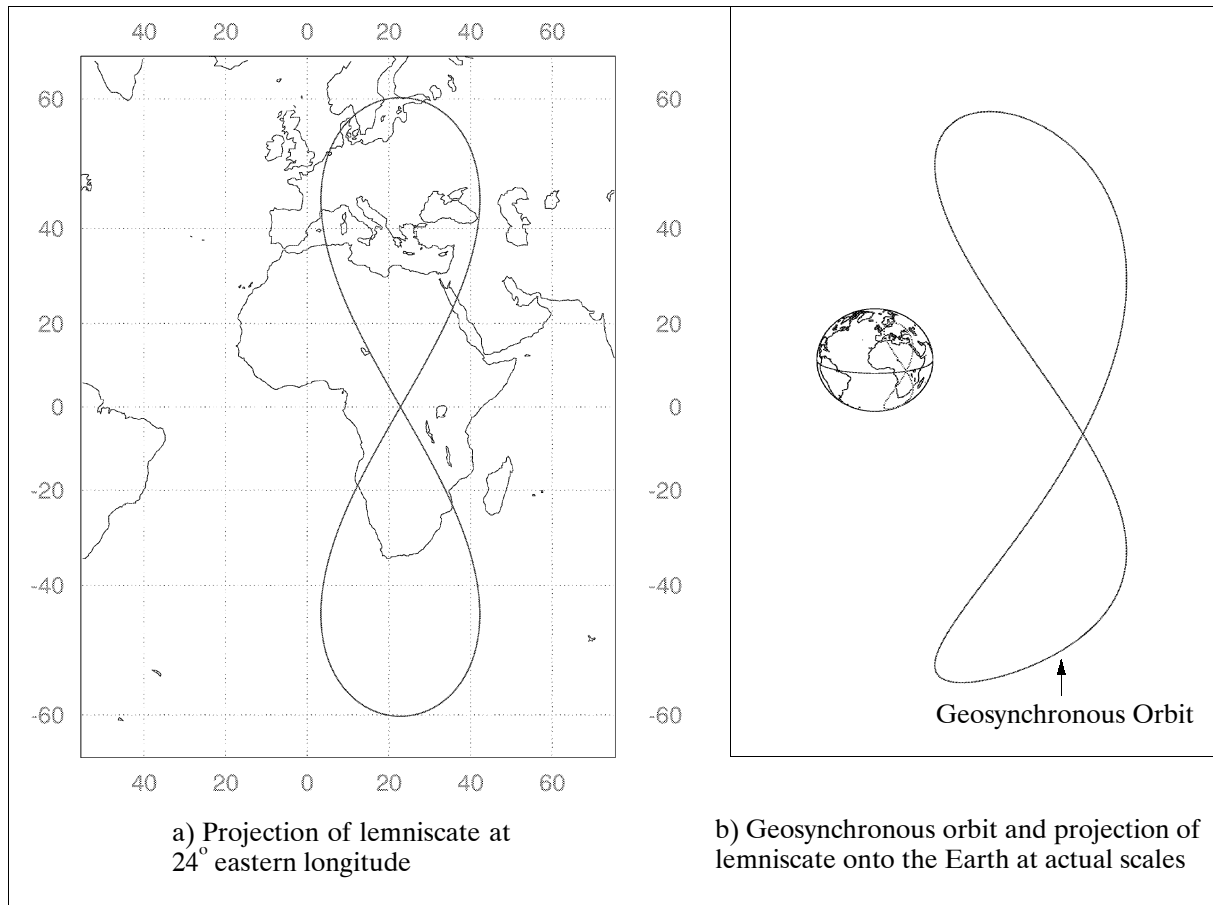

Figure 390: A lemniscate of a geosynchronous orbit with an inclination of 60°

Item 1 above is simply a special case of item 2. There are numerous applications for geosynchronous orbits of spacecraft in such fields as communications, meteorology, tracking and data relay services to LEO satellites, etc. The first geostationary communications satellite in orbit was Early Bird (later renamed to Intelsat I) which was launched in April 1965. The first geostationary weather satellite was ATS-1, launched on December 7, 1966. Some advantages of a geostationary satellites are:

- The same area of the Earth's surface (footprint) is continuously in view, providing a fixed-position relation between the satellite and its ground segment (stations, etc.). This is favorable for signal recovery of low-power communications. Broadcasts are tied to a geographical region.

- In remote sensing the continuous view of the same portion of the Earth's surface provides an opportunity to observe such things as diurnal phenomena or the history of entire weather systems (study of lighting in thunderstorms, etc.).
- The footprint of a geostationary satellite is fairly large, due to its high altitude position, providing a coverage of about 1/3 the Earth's surface.

A disadvantage of a geostationary satellite in a voice communication system is the round-trip delay of approximately 250 ms. A further drawback of the geostationary orbit is its exclusivity over the equator at zero degree inclination. It is the most wanted orbit for many applications; hence, it is also the most crowded orbit, with problems of signal interference and other problems. The coverage is of course optimal for regions close to the equator; problems usually arise at high latitudes due to very low grazing angles. - On the other hand, the geosynchronous orbit with an inclination of, say, 60°, may be of interest in the future, in particular for meteorological applications, since it provides much better observation constellations for the high-latitude regions, including the polar caps. With nodal crossing times of, say, 6:00 AM and 6 PM, there is the opportunity to observe more intensely a portion of the illuminated northern half of a continent in combination with the dark southern half (or vice versa).

O.12.3 Repeat Coverage or Temporal Resolution

Time may be regarded as the fourth variable of resolution. A dynamic Earth environment changes with time; this applies in particular to meteorological observations and vegetation (crops) observations, etc. Repeat coverage (or temporal resolution) designates the period of time that elapses until the next observation of the same geographic area can take place. Total coverage of the globe can only be provided by polar-orbiting satellites. Their orbit and swath width are usually chosen in such a way that Earth rotation accounts for a continuous and contiguous observation swath (with some overlapping) of the globe. In general each sensor aboard a satellite has a different swath width.

There is a fairly simple trade-off between spatial resolution (or IFOV) and frequency of coverage. Constraints are imposed by the sensor design, the on-board electronics, and the amount of source data that can be handled. Thus the smaller the IFOV, the more data there is to be handled for any given area on the ground and the less frequently data will be available for a given area.

Examples of repeat coverage requirements for some remote sensing applications:

- Operational meteorology (weather forecast) requires a high repeat coverage of large areas at relatively low spatial resolutions (1-5 km); the emphasis is on the measurement of progressive daily cycles. About 20 - 30 min/image of the same area for meteorological geostationary satellites (such as METEOSAT, GMS, GOES and INSAT series). Geostationary satellites permit the tracking of continuous dynamic processes with the desired viewing frequency (for example: viewing of Earth surface targets at any sun illumination angle, and viewing each point on the ground at exactly the same zenith and azimuth angles over time).
- Monitoring of renewable resources (vegetation, agricultural crops) requires a medium repeat coverage (in the order of several days and up to 2 weeks) but relatively high spectral and spatial resolutions (30 m) on a seasonal basis. Polar orbiting satellites (Landsat, POES, SPOT, Resurs, etc.) realize these requirements.

Note: There are also a number of transient phenomena that cannot be adequately seen from polar orbiting satellites, such as the diurnal variability and dynamic behavior of:

- precipitation and evaporation
- atmospheric water vapor and wind
- vegetation color

- terrestrial ecosystems and land processes
- land-ocean-atmosphere energy fluxes
- tropospheric pollutant generation and transport
- ocean color (biomass productivity)
- soil moisture and net radiation balance
- etc.
- Cartographic applications (maps) of the Earth's surface require a relatively low repeat coverage but high resolutions (spatial and or spectral). Imagery for urban growth patterns is appropriate in time intervals of a year or so.

O.12.4 LEO (Low Earth Orbit)

The term LEO is used for Earth observation satellites as well as for communication satellite constellations. These are usually circular or near-circular orbits at altitudes of less than 2000 km above the Earth's surface. The orbital period in the altitude range of 300 - 2000 km varies between 90 - 120 minutes. A satellite pass (i.e. the visibility period of a satellite above the horizon) for an observer (or a ground station) may vary from about 5 - 20 minutes, depending on a horizon pass or a zenith pass of the satellite with respect to the observer.

Below 500 km the orbital lifetime is very much reduced by atmospheric drag; however, the observational resolution of Earth surface imagery increases. With increasing altitude the orbital life increases, along with the sensor footprint, while the resolution decreases. Increasing altitudes also provide a harsher radiation environment, thereby sharply reducing the lifetime of electronic components, this in turn may be counteracted by extra shielding or component hardening.

From a communications point of view the near circular LEO orbit is providing a nearly-constant signal strength between ground and satellite. Advantages of LEO transmissions are experienced in particular with much reduced signal power needs (and path losses) and much shorter signal time delays as compared to a GEO constellation.¹⁹⁸⁹⁾ Another advantage is that LEO satellites avoid congestion (physical as well as the spectrum congestion) experienced in the spatially very limited GEO environment. Naturally, some LEO communication characteristics are disadvantageous, such as increased Doppler shifts, multipath propagation, variable signal path, and variable pass times; frequent hand-overs are needed.

The radius of a footprint of a communications satellite in LEO orbit varies from about 3000 to 4000 km. Hence, global real-time coverage can only be achieved with a satellite constellation. Several service concepts have emerged in the communications industry with regard to LEO systems.¹⁹⁹⁰⁾

- **Little LEO systems.** Refer to mobile satellite communication systems for non-voice messaging and data relay (i.e. store & forward) services. Satellite communication is usually in VHF and/or UHF bands. Examples: Faisat, GE Starsys, SAFIR, Orbcomm, Temisat, Leo One USA, Kitcomm, Gonets-D, etc.
- **Big LEO systems.** Refer to mobile satellite communication systems for global hand-held telephone service as well as mobile fax and data services (support of packet-oriented services). Satellite communication is usually in L and/or C bands (sometimes also Ka band). Examples: Iridium, Globalstar, Odyssey, etc.

¹⁹⁸⁹⁾ Note: The required signal power varies with the square of the distance. Hence, reducing the orbit from GEO to LEO translates into a multifold increase in available signal strength, allowing operation of a LEO constellation at lower power levels.

¹⁹⁹⁰⁾ Note: In a LEO communications system with handheld phone service (implying weak signals) the entire burden of link completion is placed on the satellite. Such a connection can physically be achieved only if the satellite employs the concept of very narrow-spaced spot beams (FOV of about 1°), each covering a "cell" on the Earth. Many of these beams must be employed to provide sufficient coverage of the intended service area (total footprint). The employed cell technique requires automatic handoff when a subscriber is passed from the coverage of one spot beam to that of another (the cells are moving while the subscriber is essentially stationary). In addition to the beam-to-beam handoff there is also the management of satellite-to-satellite handoff to be taken care of.

- **Broadband LEO systems.** Refer to mobile satellite communication systems for high-capacity data communications such as high-speed computer links and video telephony. Satellite communication is usually in Ku or Ka bands. Examples: Teledesic, Skybridge, M-Star.

O.12.5 MEO (Medium Earth Orbit)

Refer to near-circular orbits with altitudes in the range of about 5000 and 25000 km above surface. The orbit period may vary from about 3 to 12 hours. The GLONASS and GPS constellations are MEO examples with periods of 11.25 and 12 hours respectively. Other MEO satellite systems are LAGEOS with about 6000 km altitude, and the Inmarsat-P (communication satellite) series with altitudes of 10350 km. Maximum MEO contact times may vary from an hour to a few hours. Compared to a LEO system, hand-over is less frequent, while propagation delay is greater.

O.12.6 HEO (Highly-Elliptical Earth Orbit)

Refer to orbits with a typical perigee of 500 - 1000 km above the Earth's surface and apogees up to 20 R_E (or about 140,000 km) or more. HEO orbit periods may vary from about 10 hours to two days. Examples are the IRM and UKS satellites in the AMPTE project, each with apogees of 18.7 R_E and a period of 44.3 hours. GEOTAIL has an extreme HEO orbit with a perigee of 8 R_E and an apogee of 220 R_E . The satellites of the INTERBALL program are: 'Auroral Probe' with a perigee of 500 km and a apogee of 20,000 km, and 'Tail Probe' with a perigee of 500 km and an apogee of 30 R_E or about 190,000 km. - The high eccentricity of these orbits causes the satellite to spend about two thirds of the orbital period near apogee (referred to as apogee dwell), and during this time it appears to be almost stationary for an Earth observer. Free space loss and propagation delay in HEO are even greater than in GEO systems.

O.12.7 EEO (Elliptical Earth Orbit)

EEO refers to orbits chosen in such a fashion that maximum service provision (or viewing time) can be provided to a particular region of the Earth. This is accomplished with elliptical orbits where the apogee (by far the longest duration period of the orbit) occurs always in the intended region. Typical EEO examples are Molniya-type orbits (Russia) with apogees over the big land mass of Asia. They are characterized by an orbital period of 12 hours, apogee height of 39350 km over the northern hemisphere, perigee height of about 1000 km over the southern hemisphere, and an inclination of 63.4°. In this case the apogee is inertially fixed. The Molniya satellite spends about 11 hours (92%) of the 12 hour orbital period over the northern hemisphere. ¹⁹⁹¹⁾

An EEO could for instance also be selected for a communications system with apogees over the northern hemisphere, taking advantage of the fact that most of the world's population lives in the northern hemisphere for required service provision.

O.12.8 The Interferometric Cartwheel Orbit

The concept of the interferometric cartwheel orbit was initially proposed by D. Massonnet in 1997 (CNES internal memo); it is an R&D project of CNES since 1998. ^{1992) 1993)} The study objective is in the framework of finding cost-effective solutions to the field of active microwave observations. Particular emphasis is on satellite constellations carrying an active

¹⁹⁹¹⁾ Information provided by F. Jochim of DLR/GSOC

¹⁹⁹²⁾ D. Massonnet, "Capabilities and Limitations of the Interferometric Cartwheel," IEEE Transactions on Geoscience and Remote Sensing, Vol. 39, No 3, March 2001, pp. 506-520

¹⁹⁹³⁾ S. Ramongassie, L. Phalippou, E. Thouvenot, D. Massonnet, "Preliminary Design of the Payload for the Interferometric Cartwheel," Proceedings of IEEE/IGARSS, July 24-28, 2000, Honolulu, HI, pp. 29-32

instrument (SAR) on one spacecraft, and passive receivers (radiometers) on other (passive) spacecraft in the formation in order to obtain interferometric imagery.

Orbital cartwheel geometry:

The overall orbital geometry consists of a spacecraft with a transmitter and a receiver function (SAR or Doppler radar instrument) and one or more spacecraft with passive receivers (radiometers) in formation on the same orbit, and close enough to be able to point into the footprint illuminated by the transmitter spacecraft (master slave relation). All spacecraft are co-planar, but the eccentricity of each passive spacecraft is slightly modified. This results in other orbits with the same periodicity which describes an ellipse relative to the original orbit. Three passive satellites with the same additional eccentricity but perigees distributed along the orbit lead to a configuration as shown in Figure 391. The perigees of the three spacecraft are separated by 120° (evenly distributed). The major axis of the ellipse is in the orbit plane, the minor axis is co-planar in the vertical direction. The minor semi-axis of the ellipse is the “vertical radius of the wheel.” The major axis of the ellipse is twice the vertical radius. For a LEO constellation, a typical value of the vertical wheel radius may be in the range of 500-1000 m.

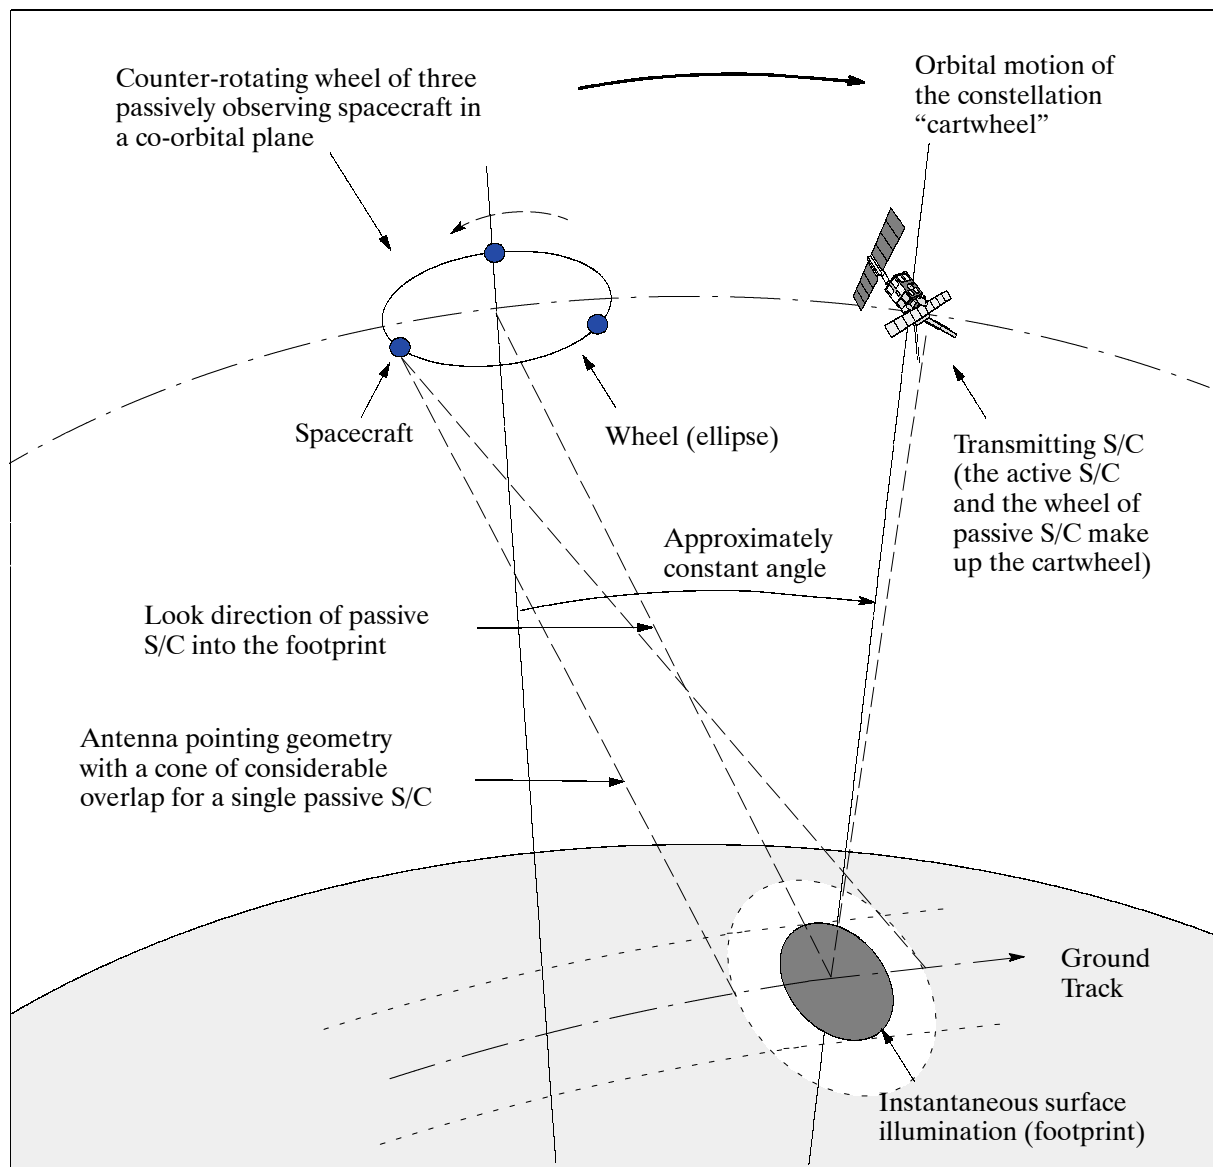

Figure 391: Orbital geometry schematics of a backward-moving cartwheel constellation

There are no severe pointing nor positioning requirements imposed by a cartwheel formation. Each passive spacecraft of the cartwheel can be provided with a small antenna whose

footprint contains at least the footprint of the active SAR instrument. Thus, S/C pointing may be done with reaction wheels. For safety reasons only, on-orbit propulsion of the passive constellation is needed: a) to keep a proper distance to the transmitting S/C, and b) for wheel configuration keeping. ^{1994) 1995)}

An advantage of the wheel configuration is the inherent stability of its vertical and horizontal baselines. Without going into orbital mechanics, it has been shown that a wheel of passively observing satellites, placed into the same orbit of a single actively observing spacecraft, remain in natural relative formation. In fact, the tandem linear motion of the counter-rotating wheel of passive spacecraft and that of the active spacecraft, resemble the typical motion of a “cartwheel,” drawn backwards across the sky. The name cartwheel was therefore natural to the CNES inventors of this particular orbital constellation.

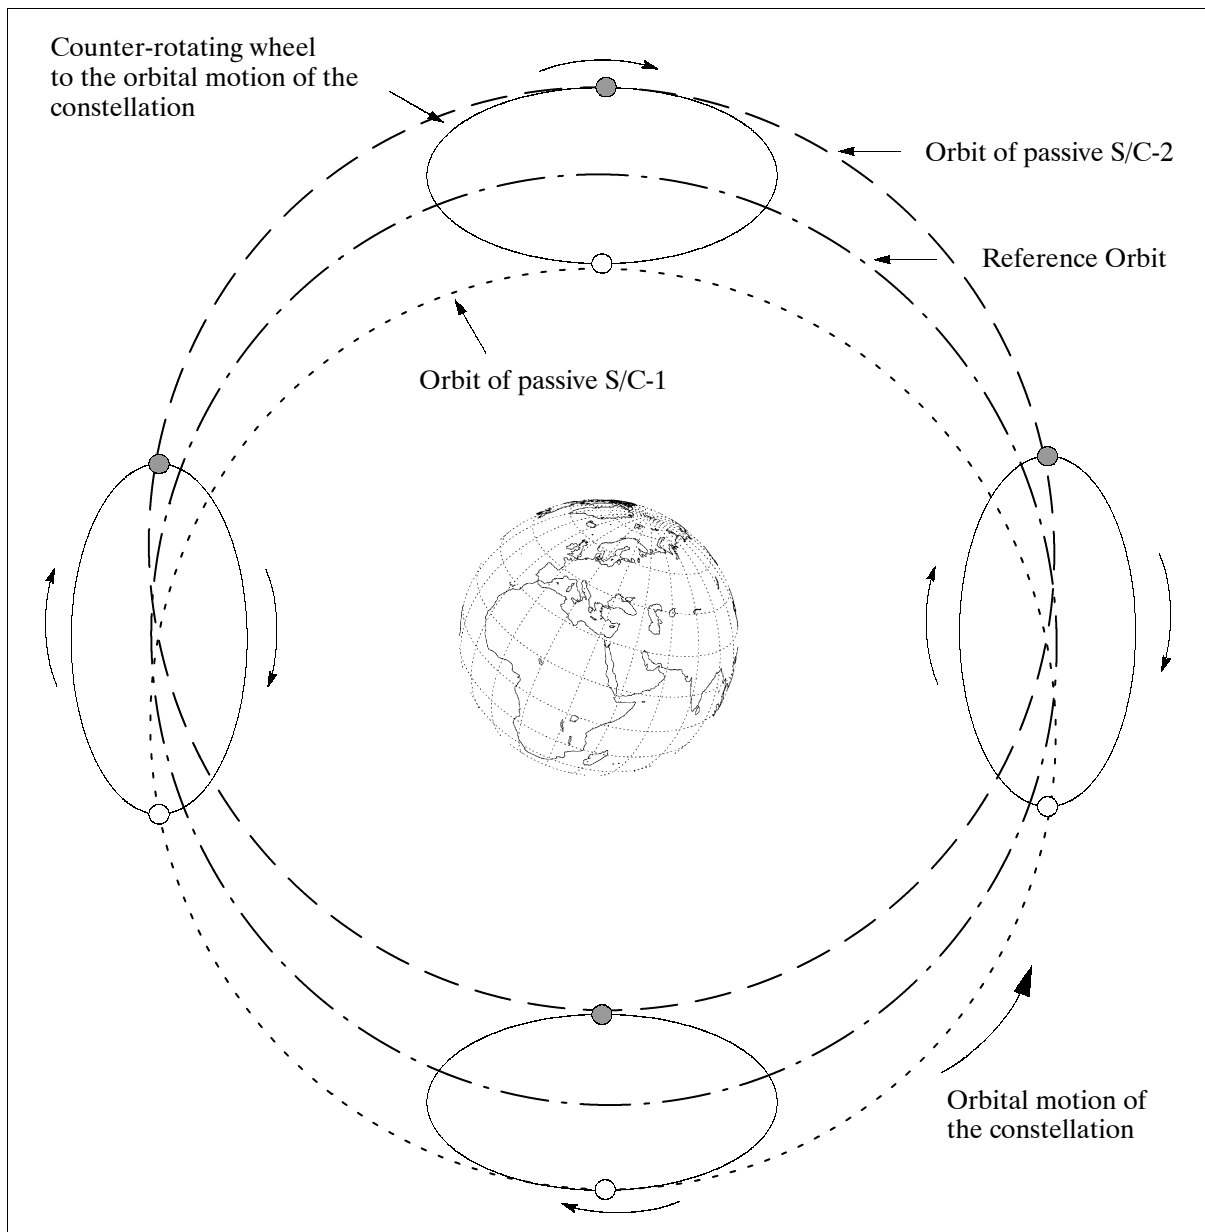

Figure 392: Schematic illustration of the wheel orbits of two passive spacecraft ¹⁹⁹⁶⁾

1994) D. Massonnet, E. Thouvenot, S. Ramongassie, L. Phalippou, “A wheel of passive radar microsats for upgrading existing SAR projects,” Proceedings of IEEE/IGARSS, July 24-28, 2000, Honolulu, HI

1996) Courtesy of Friedrich Jochim of DLR/GSOC

Naturally, the wheel may also be positioned in a forward-moving cartwheel constellation. Figure 392 illustrates how the wheel of two spacecraft rotates along a complete orbit. The active spacecraft is not shown here for reasons of clarity.

The bistatic observation concept of a cartwheel constellation permits practically the simultaneous collection of SAR imagery from various vantage points. A footprint illuminated by only one SAR instrument on a single spacecraft can be viewed, and therefore the echo detected by the receivers (radiometers) of spacecraft in the vicinity of the transmitting spacecraft. The combination of the imagery from all members of the constellation is interferometric by its very nature. The spatial resolution of the imagery will improve considerably. - The cartwheel concept provides a great potential for cost-effective missions. A wide spectrum of applications can be expected with the introduction of this new technology.

In the cartwheel observation scheme, the slave radar instruments (receivers on the wheel S/C) are not synchronized with the receiver of the SAR instrument of the master spacecraft. The duty of each slave receiver is simply to point into the footprint illuminated by the transmitter, to collect continuously the data stream of echoes emanating from the illuminated footprint with sufficient bandwidth, and to store/transmit the results (in combination with data compression). Obviously, a ground-based re-synchronization process is needed to combine the data collected by all slaves.

Signal processing background: A pair of two images acquired simultaneously from two separate points in along-track is characterized by the critical horizontal baseline. It is such that the range difference between the receivers and a given ground target changes by one wavelength from one pulse to the next. For a coherent combination of the passive images made by each receiver, the along-track separation of the receivers must stay below this critical horizontal baseline. In the same way, a critical vertical baseline is defined as an adaptation of the conventional orthogonal baseline of active interferometric systems to the passive, vertically separated systems. It is such that the range difference seen by the second receiver, across the range pixel of the first receiver, differs from the range pixel size by one wavelength. Thus, for coherent combinations of the passive images made by each receiver, the vertical separation of the receivers must stay below this critical vertical baseline.

The combination of the critical horizontal (azimuth) and the critical vertical baselines creates a rectangle called the “interferometric area.” The resolution of an interferometric product results from the coherent part common to the intersecting interferometric areas of the two receivers involved in the combination. The size of the critical baselines are inversely proportional to the associated resolutions in azimuth and range.

O.12.9 Some Orbit Selection Requirements

There are a number of factors which may influence the particular orbit selection:

- Global coverage requirement: implies a polar or near-polar orbit
- Constant illumination requirement: implies a sun-synchronous orbit
- Continuous observation requirement: implies a geosynchronous orbit
- Measurement of gravity anomalies: implies a low orbit
- Requirement to minimize the atmospheric drag: implies preference for a high orbit
- Requirement to minimize a radar sensor's power: implies preference for a low orbit

O.12.10 Walker Constellation

The Walker constellation is named after J. G. Walker of RAE [Royal Aircraft Establishment - later renamed to DERA (Defence Evaluation and Research Agency), as of July 2, 2001 DERA was renamed to QinetiQ]. Walker was a pioneer in studying Earth-coverage

problems (in particular equal-area distributions) with various satellite constellations. 1997) 1998)

A typical Walker constellation configuration is denoted by the symbols: T/P/F, where T = number of satellites, P = number of orbital planes, and F characterizes the interplane phasing (relative from plane to plane). In a symmetrical constellation of T satellites, T/P satellites are evenly spaced on each orbital plane, and P orbital planes are evenly spaced through 360° of ascending node. Example 1 of a Walker constellation 27/3/1: In this case 27 satellites are in a symmetrical Walker configuration (in three orbital planes). Example 2: 18/6/1. In this case 18 satellites are distributed in six planes ($\Delta=60^\circ$), the phasing $\phi=20^\circ$. 1999)

Figure 393: Equal distribution of a Walker constellation 18/6/1

Walker introduced a measure referred to as PU (Pattern Unit) = $360^\circ/T$ to calculate the phase angle (phase angle = $F \times PU$). Example: T/P/F = 54/9/3; then $PU = 6.667^\circ$; and the phase angle = 20° .

O.12.11 Libration Points/Lagrange Points

Libration points (also referred to as “Lagrangian points” 2000)) in space are defined as points where the gravitational forces due to two or more bodies (the sun, or planets) balance, and thus where a spacecraft can be positioned in equilibrium at zero velocity.

Lagrangian points are particular solutions of the equations of motion applied to the “Problem of Three Bodies” in an orbital plane of two massive bodies in circular orbits around a common center of gravity and a third body of negligible mass. The equations of motions always yield five points at which the third body can remain at equilibrium. Three of the points are on the line passing through the centers of mass of the two massive bodies - L_3 beyond the most massive body, L_2 beyond the less massive body, and L_1 (the point through which the mass transfer occurs) between the two bodies. The other two points, L_4 and L_5 , are located at the two points in the orbit of the less massive component which are equidistant (equilateral triangle) from the two main components, as illustrated in Figure 394. 2001) 2002)

A satellite positioned at L_4 or L_5 is regarded as stable, i.e. it will remain at the point and move along in the specific reference system (here either in the sun-Earth system or in the

Earth-moon system), while a satellite located at L_1 or L_2 or L_3 is unstable, i.e. it will wander off if slightly disturbed. However, small orbit corrections by a thruster engine can provide compensation.

Within the sun-Jupiter system the L_4 and L_5 points are known to contain a number of asteroids referred to as the ‘Trojans’. The first Trojan (Achilles) was discovered in 1906. By now, more than 50 Trojans are known.

Figure 394: Lagrangian points of the sun-Earth and Earth-moon systems

Lagrangian Points	Sun - Earth System		Earth - Moon System	
	Distance from Sun	Distance from Earth	Distance from Earth	Distance from Moon
L_1	0.99 AU = 1.48×10^8 km	0.00997 AU = 1.49×10^6 km	0.85 D = 326740 km	0.15 D = 57660 km
L_2	1.01 AU = 1.51×10^8 km	0.010 AU = 1.50×10^6 km	1.17 D = 449748 km	0.17 D = 65348 km
L_3	0.999 AU = 1.496×10^8 km	1.999 AU = 2.992×10^8 km	0.99 D = 380556 km	1.99 D = 764956 km

L_5	1.00 AU	1.00 AU	1.00 D	1.00 D
	$d_{\text{Sun}} = 1\,392\,000$ km	$d_{\text{Earth}} = 12\,740$ km (average diameter)	$d_{\text{Moon}} = 3476$ km	
Sun-Earth distance (center-center) = 1 AU (Astronomical Unit) = 1.496×10^8 km			Earth-Moon distance D = 384 400 km (center-center)	

Table 547: Values of the Lagrangian points in the sun-Earth and Earth-moon systems ²⁰⁰³⁾

Mass	$5.976 \cdot 10^{24}$ kg
Equatorial radius	6,378.14 km
Mean density	5.515 g/cm^3
Mean distance to sun	149,600,000 km
Rotational period	0.99727 days (23.9345 h)
Orbital period	365.256 days
Mean orbital velocity	29.79 km
Orbital eccentricity	0.0167
Tilt of axis (obliquity of ecliptic)	23.45°
Equatorial escape velocity	11.18 km
Equatorial surface gravity	9.78 m/s^2
Visual geometric albedo	0.37
Mean surface temperature	15°C
Atmospheric pressure	1.013 bar
Atmospheric composition	
Nitrogen	77%
Oxygen	21%
Other (trace gases)	2%

Table 548: Some Earth parameters

²⁰⁰³⁾Table values: courtesy of F. Jochim of DLR/GSOC

L_1 in the sun-Earth system is located about 1.5 million km from the Earth towards the sun (this is 1/100 of the way from Earth to the sun). Both L_1 and L_2 are ideal positions from which to look toward the universe. L_1 in particular is a good vantage point to study the Earth as well as the sun (solar wind, etc.). However, a disadvantage at L_1 is the ferocious solar radiation which might overwhelm the S/C signal. At L_2 , Earth's shadow blocks the solar radiation which is needed for power generation. A solution to this problem is the so-called “**halo orbit**” around the Lagrangian points. A S/C in a halo orbit around L_1 describes huge loops (the orbits resemble a so-called “halo” or disk about L_1) which are perpendicular to the Earth-sun axis, endlessly falling toward the balance point. Such halo orbits around L_1 , although in the order of one million km in diameter, are considered as “small” compared with cosmological distances. The view angles from Earth to such a S/C in halo orbit remain fairly constant.

O.13 Observational Scales in Modeling

Consistent space and time scales are a necessity for modeling purposes in the atmospheric sciences or for other (large-scale) phenomena such as ocean circulation, in characterizing the dynamic behavior and structure of the system under investigation. The scale provides an ordering concept (and grid size or resolution) for the parameterization of observational data. In the literature pertinent to campaign descriptions there seem to be different meanings (or vague interpretations) to such definitions as ‘macroscale’ (sometimes also referred to as ‘large-scale’), ‘mesoscale,’ and ‘microscale.’ Without going into details and into arguments of justification, I would like to refer to the article of I. Orlanski, who proposed his views on scales in 1975 (with a growing number of followers).²⁰⁰⁴ While the definitions of Figure 395 were intended for meteorological modeling, they could also serve as an evolving structure for other fields of application.²⁰⁰⁵

Process	Variables	Time	
		Day	Year
Weather and Climate Damaging frost Precipitation Evaporation ENSO	Air temperature at 0 and 2 m levels Intensity, wind velocity mm/day or mm/year Atmospheric pressure, Water temperature	≤ 1 ≤ 1 ≤ 100	
Drought cycles Ice Age	Glacial extent, air temperature		10 ≥ 300
Hydrological Cycle Flood Spring ice breakup Snowmelt Glacier	Discharge, stage, snow cover Stage Discharge, stage, snow cover Altitude	≤ 10 10 ≤ 100	10
Biosphere/Ecosystem Burning Crop planting, harvesting Recovery of temperate climate forest Recovery of damaged tundra or desert	Biomass density Height, species composition Species composition	≤ 100	1 300 300

Table 549: Durations of events of significance to BAHC

A further extension of spatial and temporal scales (besides atmospheric sciences) for modeling hydrological and ecological phenomena (moisture and energy fluxes at the soil-vegetation-atmosphere interface) was proposed by A. Becker. His definition is being used for the modeling of BAHC (Biospheric Aspects of the Hydrological Cycle) data, an IGBP core

2004) I. Orlanski, “A Rational Subdivision of Scales for Atmospheric Processes,” Bulletin American Meteorological Society, Vol. 56, No. 5, May 1975, pp. 527-530

2005) Sellers, et al., “Remote Sensing of the Land Surface for Studies of Global Change: Models-Algorithms-Experiments,” Remote Sensing of the Environment, Vol. 51, 1995, pp. 3-26

project. The scale definition of I. Orlanski for the atmospheric sciences and meteorology is basically adopted in this presentation, as outlined in Figure 396 and Table 549, while the scales for hydrology and ecology are generally an order of magnitude smaller than those for the atmospheric sciences. 2006) 2007)

O.14 On-Orbit Electric Propulsion

Since about the mid-1990s a new era of satellite propulsion technology is upon us with the introduction of on-orbit electric propulsion (EP) systems. Recent technology advances are mainly due to progress in the field of orbital energy supplies. The requirement of longer operational life times of orbital systems is also a design driver. - The EP technology provides higher specific impulse (Isp) than conventional chemical propulsion, however, at the expense of lower performance (i.e. much lower thrust levels). Typical EP systems provide spacecraft accelerations of 0.001 g or less. This implies that EP devices must thrust for much longer periods of time than a higher thrust (chemical) device to provide a given impulse. Some advantages/capabilities which make EP systems desirable for many tasks other than launching satellites. (2008) (2009) (2010)

- Provision of platform attitude maintenance. A considerable improvement of spacecraft pointing accuracy can be achieved.

2008) D. F. Robertson, "Electric Propulsion: Here at Last," Space & Communications, May-June 1997, pp. 11-15

2009) S. Ashley, "Electric rockets get a boost," Mechanical Engineering, December 1995, pp. 61-65

2010) G. Saccoccia, J. Gonzalez del Amo, D. Estublier, "Electric Propulsion: A key Technology for Space Missions in the New Millennium," ESA Bulletin, No 101, Feb. 2000, pp. 62-71

- Raising of a satellite's orbit. This may either extend a mission's life considerably, or it may provide a capability of achieving a new orbit altogether (from LEO to GEO).
- Orbit repositioning and maneuvering (station-keeping, etc.). Flexibility for unanticipated maneuvering.
- Considerable reduction in propulsion system wet mass. Advanced EP systems offer a considerable reduction in mass.
- On-board safety is improved through the elimination of hazardous fuels (inert propellants can be used with EP systems).
- For microsatellites the benefits of simplicity and economy of a particular EP system can even outweigh the higher performance of another type EP system.
- Electric propulsion provides low thrust levels for extended periods - months, or even years - resulting in considerable final velocities. Motors may be developed to propel a microsatellite from a LEO orbit into an interplanetary trajectory.

O.14.1 Basic Thruster Concepts

All EP systems generate thrust by using electrical energy (from on-board solar arrays, a nuclear reactor, or batteries) to accelerate a propellant, thereby converting it to spacecraft kinetic energy. There are three basic classes of thruster technologies (differing mainly in the type of acceleration mechanism). But prior to venturing into these thruster classes, a definition of specific impulse is due.

O.14.1.1 Specific Impulse (Isp)

In the International System of Units [SI], the unit of **specific impulse (Isp) is newton-seconds per kilogram or Ns/kg**. Hence, Isp is the impulse (a force applied for a second) exerted with 1 kg of propellant. It follows that the higher the specific impulse, the greater the performance of the engine and the less propellant required. The numerical value of the specific impulse also corresponds to the effective exhaust velocity (**m/s**) of the gas exiting the thruster in a vacuum.

Classical chemical thrusters have a low specific impulse (in the order of 3,000 Ns/kg, with gases ejected at 3,000 m/s) which entails the need for considerable quantities of propellant. Electric thrusters eject their particles at very high speed (15,000 - 100,000 m/s). Hence, their Isp of 15,000 to 100,000 Ns/kg can be 5 to 30 times greater than a conventional thruster.

In the United States, the Isp is widely expressed in units of pound-thrust per pound-weight per second, with a remaining unit of "seconds for" Isp. When comparing these "Isp second" values with those of the SI system, then the "Isp second" values have to be multiplied by the factor 9.81 m/s^2 to account for the pound-force to pound-mass ratio and to obtain the unit m/s of the SI system. In this book all Isp values are given in the SI system.

A thrust of $<100 \text{ mN}$ produced by a typical electric propulsion system is equivalent of holding an A4 paper in your hand. But functioning for long periods, such a system can ultimately provide a high velocity increment to a S/C. Electric propulsion thus has many advantages. For instance, half the mass of a typical geostationary telecommunications satellite is propellant. ²⁰¹¹⁾

O.14.1.2 Electrothermal thrusters

The propellant is heated by either an electric arc or a resistance heater (electrical heating through a wall). The hot propellant is then exhausted through a nozzle to produce thrust.

- Arcjets. The system consists of three elements: the engine (two electrodes), the power source and processor, and the propellant subsystem. An arc discharge is sustained be-

tween a cathode and anode that also serves as expansion nozzle. Typical propellants are hydrogen ($I_{sp} = 10,000 - 20,000$ m/s), ammonia, or hydrazine (5000-7000 m/s). Hydrazine arcjet systems have been operating on orbit since 1994, primarily for North-South stationkeeping on geosynchronous communication satellites.

- **Resistojets.** A propellant gas (not plasma) is fed through a resistive heat exchanger prior to expansion through a nozzle. Many propellants can be used, such as: H_2 , CO_2 , CH_4 , N_2H_4 , NH_3 , N_2 , He, Ar, H_2 , and H_2O . Typical thrusts are between several mN to several N (at efficiencies of up to 80%).
- **RF-heated thruster.** Use of radio-frequency waves to heat a plasma in a chamber.

ATOS (Arcjet Thruster on OSCAR Satellite).²⁰¹² ATOS is an example of an arcjet implementation developed at IRS (Institute for Space Systems) of the University of Stuttgart, Germany. The system consists of the arcjet thruster, the fuel supply unit and the power supply electronics. The power supply transforms the 28 VDC from the satellite power bus into the 800 W maximum current regulated arcjet power. The fuel supply unit regulates the flow of gaseous ammonia from the two fuel tanks to the thruster. Its ammonia resistant valves and ammonia vaporizer were supplied by a Russian space company. ATOS is flown on the AMSAT Phase 3D spacecraft, launched Nov. 15, 2000 from Kourou (AMSAT-3D and the STRV-1c/d satellites were secondary payloads to the PanAmSat-1R communication satellite). ATOS, with an energy input of 750 W, is an ammonia arcjet with a specific impulse I_{sp} of 4600 m/s and a thrust level of 115 mN.

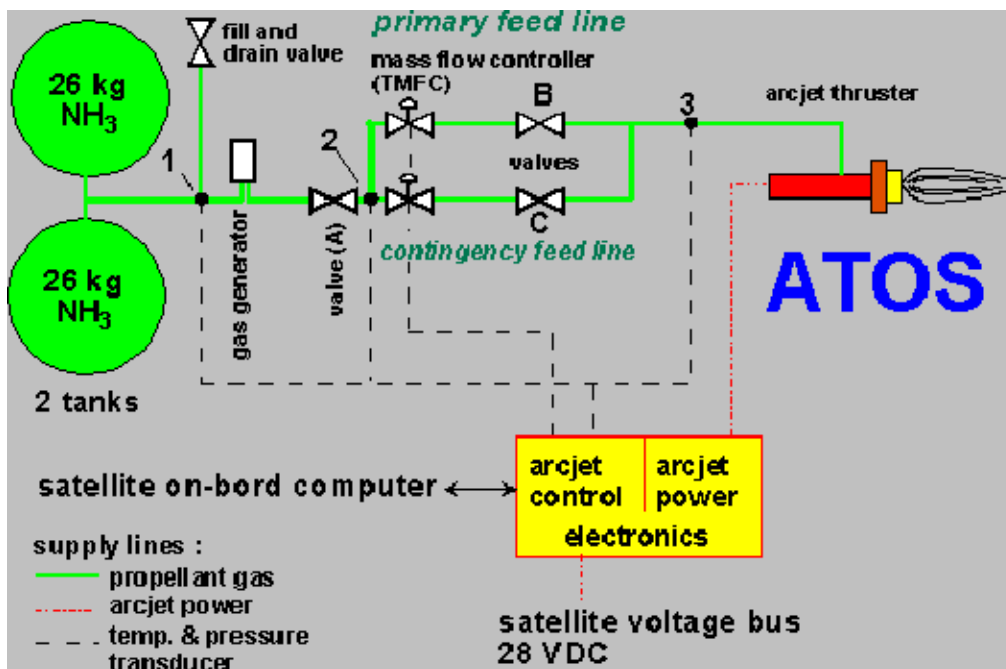

Figure 397: Schematic illustration of the ATOS system

O.14.1.3 Electrostatic thrusters

Use of electric fields to accelerate an ionized gas. This class has the following members: the ion engine, Hall-effect thrusters, and field-emission thrusters.

- **Gridded ion engines (or the ion thruster).** A gaseous (vaporized) propellant is ionized and accelerated to high exhaust velocity in an electric field. The electric field is created by applying high voltages between a series of electrically charged grids. The ions are then neutralized and leave the engine as high velocity neutral particles. Early ion engines used mercury or cesium for fuel, while newer designs use argon, krypton, or xe-

non. The Isp of the xenon ion engine is about 30,000 m/s at 0.5 kW input power with 55% thrust efficiency.

- Hall-effect thrusters (free electron drift propulsion).²⁰¹³⁾ The axial electric field developed between the discharge electrodes interacts with the radial magnetic field to generate a “Hall” current in azimuthal direction. This current, in turn, reacts against a magnetic field to generate a force on the propellant in the downstream direction. Isp from 10,000 - 20,000 m/s; lifetimes of 6000 hours have been achieved by Russian-built motors.
- Field-emission thrusters. Provision very low thrust levels (from 1 μN - 2 N) with very high accuracy and controllability (Isp from 60,000 - 100,000 m/s). In FEEP thrusters, ions are directly extracted from the liquid phase of the propellant. Thrust is obtained by exhausting a beam, mainly composed of singly-ionized atoms, produced by field emission.

O.14.1.4 Electromagnetic thrusters

In electromagnetic propulsion, thrust is generated by accelerating an ionized plasma or a conducting fluid (such as liquified Teflon) by electromagnetic fields.

- Pulsed Plasma Thruster (PPT). A PPT is an electromagnetic device which utilizes a high current discharge to ablate a solid propellant (such as Teflon) and accelerates the ionized material (plasma) through a nozzle (exhaust velocities of 10-20 km/s are obtained). A key advantage of PPTs is their extremely short pulse time (two orders less than chemical thrusters) which translates to more precise control for attitude and station-keeping maneuvers. Isp = 10,000-20,000 m/s. ²⁰¹⁴⁾
- Stationary Plasma Thruster (SPT). The SPT design represents a synthesis of Hall ion thruster and MPD thrusters. Plasma is being generated by a discharge of electrons from a ring-like discharge chamber and a magnetic field. A voltage applied to the anode causes the ions to accelerate. Thrusts between 40 and 200 mN may be obtained (Isp is about 16,000 m/s at 1.4 kW input power with 50% thrust efficiency).

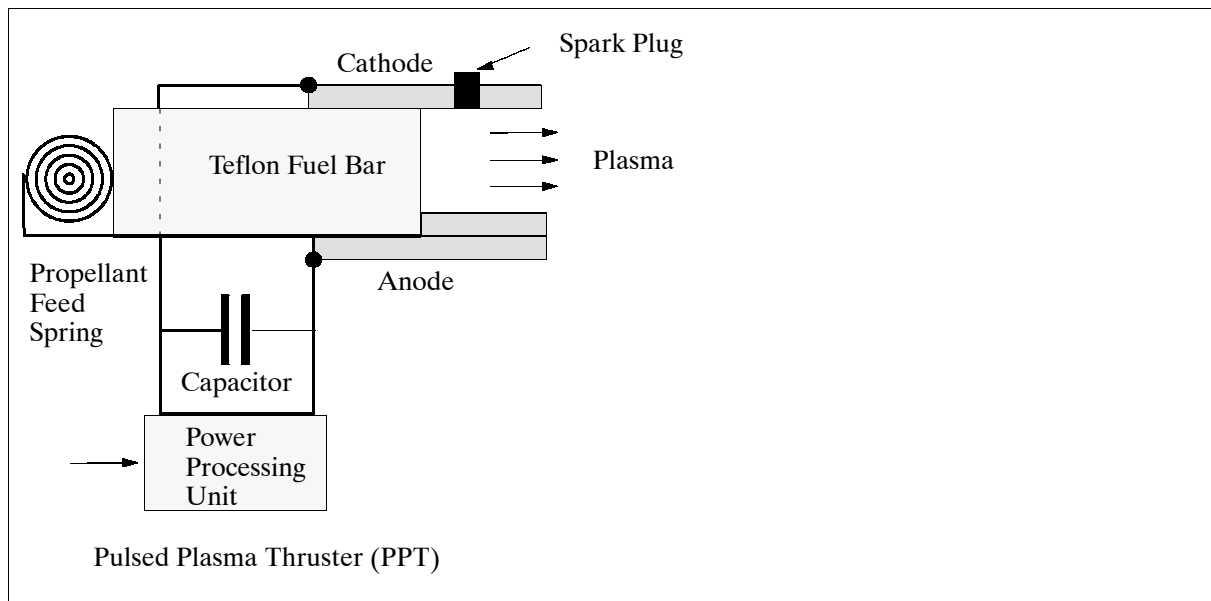

Figure 398: Schematic illustration of a PPT system

²⁰¹³⁾ The ‘Hall effect’ refers to the development of a transverse electric field in a solid material when it carries an electric current and is placed in a magnetic field that is perpendicular to the current. The electric field, or Hall field, is a result of the force that the magnetic field exerts on the moving positive and negative particles that constitute the electric current. This phenomenon was discovered in 1879 by E. H. Hall, a US physicist.

²⁰¹⁴⁾ R. J. Cassady, et al., “Pulsed PLasma Thruster Systems for Spacecraft Attitude Control,” Proceedings of the 10th Annual AIAA/USU Conference on Small Satellites, Sept. 16-19, 1996

- Magneto Plasma Dynamic (MPD) thruster. The MPD device utilizes the Lorentz²⁰¹⁵⁾ force arising from the interaction of discharge current with self-induced and/or an applied magnetic field.

Operation: Xenon gas flows at 3 mg/s into the ionization chamber through an annular plenum. The xenon atoms are ionized with energetic electrons emitted from a thermionic hollow cathode. The cathode filament emits electrons that are accelerated toward the chamber wall by a high positive-wall potential. In addition, a magnetic field is applied by concentric magnets, to increase the likelihood of electron-atom collisions. The magnetic field causes the electrons to spiral toward the walls, increasing travel time. The collisions produce a plasma equal in number of positive ions and negative electrons.

The positive ions in the plasma flow toward the extraction electrodes where they are accelerated by the negative grid potential. The grids create thousands of beamlets as the ions pass through the screens. The continuous ejection of positive ions requires neutralization to prevent gradual vehicle charging. The ion engine is controlled (throttled) by reducing the propellant mass flow.

	Resistojet	Arcjet	SPT	Ion Thruster
Propellant	N ₂ H ₄	N ₂ H ₄	Xenon	Xenon
Input electric power (kW)	0.2 - 0.8	0.5 - 2.0	0.15 - 1.5	0.4 - 2.0
Thrust (mN)	200 - 800	200 - 250	40 - 200	15 - 40
Specific Impulse, Isp (m/s)	2,700 - 3,000	4,500 - 6,000	16,000	28,000 - 35,000
Efficiency	0.9	0.33	0.48	0.75
Mission life (hours)	>390	>830	>4000	>8000

Table 550: Typical performance values of some electric propulsion systems

O.14.2 Some Developed Thruster Systems

IPS (Ion Propulsion System), developed by the NSTAR (NASA SEP Technology Application Readiness) team, where SEP is the acronym for Solar Electric Propulsion. NSTAR is a NASA technology demonstration program the started in 1992.; the prototype system was developed jointly at LeRC and JPL (IPS was built at Hughes Electronics Corp.). Note: The IPS system is also referred to as **NSTAR**. IPS is an ion engine (electrostatic thruster), consisting of three main components: the ion source, the ion accelerator, and the neutralizer.

Parameter	Description
Ion thruster exit diameter	30 cm
Input power range	0.5 - 2.5 kW
Thrust level	20 Nm at 0.5 kW; 92 Nm at 2.3 kW
Isp (specific impulse)	21,000 m/s at 0.5 kW; 30,000 m/s at 2.3 kW
Control	Throttleable in 16 discrete steps to accommodate the available power
Instrument mass	41.3 kg (without propellant)
Propellant mass	75 kg of xenon
Design operating life	8000 hours of full power

Table 551: IPS parameters for DS1

The system uses a hollow cathode to produce electrons to collisionally ionize xenon. The Xe⁺ is electrostatically accelerated through a potential of up to 1280 V and emitted from the 30 cm thruster through a molybdenum grid. A separate electron beam is emitted to produce a neutral plasma beam. The power processing unit (PPU) of the IPS can accept as much as 2.5 kW, corresponding to a peak thruster operating power of 2.3 kW and a thrust of 92 mN. Throttling is achieved by balancing thruster and Xe feed system parameters at lower

²⁰¹⁵⁾H. A. Lorentz (1853-1928) Dutch physicist.

power levels, and at the lowest thruster power, 500 W, the thrust is 20 mN. The specific impulse decreases from 3100 s at high power to 1900 s at the minimum throttle level. The input power of 2.3 kW can be throttled to 0.5 kW. The thruster with an exit plane aperture of 30 cm diameter generates 90 mN of thrust at 1.8 kW input power.

Figure 399: Schematic illustration of IPS

FEEP (Field Emission Electric Propulsion). FEEP is an electrostatic thruster technology capable of delivering very low thrust with very high accuracy and controllability. In FEEP systems a liquid propellant (cesium) is fed to the needle-like emitter; intense local electric fields cause charged liquid droplets to form spontaneously. The charged liquid droplets are extracted from the surface and accelerated by the electrostatic fields.

The thruster can accelerate a large number of different liquid metals or alloys; cesium proved to be the best choice, due to its high molecular weight and its low ionization potential. The power conversion efficiency reaches values as high as 98%. Specific impulse may be easily adjusted to meet the mission requirements. The thrust level is finely tunable, and the instantaneous switching capability permits pulsed mode operation. - FEEP features low system mass and small overall dimensions (absence of moving parts, there are no valves or pressurized gases). The FEEP propulsion concept is very suitable either for drag-free control or for high accuracy, noiseless pointing.

The FEEP concept is known since the late 1970s and was first proposed by ESTEC. Centrospazio of Pisa, Italy with ESA/ESTEC and ASI funding, developed some of the technology. Since FEEP is a generic term, an engine (engineering model) with the name of **RMT** (Radiofrequency with Magnetic field ion Thruster) was developed by Laben, an advanced electrostatic thruster, capable of providing very low thrust levels (from 1 μ N - 2 N) with very high accuracy and controllability (Isp from 60,000 - 100,000 m/s). In FEEP thrusters, ions are directly extracted from the liquid phase of the propellant. Thrust is obtained by exhausting a beam, mainly composed of singly-ionized atoms, produced by field emission. - In the 1990s, the interest in low-thrust propulsion systems generated new research and development efforts in the FEEP technology. It is evident that the potential field of use of this

thruster is not limited to the μN -level drag-free missions, but includes several applications like attitude and orbit control of small spacecraft and mutual positioning control in constellations.

The RMT propulsion system of Laben merged with **EMITS** (Electric Microthruster Test in Space) system of Centrospazio of Pisa, Italy. A demonstration is to be flown on the Shuttle GAS (Get-Away Special) system in 2001.^{2016) 2017)} The EMITS flight experiment includes two thruster assemblies, the thruster power and control electronics (developed by LABEN, Milan, Italy), several probes and diagnostic devices, a battery, and a computerized experiment control/data storage unit (developed by Techno System Developments, Naples, Italy). The total duration of the experiment will be 2 days. During that period, the thrusters will be repeatedly switched on and off and cycled through their operational envelope. The top plate of the EMITS payload is mounted just behind the GAS MDA (Motorized Door Assembly). Once actuated by the Shuttle crew, the MDA exposes to space the following items:

- A 1 mN thruster (70 mm slit length, about 60 W)
- A 30 μN thruster (2 mm slit length, less than 1 W)
- A low power neutralizer, of the thermionic oxide cathode type
- A set of diagnostic devices, including quartz crystal microbalances (QCMs) as propellant deposition sensors, electrostatic ion beam probes, and a pressure gauge.

XIPS (Xenon Ion Propulsion System), built by HSC of Hughes Electronics Corp., Los Angeles, CA (production at Electron Dynamics Division). The instrument consists of the following elements: propellant (xenon) reservoir, a power processing unit, the ion thruster (ionization chamber, gridded electrodes), and a neutralizer. As of 1997 two XIPS versions exist to serve the HS-601 and HS-702 communication satellite platforms, designed for 12 to 15 years of operation. SATMEX-5, a communications S/C of Mexico (built by Hughes with an HS-601 bus), was launched Dec. 6, 1998 from Kourou equipped with XIPS for station keeping. SATMEX-5 is operated by Satellites Mexicanos S.A. de C. V.

Thruster	Nozzle diameter	Isp	Thrust	Power Input
HS-601 HP	13 cm	25,000 m/s	18 mN	0.5 kW
HS-702	25 cm	37,000 m/s	165 mN	4.5 kW

Table 552: XIPS thruster parameters

A typical satellite is furnished with four XIPS thrusters (two primary, two redundant) for stationkeeping and S/C momentum control, all connected to the same xenon reservoir. The autonomous XIPS operations provide stationkeeping within $\pm 0.005^\circ$ limits. The XIPS model HS-702 offers in addition the option of orbit raising. The XIPS model was first flown on two commercial GEO communication satellites (HS-601 platforms) for PanAmSat Corp. of Greenwich, CT: PanAmSat-5 (PAS-5), launched July 30, 1997, then on Galaxy VIII-i, launched on Dec. 8, 1997.

RIT-10 (Radio-frequency Ion Thruster), also referred to as **RITA** (Radio-frequency Ion Thruster Assembly). An electric propulsion system of Astrium GmbH (formerly DASA), Germany. RIT systems are in the category of gridded ion engines. The xenon propellant flows inside a ceramic discharge chamber through a gas distributor. The discharge chamber itself is surrounded by an induction coil connected to an RF (Radio Frequency) generator. Free electrons within the xenon gas collect energy from the RF-induced electric field and ionize the neutral propellant atoms via inelastic collisions. The discharge is ignited by the injection of electrons from the neutralizer. Thrust is generated by the acceleration of ions in the electrostatic field applied to an extraction system consisting of the extraction anode and grids. The negative potential of these grids accelerates the positive ions out of the stat-

ic plasma. A neutralizer injects electrons into the beam to maintain its zero-charge equilibrium. 2018) 2019)

The RIT-10 system was successfully test-flown on-board the EURECA-1 platform (launch July 31, 1992 - retrieval July 1, 1993). Since then, four more RIT thruster models were designed/built at DASA or are in an advanced development phase:

- The RIT-10 thruster for ARTEMIS has a beam diameter of 9.8 cm and delivers 15 mN thrust with an Isp of 34,000 m/s and a system power of 560 W. The system provides 15,000 hours of operation at 15 mN.
- The further developed RIT-10 EVO (Evolution) thruster provides a maximum thrust of 35 mN (adjustable from 1 to 35 mN) at an Isp between 28,500 m/s and 44,000 m/s. A special beam controller was developed for this thruster, permitting thrust adjustment for air drag compensation purposes between 1 and 12 mN at a resolution of 25 μ N at a response time of 0.05 s.

Figure 400: Schematic illustration of the RIT system

- The RIT-XT extended power thruster has a beam diameter of 206 mm and provides an adjustable thrust from 25 to 150 mN at an Isp between 28,500 m/s and 55,000 m/s. The input power for 100 mN is 2800 W for an Isp = 30,000 m/s. The objective is to provide sufficient power for orbit raising applications of small satellites in LEO constellations.
- The ESA-XX thruster (breadboard model as of 2000) is a radio frequency thruster built by DASA with an extraction grid built by AEA-Culham, UK. The ESA-XX has a beam diameter of 280 mm and was tested at thrust levels between 21 and 240 mN at an Isp of up to 53,000 m/s. The input power for 240 mN at maximum Isp is 8450 W. 2020)
The ESA-XX thruster is a synergy of two European ion propulsion technologies, combining the discharge chamber of the RF ion thruster (RIT-35), with the extraction grid system of the EIT (Electron-bombardment Ion Thruster), the UK-25 system.

Table 553: Performance comparison of various RIT models

UK-10 (Electron Bombardment Ionization Thruster) IPS, also referred to as **EITA** (Electron-bombardment Ion Thruster Assembly). UK-10 is an ion engine system mainly developed by DERA, UK. The UK-10 provides a nominal thrust of 18 mN and a maximum thrust of 23 mN at an Isp of 33,000 m/s. The input power is 700 W. ²⁰²¹⁾

In the electron-bombardment-ionization scheme (Figure 401), the xenon propellant flows inside a metallic discharge chamber through a gas distributor. This gas is ionized in a DC discharge between the cathode and a concentric cylindrical anode. The efficiency of the process is enhanced by the application of an azimuthally symmetrical divergent magnetic field to the discharge chamber, generated by solenoids spaced around the periphery. Thrust is generated by the acceleration of ions in the electrostatic field applied to an extraction system (grids). The negative potential of the grids accelerates the positive ions of the static plasma. Ion beam velocities of 30-50 km/s are achieved. A neutralizer injects electrons into the beam to maintain zero-charge equilibrium in the beam.

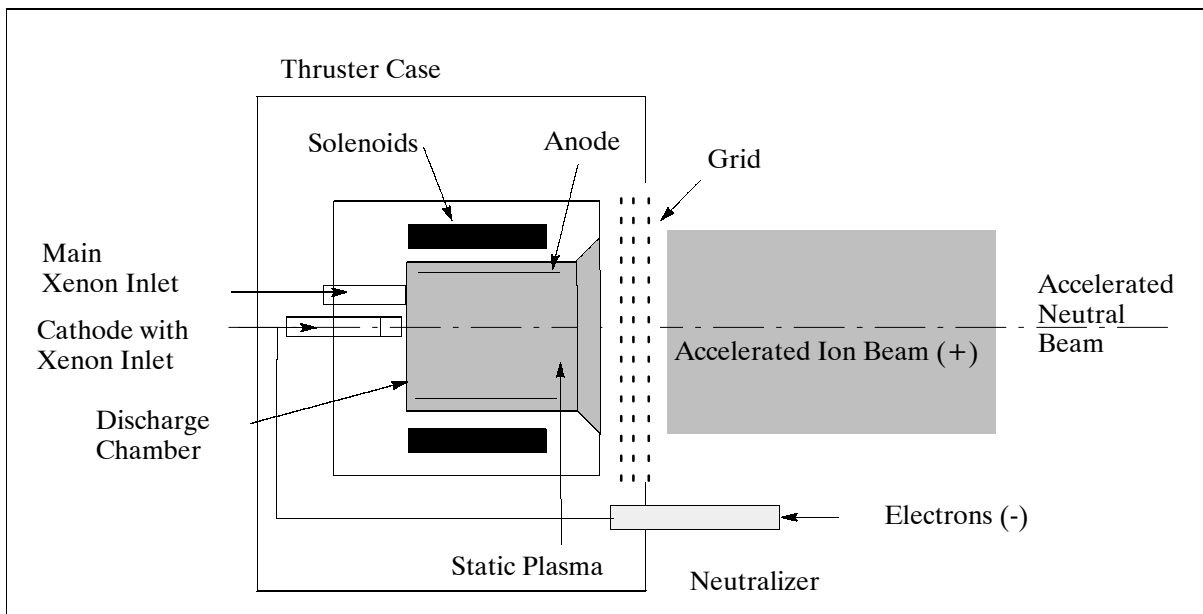

Figure 401: Schematic illustration of the UK-10 system

Parts of the UK-10 ion engine were successfully operated in space for the first time on STRV-1b (launch June 17, 1994) of DERA and used to conduct experiments associated with plasma discharging.

- The UK-10 ion propulsion system (IPS) is based on the 10 cm nominal diameter T5 thruster, coupled with PCCE (Power Conditioning and Control Equipment) and

²⁰²¹⁾ D. G. Fearn, P. Smith, "A Review of UK Ion Propulsion - A Maturing Technology," IAF-98-S.4.01, Sept/Oct. 1998, pp. 1-11

PSME (Propellant Supply Monitoring Equipment). The PCCE mass is about 12 kg, the PSME mass is 1.6 kg. The total input power at 18 mN thrust is 570 W. The initial application of the IPS is for ESA's ARTEMIS satellite.

- UK-25 IPS. The thruster is intended for such applications as orbit-raising and other transfer maneuvers. The design is very similar to the T5 configuration, featuring a 25 cm exit diameter. The thrust can be varied from 50 to 300 mN, requiring an input power of up to 10 kW at maximum thrust.

ESEX (Electric Propulsion Space Experiment). ESEX (built by TRW and supported/managed by Phillips Laboratory of USAF) demonstrates high-power ammonia arcjet propulsion technology (reliable arcjet thruster operation, power input = 26 kW) for orbit transfer, maneuvering capability, and attitude adjustment.

EPDM (Electric Propulsion Demonstrator Module). EPDM (sponsored by BMDO, managed and built by NRL in cooperation with NASA/GRC and TsNIIMASH) is flown on the STEX (Space Technology Experiment) mission of DoD (launch Oct. 3, 1998). EPDM is the first operational Hall thruster propulsion system of the USA. It's heritage is from the **RHETT** (Russian Hall Effect Thruster Technology) program of BMDO. The TAL-D55 (Thruster with Anode Layer) Hall effect thruster used in EPDM was developed by the Russian Central Research Institute of Machine Building (TsNIIMASH) in Korolev, Russia. The objective is to provide orbit-raising and stationkeeping for the spacecraft. EPDM features a 600 W, 15,000 m/s Isp xenon Hall thruster system, providing 40 mN of thrust. It consists of four subassemblies: ²⁰²²⁾

- XFS (Xenon Flow System). XFS is a high-pressure storage system with regulated pressure and mass flow. The xenon is stored in a 20 cm spherical tank at a pressure of 64 kg/cm². Two solenoid valves upstream of the pressure regulator control the flow. A high-pressure transducer accurately determines the amount of xenon remaining. Thermostatically controlled heaters provide thermal conditioning. The mass of XFS is 5.7 kg (dry).
- PPU (Power Processing Unit) built by Primex Aerospace Co of St. Petersburg, FL. PPU consists of five separate but interrelated power supplies. The anode supply provides a regulated 300 V to the TAL-D55 thruster. The PPU has an electrical conversion efficiency of about 90% with an input voltage of 30 V. The 65 W of waste heat is dissipated through the baseplate of the unit, and the spacecraft rejects it to space. The mass of PPU is 10.3 kg.
- AIU (Auxiliary Interface Unit). Conditions discrete commands and telemetry (analog and discrete) and provides thermal conditioning of the XFS, the engine assembly, and XFS valve drivers. The AIU changes pulsed discrete commands into steady-state commands required by the PPU. An electronic thermostat accurately controls the temperature of the orifice heaters in the xenon flow system. The mass of AIU is 1.9 kg, it consumes an average of 6 W.
- EA (Engine Assembly). It consists of the TAL-D55 thruster which has a nominal discharge of 1.35 kW at 300 V. In flight, the engine is used at 600 W of thrust (limited by the spacecraft's power). The thruster is mounted on top of a titanium thermal isolator to minimize the conductive heat path back to the spacecraft. The engine and isolator are mounted on a small aluminum honeycomb panel along with the orifice block and the cathode assembly. The orifice block splits the flow of the low-pressure xenon between the TAL-D55 thruster and the cathode. Precision orifices and tight temperature control on the orifice block itself maintain the accurate single point mass flow setting. During system operation, a set of stored spacecraft commands is executed to initialize and thermally condition the system, and to fire the thruster.

SPT (Stationary Plasma Thruster), developed by the Fakel Design Bureau in Kaliningrad, Russia [since 1992, a joint venture with the name of IST (International Space Technology,

Inc.) was formed with Atlantic Research Corp. of Gainesville, GA, USA]. Stationary plasma thrusters (Hall-effect thrusters) operate by ejecting xenon ions, accelerated and focused by electrical and magnetic fields, at very high speed.

Instrument Type	SPT-70	SPT-100	PPS-1350	SPT-140
Thrust (max)	40 mN	80 mN	70 mN	320 mN
Input power	750 W	1350 W	1350 W	4500 W
Applications	Over 60 systems in service on Russian S/C as of 1998	24 systems in service on Russian S/C	Under development	Under development

Table 554: Performance parameters of some SPT instrument types

The **PPS-1350** system is a Hall-effect thruster developed by SNECMA of Paris, France (thruster) and ETCA of Belgium (power processing unit). PPS stands for “Propulseur Plasmique Stationnaire,” or Stationary Plasma Thruster, and 1350 is the nominal input power. The system uses xenon gas as propellant to provide a thrust of 70 nN. The first PPS-1350 system is scheduled to fly on the Astra-1K communication satellite of SES of Luxembourg (launch in 2001) for GEO station keeping. The Skybridge broadband mobile communication LEO satellite constellation of ASI (Alcatel Space Industries) uses also PPS-1350 thrusters.

Thruster Model	Category	Manufacturer	Status
PPS-1350	Electrostatic, Hall-effect	SEP, France	Qualified for GEO station keeping and LEO S/C
ROS-99	Electrostatic, Hall-effect	Matra Marconi Space (MMS), UK, France	Qualified for GEO S/C station keeping
HPHET	Electrostatic, Hall-effect	Matra Marconi Space (MMS), UK, France	Developed for orbit transfer of GEO and LEO S/C, qualification in 2001
RIT-10	Electrostatic, gridded ion engine	DASA, Germany	Under qualification for GEO S/C station keeping (2000)
T5	Electrostatic, gridded ion engine	MMS, UK	Under qualification for GEO S/C station keeping (2000)
T6	Electrostatic, gridded ion engine	DERA, UK	Engineering model for GEO station keeping
RMT	Electrostatic, gridded ion engine	Laben-Proel, Italy	Engineering model
RIT-15	Electrostatic, gridded ion engine	DASA, Germany	Advanced breadboard
ESA-XX	Electrostatic, gridded ion engine	DASA, Germany, AEA, UK	Breadboard
FEPP / EMITS	Electrostatic field emission	Centrosazio, Italy	System ready, flight qualification in 2000
Indium LMIS	Electrostatic field emission	ARC (Austrian Research Center), Austria	Breadboard
Ammonia arcjet	Electrothermal	IRS, Germany	Qualified for Amsat P3-D
Hydrazine arcjet	Electrothermal	FIAT-Avio	Engineering model
MPD thrusters	Electromagnetic	Centrosazio, Italy, IRS, Germany	Laboratory models

Table 555: European developments in electric propulsion (table from reference 2010)

HPHET (High-Power Hall-Effect Thruster), an ESA/industry co-funded development designed and built by MMS and its subcontractors (DERA, Centrosazio). The system is in the 3 kW class.

O.15 Summary of World Data Centers (WDCs)

The ICSU (International Council of Scientific Unions) Panel on World Data Centers (Geophysical, Solar & Environment) was established at its 12th General Assembly in 1968. The

Panel oversees the operation of about 40 WDCs, which are maintained by their host countries and are responsible for collecting, archiving, exchanging, and distributing a wide range of data. These data provide baseline information for research in many ICSU discipline, especially for monitoring changes in the geosphere and biosphere.²⁰²³⁾

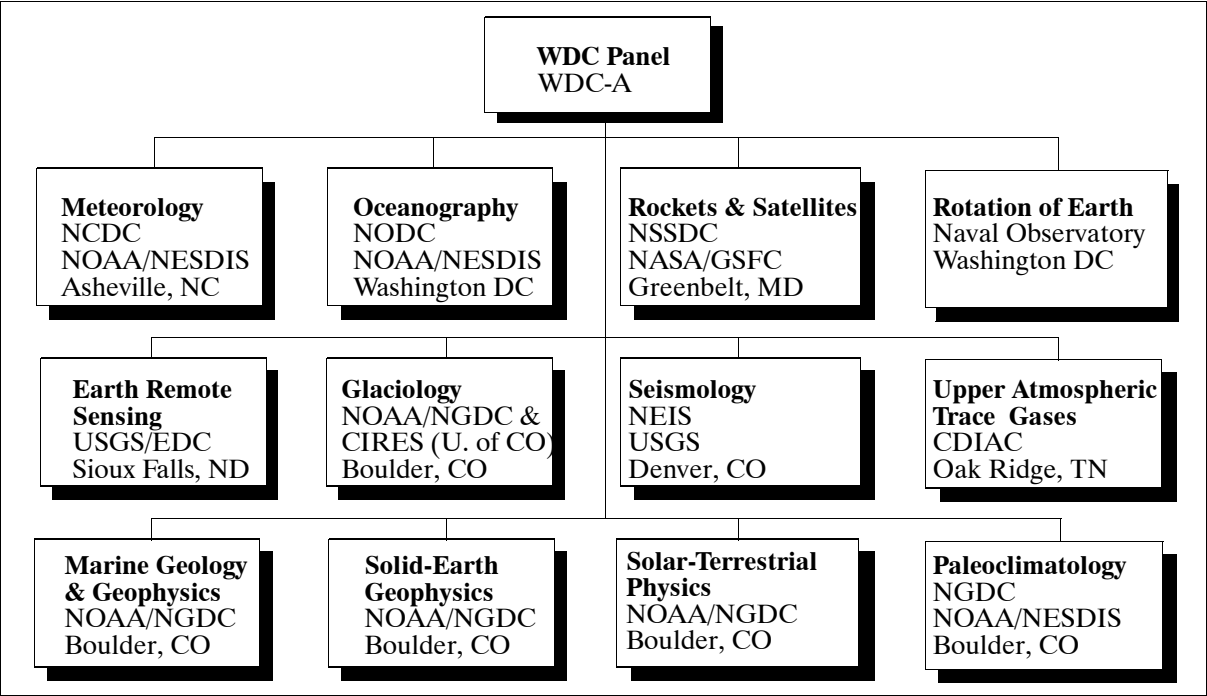

Figure 402: Structure of World Data Center A (USA)

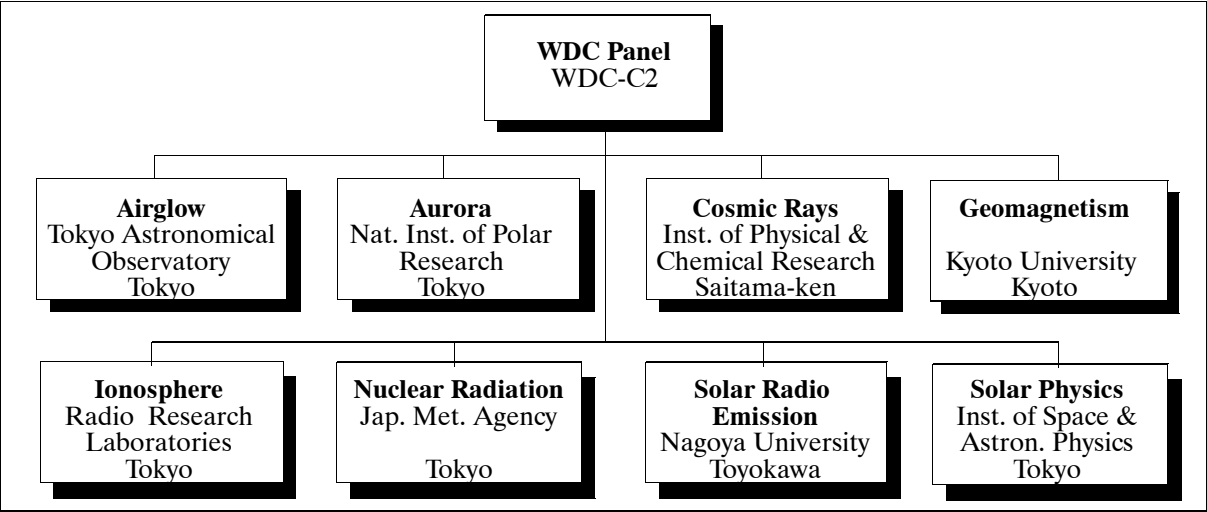

Figure 403: Structure of World Data Center C2 (Japan)

The WDC system is funded by the national host countries and grouped as follows:

WDC-A in the USA	WDC-B in Russia and CIS
WDC-C1 in Europe	WDC-C2 in Japan
WDC-D in China	

Table 556: Overview of WDC locations

O.16 Committee on Earth Observation Satellites - CEOS

CEOS was created in 1984 as a result of the international Economic Summit of Industrialized Nations (G-7 Versailles Summit of 1982) and serves as the focal point for international coordination of space-related, Earth observation activities.²⁰²⁴⁾

Policy and technical issues of common interest related to the whole spectrum of Earth observation satellite missions and data received from such are addressed. CEOS encourages complementarity and compatibility among spaceborne Earth observing systems through coordination in mission planning, promotion of full and nondiscriminatory data access, setting of data product standards, and development of compatible products, services, and applications. The user community benefits directly from this international coordination.

Members are those national and international government agencies with funding and program responsibilities for a satellite Earth observation program currently operating or in the later stages of system development. CEOS members include (1995): ASI (Italy), BNSC (United Kingdom), CAST (China), CNES (France), CSA (Canada), CSIRO (Australia), ESA and EUMETSAT (Europe), DARA (Germany), INPE (Brazil), ISRO (India), NASA and NOAA (USA), NRSCC (China), NSAU (Ukraine), RKA and ROSHYDROMET (Russia), SNSB (Sweden), STA (Japan).

Governmental entities with a space-based Earth observation program in the early stages of development or with significant ground segment activity that supports CEOS member agency programs may be invited to participate as observers. Current (1995) observers are: BOST (Belgium), CCRS (Canada), CEC (Commission of the European Communities), CRI (New Zealand), and NSC (Norway).

²⁰²⁴⁾L. Moodie, "Committee on Earth Observation Satellites (CEOS)," CEOS Newsletter No. 1, Summer 1993

Affiliate members of CEOS are: International Council of Scientific Unions (ICSU), France; International Geosphere-Biosphere Program (IGBP), Sweden; Intergovernmental Oceanic Commission (IOC), France; World Climate Research Program (WCRP), Switzerland; World Meteorological Organization (WMO), Switzerland; United Nations Environment Program (UNEP), Kenya; Global Climate Observing System (GCOS), Switzerland; Global Ocean Observing System (GOOS), France.

The CEOS plenary meets once a year. There are two working groups, each with four active subgroups as illustrated in Figure 407. The chairmanship of the working groups and subgroups is indicated.

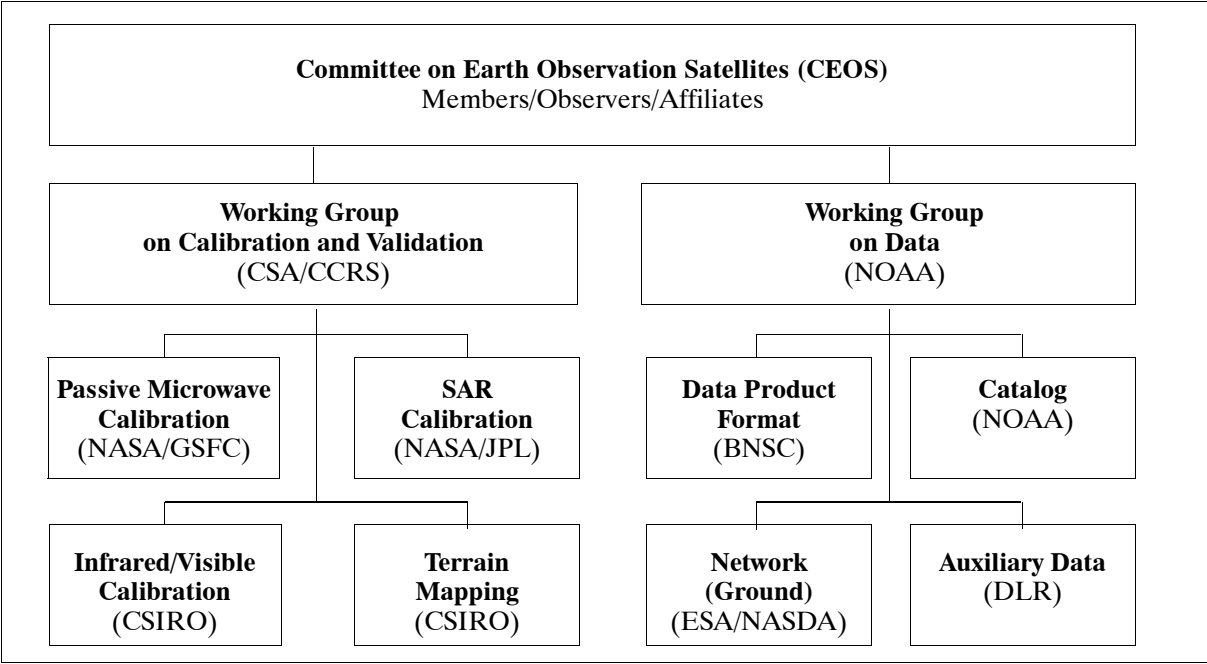

Figure 407: CEOS working group structure

Name of Launch Site	Resp. Organization (Country)	Location	Remarks
Baikonur Cosmodrome (Tyuratam Leninsk)	CIS (Kazakhstan)	45.6° N, 63.4° E	since 1957, launch of manned S/C, interplanetary S/C and geostationary S/C
Plesetsk (northern Cosmodrome)	Russia/CIS	62.8° N, 40.1° E	since 1966, launch of polar orbiting satellites
Kapustin Yar (Volgograd Cosmodrome)	Russia/CIS	48.4° N, 45.8° E	since 1962, launch of small satellites and interplanetary space probes
Cape Canaveral Air Force Station (CCAFS), FL	USAF/NASA (USA)	28.5° N, 80.0° W	since 1958, launch of manned S/C, interplanetary S/C, GEO satellites, etc.
Kennedy Space Center, FL	NASA (USA)	28.5° N, 80.0° W	since 1967, Complex 39 (launch of Saturn V vehicle, adapted to launch the Shuttle)
Vandenberg AFB, CA	USAF/NASA (USA)	34.4° N, 120.35°W	since 1959, launches of S/C into polar orbit
Vandenberg AFB, CA Commercial spaceport	Spaceport Systems International L.P.	34.4° N, 120.35°W	since 1998 (a joint venture of ITT Industries and CA Commercial Spaceport Inc.) launches of S/C into polar orbit
Wallops Island, VA	NASA/GSFC WFF (USA)	37.8° N, 75.5° W	since 1961, launch of sounding rockets and Scout launcher for small satellites, commercial launches since 1997
Edwards AFB, CA	USAF (USA)	35.0° N 118.0° W	Space Shuttle returns since 1981
Tanegashima Kagoshima Space Center	ISAS, U. of Tokyo, (Japan)	31.2° N, 131.1° E	since 1970, launch of scientific satellites
Tanegashima Space Center (TNSC)	NASDA (Japan)	30.4° N, 131.0° E	since 1975, launch site for scientific and commercial satellites
SHAR Sriharikota	ISRO (India)	13.9° N, 80.4° E	since 1980, launch of ISRO satellites
San Marco Platform (off the coast of Kenya)	CRA, U. of Rome (Italy)	2.9° S, 40.3° E	since 1967, launch of Scout rockets for NASA/ASI
Guiana Space Centre Kourou (Fr. Guiana)	CNES/ESA	5.2° N, 52.8° W	since 1970, launch of scientific and commercial satellites
Woomera Range	WRE (Australia)	31.1° S, 136.8° E	since 1967, launch of sounding rockets since 1999, launch of LEO S/C (Kistler)
Jiuquan SLC	China	40.6° N, 99.9° E	since 1970, launch of experimental satellites
Xichang SLC	China	28.25° N, 102.0° E	since 1984, launch of satellites into geost. and polar orbits
Taiyuan/Wuzhai	China	37.5° N, 112.6° E	since 1988, launches of CZ-4A and -4B into polar orbits for remote sensing
Esrangle, Kiruna	SSC (Sweden)	67.9° N, 21.0° E	launch of sounding rockets and balloons
Alcántara Launch Center	CTA/INPE (Brazil)	2.3° S, 44.4° W	in preparation for satellite launches
Palmachim/Yavne	Israel	31.5° N 34.5° E	since 1989, launch of LEO satellites into westward direction (Ofeq series)
Svobodny Cosmodrome	Russia	51.4° N, 128.3° E	since 1996, Start-1 launcher (Zeya, etc. EarlyBird)
Sea Launch	Partnership of Boeing Co. USA, Yuzhnoye, Ukraine RKK Energiya, Russia, and Kvaerner Maritima A.S. Oslo, Norway	Pacific Ocean	since March 27, 1999, inaugural launch of two-stage Zenit (Zenit-3SL and Zenit-2) rockets of the Yuzhnoye Design Bureau. The first commercial launch was on Oct. 9, 1999. The Sea Launch home port is Long Beach, CA for the command ship and launch platform
Poker Flat Research Range (PFRR), AK	University of Alaska (USA)	65.117° N 147.60 W	since 1968 rocket launch facility (auroral and meteorological research), located about 50 km north of Fairbanks
Kodiak Launch Complex on Kodiak Island, AK	Alaska Aerospace Development Corporation	57.445° N 152.34°W	The first launch is scheduled for Aug. 2001, PICOSat of AFRL, Athena 2 vehicle (along with Starshine).

Table 557: Coordinates of satellite launch sites around the world

O.17 Space Shuttle Mission Chronology

The following table contains brief information on all Shuttle flights with regard to orbits, launch/landing dates, orbiter type, and payload complement. ²⁰²⁵⁾ ²⁰²⁶⁾ ²⁰²⁷⁾ ²⁰²⁸⁾ All payload abbreviations are defined in Appendix B (Acronyms and Abbreviations) starting with page 1393; however, no descriptions are given for these Shuttle payloads (which is beyond the scope of this book). The interested reader may consult the corresponding NASA home-pages on internet.

Note: Following STS-9 (Space Transport System) the flight numbering system was changed. Thus, the next flight, instead of being designated STS-10, became STS 41-B. The new numbering system was supposed to be more specific; the first numeral stood for the fiscal year of the launch, the “4” for 1984. The second numeral represented the launch site, 1 for KSC, and 2 for VAFB. The letter “B” designated the launch in the fiscal year. Following the Challenger accident (Jan. 28, 1986) NASA reestablished the original numbering system.

Mission Incl., Alt.(km)	Launch/ Landing Date	Orbiter	Mission Highlights / Payload Complement
Legend: I = Inclination (°) A = Nominal Altitude (km)			
STS-1 I:40.3°, A:307	12. April 1981 14. April 1981	Columbia	Major systems tested, orbiter sustained tile damage
STS-2 I:38°, A:290	12. Nov. 1981 14. Nov. 1981	Columbia	OSTA-1 payload (including SIR-A, MAPS, OCE, SMIRR), see chapter J.19
STS-3 I:38°, A:272	22. Mar. 1982 30. Mar. 1982	Columbia	Get Away Special (GAS), Spacelab pallet mounted, OSS-1 payload, MLR, EEVT, HBT, SSIP
STS-4 I:28.5°, A:364	27. June 1982 4. July 1982	Columbia	DoD Payload, Get Away Special (GAS), CFES, MLR, IECM, SSIP
STS-5 I:28.5°, A:340	11. Nov. 1982 16. Nov. 1982	Columbia	ANIK C-3 and SBS C satellites, Get Away Special, SSIP
STS-6 I:28.5°, A:330	4. April 1983 9. April 1983	Challenger	1 st EVA, TDRS-1, CFES, MLR, RME, NOSL, Get Away Specials
STS-7 I:28.5°, A:360 km	18. June 1983 24. June 1983	Challenger	ANIK-C2 and PALAPA-B1 satellites, Get Away Specials, 10 experiments mounted on SPAS-01 (MOMS-01), OSTA-2 payload, CFES, MLR, SSIP
STS-8 I:28.5°, A:353	30. Aug. 1983 5. Sept. 1983	Challenger	INSAT-1B satellite, CFES, SSIP, ICAT, RME, Get Away Specials
STS-9 I:57°, A:287	28. Nov. 1983 8. Dec. 1983	Columbia	Spacelab-1 mission (ESA), see J.22
STS-41-B (10) I:28.5°, A:300 km	3. Feb. 1984 11. Feb. 1984	Challenger	WESTAR-6 and PALAPA-B2 satellites, GAS, SPAS-2, MOMS-01, Cinema-360 camera, ACES, MLR, RME, IEF
STS-41-C (11) I:28.5°, A:580	6. April 1984 13. April 1984	Challenger	SMM satellite repair in orbit, LDEF deployment (57 experiments), IMAX camera, RME, Cinema-360, SSIP
STS-41-D (12) I:28.5°, A:340 km	30. Aug. 1984 5. Sept. 1984	Discovery	3 satellites (SBS-D, SYNCOM IV-2, TELSTAR), OAST-1, CFES III, RME, SSIP, IMAX camera, CLOUDS
STS-41-G (13) I:57°, A:352	5. Oct. 1984 13. Oct. 1984	Challenger	ERBS satellite, OSTA-3, LFC, IMAX camera, CANEX, APE, RME, TLD, SIR-B, Get Away Specials
STS-51-A (14) I:28.5°, A:342	8. Nov. 1984 16. Nov. 1984	Discovery	TELESAT-H (ANIK) and SYNCOM IV-1, retrieval of PALAPA-B-2 and WESTAR-VI, DMOS, RME
STS-51-C (15) I:28.5°, A:407	24. Jan. 1985 27. Jan. 1985	Discovery	DoD payload
STS-51-D (16) I:28.5°, A:527	12. April 1985 19. April 1985	Discovery	TELSAT-I (ANIK C-1) and SYNCOM IV-3 satellites, CFES III, SSIP, AFE, Get Away Specials, PPE
STS-51-B (17) I:57°, A:411 km	29. April 1985 6. May 1985	Challenger	Spacelab-3 mission ESA, see J.23 [material sciences, life sciences, fluid mechanics, atmospheric physics (ATMOS), and astronomy], Get Away Specials (NUSAT)
STS-51-G (18) I:28.5°, A:405	17. June 1985 24. June 1985	Discovery	MORELOS-A, ARABSAT-A and TELSTAR-3D satellites, SPARTAN-1, Get Away Specials, HPTE, ADSF

Mission Incl., Alt.(km)	Launch/ Landing Date	Orbiter	Mission Highlights / Payload Complement
STS-51-F (19) I:49.5° A:383 km	29. July 1985 6. Aug. 1985	Challenger	Spacelab-2 mission, [life sciences, plasma physics (PDP), astronomy (XRT, IRT), high-energy astro-physics, solar physics (SUSIM, HRTS, CHASE, SOUP), atmospheric physics, and technology research IPS]
STS-51-I (20) I:28.5°, A:514	27. Aug. 1985 3. Sept. 1985	Discovery	ASC-1, AUSSAT-1, and SYNCOM IV-4 satellites, PVTOS
STS-52-J (21) I:28.5°, A:590	3. Oct. 1985 7. Oct. 1985	Atlantis	DoD mission
STS-61-A (22) I:57°, A:383	30. Oct. 1985 6. Nov. 1985	Challenger	Spacelab D1 (German mission), GLOMR satellite of DARPA deployed from Get Away Special canister
STS-61-B (23) I:28.5°, A:416 km	26. Nov. 1985 3. Dec. 1985	Atlantis	MORELOS-B, AUSSAT-2, and SATCOM satellites, EASE, ACCESS, CFES, DMOS, MPSE, OEX, Get Away Special, IMAX cargo bay camera (ICBC)
STS-61-C (24) I:28.5°, A:392	12. Jan. 1986 18. Jan. 1986	Columbia	SATCOM KU-1 satellite, CHAMP, MSL-2, Hitchhiker-G1, IR-IE, IBSE, HPCG, SSIP, Get Away Specials
STS-51-L (25)	28. Jan. 1986	Challenger	Accident !!!! (catastrophic failure) TDRS-B, SPARTAN-Halley
STS-26 I:28.5°, A:376	29. Sept. 1988 3. Oct. 1988	Discovery	TDRS-3 satellite, PVTOS, PCG, IRCFE, ARC, IFE, MLE, PPE, ELRAD, ADSF, SSIP, OASIS-1
STS-27 I:57°, A:460	2. Dec. 1988 6. Dec. 1988	Atlantis	DoD payload, deployment of USA-34, this code name designates the first high-resolution imaging radar S/C of the US military (also known under the name Lacrosse-1). Orbit of Lacrosse-1 was raised to 668 km x 703 km.
STS-29 I:28.5°, A:340	13. Mar. 1989 18. Mar. 1989	Discovery	TDRS-4 satellite, OASIS-1, SHARE, PCG, CHROMEX, SSIP, AMOS, IMAX camera
STS-30 I:28.8°, A:340	4. May 1989 8. May 1989	Atlantis	Magellan/Venus radar mapper S/C, MLE, FEA, AMOS
STS-28 I:57°, A:	8. Aug. 1989 13. Aug. 1989	Columbia	DoD payload
STS-34 I:34.3°, A:342	18. Oct. 1989 23. Oct. 1989	Atlantis	Galileo S/C to Jupiter, SSBUV, GHCD, PM, STEX, MLE, IMAX camera, AMOS, SSIP
STS-33 I:28.5°, A:	22. Nov. 1989 27. Nov. 1989	Discovery	DoD payload
STS-32 I:28.5°, A:389	9. Jan. 1990 20. Jan. 1990	Columbia	SYNCOM IV-F5 satellite (DoD), retrieval of LDEF, CNCR, PCG, FEA, AFE, L3, MLE, IMAX, AMOS
STS-36,A:811 I:62-65°	28. Feb. 1990 4. Mar. 1990	Atlantis	DoD payload (AFP-731)
STS-31 I:28.5°, A:703	24. April 1990 29. April 1990	Discovery	HST satellite, IMAX (ICBC), APM, PCG, RME III, IPMP, SSIP, AMOS
STS-41 I:28.5°, A:340	6. Oct. 1990 10. Oct. 1990	Discovery	Ulysses spacecraft (ESA/NASA), SSBUV, ISAC, CHROMEX, VCS, SSCE, IPMP, PSE, RME III, SSIP, AMOS
STS-38	15. Nov. 1990 20. Nov. 1990	Atlantis	DoD payload
STS-35 I:28.5°, A:520	2. Dec. 1990 10. Dec. 1990	Columbia	ASTRO-1 observatory (consisting of HUT, WUPPE, UIT, BBXRT, and IPS), SAREX-2, AMOS
STS-37 I:28.5°, A:518	5. April 1991 11. April 1991	Atlantis	GRO (Gamma Ray Observatory), CETA, APM, SAREX II, PCG, BIMDA, RME III, AMOS
STS-39 I:57°, A:298	28. April 1991 6. May 1991	Discovery	DoD classified mission including unclassified payload: AFP-675, IBSS, CIV, CRO, SPAS-II, STP-1, RME III, CLOUDS-1
STS-40 I:28.5°, A:340	5. June 1991 14. June 1991	Columbia	SLS-1 (Spacelab Life Sciences-1), Get Away Specials, MODE, OEX, GBA-2
STS-43 I:28.5° A:340 km	2. Aug. 1991 11. Aug. 1991	Atlantis	TDRS-5 satellite, SHARE II, SSBUV, TPCE, OCTW, APE-B, PCG III, BIMDA, IPMP, SAMS, SSCE, UVPI, AMOS
STS-48 I:57°, A:657	12. Sept. 1991 18. Sept. 1991	Discovery	UARS satellite, APM, MODE, SAM, CREAM, PARE, PCG II-2, IPMP, AMOS
STS-44 I:28.5° A:416 km	24. Nov. 1991 1. Dec. 1991	Atlantis	DoD mission, DSP (Defense Support Satellite), plus unclassified payloads: IOCM, AMOS, CREAM, SAM, RME III, VFT-1, UVPI
STS-42 I:57° A:348 km	22. Jan. 1992 30. Jan. 1992	Discovery	IML-1 (International Microgravity Laboratory-1), Get Away Specials, GOSAMR-1, IMAX, IPMP, RME III, SSIP, GBA-3

Mission Incl., Alt.(km)	Launch/ Landing Date	Orbiter	Mission Highlights / Payload Complement
STS-45 I:57°, A:340	24. Mar. 1992 2. April 1992	Atlantis	ATLAS-1 payload (ATMOS, MAS, SSBUV, ACRIM, SOLCON, SOLSPEC, SUSIM), Get Away Special, IPMP, STL-01, RME III, VFT-2, CLOUDS, SAREX II
STS-49 I:28.4°, A:390	7. May 1992 16. May 1992	Endeavour	EVA, Intelsat-VI capture and redeployment, ASEM, CPCG, UVPI, AMOS
STS-50 I:28.5°, A:350	25. June 1992 9. July 1992	Columbia	USML-1 (US Microgravity Lab-1), IPMP, SAREX II, UVPI
STS-46 I:28.5° A:502 km	31. July 1992 8. Aug. 1992	Atlantis	EURECA-1 satellite, TSS-1 (Tethered Satellite System), EOIM-III/TEMP, CONCAP II and III, ICBC, LDCE, AMOS, PHCF, UVPI
STS-47 I:57°, A:346	12. Sept. 1992 20. Sept. 1992	Endeavour	Spacelab-J (Japan), Get Away Specials, ISIAH, SSCE, SAREX II, AMOS, UVPI, GBA-4
STS-52 I:28.5° A:302 km	22. Oct. 1992 1. Nov. 1992	Columbia	LAGEOS-II, USMP-1, CANEX-2, SVS, MELEO, QUELD, PARLIQ, OGLOW-2, SATO, CTA, CMIX, CPCG, CVTE, HPP, PSE, SPIE, UVPI, TPCE, ASP
STS-53 I:57° A:370 km	2. Dec. 1992 9. Dec. 1992	Discovery	DoD payload GCP, Get Away Specials, CRYOHP, ODERACS, BLAST, CLOUDS, CREAM, FARE, HERCULES, MIS-1, RME III, STL, VFT-2
STS-54 I:28.5°, A:296	13. Jan. 1993 19. Jan. 1993	Endeavour	TDRS-6 satellite, DXS, CGBA, CHROMEX, PARE, SAMS, SSCE
STS-56 I:57°, A:296	8. April 1993 17. April 1993	Discovery	ATLAS-2 payload (ATMOS, MAS, SSBUV, ACRIM, SOLCON, SOLSPEC, SUSIM), SPARTAN-201, SUVE, CMIX, PARE, STL-1, CREAM, HERCULES, RME III, AMOS

STS-98 I:51.6°, A:310	07. Feb. 2001 20. Feb. 2001	Atlantis	ISS-07-5A assembly flight. Payloads: US Lab Destiny, ORU, PDGF
STS-102 I:51.6°, A:225	08. Mar. 2001 21. Mar. 2001	Discovery	ISS-07-5A1 assembly flight. Payload: Leonardo Multipurpose Logistics Module (MPLM)
STS-100 I:51.6°, A:310	19. Apr. 2001 01. May 2001	Endeavour	ISS-09-6A assembly flight. Payload: Raffaello MPLM-1, Racks/SLP, Canadarm2 (SSRMS,SPDM), LCA,RU, UHF Antenna
STS-104 I:51.6°, A:225	12. July 2001 24.July 2001	Atlantis	ISS-7A assembly flight. Payload: Airlock and support systems
STS-105	10. Aug. 2001 22. Aug. 2001	Discovery	ISS-7A.1 logistics flight. Payload: Donatello (MPLM-3)

O.18 Solar Wind and the Magnetosphere - An Introduction

Throughout history mankind has always known that life on Earth is dependent on light and heat from the sun, but beyond our senses, electromagnetic forces also link the sun and the Earth in a dynamic interplay that generates and characterizes our protective near-Earth environment and sparks the displays called the northern and southern lights. The space missions and space science of modern times have greatly improved knowledge of these electromagnetic forces and the overall energy transport in the sun-Earth system.²⁰²⁹⁾

The regions of space defined by the electromagnetic link include the sun and its sphere of influence - the heliosphere - and the Earth and its much smaller sphere of influence - geospace. Geospace includes the near-Earth space and reaches toward the sun, where the sun's heliosphere is disturbed by Earth's magnetic field.

Energy streams out from the sun toward the Earth in the form of a solar wind of electrified particles (1, see Figure 408). This hot, ionized gas, called plasma, streams toward Earth at about 1.5 million km per hour, carrying particles and magnetic fields from the sun outward past the planets (with the sun-Earth distance of 150 million km, the plasma needs about 100

²⁰²⁹⁾ Taken from the introduction of the NASA/GSFC brochure: "ISTP Global GEOSPACE Science - Energy Transfer in Geospace (ESA/NASA/ISAS)," 1992, Courtesy of NASA/GSFC, Greenbelt, MD

hours of travelling time). Earth is shielded from the full blast of these particles by its magnetosphere, the region around the Earth dominated by the Earth's magnetic field.

Figure 408: Characteristic model of the Earth's magnetosphere

As the solar wind approaches the Earth's magnetic field, a highly supersonic shock wave is created sunward of the Earth, similar in shape to the shock wave created when a jet plane breaks the sound barrier, but much stronger. This shock wave is called the bow shock (2). Most of the solar wind particles are heated and slowed down at the bow shock and detour around the Earth through a volume of space called the magnetosheath (3). Some particles are actually reflected back from the bow shock into the solar wind stream in a region of turbulence called the foreshock (4).

As the solar wind flows around the Earth, it stretches the Earth's magnetosphere out into a long tail, the magnetotail (not shown in Figure 408). Some of the particles being carried past the Earth leak through the barrier at the boundary of the Earth's magnetic field, called magnetopause (5), and are trapped inside the magnetosphere and stored in the plasma sheet (6) and Van Allen radiation belts (7). Some particles rush through funnel-like openings at the

poles, called polar cusps (8). Some energetic particles come down along magnetic field lines and enter into the Earth's upper atmosphere. Particles accelerated in the magnetotail excite atoms and molecules in the Earth's atmosphere. These atoms and molecules then emit light known as the northern and southern lights (or auroras) in the auroral ovals (9), giving a visible signature of this energy transfer from the sun to the Earth.

Figure 409: Schematic of the layers of the Earth's atmosphere

The sun is an active star whose variability affects the flow of the solar wind. For example, solar-flare explosions, associated with sunspots, can cause strong gusts of solar wind. Alterations in the Earth's environment caused by these solar phenomena happen on different time scales from less than a minute to over a century. The sun's variations (for example, solar X-ray bursts) can affect specific regions on Earth within the time required for light to travel from the sun to the Earth (8 minutes). Longer timescale, global solar variations may affect long-term climatic changes.

The best known terrestrial effects of solar activity are the geomagnetic storms and auroras that occur within a few days following major solar flares. In turn, the auroras contribute to the heating and ionizing of the upper atmosphere that generate the ionosphere, located at about 150-250 km above the Earth, where the neutral atmosphere gives way to ionized plasma.

Above our atmosphere, ions and charged particles bounce along and spiral around magnetic field lines, deflected from direct impact on the atmosphere and the people below. Thus, the geomagnetic field forms a mantle protecting us from harmful cosmic radiation.

Events on the sun can trigger changes in the electrical and chemical properties of the atmosphere, the ionosphere, the magnetosphere, the ozone layer, and high-altitude temperatures and wind patterns. These changes cause magnetic storms, communications static, power blackouts, and navigation problems for ships and airplanes with magnetic compasses. Also, satellites and spacecraft can be damaged or can reenter Earth's atmosphere prematurely because of solar storms.

Figure 410: Temperature profile of the standard atmosphere

O.19 Frequency Designations

ITU provides general frequency band allocations (10 bands) for the electromagnetic spectrum as illustrated in Table 558 and in Figure 413 (ELF to EHF). However, these ranges are rather wide for practical RF applications (which are normally limited by waveguide designs). Radar engineers still use the old letter designations to denote the general frequency band at which a radar operates. The original letter designations (P, L, S, X and K) were introduced Before and during World War II. The nomenclature P-band is no longer in use since the 1960s. It has been replaced by UHF.

It turns out there is no uniform standard for the letter designations around. There seem to be quite a few different bandwidths definitions, originating from various sides of the communication industry and from research. New frequency band standards were introduced by such bodies as NATO. According to this scheme the spectrum between 0.1 - 100 GHz was given the letter designations from A to M in alphabetic and ascending frequency order.

The remote sensing community seems to adhere to the old frequency band designations in spite of these new developments. The sensor names and parameter definitions in this book are manifestations of the old standards.

ITU Designation	Name of Frequency Band	Frequency Band	Wavelength (λ)	Remarks/Use
ELF	Extremely Low Frequency (Megametric waves)	$30 < 3000 \text{ Hz}$	$10^4 - 100 \text{ km}$	Alternating current (50 - 60 Hz)
VF	Voice Frequency	$300 < 3000 \text{ Hz}$	$10^3 - 100 \text{ km}$	Voice
VLF	Very-low Frequency (Myriametric waves)	$10 < 30 \text{ kHz}$	$30 - 10 \text{ km}$	Radiotelegraphy
LF	Low Frequency (Kilometric waves)	$30 < 300 \text{ kHz}$	$10 - 1 \text{ km}$	Radiotelegraphy, radio
MF	Medium Frequency (Hectometric waves)	$300 < 3000 \text{ kHz}$	$1000 - 100 \text{ m}$	Radio, (AM radio)
HF	High Frequency (Decametric waves)	$3 < 30 \text{ MHz}$	$100 - 10 \text{ m}$	Radiotelephony, radio navigation, amateur radio
VHF	Very-High Frequency (Metric waves)	$30 < 300 \text{ MHz}$	$10 - 1 \text{ m}$	Radio, TV, radio navigation, radiobeacon, (FM radio)
UHF	Ultra-High Frequency (Decimetric waves)	$300 < 3000 \text{ MHz}$	$1 \text{ m} - 0.1 \text{ m}$	TV, radiobeacon, satellite control, radiolocation, radio
SHF	Super-High Frequency (Centimetric waves)	$3 < 30 \text{ GHz}$	$10 - 1 \text{ cm}$	Radar, radiobeacon, satellite broadcast, Maser, MW heating
EHF	Extremely-High Frequency (Millimetric waves)	$30 < 300 \text{ GHz}$	$10 - 1 \text{ mm}$	
-	(Decimillimetric waves)	$300 < 3000 \text{ GHz}$	$1 - 0.1 \text{ mm}$	
<div style="display: flex; justify-content: space-between; align-items: center;"> <div style="text-align: center;">  <p>← ITU Radio Spectrum</p> </div> <div style="text-align: center;">  <p>← Microwave Spectrum</p> </div> </div>				
IR	Infrared	$3 \times 10^{11} \text{ Hz} - 3.8 \times 10^{14} \text{ Hz}$	$1 \text{ mm} - 0.78 \mu\text{m}$	Heat sounding, laser communication
VIS	Visible Light	$3.8 \times 10^{14} \text{ Hz} - 7.9 \times 10^{14} \text{ Hz}$	$0.78 - 0.38 \mu\text{m}$	Light telephony, laser, electrooptical distance measurements
UV	Ultraviolet	$7.9 \times 10^{14} \text{ Hz} - 3 \times 10^{16} \text{ Hz}$	$0.38 - 0.01 \mu\text{m}$	Light telephony, laser, electro-optical distance measurements
X-Ray	X-ray (Soft band)	$5 \times 10^{15} \text{ Hz} - 3 \times 10^{19} \text{ Hz}$	$60 - 0.1 \text{ nm}$	X-ray diagnostics, -medical therapy
X-Ray	X-ray (Medium band)	$3 \times 10^{19} \text{ Hz} - 3 \times 10^{20} \text{ Hz}$	$10^{-2} - 10^{-3} \text{ nm}$	Materials testing
X-Ray	X-ray (Hard band)	$3 \times 10^{20} \text{ Hz} - 2 \times 10^{25} \text{ Hz}$	$10^{-3} - 10^{-8} \text{ nm}$	Atomic particle transitions
γ -Ray	Gamma rays	$8 \times 10^{17} \text{ Hz} - 4.7 \times 10^{21} \text{ Hz}$	$0.4 - 10^{-4} \text{ Hz}$	Radiology, material testing

Table 558: ITU frequency band allocation of the electromagnetic spectrum ²⁰³⁰⁾

The Alphabet Soup of Frequency Bands

I am using a web-text by Jorn Christensen (<http://satsys.etri.re.kr/tech/FreqBand.html>), published in 1996 in “Satellite Industry Directory,” Phillips Business Information, Inc. In Table 559, I have added to his IEEE definitions the ASPRS definitions as well. A further web-reference is: <http://www.naval.com/radio-bands.htm>

The frequency bands used for space radiocommunications are often denoted by various letters such as C-band, L-band, S-Band, etc. This practice of denoting frequency bands by letters has its origin in radar (radio detecting and ranging). Table 559 shows the standard letter

²⁰³⁰⁾ “Reference Data for Radio Engineers,” ITT (International Telephone and Telegraph Corp.), Sixth Edition 1982

designations for radar frequency bands of ASPRS (American Society for Photogrammetry and Remote Sensing) and of IEEE (Institute of Electrical and Electronic Engineers). There are many more definitions around, depending on author or institute.

Radar Band	Wavelength Range	Frequency Range			
P-band	136 - 77 cm	220 - 390 MHz			
UHF	100 - 30 cm	300 - 1 GHz	Radar Band	Wavelength Range	Frequency Range
L-band	30 - 15 cm	1 - 2 GHz	L-band	30 - 15 cm	1 - 2 GHz
S-band	15 - 7.5 cm	2 - 4 GHz	S-band	15 - 7.5 cm	2 - 4 GHz
C	7.5 - 3.75 cm	4 - 8 GHz	C	7.5 - 3.75 cm	4 - 8 GHz
X	3.75 - 2.4 cm	8 - 12.5 GHz	X	3.75 - 2.5 cm	8 - 12 GHz
Ku	2.4 - 1.67 cm	12.5 - 18 GHz	Ku	2.5 - 1.67 cm	12 - 18 GHz
K	1.67 - 1.18 cm	18 - 26.5 GHz	K	1.67 - 1.11 cm	18 - 27 GHz
Ka	1.18 - 0.75 cm	26.5 - 40 GHz	Ka	1.11 - 0.75 cm	27 - 40 GHz
V		40 - 75 GHz	V	0.75 - 0.40 cm	40 - 75 GHz
W		75 - 110 GHz	W	0.40 - 0.275 cm	75 - 110 GHz
			mm-band	2.75 - 1.0 mm	110 - 300 GHz
			Sub-mm-band	1.0 - 0.1 mm	300 - 3000 GHz
ASPRS Definitions			IEEE Definitions		

Table 559: Radar band letter designations of ASPRS and IEEE

The following comments pertain to Table 559:

- The official ITU designation for UHF extends from 300 to 3,000 MHz. In radar practice, however, the upper limit is usually taken as 1,000 MHz with the L- and S-band being used to describe the higher UHF region.
- The radar UHF band is sometimes called the P-band
- The designation “mm-band” is derived from “millimeter wave radar”, and is also used to refer to V- and W-bands, when general information relating to the region above 40 GHz is to be conveyed.

The ASPRS radar band designations can also be found in the following reference: “Principles & Applications of Imaging Radar,” 1998, edited by Floyd M. Henderson & Anthony J. Lewis, published by ASPRS in cooperation with John Wiley & Sons, Inc., p. 138, ISBN: 0-471-29406-3. The book is volume 2 of the 3rd edition (series): Manual of Remote Sensing.

Allocation of Frequency Bands

The ITU does not define a specific service such as “radar”, but defines the various services that use radar such as radiolocation, radionavigation, meteorological aids, earth exploration satellite and space research. Only small parts of the above bands are allocated to services that use radar since radar does not share frequencies well with other radiocommunication services.

Frequency bands are allocated to various types of services at international conferences held every two years, called World Radiocommunication Conferences, or WRCs (previously these conferences were called World Administrative Radiocommunication Conferences, or WARC). There is always contention between the various service proponents to gain access to the maximum amount of spectrum, and therefore bands are often allocated to more than one service. When this happens, all of the services must share the frequencies under certain operating constraints, such as maximum power flux density limits. For the purpose of allocating frequencies to various radiocommunication services, the world has been divided into three regions.

When allocating frequencies the objective is to make the same allocation in all regions, i.e., worldwide. This lessens the potential for interference between regions and brings econo-

mies of scale to the manufacturing of radiocommunication equipment. However, it is not always possible to make a frequency allocation worldwide since the use of the spectrum has developed differently in the various regions. Therefore, allocations often vary from region to region. Within a region it is not always possible to get a consensus among administrations on what the allocations are to be for certain frequency bands. Even within an administration many interest groups are involved in setting the agenda for a WRC.

Since the ITU functions by consensus, a “consensus” is often archived by putting the exceptions into footnotes that apply to a frequency allocation. For example, at WARC 92 a world wide allocation was made for the broadcasting satellite service (BSS) for digital audio broadcasting but some countries chose alternative frequencies for this service or decided that this allocation should not be effective until the year 2007. Such conditions are reflected in footnotes to the appropriate frequency allocations.

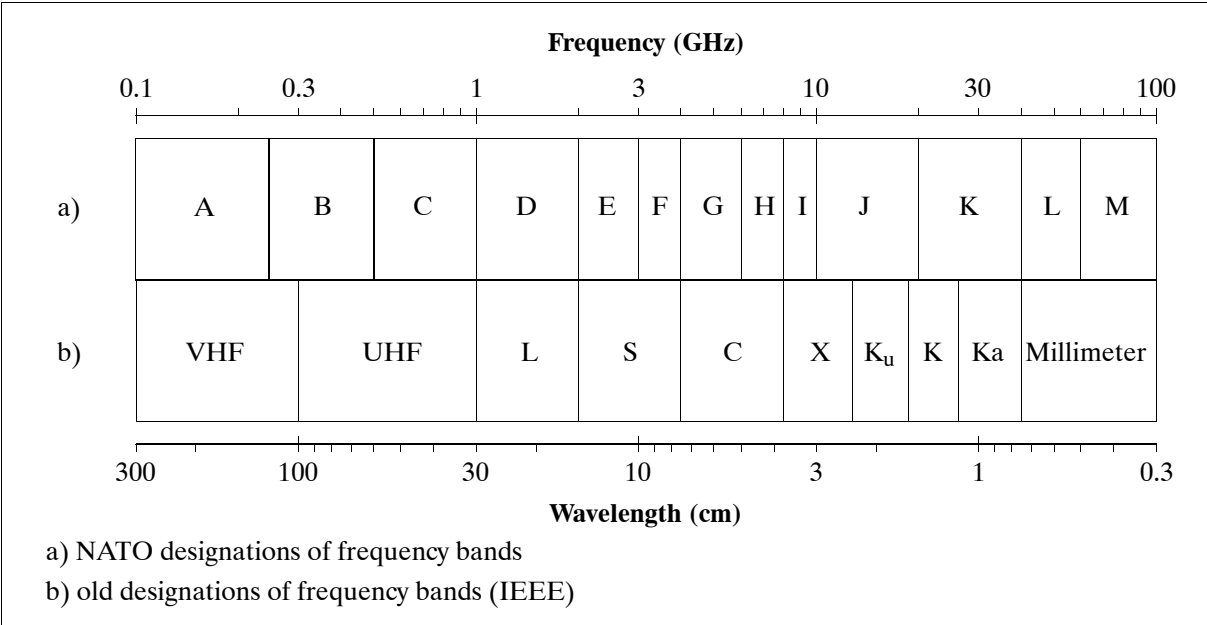

Figure 411: Illustration of frequency band allocations by different bodies

Radio Wave Propagation

Electromagnetic waves propagate in space at the speed of light (c), approximately 300,000 km/s. The wave amplitude varies periodically in time with frequency (f) measured in periods per second (Hz). The distance from crest to crest is the wavelength (λ), measured in meters. The relationship between these three parameters is $f = c/\lambda$.

Radio waves with frequencies of the order of 1 megahertz (MHz) can be reflected by the ionized atmosphere, or refracted when entering or coming out of these ionospheric layers, or even attenuated when crossing them. These effects, which influence the ray path, depend on the wavelength (or frequency), and the angle of incidence. Thus, radio messages can be sent to considerable distances, over the horizon and to the antipodes. Yet, some frequency limitations remain; the highest frequencies are not reflected at all. This last property makes space telecommunication possible. However, at the higher frequencies, radiation is affected by the atmospheric particles and molecules encountered, such as ice, rain drops, water vapor, and oxygen (see also Figure 412).

Part P Survey of Airborne Sensors

Airborne observations with dedicated instruments have their own history in contributing to advances in the Geosciences and extending our general knowledge in many fields, including the numerous surveys for natural resources. These observations cannot simply be regarded as an appendix to spaceborne observations, as one might assume with virtually all the publicity on the spaceborne front; rather, airborne observations add another dimension to Earth observation and provide a wide field of applications of their own. They are the most efficient means by which laboratory- and ground-based observations can be extended to regional observations. The science community needs data on the local and regional scales for calibration of its global data from spaceborne observation and for understanding overall concepts.²¹¹³⁾

Logistical and operational complexity in the field of airborne sensors easily matches that of spaceborne sensors. Spaceborne sensors are usually identified with a unique spacecraft and mission of considerable length; the mission and its goals are well publicized; there is usually a long lead time prior to any data analysis (complex space missions require in general long planning periods).

On the other hand, airborne missions are characterized by their relative short durations, by their regional confinement to a particular survey, by their adaptability to new requirements, and by the relatively rapid availability of airborne sensor data. Airborne instruments may be upgraded when a new technology becomes available, or when a better storage concept is affordable. Airborne sensors appear on and disappear from the scene of Earth observation, sometimes without much notice. It is indeed a tough job for anyone to keep track of the sensor zoo. The following list presents only a few scenarios of the degrees of freedom and the general environment encountered with airborne sensors.

1) Aircraft sensor complement.

- Dedicated instrumentation (fixed sensor complement) in support of a particular program (like atmospheric research, oceanography, land processes, cloud and meteorological research, photo-mapping surveys, etc.; some support may also be multidisciplinary in nature).
- Changing sensor complement. A mission is planned for a certain time period with instruments brought in and out of the aircraft for each mission by the investigators.
- Support of instrument development. A new or advanced (complex) spaceborne sensor technology generally requires a considerable degree of maturity and instrument testing before the instrument may be flown successfully on a satellite. There are normally a number of steps (programs) prior to the commitment of satellite sensor experimentation/operation that validate the required instrument performance of critical subsystems, the overall measurement performance, data processing algorithms, and other system parameters to provide a sound basis for the intended applications.

The field of airborne sensors can be regarded as the proving ground for future spaceborne sensors. The airborne concept permits an environment for repeated instrument access on all levels, ideally suited for experimentation and validation; test flights can manage with a lot of provisional gadgets and arrangements; limitations on instrument weight and power consumption are not as restrictive as on the intended satellite mission. Complexity can be handled in an orderly way, which reduces considerably the risk of failure. The cost of airborne instrument experimentation along with its infrastructure is relatively low compared to spaceborne experimentation.

²¹¹³⁾ W. B. Johnson, S. H. Melfi, "Airborne Geoscience: The Next Decade," The Report of the Special Interagency Task Group on Airborne Geoscience, February 1989, NASA, NOAA, NSF

2) Applications

- Airborne data collection is being provided for a number of research projects or simply for surveys, seemingly independent of spaceborne data.
- Airborne in-situ sensors provide complementary data for use with other remotely collected data.
- In-situ data gathered from airborne sensors is being used as a calibration standard for surface-based or for spaceborne sensors.

3) Data resolution requirements on mesoscale.

There are a number of remote sensing applications on a regional level that require a certain degree of repeat coverage and/or very high spatial resolutions that cannot be provided by an instrument in a satellite orbit (high-quality topographic maps). Other airborne applications require a very fine quantization of spectral information (very many and very narrow bands, which so far could not be provided in spaceborne instruments due to severe data constraints).

4) International programs and campaigns

Recent years have seen worldwide coordinated campaigns with data collected over a predefined region from similar spaceborne and airborne sensors for the analysis of better models.

5) Types of aircraft for mission requirements (and combinations thereof):

- Small aircraft
- Mid-sized aircraft
- Long-range aircraft
- High-altitude jet aircraft
- Ultra-high subsonic aircraft

6) Peripheral equipment and services

- Aircraft are generally equipped with computer-controlled data-logging and display systems that record data and provide real-time control and graphic output during flight. Some future applications may also request a communication link to a ground station in order to provide the experimenter with real-time access to his data.
- Aircraft also provide a number of online supportive services for their payload such as: instrument power supply, positional and timing data, environmental data, etc. Some research aircraft offer several navigation systems as well as GPS for navigation and instrument pointing. For an experimenter, accurate knowledge of platform and target position, velocity and time provide fundamental parameters for the interpretation of data.

7) Users of airborne data:

- Investigators and co-investigators of a particular instrument
- Researchers who require access to specific databases of airborne instrument data
- Users who query directories and catalogs for relevant data

Some countries maintain a strong engagement in the field of airborne observations. It is an effective and usually also an affordable field of activity for government-sponsored programs as well as for commercial service providers to contribute with their observational data to advances in science and to survey the country in its multifaceted aspects (resources, mapping, etc.).

This survey of airborne sensors does not spell out the observational needs for particular national programs; rather, it provides technical sensor descriptions so that readers may use this information for their own purpose. There are certainly many opportunities for resource

sharing on various levels. This applies to aircraft, instruments, as well as airborne observational data. Some context information is provided whenever available and suitable [this applies to data (such as chapters P.83 and P.139) as well as to special aircraft (such as chapters P.80, P.96, P.161 and Q.39)]. In view of the widespread use of airborne sensors in all fields of Geoscience and the broad spectrum of commercial applications, there is no claim to completeness of this survey. The sensors are listed in alphabetical order.

P.1 AAHIS (Advanced Airborne Hyperspectral Imaging Spectrometer)

AAHIS is a hyperspectral imaging sensor (research tool) that has been built by SAIC (Science Applications International Corporation) of San Diego, CA, with ARPA funding. It is owned and operated by SETS Technology Inc. of Hawaii. The instrument is of CHRISS heritage, first test flights of AAHIS were conducted in 1994 on an Aztec aircraft. The objective is to demonstrate hyperspectral imaging technology for a variety of shallow-water, beach, and near-shore land remote sensing applications (support of marine defense and environmental ocean research).

The AAHIS instrument consists of the following system components:

- a fixed focal length camera lens frontend
- an all-reflective imaging spectrograph to disperse and re-image the radiation
- a CCD digital camera in the output plane of the spectrograph
- a camera controller and a monitor system
- a data storage system (5 GByte capacity)
- a color CCD spotting camera and SVHS tape recorder (for synoptic ground views, data correlation, processing)
- a GPS navigation system (aircraft)

Parameter	Value	Parameter	Value
Spectral range	440 - 880 nm	CCD detector	384 pixels (1 line across)
Number of bands	288	Camera frame rate	45/s nominal
Spectral resolution	3 nm	Frame transfer time	1.4 ms
Front-end focal length	50 mm	Integration time	25 ms (at 38 frames/s)
Focal ratio	f/4	On-chip spatial binning	2
FOV	0.2 radians	On-chip spectral binning	2 x 2
IFOV along track	1 mrad	S/W spectral binning	2
		Data recording rate	1.25 MByte/s

Table 570: System parameters of AAHIS

The spectrograph of AAHIS²¹¹⁴⁾ has a resolution at the slit of 30 line-pairs/mm and a slit height of 10 mm, yielding a cross-track resolution of 300 elements. A 50 mm foreoptics system is used in the AAHIS configuration, providing a cross-track FOV of 0.2 radians. At an altitude of 1000 m, the swath is 200 m, with a resolution of 0.66 m. The along-track resolution can be adjusted with the slit width. The nominal slit has a width of 50 μm, giving an along-track resolution of 1 mrad. High data rates are reduced by binning pixels to 2 or 4 in the spectral dimension (2-binning provides 144 resolved colors, while 4-binning yields 72 colors). A cooled CCD detector array of 576 x 384 pixels is employed. Half of the active array is used for image storage (frame transfer mode). This leaves an array of 384 x 288 pixels for imaging. The spectral bands (288) of 3 nm bandwidth overlap, resulting from the fact that the point spread function of the instrument is larger (35 μm) than the pixel pitch on the CCD (22 μm).

²¹¹⁴⁾Information provided by R. Anderson of SAIC, San Diego

P.2 AAMAS (Aircraft-borne Automatic Mass Spectrometer)

An in-situ instrument designed and built by MPIK (Max-Planck Institut für Kernphysik), Heidelberg, with the objective for improved detection and collisional analysis of atmospheric ions and trace gases. AAMAS-1 has been operational since 1991 and participated in the following campaigns: EASOE, STREAM, and POLINAT. AAMAS-2 is an upgraded version of AAMAS-1 (improved mass resolution of the spectrometer and a larger volume of the cryogenic pump from 0.9 l to 1.5 l); it has been operational since early 1995, participating in STREAM-II (February 1995). AAMAS-2 is also participating in the STREAM-III campaigns (of 1996 and 1997) and POLINAT. It is also considered to fly in the CHORUS campaign in 1998. Instrument mass ~ 100 kg, power ~ 25 W, 28 V.^{2115), 2116), 2117)}

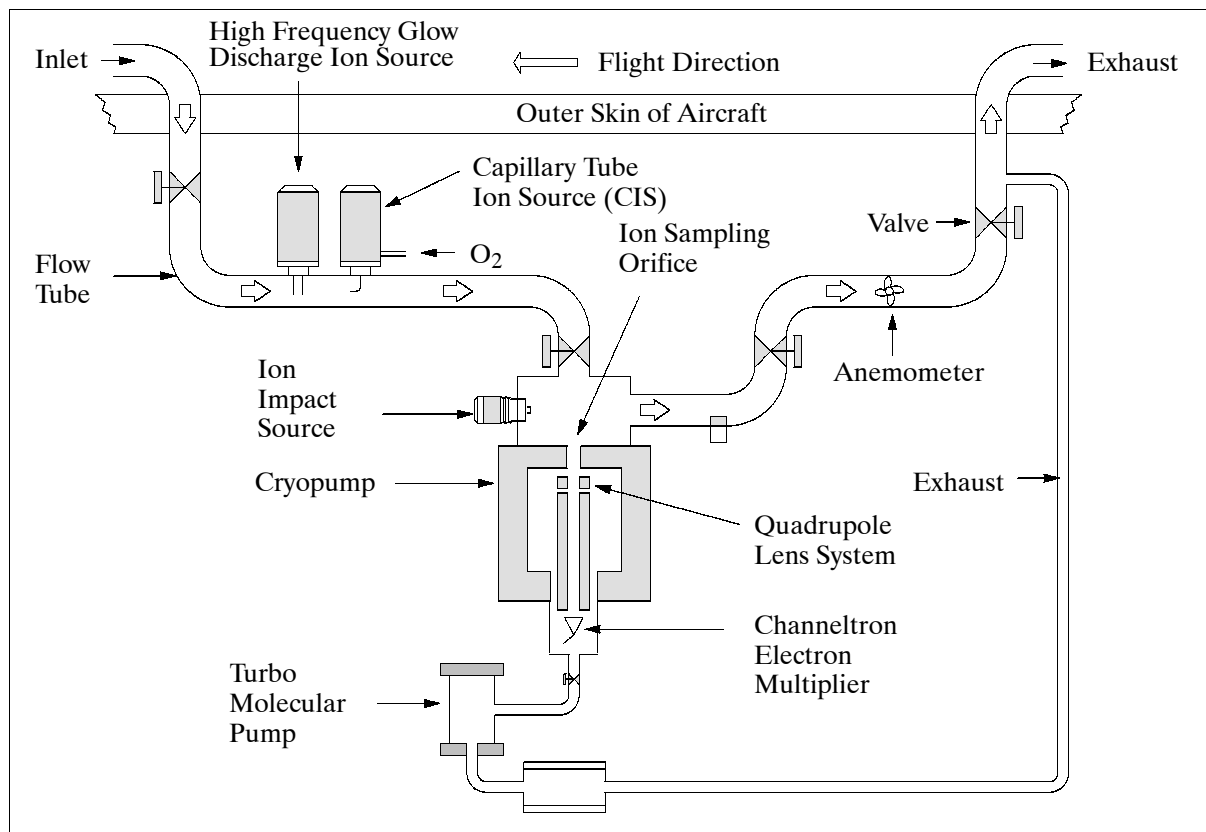

Figure 424: Schematic illustration of the AAMAS-2 instrument

The AAMAS instrument consists basically of a flow tube and a cryogenically pumped quadrupole mass spectrometer. Atmospheric air is sampled by an air intake and subsequently passed through the flow tube to the mass spectrometer. A high-frequency glow discharge ion source is mounted at an upstream distance of 120 cm from the sampling cone of the mass spectrometer. AAMAS features three basic modes of operation: CIMS (Chemical Ionization Mass Spectrometry), TRACIMS (Transformation CIMS), and IOMAS (Ion Mass Spectrometry). The CIMS method relies on reactions of ambient or artificially produced ions with trace gases. - The following gases can be measured with a time resolution of 3 seconds: SO_2 , SO_3 , H_2SO_4 , HNO_2 , HNO_3 , HNO_4 , HCN , HF , HCl , NH_3 , $(\text{CH}_3)_2\text{CO}$, CH_3OH , CH_3CO , CH_3CN .

P.2.1 TQMS (Triple Quadrupole Mass Spectrometer)

TQMS is a tandem mass spectrometer designed and developed by MPIK, Heidelberg. The objective is to provide improved detection and collision analysis of atmospheric ions and trace gases. The TQMS instrument consists of three coupled quadrupole systems and can be used for various tasks (operational modes) including: normal mass scanning, CID (Collision-Induced Dissociation) of mass-selected ions, energy distribution measurements, and investigations of metastable ions. TQMS measures the same constituents as AAMAS (see P.2), but provides an improved analysis capability for all trace gases. The calculation of OH is possible with measured concentrations of SO_2 and H_2SO_4 .²¹¹⁸⁾

Figure 425: Schematic illustration of the TQMS instrument

The instrument consists of the following major parts: 1) the flow tube system which samples outside air, 2) two ion sources, an OIS (Open Ion Source) gas discharge, and a CIS (Capillary tube Ion Source), 3) the triple quadrupole mass spectrometer with gas target and ion detector, a channel electron multiplier operated in pulse counting mode, and 4) the pumping system including two cryogenically cooled high-speed adsorption pumps and a turbomolecular pump. The gas flow through the tube is driven by the aircraft velocity. The reaction zone for ACIMS (Active Chemical Ionization Mass Spectrometry) measurements located between the ion sources and the mass spectrometer has a length of 68 cm for OIS and 76 cm for CIS. The mean gas velocity in the tube is between 50 - 70 m/s (total gas flow is about $6.3 - 8.8 \times 10^4 \text{ cm}^3 \text{ s}^{-1}$). Only a small portion of about $3.5 \text{ cm}^3 \text{ s}^{-1}$ enters the high vacuum vessel containing the mass spectrometer. A freely expanding gas jet is formed behind the ion sampling orifice. The neutral gas is pumped by freezing-out onto cold surfaces of the gold-plated cryo pumps. Most of the atmospheric gas is frozen out by the first cryopump. The second cryopump is mainly used to freeze out the target gas molecules. The cryopumps are cooled with liquid neon having a temperature of 27 K at atmospheric pressure. Since the

²¹¹⁸⁾O. Möhler, Th. Reiner, F. Arnold, "A novel aircraft-based tandem mass spectrometer for atmospheric ion and trace gas measurements," Review of Scientific Instruments, Vol. 64, No. 5, May 1993, pp. 1199-1207

atmospheric gases of helium and neon are not frozen at this temperature, a small turbomolecular pump is used to extract these gases from the mass spectrometer vessel.

Parameter/System	Quadrupole Lens	Quadrupole System 1	Quadrupole System 2	Quadrupole System 3
Rod length (mm)	30	270	100	300
Rod diameter (mm)	16			
Max RF voltage (kV)	5			
RF frequency (MHz)	1.6			
Rod offset (V)	0- \pm 100			
Mass range (amu)	RF only	0 - 150	RF only	0 - 190
Δm 50% (amu)	-	0.7 - 2	-	0.7 - 2

Table 571: Parameters of TQMS

Initial flights with TQMS were conducted on board the DLR Falcon aircraft in September/October 1991. TQMS as well as AAMAS instruments participated or are scheduled to participate in the following campaigns: EASOE, SESAME, STREAM, and POLINAT.

P3 ADS40 (Airborne Digital Sensor 40)

ADS40²¹¹⁹⁾ is a commercially available innovative digital camera system of LH Systems GmbH, introduced at the ISPRS 2000 Congress in Amsterdam. The concept of ADS40 represents a multi-year joint development effort of LH Systems GmbH of Heerbrugg, Switzerland and of DLR (Berlin-Adlershof, Institute of Space Sensor Technology and Planetary Exploration). The overall objective is the provision of an affordable imaging system with state-of-the-art technology, designed in particular for functional performance and services to support a range of demanding applications (with high spatial/spectral resolution and photogrammetric accuracy) in the field of remote sensing.^{2120) 2121) 2122)}

Spectral ranges Band 1 blue: (460 nm \pm 30 nm) Band 2 green: (560 nm \pm 25 nm) Band 3 red: (635 nm \pm 25 nm) Band 4 NIR1: (730 nm \pm 25 nm) Band 5 NIR2: (860 nm \pm 25 nm) PAN (465 - 680 nm)	Characteristics of bands Weak chlorophyll absorption for vegetation, max. water absorption Max. reflectance of green vegetation, chlorophyll detection in water 2nd chlorophyll absorption band, discrimination of vegetation Discrimination of vegetation, of biomass and of soil, shorelines, Three PAN bands, each with 2 x 12 k staggered elements
Focal length of telescope	62.5 mm, f-number: 4
FOV	64°, corresponding to a swath width of 3.75 km at 3 km AGL
GSD (Ground Sample Distance)	16 cm for PAN and 32 cm for MS (multispectral) data at 3 km AGL (Above Ground Level)
Read-out frequency per line	Up to 800 Hz
Stereo angle forward to nadir	28.4°
Stereo angle nadir to backward	14.2°
Stereo angle forward to backward	42.7°
Pixel size (pitch)	6.5 mm
PAN CCD line staggered	2 x 12,000 pixels (silicon detector)
MS CCD	12,000 pixels (silicon detector)
Dynamic range	12 bit (raw data mode)

2119) The designation ADS40 was chosen to signify the digital three-line pushbroom sensor technology employed and to differentiate the new concept from the previous RC30 (Aerial Camera System) analog (film) camera of Leica

Radiometric resolution	8 bit
Normalization mode	8 bit linear
SNR	>6 bit in the MS bands, and >8 bit in PAN
Data compression factor	2-20 (either JPEG or lossless compression can be selected)
Source data rate	up to 360 Mbit/s
Recording interval/line	> 1.2 ms
Instrument input voltage	28 VDC
Power average, peak	820 W, 920 W for ADS40 (incl. PAV30) 80 W, for Mass Memory System
Mass, size of SH40 (Sensor Head)	<70 kg, with a diameter of 46 cm and a height of 74 cm
Mass of CU40 (Control Unit)	22 kg, 19 inch rack-mountable
Mass of MM40 (Mass Memory)	<23 kg, a removable and portable hard disk pack of 6 x 36 GB
Mass of OI40 (operator I/F)	8 kg
IMU/GPS (Applanix system)	LN 200 IMU integrated in SH40, GPS & POS integrated in CU40
Operating temperature	-20° C to 55° C, storage: -40° C to 85° C (optics: 70° C)
ADS40 operating altitude range	0 - 7600 m above MSL (Mean Sea Level)

Table 572: Characteristic performance parameters of the ADS40

The instrument is based on the three-line pushbroom scanning concept (of MOMS, DPA, and WAOSS heritage), providing a panchromatic stereo and a multispectral imaging capability in parallel. The system consists of the following components: Sensor head (SH40) including the optics system, IMU (Inertial Measurement Unit) integrated in SH40, control unit (CU40), GPS position and orientation system, integrated in SH40, a software package FCMS (Flight Control Management System), POS (Position and Attitude Computer) integrated in CU40, MM40 (Mass Memory) system (the PAV30 system is optional), and an operator interface (OI40). ^{2123) 2124) 2125)}

ADS40 provides panchromatic stereo imagery using three CCD line arrays and up to five further CCD line arrays for multispectral imagery in VIS and NIR (2 bands). The FPA detector system features eight line arrays in parallel, three of those are used for panchromatic imaging in the three-line system (forward, nadir, backward); the next three narrow bands are used for color imagery (red, green, blue); in addition, there are two NIR bands (hence, a total of five multispectral bands). Each panchromatic (PAN) line consists physically of two linear line arrays, each with 12,000 pixels but staggered by a half pixel shift. The RGB color detector line arrays, also with 12,000 pixels, are optically superimposed by the system, implemented with cascaded dichroic beamsplitters, which divide the incident light beam into three color components followed by a narrow filter band (the RGB bands are also co-registered). The telecentric design of the optics system maintains position and width of all filter edges over the entire FOV (width of the swath), thus providing constant spatial high resolution imagery of all pixel elements of the array, also at the edges of the swath. - The FPA is temperature controlled with a Peltier cooling system.

The SPM (Signal Processing Module) is the main processing unit in the camera head for real-time analog signal processing and error correction. Each CCD channel is assigned with an ASP (Analog Signal Processor) for the complete signal processing chain, including a 12 bit A/D conversion (data quantization). The instrument has a real SNR of 8 bit in a dynamic range of 12 bit. - The DSP (Digital Signal Processing) unit, with an input data rate of several hundred MByte/s, performs data normalization resulting in an 8-bit data stream which is written into the compression memory. All normalized data are then compressed either by JPEG or lossless algorithms in the DSP unit, depending on the selection made by operator.

Some further ADS40 instrument features are: pressure stabilized optics, temperature stabilization/compensation of the FPA and optics, compensation for condensation, electronic

²¹²⁵⁾ <http://www.lh-systems.com/products/brochures/>

environmental control, and fully automatic camera control. The radiometric calibration procedure guarantees stability of the sensor sensitivity.

A suitable software package is available to support the wide range of image post-processing functions on the ground (DTM generation, orthophotos, mapping, image analysis, classification, etc.).

P.4 Aerosol Experiment

The Aerosol Experiment is a program of the University of Hannover (Zentrum für Strahlenschutz und Radioökologie), Germany, with the objective to measure and analyze aerosol size and distributions in regions of the Northern Hemisphere (Europe). The aerosol experiment is part of the ozone program of a German Ministry, BMFT, and conducted on a Transall C-160 aircraft (along with other instruments: MIPAS-FT, DOAS, OLEX, and TRI-TIUM) that started in 1990/91. The aerosol instrumentation consists of commercially available laser spectrometer probes of PMS Inc. (Boulder, CO) for continuous on-line and in-situ measurements of aerosol particles, and impactor probes for discontinuous aerosol observations (i.e. collection of particles only during a portion of a flight).²¹²⁶⁾

Sensors:

PMS LAS-X (Laser Aerosol Spectrometer with Passive Cavity). Objective: measurement of optical particle sizes in the range from 0.09 - 3.00 μm in diameter.

The instrument is an optical system using a laser beam in a high-order multimode 5 mW He-Ne tube with a wavelength of 632.8 nm. Particles passing through the laser beam in the sampling aperture scatter photons into the optics in a size characteristic way. The instrument offers 15 channels plus one oversize channel for particle sizing (particle resolution: 0.007 - 0.5 μm). The photodetector is combined with an amplifier for low level signals and a discriminator to relate every scattered pulse to one of the 16 channels. Each of the 16 channels is capable of memorizing a population of up to 20 million particles.

Note: the original Rosemount inlets of the instrument (mounted in the right-hand side emergency exit in front of the engines) have been replaced by a new 'smooth' inlet, in order to reduce the loss of larger particles by impaction before reaching the detector.

PMS LPC 550 (Laser Particle Counter). The instrument measures optical particles in the range from 3.0 - 30.0 μm within three channels and one oversize channel (particle resolution: 2 - 15 μm). The particle detection, counting and data processing corresponds to that of LAS-X.

LPI 80 (Low-Pressure Impactor, built at the U. of Vienna, Austria). Particle classification in the range from 0.05 - 16.0 μm diameter within six stages at a flow rate of 4.8 m^3/h . Resolution: 0.08 - 9.9 μm .

High-Volume Sampler with Normal Pressure Impactor, Impactor model: Sierra M235 (Ströhlein, Kaarst, Germany). Particle classification in the range from 0.49 - 7.20 μm in five stages plus a backup filter at a flow rate of 68 m^3/h . Resolution: 0.46 - 4.20 μm .

The impactor probes collect aerosol particles in a size-classified manner. A mass/size distribution is obtained; chemical analysis can be performed. The initial probes (in the period 1990-92) used low-pressure impactors, which were replaced in 1993 by a high-volume sampler with normal-pressure impactor.

P.5 AeS-1 (Aerosensing-1)

AeS-1 is a combined P-band and X-band SAR instrument assembly, designed and built by Aerosensing Radarsysteme GmbH at Oberpfaffenhofen, Germany. The compact and rela-

²¹²⁶⁾Information provided by M. Below of the University of Hannover

tively lightweight radar system, first introduced in the fall of 1996, has been installed and flown on various types of small-aircraft platforms, such as a Cessna 207A, a DO-228, an Aerocommander, and a Turbine Commander. The overall objective is the provision of a full service spectrum to customers, including overflights, data acquisition/handling and processing (geocoding) as well as analysis.^{2127) 2128)}

The AeS-1 instrument can be operated either in normal SAR mode (using a single cross-track antenna) for P-band data acquisition, or in InSAR mode (using the double cross-track antenna system) for X-band support. AeS-1 also offers an along-track interferometric operations capability with a baseline of 60 cm; this support is used for ocean surface current measurements and for traffic monitoring. The instrument assembly consists of the following subsystems:

- Two antennas, each of size 36 cm x 13 cm x 15 cm. The mass of each antenna is 3 kg. Both antennas are mounted to the fuselage with a boom construction, providing sufficient vibration rigidity and position stability. The effective interferometric baseline length is either 0.5 m or 1.8 m.
- The transmitter/receiver subsystem uses a high-precision local oscillator, a digital chirp generator, and a TWT-based (Travelling Wave Tube) output amplifier.
- Clock generator, control computer and three disk array units. The maximum recording data rate for each unit is 32 MByte/s. Each disk array can store up to 144 GByte of data.
- Flight control subsystem. Aircraft position is measured by an L1 and L2 GPS receiver with RTK (Real-Time Kinematic) capability in a DGPS ground segment environment - and by INS. The target position can be estimated in a post-processing step to absolute accuracies of <10 cm.

Parameter	P-band System	X-band System
Carrier frequency, wavelength	380 - 415 MHz, 72 cm	9.35 - 9.75 GHz, 3 cm
Bandwidth	70 MHz	400 MHz
Polarization	HH	HH
Antenna suppression angle	45° (midrange) 22°	
Antenna beam width		
InSAR baseline		0.5 m or 1.8 m
Ground range resolution	2.5 m	< 0.5 m
Peak power, PRF	2.5 kW, up to 16 kHz	
Swath width	1-15 km (depending on flight altitudes)	
Flight altitudes, aircraft speed	500 - 9000 m, 50 - 200 m/s	
Instrument mass; size; power	200 kg (including antennas); 1.1 m x 1 m x 0.6 m; 28 V, 60 A max.	

Table 573: Some system parameters of the AeS-1 instrument assembly

The AeS-1 instrument is supported by a number of software tools for automatic system operation. The flight control subsystem features a pilot-guidance display with indications of real-track and nominal-track positions. An end-to-end interferometric processing chain of AeS-1 data is offered to permit ground topography estimation. In the case of P-band observations, interferometric data can be acquired with repeat-pass support.

Applications: The range of data applications include in particular DEM (digital Elevation Model) generation. The P-band data, with their vegetation and ground-penetration capability, permit the derivation of ground topography of vegetated regions as well as ground moisture studies. Some initial mapping missions with the AeS-1 instrument include: Indonesia (July 1997 to January 1998 - 46,000 km² were mapped with an image resolution of 2.5 m x 2.5 m and a height accuracy of 2 m); Brazil (October 1998 - an area of 10,000 km² was mapped with an image resolution of 0.5 m x 0.5 m and a height accuracy of 0.25 m); and Ven-

ezuela (end of Oct. 1998 to January 1999 - an area of 268,000 km² was mapped with an image resolution of 5 m x 5 m and a height accuracy of 5 m). ²¹²⁹⁾

P.6 AES (Airborne Emission Spectrometer)

AES is a JPL (sponsored by NASA, NOAA and EPA) infrared Fourier Transform Spectrometer intended for the investigation of the chemistry and physics of the Earth’s lower atmosphere (the troposphere) from airborne platforms such as the NASA/JPL DC-8 and P-3 research aircraft. AES is complementary to, and a test-bed for, the spaceborne TES (Tropospheric Emission Spectrometer) on EOS platforms. AES was first flown in 1994; it took part in the SOS (Southern Oxidants Study) campaign in Nashville, TN, (June/July 1995) using the C130 aircraft.

AES is a Michelson-type interferometer with the plane mirrors replaced by cube-corners. It has four detector systems (one for each wavelength region) each containing four elements. This permits AES to generate 16 spectra simultaneously over the same target area. As a prototype of TES, AES will provide critical data on both the acquisition methodology and on regional atmospheric chemistry. After TES is launched, AES will continue to play its role in correlative measurements through underflights of the EOS spacecraft.

Application: tropospheric chemistry.
The key issue is to understand how the lower atmosphere cleanses itself of both natural and anthropogenic trace gases (commonly referred to as pollutants). These gases can be injurious to the health of all living things and in some cases, through transport into the stratosphere, participate in depletion of stratospheric ozone. The sources, sinks and distributions of these gases is not well understood - no global inventory exists (PI: R. Beer).²¹³⁰⁾

Item	TES	AES
Sponsors	NASA/GSFC	IC, NASA/HQ, NOAA, EPA
Platform	EOS (AM-2)	Aircraft, ground
Spectral range	600 - 4350 cm ⁻¹ (2.3-16.7 μm)	650-4250 cm ⁻¹ (2.4-15.4 μm)
Spectral coverage	105%	96%
Spectral resolution	0.1 cm ⁻¹ downlooking 0.025 cm ⁻¹ limb-viewing	0.1 cm ⁻¹
Operating temperature	150 K (radiative)	Ambient
Focal plane arrays	4 x 1 x 32 (MCT PC & PV)	4 x 1 x 4 (MCT PV & PC)
Focal plane temperature	65 k (Stirling cycle cooler)	65 K (pumped LN ₂)
Pointing	automatic	Interactive
Field of regard	Limb-to-limb (45° forward)	30° cone about nadir
Spatial resolution	2.3 x 23 km limb viewing 0.5 x 5 or 5 x 50 km downlooking	7 x 70 m

Table 574: A comparison of TES and AES instruments ²¹³¹⁾

P.7 AHSTRA (Airborne Heterodyne Spectrometer THz Astronomy)

An instrument designed and built by the Max-Planck-Institute for Radio Astronomy, Bonn (PI: H. P. Röser) with the objective of airborne astronomical observations with high spectral resolving power ($\lambda/\Delta\lambda \geq 10^6$). AHSTRA operates in the frequency range from 1 - 3 THz ($\lambda = 50 - 300 \mu\text{m}$) and was flown several times on the Kuiper Airborne Observatory (NASA/ARC C-141 aircraft). The first AHSTRA flight was conducted in 1985. Since 1994 AH-

²¹³⁰⁾Paper provided by R. Beer of JPL
²¹³¹⁾R. Beer, “6th TES/AES Science Team Meeting,” The Earth Observer, Vol. 4, No. 6, Nov/Dec 1992, pp. 8-10

STRA has been operated by DLR/ISST (Berlin/Adlershof). As of 1996 an improved AH-STRA version is being built for observations from SOFIA (Stratospheric Observatory For Infrared Astronomy), a NASA aircraft in the planning phase.²¹³²⁾

AHSTRA observes the chemical composition and physical state (density, temperature, dynamics) of the interstellar medium and environments of young stellar objects by measuring the major cooling transitions of interstellar molecules like CO, OH, and atoms and ions (eg., CI, CII). The instrument provided first measurements of highly excited rotational transitions [CO (7-6), CO (9-8), CO (11-10), CO (12-11), and CO (14-13)] of interstellar carbon monoxide.

AHSTRA is a heterodyne receiver with an optically pumped far-infrared gas laser as local oscillator. The incoming weak signal radiation is mixed in a GaAs Schottky barrier diode detector system with strong LO radiation. The IF (Intermediate Frequency) of 2 - 18 GHz is amplified, filtered, and downconverted in a second mixing stage. An acousto-optical spectrometer is used as backend for spectral analysis.

Mixer	GaAs Schottky diode in on open structure mount
Local oscillator (LO)	Optically pumped far-infrared gas laser
1st IF	2-18 GHz
2nd IF	1.5 - 2.5 GHz
Spectrometer backend	Acousto-optical spectrometer (AOS), 1 GHz bandwidth, 1.3 MHz resolution
Sensitivity	T _{sys} (DSB) = 2,700 K at 0.800 THz to 8,600 K at 2.5 THz

Table 575: Parameters of the AHSTRA heterodyne receiver

P.8 AIMR (Airborne Imaging Microwave Radiometer)

AIMR ²¹³³⁾ is a passive microwave radiometer developed and built by MPB Technologies Inc. of Claire, Quebec, for the Ice Branch of the Atmospheric Environment Service (AES) of Canada. The instrument was flown on ice reconnaissance missions off the coast of Labrador on an Electra aircraft starting in February 1989. - When the Electra was no longer available to AES, AIMR could not be used anymore. This resulted eventually in loaning AIMR to NCAR in Boulder, CO. NCAR developed a mount for AIMR inside their Lockheed C-130 Hercules aircraft and used the radiometer on several projects. In 1998, AIMR was upgraded by NCAR. ²¹³⁴⁾

AIMR has four radiometric channels, two orthogonally polarized channels at 37 GHz and two at 90 GHz. The channels are polarized in a manner such that the amount of vertically polarized radiation and the amount of horizontally polarized radiation can be uniquely calculated at most look angles of the instrument. These channels are detected and amplified by receivers whose outputs are digitized and written on tape by a set of computer systems. The images produced by AIMR are the brightness temperatures at each sample location.

AIMR uses a scanning antenna, consisting of a 25 cm in diameter (minor axis) elliptical mirror constructed from black anodized aluminum. The antenna is mounted at 45° from its spin axis which is in the direction of the flight path. A beam width of about 1° is provided for the 90 GHz channels and 2.5° for the 37 GHz channels. The maximum rotational velocity of the antenna is 4.9 rps. The ground coverage is about 2400 m at an AGL of 1400 m for the 37 GHz channel, and the footprint of the 90 GHz channel is about 25 m in diameter.

Four channels at 2 frequencies and 2 polarizations	37 and 90 GHz
Resolution (3 dB beamwidth, 90 GHz) Resolution (3 dB beamwidth, 37 GHz)	1° corresponds to 50 m (altitude of 3 km) 2.5°
Radiometric sensitivity (37 GHz)	<1 K
IF bandwidth	0.5 - 2.0 GHz for 37 GHz channel 2.0 - 4.0 GHz for 90 GHz channel
FOV, Quantization	±60°, 12 bit

Table 576: AIMR system parameters

Applications: ice reconnaissance, soil moisture, oil spill mapping, snow depth mapping, crop and forestry monitoring, ocean temperature and salinity, water pollution studies.

The modified AIMR system of NCAR flies in a C-130 aircraft. It was used in the SHEBA campaign in May and July 1998. Later in 1998, AIMR was used in the WIFE program to study wild fires. In Feb. and March 1999, AIMR was flown in the INDOEX campaign.

P.9 AIMS-1000 (Airborne Imaging Mapping and Surveillance System)

AIMS-1000 is a commercially available instrument designed and built by Southern Applied Technologies in Birmingham, Alabama. The instrument can be used for the following applications: topographic mapping of surface area, mapping of vegetation, detection of power transmission lines and mapping their sag, etc. The system became operational in 1994 and is flown on a Cessna RU-206G aircraft.

The instrument consists of a scanning laser altimeter, an infrared imager, and a color camera. The receiver of the laser altimeter measures the travel time of each reflected pulse. A scanning mirror assembly is used to steer the laser and the return pulse. The system is capable of scanning across-track (roll axis of plane) and along-track (pitch axis of plane). A CCD camera, pointed in parallel to the scan area, allows the operator to adjust the scan width and to steer the scan area. With a scan rate of 3 Hz the laser footprints overlap slightly in the across-track direction; the spacing of footprints depends on the aircraft speed.²¹³⁵⁾

Laser source	Diode-pumped Nd:YAG	Receiver	APD silicon detectors
Transmitter wavelength	1064 nm	Receiver aperture	13 cm diameter
Laser energy/pulse	250 mJ	Scan rate	3 Hz
PRF	1 kHz	Operating altitude	300 m
IFOV	2 mrad	Data rate	1000 Hz
FOV	20° in roll, 10° in pitch		

Table 577: Parameters of the AIMS scanning laser altimeter

All data of the altimeter, GPS location, aircraft attitude data, and time stamp is collected and stored by the on-board computer system for post-flight processing. The scanner angle is combined with the aircraft attitude data to determine the angle between the laser and nadir.

An Inframetrics 8-12 μm infrared imager is a separate sensor mounted along with a visible camera on the left wing of the aircraft. This instrument is used for thermographic studies.

P.10 AirCam

AirCam™ is a multispectral imager instrument of Kestrel Corporation, Albuquerque, NM. It is a compact and radiometrically calibrated imaging system, based on CCD detector

²¹³⁵⁾Information provided by R. Stokes of Southern Applied Technologies, Birmingham, Alabama

technology, and suitable for a wide range of surveying and mapping applications. The self-contained design incorporates a downwelling sensor, a GPS receiver, line-of-sight resolvers, and a pilots “fly-to” display. AirCam was initially flown in 1994 and has been commercially available since mid-1995. Three instruments are being operated at the end of 1995.

AirCam uses several different cameras depending on user specifications. In all cases the cameras are starring arrays (with progressive scan). The basic system is built with a Pulnix TM-9700 camera with both digital and analog ports. A wide-format version (1024 x 1024 pixels) uses the EG&G MD4013 with an electronic shutter. Each camera in the system records one spectral band selected by a removable filter. As the instrument adds spectral bands beyond the basic three, a new camera is added. The cameras are boresighted to a common optical line of sight to within one pixel and have the same FOV. All cameras capture an image at the exact same time. The images are superimposed to create a composite. The VNIR band detectors of the system are not actively cooled; rather, the camera operating temperature is recorded. Radiometric calibration is adjusted by means of a conversion table.²¹³⁶⁾

Imager	3 (or optionally 4) large-format CCD cameras
Spectral coverage	350-1100 nm in 3 or 4 bands (Landsat TM bands 1,2,3,4; or user-selectable)
IFOV (spatial resolution)	1.0 mrad (corresponds 1 m resolution at 1000 m height above ground)
FOV	0.8 radians (corresponds to 800 m swath at 1000 m height above ground)
Shutter speed	1/60 - 1/32,000 s
Position accuracy	< 100 m with GPS selective availability (SA) ‘on,’ < 35 m with SA ‘off’
Operating system	PC-based, MS-DOS interface
Output data format	Band-sequential and band-interleaved by pixel, TIFF with header
Operating environment	up to 6000 m altitude, -20°C to 50°C, passive vibration isolation
Instrument mass	23.5 kg (4.5 kg imager, 18 kg electronics)
Power	15 A at 12 VDC, < 200 W
Display	SVGA (Super Video Graphics Adapter) monitor
Data recorder	1.2 GByte internal disk that holds over 1000 frames (a frame is the combined output of image data from the three cameras)
Data rate	One frame per 4 seconds (~ 3 MByte/s) is possible
Attitude sensor	Solid state (heading, pitch, roll)
Software	Custom S/W for mission planning, image acquisition, post mission data review and processing (including georeferencing) and archival support

Table 578: Performance parameters of AirCam

Kestrel calibrates the AirCam system using a Labsphere uniform illumination source which in turn has been calibrated against NIST sources. A software package is provided with the AirCam instrument which automatically mosaics individual frames into a complete composite image of the total observed area.

P.11 AIRDAS (Airborne Disaster Assessment System)

AIRDAS^{2137), 2138)} is a four-channel scanning instrument designed and built as a cooperative effort between NASA/ARC and the US Forest Service (Pacific Southwest Station). The objective is to provide reliable fire intensity data from an airborne instrument without the ever-present problem of saturation. Another instrument goal is to support disaster assessment management by providing real-time images on board the aircraft. AIRDAS can also support real-time telemetry to the ground as provided by additional hardware and software. The system has been operational since late 1992.

²¹³⁶⁾Information provided by L. J. Otten of Kestrel Corporation

²¹³⁷⁾‘AIRDAS Digital Scanner,’ information brochure of NASA/ARC provided by J. C. Brass

²¹³⁸⁾V. G. Ambrosia, J. A. Brass, et al., “AIRDAS, Development of a Unique Four Channel Scanner for Natural Disaster Assessment,” Proceedings of the 1. International Airborne Remote Sensing Conference and Exhibition,” Strasbourg, France, September 12-15, 1994, Volume II, pp. 129-141

Applications: The instrument is designed to collect spectral information in four separate bands. In the case of fire analysis the VIS band allows determination of the extent and movement of the smoke plume, as well as distinguishing surface features. Band 2 (NIR) allows an analysis of vegetative composition as well as identifying very hot fire fronts, while penetrating the smoke plume. Band 3 (MWIR) is intended for the analysis of distinct fire temperatures; it is also capable of penetrating the smoke plume. Band 4 (TIR) is designed to collect thermal data on Earth background temperatures and on the lower temperature soil heating conditions behind fire fronts.

The AIRDAS scanning system features a detector element for each spectral band, the following detector materials are chosen: Band 1 (Si); Band 2 (InGaAs); Band 3 (InSb); Band 4 (HgCdTe). High temperature radiation is measured with the use of a two-step, linear curve preamplifier on the three infrared bands. In this setup, the dynamic range of the three bands (radiance versus digitizer output) is divided into two linear segments with an adjustable break-point. This configuration allows for the detection of a greater range of temperature profiles than is possible with standard signal pre-amplifiers. - The instrument uses a filter system for a user-driven channel selection.

The instrument is calibrated to NASA standards; thermal response is monitored against a high-temperature target of known emissivity.

The AIRDAS system is designed to be flown on small and large aircraft. The system requires a scanner port (18 x 36 cm) on the aircraft underside. At the end of 1995 AIRDAS instruments are flown on: a Navajo by the Los Angeles County Fire Department, a King Air of NCAR, the NASA/ARC C-130B, a Navy P-3 Orion, a Brazilian Learjet-31 (owned by LIDER of Brasilia), and a NASA/ARC Learjet-24. Recorded with the imagery are other ancillary data including navigation, air speed, altitude and attitude data. - Instrument upgrades are being considered for increased telemetry capability and possibly an eight-channel version.

AIRDAS Band	Landsat TM Band	Wavelength Region	Spectral Range
1	3	0.61 - 0.68 μm	VIS
2	5	1.57 - 1.70 μm	NIR
3	*	3.60 - 5.50 μm	MWIR
4	6	5.50 - 13.0 μm	TIR
Sensor Parameters		System Parameters	
FOV	108°	Power	28 V DC @ 20 amps
IFOV	2.62 mrad	Total instrument mass	122 kg
Scan rate	5-20 scans/s	Data quantization	16 bit
Digitized swath width	720 pixels	Detectors	non-linear detector amps
Ground resolution	8 m at 3000 m altitude	Data recording system	Exabyte 8500, 5 GB

Table 579: AIRDAS parameter specification

P.12 AirMISR (Airborne Multi-angle Imaging SpectroRadiometer)

AirMISR was developed and built by JPL as an adjunct to the MISR instrument flown on the NASA Terra spacecraft. The objective is to provide ground truth data, i.e. independent measurements of aerosol, cloud, and surface bidirectional reflectance properties from the NASA ER-2 aircraft.²¹³⁹⁾ Unlike MISR, which contains nine individual cameras pointed at discrete look angles, AirMISR utilizes a single pushbroom camera in a pivoting gimbal mount. The AirMISR camera has been fabricated from MISR brassboard and engineering

²¹³⁹⁾D. J. Diner, L. M. Barge, C. J. Bruegge, T. G. Chrien, J. E. Conel, M. L. Eastwood, J. D. Garcia, et al., "The Airborne Multi-angle Imaging SpectroRadiometer (AirMISR): Instrument description and first results," IEEE Transactions on Geoscience and Remote Sensing, 1998, Vol. 36, pp. 1339-1349.

model components, and thus has similar radiometric and spectral response as the MISR cameras. The AirMISR camera utilizes four CCD detector arrays to simultaneously acquire data in four spectral bands, and is pointable from 70.5° forward of nadir to 70° backward, the same angular range covered by MISR.

The AirMISR camera consists of a MISR brassboard lens assembly mated to a spare camera head assembly. The lens is a super-achromatic, 7 element, refractive, f/5.5, telecentric design, rendered polarization insensitive to < 1% uncertainty by a double plate Lyot depolarizer. The full swath field-of-view (FOV) is 30°. The camera head is a fully assembled MISR engineering model spare, and includes a four element spectral filter, CCD focal plane array, stray light masks, and a passive thermal defocus compensation system that corrects for changes in focus due to temperature-induced variations in the lens refractive indices. The CCD architecture consists of four line arrays with 1504 active 21 mm x 18 mm pixels per line. The camera has its own camera head electronics mounted to the camera head. Integration time is individually commandable for each of the line arrays up to a maximum value of 40.8 ms (the fixed line repeat time). The gimbal is driven by an Aerotech off-the-shelf actuator and controlled through an RS-232 interface. The rotary stage slews at about 20°/s and is accurate to 0.1°.

From ER-2 flight altitudes, the AirMISR camera has an instantaneous footprint of 7 m cross-track x 6 m along-track in the nadir view and 21 m x 55 m at the most oblique angle. Lines of image data are acquired every 40.8 ms, resulting in an along-track sample spacing, regardless of view angle, of 8 m for an aircraft ground speed of 200 m/s. Thus, it is possible to compensate for the variable footprint dimensions with angle in the ground data processing. It is also possible to make use of the higher resolution imagery if desired.

Nominal view angles at Earth's surface	0.0° (nadir) and 26.1°, 45.6°, 60.0°, 70.5° forward and backward of nadir
Optics	Telecentric f/5.5 super-achromat, 58.8 mm focal length
Detectors	Silicon CCDs
Spectral band centers (nm)	446, 558, 672, 866
Spectral bandpasses (nm)	42, 29, 22, 40
Radiometric calibration	Uses laboratory integrating sphere and high quantum efficiency photodiodes
Geolocation and attitude correction	Implemented in ground software using aircraft inertial navigation system/global positioning system data, and image tie-pointing

Table 580: Instrument parameters of AirMISR

An AirMISR observation sequence is divided into nine segments, each at a specific MISR look angle. The gimbal pivots aft between segments to repeat the pushbroom data acquisition of the same area on the ground from the next angle. This process is repeated until all nine look-angles of the target area are collected. The swath width is governed by the camera FOV, and varies from 11 km in the nadir direction to 32 km at the most oblique angle. The along-track image length at each angle is dictated by the timing required to obtain overlap imagery at all angles, and varies from about 9 km in the nadir to 26 km at the most oblique angle. Thus, the nadir image dictates the area of overlap that is imaged from all nine look angles. Since this approach ensures identical calibration at all angles, AirMISR is a useful component of the spaceborne MISR calibration. Instrument participation in campaigns: FIRE III-ACE (1998), KONVEX (1999), and SAFARI (2000).

P.13 AIRSAR (Airborne SAR)

AIRSAR is a NASA/JPL multifrequency instrument package aboard a DC-8 aircraft and operated by NASA's Ames Research Center at Moffett Field, CA (operational since late 1987) in support of assigned measurement campaigns.

The AIRSAR system has a single STALO clock and a single digital chirp generator which generates the chirp waveform at L-band. The L-band chirp signal is up-converted to C-band and down-converted to P-band and provided to TWT amplifiers in the case of the L-band and C-band radars, and to a class C solid state amplifier in the P-band case. After amplification, these signals are transmitted to the AIRSAR antennas, all of which are dual polarized microstrip patch arrays. The AIRSAR antennas are all mounted body-fixed to the fuselage of the DC-8 aft of the left wing.²¹⁴⁰⁾

Transmit polarization diversity is achieved by alternately transmitting the signals using horizontal or vertical polarizations. Receive polarization diversity is accomplished by measuring six channels of raw data simultaneously, both H and V polarizations at all three frequencies. The video data are digitized using 8-bit ADCs, providing a dynamic range in excess of 45 dB. The digital data from the six radar channels are then multiplexed to form an extended ‘range line,’ combined with navigation data, and stored on tape using one or more of three high density recorders.

In addition to the polarimetric mode, the AIRSAR system can also be operated in the along-track (ATI) and cross-track interferometry (XTI) modes. These modes are implemented by the addition of three more antennas; one L-band antenna located just forward of the left wing of the DC-8, and two C-band vertically polarized antennas arranged one above the other and placed just forward of the three dual polarized antennas used in the polarimetric mode.

Parameter	P-band	L-band	C-band
Wavelength (cm)	67-70	24	5.65
Look angle (°)	0-70		
Chirp bandwidth (MHz)	20 [or 40]		
Chirp RF frequency (MHz)	448.75-428.75 [447.50-407.50]	1258.75-1238.75 [1257.50-1217.50]	5308.75-5288.75 [5307.50-5267.50]
Calibration tone (MHz)	428.5546875	1238.5546875	5288.5546875
Video frequency (MHz)	450.00 - f _{rf}	1260.00 - f _{rf}	5310.00 - f _{rf}
Chirp duration (μs)	10 or 5		
Peak transmit power (dBm)	60	67	59
Antenna polarization	H and V dual microstrip patch array		
Bit/sample	8		
Data recording	3 HDDR's, full multiplex redundancy		
Data rate (Mbit/s)	10		
Data acquisition modes	3 frequency quad-polarization, dual frequency ATI, XTI		
Image Characteristics (Polarimetry Products)			
Multilook (standard)	16-look compressed Stokes matrix		
Image size (range x azimuth, pixels)	1280 x 1024 per frequency		
Bytes/pixel	10		
Pixel size (range x azimuth, m)	6.66 x 12.1 [3.33 x 6]		
Single-look (special)	1-look compressed scattering matrix		
Image size (range x azimuth, pixels)	4 files of 1280 x 1024 per frequency		
Bytes/pixel	10 for 4 polarizations		
Pixel size (range x azimuth, m)	6.66 x 12.1 [3.33 x 6]		
Nominal aircraft altitude	26,000 ft (~ 7300 m)		
Nominal aircraft velocity	420 knots (~ 216 m/s)		

Table 581: Summary of AIRSAR system parameters²¹⁴¹⁾

The ATI mode, used to measure wind surface velocities, utilizes the aft polarimetric L-band and C-band antennas, the front L-band antenna, and the bottom XTI antenna. Signals are

²¹⁴⁰⁾J. van Zyl, R. Carande, Y. Lou, T. Miller, K. Wheeler, “The NASA/JPL Three-Frequency Polarimetric AIRSAR System,” JPL paper

²¹⁴¹⁾Note: the values in the square brackets [] are for the 40 MHz Mode

transmitted alternatively out of the aft and front L-band and C-band antennas, and signals are received through the front and aft antennas simultaneously. The P-band Radar is operated in the standard polarimetric mode.

In the XTI mode used to measure topography (see TOPSAR), two vertically polarized antennas are used which are mounted above each other at C-band. The C-band signals are transmitted out of the bottom antenna and the returned signals are received simultaneously through the top and bottom antennas. The L-band and P-band radars are operated in the standard polarimetric mode.

AIRSAR data processing: A variety of processors and processing techniques is used to process AIRSAR data to imagery. A real-time correlator is part of the AIRSAR radar equipment and produces low-resolution (≈ 25 m) two-look survey imagery. The same on-board equipment can generate a slightly higher resolution (15 m) 16-look image of a smaller area (12 km x 7 km) within 10 minutes of acquisition using the quicklook processor. These on-board processors are useful for assessing the health of the radar.

Final processing of selected portions of the AIRSAR data to high-quality image products is done offline after the campaign. Products are provided by two different systems: the frame processor and the synoptic processor.

P.13.1 TOPSAR (Interferometric Radar Topographic Mapping Instrument)

The TOPSAR project at JPL is an experimental interferometric radar experiment for topographic mapping applications on a DC-8 aircraft along with a modified AIRSAR instrument. For this purpose the AIRSAR on the DC-8 aircraft was augmented with a pair of C-band antennas displaced across track to form an interferometer sensitive for topographic variations of the Earth's surface. The antennas were sponsored by ASI, while the AIRSAR modifications were sponsored by NASA. A new data processor was developed at JPL for the production of topographic maps. Data were acquired over several sites in the US and Europe in the summer of 1991 in a number of flight campaigns.²¹⁴²⁾

Concept: A radar interferometer is formed by relating the signals from two spatially separated antennas. The separation of the two antennas is called the baseline. The spatial extent of the baseline is one of the major performance drivers in an interferometric radar system - if the baseline is too short, the sensitivity to signal phase differences may be too small for detection; if the baseline is too long, additional noise due to spatial decorrelation may corrupt the signal.

The TOPSAR implementation uses much of the AIRSAR hardware (several modifications were made to optimize the performance in the topographic mapping mode). When in use TOPSAR effectively replaces the C-band polarimeter instrument, but the L- and P-band systems are undisturbed and operate together with the topographic mapper. The combined instrument produces simultaneous L- and P-band fully polarimetric plus C-band VV polarized backscatter images in addition to the topographic product.

The objective was to provide an operational instrument capable of delivering digital elevation models (DEMs) at a height accuracy of 2 m and a spatial resolution of 10 m. This goal was not met - topographical maps with a height accuracy of 3-40 m were produced. The discrepancy is due to a lack of proper aircraft motion compensation algorithms in the data processor.

As a consequence, a new processing scheme was developed featuring aircraft motion compensation, absolute phase retrieval, and three-dimensional location. The new processor has

²¹⁴²⁾H. A. Zebker, S. N. Madsen, J. Martin, K. B. Wheeler, T. Miller, Y. Lou, G. Alberti, S. Vetrilla, A. Cucci, "The TOPSAR Interferometric Radar Topographic Mapping Instrument," IEEE Transactions on Geoscience and Remote Sensing, Vol. 30, No. 5, Sept. 1992, pp 933-940

been tested using data which were acquired with extreme aircraft motion. This technique permits the generation of rectified height maps without any use of ground reference points. The topographic maps generated by the radar were compared to DEMs derived using conventional optical stereo techniques. The rms errors typically varied from 2.2 m in relatively flat terrain up to 5.0 m in mountainous regions.²¹⁴³⁾

Figure 426: General two-antenna interferometer geometry

Parameter	Value
RF frequency	5.288 GHz (C-band)
Bandwidth	40 MHz
Peak power	1 kW
Pulse repetition rate	2.64 m ⁻¹
Pulse length	5 μs
Antenna length, antenna width, baseline length	1.5 m, 0.1 m, 2.58 m
Antenna azimuth beamwidth	2°
Antenna elevation beamwidth	30°
Look angle	30-55°
Flight altitude	≈ 9 km
Slant range (near/far)	10/15 km
Data rate	80 Mbit/s (on-board recording)

Table 582: TOPSAR radar system parameters

The TOPSAR²¹⁴⁴⁾ mode of AIRSAR was upgraded in 1994 with the addition of another vertically-polarized L-band microstrip antenna (built by the Institute of Microwave Techniques at the University of Karlsruhe, Germany). The L-band interferometer is then formed using the new antenna and the vertical feed of the AIRSAR antenna. The upgrading of the system allows the TOPAR to collect C- and L-band interferometric images simultaneously for topographic mapping. The differences between topographic maps acquired allows calculation of the differential penetration characteristics of the dual-frequency radar waves for different Earth terrain types. First flight tests of the upgraded instrument took place in March 1995.

P.14 AIS (Airborne Imaging Spectrometer)

NASA²¹⁴⁵⁾ instruments AIS-1 and AIS-2 (AIS-1 was flown from 1982-1985, AIS-2 from 1986-1987). AIS is one of the first types of airborne imaging spectrometers ever built; it is a pushbroom scanner developed at JPL.

- AIS-1 sensor: CCD area array detectors
Spectral range: 900 - 2100 nm ('tree' mode)
1200 - 2400 nm ('rock' mode)
Spectral resolution: 128 bands, 9.3 nm bandwidth
IFOV: 1.91 mrad
Spatial resolution: 12 m (at 6 km altitude)
Swath width: 365 m (at 6 km altitude).
- AIS-2 sensor: CCD area array detectors
Spectral range: 800 - 1600 nm ('tree' mode)
1200 - 2400 nm ('rock' mode)
Spectral resolution: 128 bands, 10.6 nm bandwidth
IFOV: 2.05 mrad
Spatial resolution: 12 m (at 6 km altitude)
Swath width: 787 m (at 6 km altitude)

Applications: geochemistry, mineral identification, identification of altered rocks, geobotany, vegetation stress, etc.

P.15 AISA (Airborne Imaging Spectrometer for different Applications)

AISA is a commercially available hyperspectral imaging instrument (operational since beginning of 1993) of Spectral Imaging Ltd. (Specim) of Oulu, Finland, with the objective to provide users with a wide variety of application configurations. The instrument has been developed in cooperation with the Finnish Technical Research Institute and with contractual expertise from NASA. AISA is a programmable pushbroom imaging spectrometer based on CCD technology. One of the dimensions of the 2-D CCD elements is aligned to the image spectral content of the light dispersed by a reflection grating. The other dimension is used for imaging the spatial content of the light passing through a slit. Applications: hydrology, geology, forestry, agriculture, etc. . ²¹⁴⁶⁾ ²¹⁴⁷⁾ ²¹⁴⁸⁾

AISA provides the following selectable features: ²¹⁴⁹⁾ ²¹⁵⁰⁾

- Number of channels: 1-286
- Frequency spectrum: 430 - 900 nm with a spectral sampling of 1.63 nm
- Bandwidth: 1.63 - 9.8 nm
- Spectral, spatial, or combined spectral/spatial modes

The main components of the AISA instrument are the frontend or sensor head, the data acquisition unit, and the integrated GPS/INS unit. The front-end consists of the optics, FO-

DIS (Fiber Optic Downwelling Irradiance Sensor), spectrograph, CCD elements, the CCD detector electronics, and the control unit. The data acquisition unit consists of a Pentium PC and a large-capacity hard disk. The CCD source data is synchronized and digitized with 12 bit quantization. The recorded data are annotated with auxiliary flight data and (D)GPS/INS data. The FODIS sensor provides simultaneous downwelling irradiance measurements using the same spectrograph and CCD detector as the image. The three-axis GPS/INS unit, referred to as C-MIGITS II, provides Kalman-filtered position data and three-axis attitude data in real-time.

AISA provides four operational modes. These are:

- **Mode A:** This mode provides full spatial (384) and full spectral (288 pixels) information. The mode is mainly for calibration, testing and demonstration purposes. However, it can also be used as an operative mode in low velocity and/or high-altitude air surveys.
- **Mode B:** Full spatial but reduced spectral mode. The number of spatial pixels is a) 384 with no binning, or b) spatial binning (summing) of 2, 4 or 8 pixels selectable for low signal level measurements, or c) programmable spectral sampling (1.5 to 9.4 nm with 450 nm wavelength range). The programmable number of channels is limited only by the available integration time.
- **Mode C:** Full spectral but reduced spatial mode. This provides full hyperspectral information (288 pixels) and a) fixed number of equally spaced looks (47), b) spatial binning (summing) of 2, 4 or 8 pixels selectable for low signal level measurements. Mode C is suitable for hyperspectral applications with varied spatial resolution (binning).
- **Mode D:** Variable spectral and spatial mode. This provides programmable scene recovery channels with programmable bandwidth number of spectral channels.

The AISA instrument can be flown on light aircraft (Cessna 152 or 182). A nominal flight altitude is 1000 m; this configuration provides spatial resolutions of 1 m across track.

Table 583: Technical specification parameters of AISA

P.16 ALAS (Airborne Laser Altimeter System)

ALAS²¹⁵¹⁾ is a NASA/GSFC developed research instrument which measures the laser pulse time-of-flight and the distortion of the pulse waveform due to reflection from Earth surface terrain features. The objective is to provide a capability for ranging and waveform studies of Earth surface topography (precursor instrument for a spacecraft sensor) with high resolutions and accuracies. The instrument was developed in the period 1986-90. The platforms for instrument operations are: T-39 Sabreliner and P-3-B aircraft, both stationed at WFF (Wallops Flight Facility, VA).

ALAS is a nadir-pointing lidar operated in a repetitively pulsed mode. The resulting laser ranging echo information (series of pulse time-of-flight values) is analyzed for the derivation of the surface elevation profiles. This is also referred to as laser altimetry. In addition, the shape of the reflected waveform in the laser footprint contains information whose interpretation (three axis position knowledge) provides such parameters as: surface slope, roughness, and reflectivity.

The source laser of ALAS is a diode-pumped, Q-switched Nd:YAG operating at its fundamental wavelength of 1064 nm. A reflector telescope and silicon avalanche photodiode (Si APD) are the basis of the optical receiver. A high-speed time-interval unit and a separate high-bandwidth waveform digitizer (computer-controlled) are used to process the back-scattered pulse information. The platform is equipped with proper navigation equipment, roll and pitch gyros, and a DGPS receiver for two-axis pointing and for a time reference.

The ALAS telescope is a narrow-field device used for high resolution profiling of terrain in low altitude (< 1 km) missions and lidar measurements of vegetation in higher altitude (> 1 km) profiling missions. For simulation of space flight laser altimeter operation with large sensor footprints in the 30-70 m class, a wide-field-of view (Sasquatch) telescope is used in place of the actual ALAS telescope. Sasquatch has a 10 mrad FOV. The Sasquatch configuration is typically flown at high altitudes in order to maximize the footprint size.

Laser transmitter		Lidar Receiver	
Laser type	diode-pumped Nd:YAG	Telescope type	f/0.8 diamond-turned aluminum parabola
Wavelength	1064 nm	Telescope diameter	0.38 m
Pulse energy	0.3 mJ	Optical filter	2 nm bandpass
Pulse width	4 ns FWHM	Detector type	Si APD, 1.5 mm dia.
Repetition rate	1- 100 Hz (55 Hz for contiguous measurements)	FOV = IFOV	2.5 mrad, 10 mrad
Divergence	2 mrad	Bandwidth	120 MHz
Cooling	Conduction to telescope	Time-interval counter	156 ps resolution
Total instrument mass	35 kg	Waveform digitizer	100 channels, 742 ps res. 11-bit amplitude resolution 400 MHz bandwidth

Table 584: Parameter specification of the ALAS instrument

The ALAS pulsed laser transmitter is a new device designed and built at GSFC in the spring 1993. It incorporates a diode-pumped, Q-switched, cavity-dumped Nd:YAG laser oscillator design that delivers a single spatial mode output pattern. In operation two in-line, Nd:YAG oscillator crystals are optically pumped with pulsed diode laser radiation at 808 nm wavelength for a duration of ~200 μs. The polarization-coupled oscillator pulse output is directed into a double pass diode-pumped amplifier. There it encounters a further rotation of polarization that prevents the laser pulse from returning to the oscillator and produces the observed output pulse with more pulse energy by factor of 2 or 3. This new ALAS laser is

²¹⁵¹⁾J. L. Bufton, J. B. Garvin, J. F. Cavanaugh, L. Ramos-Izquierdo, T. D. Clem, W. B. Krabill, "Airborne Lidar for Profiling of Surface Topography," Optical Engineering, January 1991, Vol. 30, No. 1, pp. 72-78

capable of producing 300 μJ pulses at a repetition rate of 50 pulses per second ~ 4 ns FWHM pulse width. IFOV = 2 mrad.

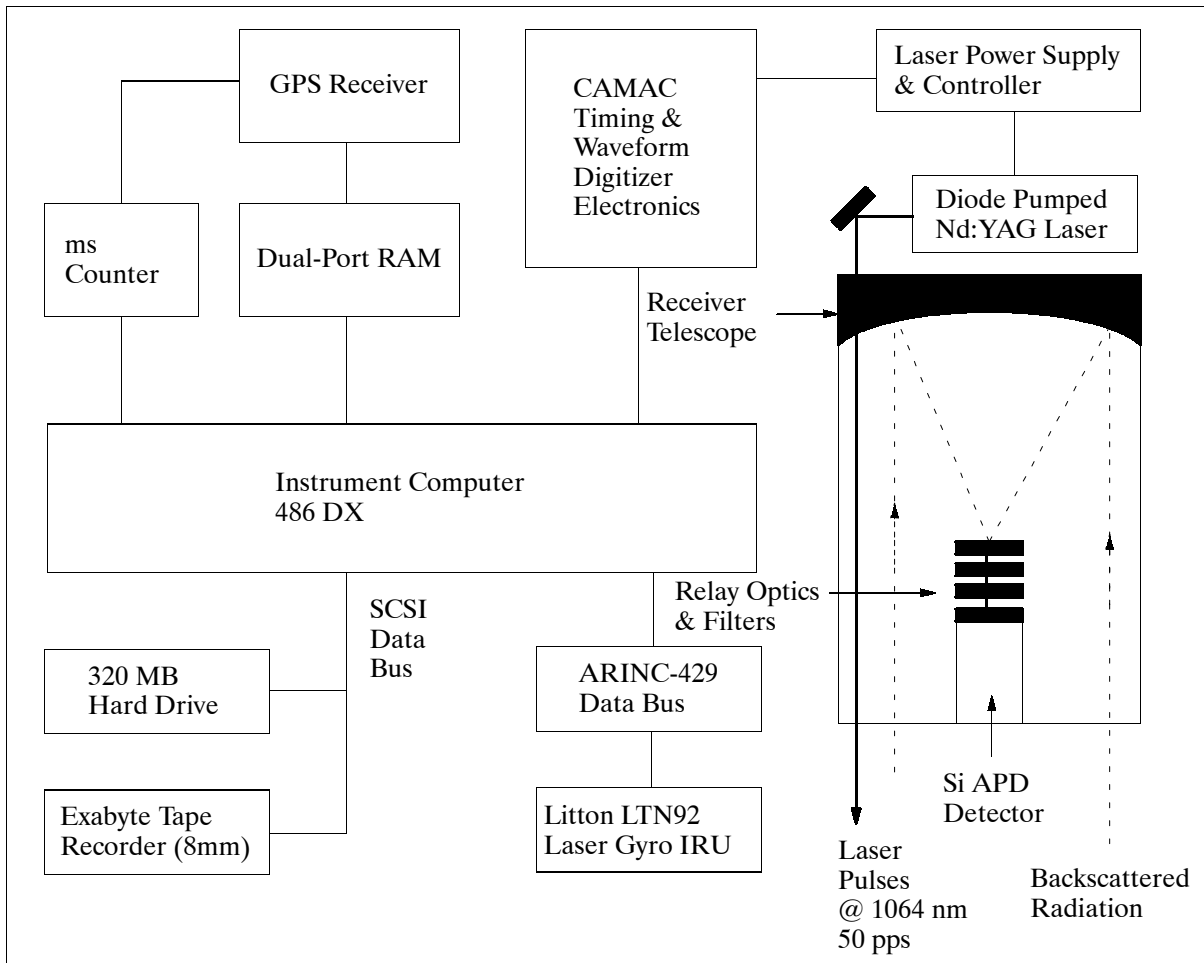

Figure 427: Functional block diagram of ALAS

Airborne operation of ALAS is based on a high SNR environment (> 40 dB) in which each laser pulse can be used for a unique range measurement and for waveform data interpretation. No pulse-to-pulse averaging is used for terrain profiles. Laser altimeter signal strength depends on the laser pulse power backscattered from the target surface and collected by the receiver telescope. With an IFOV of 2.0 mrad the laser footprint on the Earth surface turns out to be 2.0 m in diameter per km of altitude.

P.17 ALF (Airborne Laser Fluorosensor)

ALF is a proprietary survey exploration instrument of World Geoscience Corp. LTD of Perth, Australia (ALF was purchased from BP Exploration in 1992, version MK3). The instrument is used to detect petroleum on the sea surface which has leaked or seeped from undiscovered oil fields. ALF is installed in a twin engine aircraft and flown at altitudes of 100 m above sea level or less.

The ALF instrument consists of a pulsed (50 Hz) UV laser, an imaging telescope, an electro-optical detector, and a data logger computer. The laser beam is transmitted vertically downward to illuminate the sea surface. A characteristic fluorescence response is produced by the presence of surface oil. The returning light is collected by a 16 inch Newtonian reflecting telescope. This beam is split into its constituent spectral colors and converted into digital signals by a diode array detector. The data are stored digitally by the data logging

computer system, which simultaneously records GPS navigational information. Oil films can be detected down to a thickness of about 0.05 μm . ALF offers the following surveying capabilities:²¹⁵²⁾

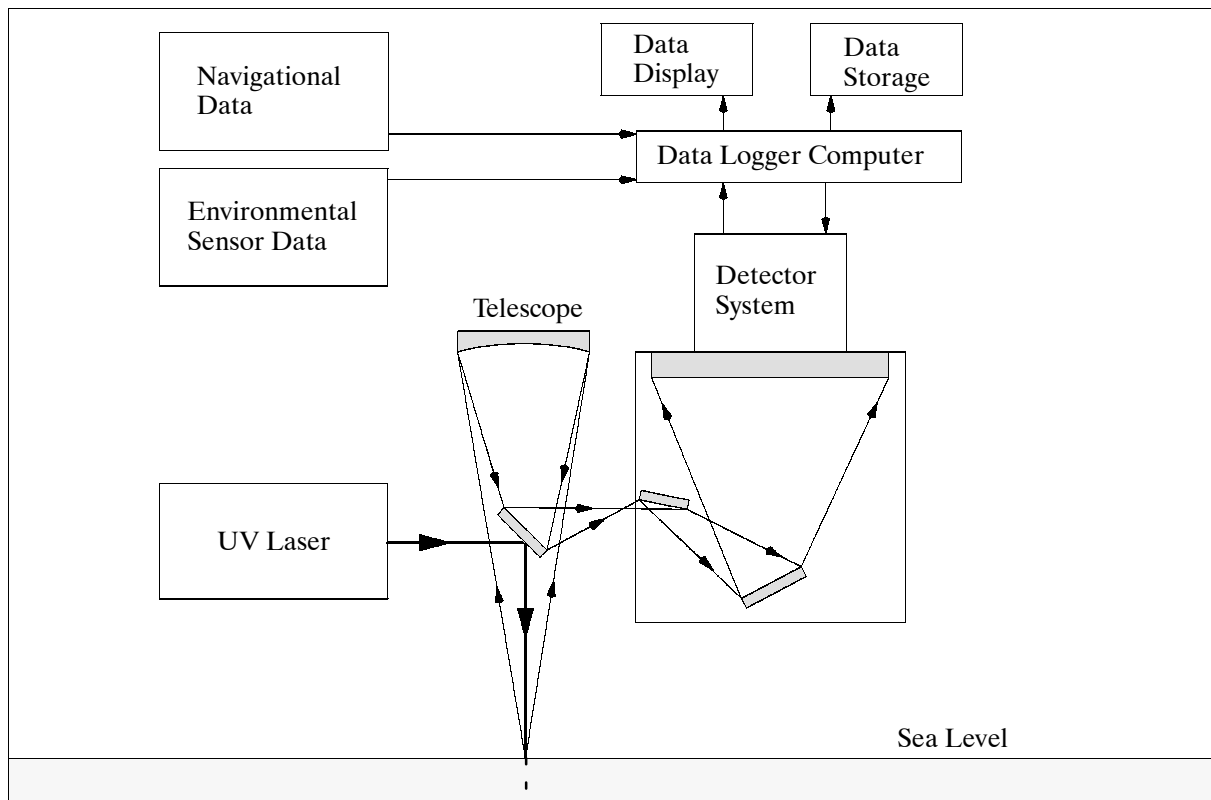

Figure 428: Basic system components of the ALF instrument

- **Pollution:** ALF can distinguish fresh petroleum films on the sea-surface from other oil slicks of non-seep origin (which have negligible fluorescence). It cannot distinguish seeped oil from freshly spilled crude oil. However, repeat flying eliminates pollution problems, as pollution slicks lose their fluorescent component quickly by evaporation (and also change their position, whereas seeped oil reappears at or near its point of origin).
- **Algae:** Some algae such as trichodesmium produce a very weak blue fluorescence (but concentrations are orders of magnitude lower than very thin oil films).
- **Flat water slicks:** ALF can distinguish flat water slicks due to wind and current action. These are nonfluorescent and can confuse other passive slick mapping sensors.
- **Sun glint:** Sun glint occurs when the detectors are swamped by sunlight reflecting directly off the sea-surface into the telescope. Sun glint and oil spectra are easily distinguished by their spectral signature.

In a typical survey, ALF data are acquired over uniformly spaced flight lines aligned across the site of interest and/or perpendicular to the dominant current direction. The ALF operator monitors data as it is collected and records environmental parameters such as sea state, plus any unusual features on the sea surface. After the flight the data are processed to identify fluorescence anomalies (fuors), and the video flight logs are screened to eliminate anomalies due to nonoily features such as algal mats. Finally, a survey map showing the locations of the fluorescence anomalies is generated for exploration interpretation.

Miniaturized solid state laser with an emission wavelength of 255 nm.

The wavelength of the older MK2 instrument was 308 nm. The new wavelength (255 nm) provides a wider spectral window and better discrimination of slick types.

Installed system mass of 300 kg

Maximum current draw of 90 A from aircraft 28 V DC supply
Sampled area of 20 m ² per laser shot
Laser firing and fluorescence spectra data collected synchronously at 50 Hz
176 channels (minimum) of spectral data acquired over a wavelength range of 250 - 700 nm, with channels positioned to concentrate on features of interest, i.e. the laser backscattered light, the seawater Raman signal, and the 300 - 700 nm fluorescence signal.
In-flight quicklook display capability of a number of system parameters
An integral part of the system is a UV/VIS camera and video recorder system targeted at the sea surface being surveyed by ALF. This arrangement is very useful for post flight checking.

Table 585: Technical features/specifications of the ALF MK3 instrument

P.18 ALIAS (Aircraft Laser Infrared Absorption Spectrometer)

ALIAS²¹⁵³) is a JPL instrument, developed for NASA's 'Upper Atmospheric Research Program' (UARP), which started operation in 1990 (instrument mass = 75 kg). The instrument is of BLISS (Balloon-borne Laser In-Situ Sensor) heritage which had 11 successful flights during the period 1983-92 (instrument mass of 1000 kg). ALIAS is flown on ER-2 aircraft with over 50 flights by the end of 1993. Most of the flights resulted from two major campaigns, namely AASE-II (Airborne Arctic Stratospheric Expedition, at Fairbanks Alaska, and Bangor, Maine) and SPADE (Stratospheric Photochemistry, Aerosols and Dynamics Experiment). Since 1992 a further instrument, ALIAS-II, is being developed and built for PERSEUS A with an instrument mass of about 25 kg.

P.18.1 ALIAS-I on ER-2 Aircraft

ALIAS (or ALIAS-I)²¹⁵⁴) is a high-resolution (0.0003 cm^{-1}) scanning TDL (Tunable-Diode-Laser) spectrometer designed to make direct and simultaneous measurements of HCl, NO₂, HNO₃, CO, CH₄, and N₂O (including vertical profiles of CH₄ and N₂O) in the polar stratosphere at sensitivities of tens of parts-per-trillion (1 ppt = 10^{-12}) over a 30 second integration time.

The measurement technique is based on tunable lead-salt diode lasers operating from 3.4 - 8 μm and scanning over absorption lines recorded with second-harmonic absorption spectroscopy over an 80 m path length in a 1 m multipass optical Herriott cell. A single liquid-nitrogen dewar contains all four TDLs and four HgCdTe IR detectors on a single cold finger. The light from the laser is collected by half-inch Zn-Se lenses and directed through a wedged Zn-Se window through one of four coupling holes in a 15.24 cm diameter Au-coated Al spherical mirror forming the Herriott cell. After traversing 80 passes of the Herriott cell, the beams exit the same entrance holes and are directed back to the dewar, where they are directed onto Zn-Se collection lenses in front of the appropriate HgCdTe detector. Second-harmonic detection frequencies in the 20-40 kHz range are used in conjunction with a 10 Hz fast-sweep ramp for spectral scanning. Data collection is based on averaging spectral scans for recording spectra from 0.3-60 seconds.

The ALIAS-I instrument has four optical subsystems: a liquid-nitrogen-cooled dewar containing lasers and detectors, a moveable lens assembly, optical bench supporting steering of mirrors and reference wavelength cells, and the multipass Herriott cell.

P.18.2 ALIAS-II on Perseus Aircraft

ALIAS-II objectives for NASA's AESA/HSRP Program:

²¹⁵³) Information provided by C. R. Webster of NASA/JPL

²¹⁵⁴) C. R. Webster, R. D. May, C. A. Trimble, R. G. Chave, J. Kendall, "Aircraft (ER-2) laser infrared absorption (ALIAS) for in-situ stratospheric measurements of HCl, N₂O, CH₄, NO₂ and HNO₃," Applied Optics, January 20, 1994

- 1) To provide measurements (high spatial resolution in latitude and longitude) of N₂O, CH₄, and H₂O as part of a reference chemical climatology database for the lower stratosphere and upper troposphere regions. This database can be used for calibration and testing of global models, and as an indicator of change in atmospheric composition.
- 2) To quantitatively characterize the emission of H₂O into the emission plumes, and its mixing by shear winds and diffusion from injection through the 5-20 day formation of zonally-uniform distributions. This occurs in conjunction with the additional ALIAS-II measurements of the tracer N₂O for identifying transport and redistribution of emissions near and above the tropopause, and of CH₄ to assess perturbations to the initial air parcel photochemistry.
- 3) To investigate the mechanisms responsible for the stratosphere/troposphere exchange of water vapor, through measurements in the middle/upper tropopause and the tropopause region. ALIAS-II will make extensive measurements of H₂O as a function of both altitude and latitude, as input for model predictions of global warming.
- 4) To investigate plume chemistry and physics with regard to the formation and growth of ice particles within the plume, and their possible fallout. ALIAS-II measurements of gas-phase H₂O (and N₂O as tracer) will identify the extent of dehydration locally within regions of particle formation from an aircraft platform entering either the plume region or a similar environment.

The ALIAS-II instrument is a 2-channel version of the ALIAS (ER-2) instrument, with identical electronics, dewar configuration, and instrument- and data processing- software. In this configuration ALIAS-II measures the trace gases in a very clean, open path (important for H₂O) defined as the 5 m round-trip from the nose to the wing. This is achieved by using a miniaturized multireflector assembly on the wing.

Channel No.	Trace Gas	Wavenumber	Expected Mixing-Ratio	Minimum-detectable Mixing-ratio	
1	N ₂ O	1277	305 ppbv	at 500 mbar	4 ppbv
	N ₂ O	1277	80 ppbv	at 50 mbar	
1	CH ₄	1277	1.7 ppmv	at 500 mbar	20 ppbv
	CH ₄	1277	0.8-1.4 ppmv	at 50 mbar	
2	H ₂ O	1636	50-700 ppmv	at 500 mbar	20 ppbv
	H ₂ O	1636	1.5-5.5 ppmv	at 50 mbar	

Table 586: ALIAS-II Measurement Capability of Trace Gases

In an alternative configuration, a Herriott-cell design copied from ALIAS-I spans the 2.5 m distance, and achieves a path length of about 120 m in an optical system designed to accommodate wing motions. With a change of diode laser sources, this alternative configuration will allow ALIAS-II to make measurements of CO, and NO₂ (or HCl) with higher sensitivities than can be done in the ER-2 experiment.

Instrument	Species measured simultaneously	Measurement time
ALIAS-I (ER-2) (5 gases)	N ₂ O, CH ₄ , CO, HCl, NO ₂	0.3 s 30 s 60 s
ALIAS-II (Perseus) (2 or 3 gases)	i) CO plus NO ₂ or HCl ii) N ₂ O, CH ₄ , H ₂ O	0.3 s, 60/30 s 0.3 s

Table 587: Overview of measured species of the ALIAS instruments

P.19 ALPS (Airborne Laser Polarization Sensor)

ALPS is an active NASA/GSFC sensor featuring multispectral radiometric and polarization measurements using a polarized laser light source. ALPS provides a source of optical

scattering measurements in the field to characterize terrestrial surfaces in their natural state (information that depends on surface texture, dielectric properties, transmittance, reflectance, and absorption). ALPS is a prototype, applications-oriented instrument for active optical remote sensing. The instrument is a single spot, nonimaging sensor, measuring the degree of depolarization caused by a surface.²¹⁵⁵⁾

The ALPS instrument consists of a pulsed, polarized laser source, an optical receiver system, a video camera and recorder, and data acquisition and analysis hardware and software. The choice of laser wavelengths is limited to two frequencies from the UV to the NIR spectral range by the photo-cathode response of the Photo Multiplier Tube (PMT) detectors. A pulsed (7ns) Nd:YAG laser is employed. It operates in the NIR at 1064 nm and in the VIS at 532 nm. ALPS employs twelve PMT detectors configurable to measure desired parameters such as total backscatter and polarization state, including azimuthal angle and ellipticity, at different UV and NIR wavelengths simultaneously.

ALPS has been flown in several NASA campaigns on a HU-1B helicopter. The instrument is also known under its old name PALIS (Polarized Airborne Laser Imaging Sensor) prior to the designation ALPS.

P.20 ALTM (Airborne Laser Terrain Mapping)

ALTM is a commercially available lidar instrument designed and built by Optech Systems Corp. of North York, Ontario, Canada (software by TopScan GmbH of Stuttgart, Germany). The all-digital and highly automated instrument may be used in the following applications: topographic mapping of surfaces; power transmission line, road and pipeline planning; power line clearance surveys; tree height mapping for forest inventories; coastal area mapping, shoreline control; erosion monitoring, etc. The system became operational in 1993; it can be flown on a variety of light aircraft.²¹⁵⁶⁾

The airborne module consists of the infrared laser instrument with its subsystems, a carrier-phase DGPS receiver (aircraft location), an IRS (Inertial Reference System) for aircraft attitude, a color video camera (with time annotation, NTSC or PAL video format) for over-view monitoring, a computer system for instrument control (touch-screen display), and a data storage system (8 mm digital tape). The ground-based module consists of a data processing software package by Topscan for all data types (sensor data, housekeeping data, and the location/attitude data), and permitting a variety of display options, DTM (Digital Terrain Model) generation, and archiving functions.²¹⁵⁷⁾

Parameter	Value	Parameter	Value

Table 588: Parameters of the ALTM instrument (1020 model)

As time went by improved ALTM instrument versions were developed. The first model of

2155) J. E. Kalshoven, P. W. Dabney, “Remote Sensing of the Earth’s Surface with an Airborne Polarized Laser,” IEEE Transactions on Geoscience and Remote Sensing, Vol. 31 No. 2, March 1993, pp. 438-446
2156) Information provided by J. Lindenberger of TopScan GmbH, Stuttgart, Germany
2157) B. Gutelius, “Engineering Applications of Airborne Scanning Lasers: Reports From the Field,” PE&RS, April 1998, pp. 246-253

1993 has the designation ALTM 1020, the latested model in 1999 is ALTM 1210.²¹⁵⁸⁾ The latter instrument has a PRF of 10 kHz and allows operating altitudes from 1200 m to 2000 m (AGL). This translates into extended ground coverage capability (swath width at 2000 m is about 1400 m).

P.21 AMMR (Airborne Multichannel Microwave Radiometer)

AMMR is an operational passive radiometer system existing since 1980, owned by NASA/GSFC. AMMR consists of an array of single-beam radiometers at the frequencies of 10, 18.7, 21, 37, and 92 GHz. These radiometers are installed in the windows on the left-hand side of the DC-8 aircraft. The 18.7, 37, and 92 GHz units are dual polarized. All radiometers have a beam width of about 6° ; all have a temperature sensitivity of about 0.5 K and a calibration accuracy of ± 4 K. The major application of AMMR is for precipitation measurements, although other surface parameters like sea ice, snow and vegetation covers can also be measured. AMMR took part in the TOGA/COARE mission in January/February 1993.

P.22 AMMS (Airborne Microwave Moisture Sounder)

AMMS is a four-channel mechanically scanned imaging radiometer with frequencies at 92, 183.3 ± 2 , 183.3 ± 5 , and 183 ± 9 GHz. The sensor is owned and operated by NASA/GSFC. The major applications of AMMS are to measure precipitation, clouds and water vapor profiles. It has a 15 cm aperture giving an angular resolution of about 2° at 92 GHz and 1° at 183 GHz. AMMS is a cross-track scanner having an angular swath of $\pm 45^\circ$. It first became operational in 1981.²¹⁵⁹⁾

In recent operation the temperature sensitivity of the sensor was found to deteriorate appreciably. Based on the data acquired in a previous mission in September 1990, the temperature sensitivities at the four frequencies (92 GHz, 183.3 ± 2 , 183.3 ± 5 , and 183 ± 9 GHz) were found to be about 4.1 K, 4.5 K, 4.3 K, and 7.5 K, respectively. The calibration accuracy was in the order of 1 K in the brightness temperature range of 250-300 K and could be as much as 2-3 K at a brightness temperature range of < 200 K. Because of the poor temperature sensitivity, the sensor is no longer being used for water vapor profiling; it can provide very useful microwave signatures from precipitation associated with convective systems.

AMMS is normally installed in the NASA DC-8 aircraft, flying in the altitude range of 10-12 km. The sensor took part in the TOGA/COARE mission in the Pacific during January/February 1993.

P.23 AMPR (Advanced Microwave Precipitation Radiometer)

AMPR^{2160), 2161)} is a NASA/MSFC-sponsored instrument of Georgia Technical Research Institute (GTRI) heritage with the objective to support the development and validation of current and future satellite precipitation retrieval algorithms of oceanic and land-based systems. The instrument is a low-noise passive system providing multifrequency microwave imagery with high spatial resolution.

AMPR is a cross-track scanning total power microwave radiometer with four channels centered at 10.7, 19.35, 37.1 and 85.5 GHz. It has a dual lens antenna to accommodate two sepa-

²¹⁵⁹⁾ Information provided by J. R. Wang of GSFC

²¹⁶⁰⁾ Information provided by R. E. Hood and R. W. Spencer of NASA/MSFC

²¹⁶¹⁾ R. W. Spencer, R. E. Hood, et al., "High-Resolution Imaging of Rain Systems with the Advanced Microwave Precipitation Radiometer," Journal of Atmospheric and Oceanic Technology, Vol. 11, No. 4, Aug. 1994, pp. 849-857

rate feedhorns. One horn is a copy of the feedhorn used for SSM/I (on DMSP, see G.1). This horn feeds the 19.35, 37.1 and 85.5 GHz channels with a 13.5 cm diameter lens. The other AMPR feedhorn was designed by GTRI to accommodate the 10.7 GHz frequency. The lens for this horn has a diameter of 24.7 cm.

AMPR is flown in the Q-bay of the ER-2 aircraft. The dual antenna and scanning mirror extend below the aircraft body into a hatch opening. The instrument has a 90° total scan centered at nadir. The observations are contiguous at 85.5 GHz and coincident at all four channels, leading to oversampling at the lower frequencies. A rotating polarization scheme for all four channels is used during scanning. Polarization varies from vertical (V) at 45° to the left of nadir to horizontal (H) at 45° to the right of nadir. At nadir the polarizations are equally mixed. The scanning strategy allows dual-polarized information to be collected at the extreme scan angles with opposite aircraft passes over a given target.

Parameter	85.5 GHz	37.1 GHz	19.35 GHz	10.7 GHz
Bandwidth (MHz)	1400	900	240	100
Temperature resolution (°C)	0.3	0.2	0.5	0.2

Instrument mass		152 kg (radiometer+power supply+data system)		
Contiguous footprints @ 85.5 GHz; lower frequencies are oversampled by the beamwidth ratio four SSM/I ports are available for additional channels External warm (heated) and cold (ambient) calibration targets enclosed in Styrofoam				

Table 589: Characteristics of the AMPR instrument

The AMPR receiver subsystem is a heterodyne system: the radiation collected between 10.7 and 85.5 GHz is downconverted, amplified and detected at the IF (intermediate frequency) level. The analog output is transferred via an integrate and dump circuit to the data acquisition subsystem (DAS). The 10.7 GHz receiver uses a dielectrically resonating oscillator to downconvert the energy to IF. This mixer IF output is then fed to an integrated detector and a low-pass filter. - The 19.35 - 85.5 GHz channels each use a Gunn diode local oscillator for downconversion, with a beam-lead diode mixer and low-noise IF amplifiers.

The AMPR is calibrated with two high-emissive loads external to the radiometers and the antennas. The measured brightness temperatures are independent of instrument temperature and gain changes, due to this “external” calibration design (provided that the changes occur on time scales longer than the interval between calibration scans). Every fourth scan cycle, the scanner moves the reflector to a position where the two calibration loads are viewed, one at a time, by the lens-horn systems.

AMPR has been flown on numerous missions such as CaPE (1991), STROM-FEST (1992), TOGA/COARE (1993), and CAMEX (1993 and 1995).

P.24 AMPS (Airborne Multisensor Pod System)

AMPS is a US DOE-sponsored (Department of Energy) observation program consisting of a sensor platform for aerial data collection and a ground-based data management system

for data archiving, analysis, and distribution. The program has been developed and is being operated by the following DOE laboratories: RSL (Remote Sensing Laboratory) of EG&G Energy Measurements Inc., Las Vegas, NV; Sandia National Laboratories (SNL), Albuquerque, NM; Pacific Northwest Laboratory (PNL) of Richland, Washington (WA); Savannah River Technology Center (SRTC), Aiken, SC; Lawrence Livermore National Laboratory (LLNL), Livermore, CA; and the US Navy. The primary objective of the AMPS program is to collect multisensor data that can be used for many different applications (including treaty verification) in the area of remote sensing research. ²¹⁶²⁾

As of 3/1995 a modified Lockheed RP-3A (four-engine turboprop aircraft (flight altitudes range between 100 m and 8500 m AGL, speed: 75-150 m/s) is utilized as an aerial platform and flown by the Navy Air Warfare Center (NAWC) at Point Mugu, CA. The aircraft is equipped with GPS and INS, including P-code GPS. The location data is available to the pods and to the sensors. The AMPS sensor complement is arranged in three different assemblies, referred to as ‘pods’ [a pod is a cylindrical structure of about 5 m length, 1 m diameter and 1000 kg max mass; pod services include electrical power, cooling, and control systems which differ in concept and detail from pod to pod]. Pod-1 contains the Sandia SAR (SNL); Pod-2 carries a suite of six imaging sensors (RSL); Pod-3 carries several sensors for effluent species identification (LLNL). Additional pods may be added for future requirements. - AMPS checkout flights started in April 1994, the system went semi-operational in June 1994. About four to five missions per year are flown, each lasting 1-2 weeks, covering multiple regions and targets in the USA. Other P-3 aircraft by NRL and by NOAA are being considered/modified to fly the (single set) AMPS pods with their sensor complements.

Data management (archiving and data distribution) of the AMPS program is the responsibility of PNL, but each laboratory has responsibility for its own data reduction. In general, the AMPS program has adopted an open data policy (some data sets are for restricted users). Some typical and representative data sets are made available at the AMPS web site (<http://www.amps.gov>).

P.24.1 Sony DXC-750 3-CCD Video Camera

The instrument is a high-resolution color video camera used for daylight observations. The image is generated by three CCDs (three-chip interline transfer CCD), each featuring an array of 380,000 pixels. Electronic shutter options enable the camera to produce clear images in still or slow-motion playback of fast-moving objects. - The data of the video camera are recorded onto a Sony DVR-2 digital cassette recorder.

Parameter DXC-750	Value	Parameter DVR-2	Value
CCD array	768 x 493 pixels	Sampling frequency	14.3 MHz
Scanning system	522 lines, 2:1 interface	Linear quantization	8 bit
Horizontal resolution	700 lines	SNR	54 dB
Sensitivity	2000 lux, f/5.6 at 3200 K	Video bandwidth	6 MHz
Min operating light level	20 lux	Mass of recorder	12 kg
SNR	60 dB	Power	65 W
Shutter speeds	1/125 to 1/10,000 s		
Mass	3.7 kg		

Table 590: Parameters of DXC-750 and DVR-2 devices

P.24.2 Wild RC30 Large Format Camera

A nadir-pointing camera which acquires high-resolution photographic imagery. Three color-corrected lenses are available with the camera. Optical filters are used to control the

²¹⁶²⁾Information provided by J. Bradley, SNL, Albuquerque, NM and by R. Finucane of LLNL, Livermore, CA

spectral bandwidth reaching the film. The instrument utilizes film widths of 240 mm with film lengths of 120 m. A useful image area of 23 x 23 cm per frame results in 420 high-resolution images per roll. The camera mount is adjustable for in-flight tilt and drift corrections. Some characteristics: shutter speeds = 1/100 to 1/1000 s; super-wide-angle lens (f=88 mm, f/4), wide-angle lens (f=150 mm, f/4), and lens (f=213 mm, f/4); mass of instrument = 182 kg; operating voltage = 28 VDC. See also P.117.

P.24.3 AGEMA Thermal Imager

A commercially available passive infrared sensor (AGEMA) with nighttime imaging capability (nadir pointing). The instrument features a dual-lens germanium telescope with 2.5 x or 9 x magnification options for radiation collection. Its lens is a 200 mm germanium telescope offering two power options with continuous 300 m from 2° to 12°. The system is cooled by a Sterling engine. The instrument data are recorded onto a high-resolution video recorder (TEAC V-80AB-F); tape format = Hi-8mm and 8 mm; recording time = 120 minutes; resolution = 400 TV lines; signal standard = NTSC/PAL or RS-170/CCIR; SNR = 43 dB; mass = 3 kg.

Parameter	Value	Parameter	Value
Spectral range	8 - 12 μ m	IFOV (resolution)	0.6-0.15 mrad
FOV (narrow)	5° x 3.3°	Sensitivity	< 0.1°C
FOV (wide)	2.0° x 13.3°	Detector type	HgCdTe

Table 591: Parameters of the Thermal Imager

P.24.4 Sandia SAR

The Ku-band imaging instrument was designed and built by Sandia National Laboratories of Albuquerque, NM. - Applications: exploration for natural resources, treaty verification, surveillance, and navigation.

The system is mounted into pod 1 and consisting of a three-axis stabilized gimbal-mounted phased array antenna, the RF frontend, the INS, and a video camera (used only for scene documentation). Further SAR components are: a transmitter assembly that includes a transmitting wave tube amplifier and an optical delay line for health checks; an integrated radar receiver and image formation processor; control electronics, display monitors for SAR and video imagery, and an AMPEX DCRSi data recording system. -Pod 1 is mounted underneath the right wing of the aircraft, about 2.2 m away from the aircraft center line (Station No. 15).

SAR upgrades in 1995: operation of strip map mode and spotlight mode. By the beginning of 1996 the antenna will have been replaced with two parabolic horn-fed antennas for interferometric SAR operations, offering the capability of generating accurate terrain maps.

Parameter	Value	Parameter	Value
RF center frequency	14.850 GHz (Ku-band)	Swath width	750 m to 2900 m
Wavelength	2 cm	Spatial resolution	1 - 3 m
System bandwidth	60 - 180 MHz	Quantization	8 bits (phase history)
Antenna polarization	VV	Quantiz. image pixels	16 bit (magnitude)
Antenna gain	27.3 dB	Quantiz. image pixels	12 bit (phase)
Azimuth beamwidth	2.5°	Data rate	107 Mbit/s max
Elevation beamwidth	10°	Data recorder	Ampex DCRSi
Depression angle	10° - 60°	Data capacity	45 GByte
Transmitted peak power	70 W (500 W future)	Motion compensation	Real-time

Table 592: Parameters of the Sandia SAR instrument

P.24.5 COHU 5560 Low Light Camera

The commercially-available video instrument provides high-resolution images under extremely limited light conditions. The camera features an image intensifier assembly which is fiber-optically coupled to a CCD detector array of 5560 pixels.

The monochrome TV camera operates in the spectral range from 0.4 - 0.8 μm ; resolution: 520 horizontal and ($>$) 350 vertical lines; sensitivity: 2854 K faceplate illumination, full video = 10^{-4} fc (0.001 lux), usable picture: 0.25×10^{-4} fc (footcandle); SNR: 40 dB. The camera data is recorded onto a TEAC V-80AB-F video recorder.

P.24.6 CASI (Compact Airborne Spectrographic Imager)

CASI is a commercially available hyperspectral imaging instrument of ITRES Research Limited of Calgary, Alberta, Canada. It is operated by RSL of EG&G, Las Vegas, NV. CASI is described in chapter P.50. CASI is operated in spectral or spatial mode (whereby the mode must be set up in preflight). In spectral mode, 288 channels, 39 look directions, 3 nm bandpass, noncontiguous spatial coverage; pixel size is a function of the number of look directions, altitude, and ground speed. The resulting pixels are not square. In spatial mode, 512 cross-track pixels, FOV=34.2°, pixel width=0.0012 x AGL; pixel length is a function of altitude, ground speed, number of spectral bands, and integration time.

P.24.7 AMS (Airborne Multispectral Scanner)

AMS is a commercially available instrument of Daedalus Enterprises of Ann Arbor, Michigan, operated by RSL of EG&G, Las Vegas, NV. The instrument is defined in chapter P.63.5. AMS provides calibrated thermal information for determining radiometric temperature relationships for various remote sensing applications.

P.24.8 EGS (Echelle Grating Spectrometer)

EGS is a high-resolution nonimaging passive optical spectrometer, designed and built by LLNL (PI: C. G. Stevens), measuring the mid-infrared spectral absorptions of airborne chemicals (identification and quantification of molecules associated with chemical and nuclear weapon production). The instrument uses reflected sunlight to determine the molecular absorption in an effluent plume. EGS features a 2-D InSb detector array with a high spectral resolution of 0.08 to 0.09 cm^{-1} . The resolution is matched to the line widths of gases at atmospheric pressures. The instrument has a very coarse Echelle grating and prism combination for cross dispersion to develop a 2-D spectral layout onto the detector array.

The EGS consists of light gathering optical elements, dispersion grating, prism, a 320 x 256 InSb detector array, and associated electronics. It has no moving parts. MOD1 and MOD2 refer to two different models of the instrument. MOD2 is expected to be operational by the end of 1995. The data rate and storage is variable and operator selectable. The instrument integrates the optical signal for up to 100 s, or can make repeated measurements at 1 Hz.

Parameter	MOD1	MOD2
Grating ruling	23 lines/mm	3 lines/mm
Detector array	256 x 265	512 x 512
Detector temperature	63 K	60 K
Spectrometer temperature	290 K	150 K
Collection optics (aperture dia.)	7.6 cm	25 cm
Dwell time	10 - 100 s	10 - 100 s
Spectral range	2.0 - 2.5 μm	2.0 - 4.0 μm
Spectral resolution	up to 0.2 cm^{-1}	0.1 cm^{-1} nominal
HF (hydrogen fluoride) detection limit	1 ppm m^{-1}	0.1 ppm m^{-1}

Table 593: EGS instrument parameters

P.24.9 AC-ITMS (Air Concentrator-Ion Trap Mass Spectrometer)

AC-ITMS (LLNL instrument) is a state-of-the-art Teledyne MEC HST ion trap mass spectrometer, modified and adapted for airborne use. It selectively collects and analyzes in near-real-time the organic and organo-metallic compounds in the atmosphere. The instrument sensitivity for the detection of chemical weapons and nuclear-related signatures of atmospheric species is generally below one part-per-trillion ($1 \text{ ppt} = 10^{-12}$) with better than unit mass resolution. This is achieved in the AC-ITMS by the addition of a high-volume air sampler at the pre-concentrator stage. The pre-concentrator adds a 10^3 to 10^5 -fold increase in sensitivity over the one part-per-billion ($1 \text{ ppb} = 10^{-9}$) sensitivity of the ion trap mass spectrometer alone. AC-ITMS operates as a batch processor, collecting and concentrating sufficient chemical species for detection in the ion trap. The detection range extends to as far as 10 to 100 km downwind, depending on the intensity of the release and on the level of background interference.

Base sensitivity: ppm range; enhanced sensitivity: ppt range; sensed volume: 1-100 m³; analysis cycle time: 2-5 minutes; collection time: 30-120 s; nominal mass number range: 40-250 amu (atomic mass unit); resolution: 0.01 cm⁻¹. The data rate and storage is variable and operator selectable. The instrument is capable of 0.5-2.0 m³/min sampling rate, with the data rate varying from 1 Hz to one sample every 10 minutes.

P.24.10 TTS (Target Tracking System)

TTS (Versatron Skyball Model 18, operated by LLNL) is a triple-payload surveillance system packaged into a 35.5 cm (14 inch) diameter, four-axis gyro-stabilized turret. A gimbal-mounted video camera (DLTV = Day Light Television) functions as a general survey instrument and primary tracking input for the pod. The video camera acquires and tracks ground targets of interest. A FLIR (Forward Looking Infrared) camera produces imagery in the spectral range of 3-5 μm , which is basically the same range as that of EGS on the same pod. The third sensor in this assembly is a laser range finder to assist in the tracking of targets (the laser range finder will be added in 1996). Both cameras (DLTV and FLIR) of TTS provide pointing information to the other effluent sensors on the pod (EGS, AC-ITMS). DLTV and FLIR data may be recorded (simultaneously or selectively) at full video rates.

Parameter	FLIR	DLTV
Spectral range	3-5 μm	0.4-0.7 μm (VIS), monochrome
FOV (narrow)	2.09° x 2.72°	1.7° x 2.3°
FOV (wide)	8.36° x 10.88°	16.7° x 21.8°
Resolution	512 x 512 pixels (CCD array)	570 x 485 TV lines
Minimum sensitivity	NEAT: 0.15 K (BB @ 300 K)	0.5 lux, f/1.4

Table 594: Parameters of the TTS instrument assembly

P.24.11 AKS (Aerial Krypton Sampler)

AKS was designed and built by SRTC (Savannah River Technology Center, Aiken, SC). The assembly (on pod 3) collects whole air samples for later analysis of radioactive ⁸⁵Kr components at the SRTC laboratory. The sorbent container beds are filled with a synthetic mordenite material, with a microcrystalline structure, optimized to collect krypton (krypton 85 is a high-value signature effluent that easily escapes from nuclear reactors and nuclear reprocessing operations into the environment unless great efforts are made to contain or cryogenically trap it).

To collect a sample of purified krypton, 100 liter of air are first passed through two air purification cells to remove the CO₂ and H₂O, and then through a mordenite sorbent bed, where the krypton in the air stream is trapped. Whole air is sampled at a rate of 10 l/min for a total

collection cycle of about 10 minutes per sample. Six sorbent beds compose each collection module. The two modules are operated serially for up to two hours of continuous sampling. The entire assembly is relatively compact with a mass of about 60 kg. Sensitivity: ppb range; sensed air volume: 0.1 m³.

P.24.12 R-TARAC (Real-Time Airborne Radionuclide Analyzer and Collector)

R-TARAC (LLNL sensor) senses radioactive particles in near real-time from an airborne platform. The short-lived radionuclides detected by R-TARAC include the halogen radionuclides (organic and elemental radiodines and radiobromines) and daughter decay products of the noble gases (Xe, Ar, Kr) strongly associated with nuclear proliferation.

R-TARAC samples air at about 50 m³ per minute and collects vapor species and particulates on filter cartridges. The energy spectrum characteristics of each gamma-emitting radionuclide is detected by a high-sensitivity, gamma-ray spectrometer. Shorter-lived radionuclides, producing more than 10 disintegrations per minute and per m³, at gamma energies not directly overlapping those of the radon daughters, can be detected. For a radionuclide with a half-life of 4 hours, R-TARAC's sensitivity detects as few as 5000 atoms per m³ of air.

Sensitivity: about 5000 atoms/m³; detector type: intrinsic germanium diode, detector temperature: 77 K; sensed air volume: about 50 m³; analysis cycle time: 1 minute; sample collection time: 1 minute; data output: on-board display and data recording.

P.25 AMSOS (Airborne Millimeter & Submillimeter-wave Observing System)

AMSOS is a heterodyne spectrometer designed and developed at the U. of Bern, Switzerland, with the objective to observe rotational transitions of various molecules in the millimeterwave and submillimeter-wave ranges with a heterodyne total-power radiometer/spectrometer (passive remote sensing). The shape and intensity (abundance) of the recorded spectra permit calculation of stratospheric and mesospheric trace-gas distributions as a function of altitude and latitude. Typical abundance profiles of molecules (such as: H₂O, O₃, ClO, and HCl) can be obtained in an altitude range of 15 - 70 km.

The AMSOS 'frontend configuration 1' (183 GHz) was initially flown in 1986 on a DLR Falcon aircraft and has been modified for installation on a Learjet 35A of the Swiss Air Force in 1992. Since 1993 periodic flights in different seasons have been performed over a wide range of latitudes. Successful flights from Spitzbergen (78° N) to the Cape Verde Islands were conducted using the 183 GHz receiver to measure middle atmospheric water vapor distributions during different seasons (1993 MAS instrument validation on Shuttle ATLAS mission).^{2163), 2164)}

The AMSOS instrument consists of the following units: input optics, the frontend, the control and data acquisition electronics, and the spectrometer. The input optics are comprised of the rotating and parabolic mirror, the aircraft window, the path modulator, and the Martin-Puplett interferometer as a sideband filter. Reflections inside the optics are reduced with a path-length modulator and corrugated surfaces of the polyethylene window. The main parts of the frontend are the subharmonically pumped Schottky mixer (uncooled) with the corresponding IF section and the phase-locked local oscillator. As of 1995 two frontends of AMSOS are in use as defined in Table 595. The 'frontend configuration 2' is an ESTEC breadboard instrument with the designation SMS (see SUMAS description under P.193). The spectrometer consists of five different filter banks. It is planned to use wideband

and narrowband Acousto-Optical Spectrometers (AOS) and a Chirp Transform Spectrometer (CTS) in future flights.

Frontend configuration	1	2
Center frequencies	183.31 GHz and 184.38 GHz	625 - 650 GHz
IF frequency	3.7 GHz	12.5 GHz
Frequency stability	$<10^{-7}$	$<10^{-7}$
SSB noise temperature	4600 K uncooled	4000 - 10,000 K uncooled
Image rejection	>30 dB	>20 dB
Calibration	Heated load and N ₂ load, triple switched total power	
Spectrometer Channels	5 filterbanks	2 AOS
Resolution	78	1250 and 1024
Bandwidth	50 kHz - 100 MHz	40 kHz and 1.8 MHz
Antenna beamwidth	1° (3 dB)	
Antenna elevation	15°	
Power supply	220 V converter, 750 W	
Instrument size, mass	2 standard 19 inch racks, each with a mass of about 80 kg	

Table 595: Parameter definition of the AMSOS heterodyne instrument

Observational flight altitudes of the Learjet are normally conducted at 12 - 14 km (aircraft speed of 650 km/h). Typical observing angles from the aircraft window are between 5 and 15° elevation. Typical line amplitudes (K brightness temperatures) at 12 km altitude and an elevation angle of 15° are: 130 K for H₂O, 50 K for O₃, 15 K for HCl, and 1.5 K for ClO. The aircraft provides radio navigation and GPS receiver data for instrument data annotation.

P.26 AMSS MK-II (Airborne Multi-Spectral Scanner)

AMSS is a commercially operated sensor of Geoscan PTY Ltd., West Perth, Australia aboard an aircraft with a stabilized (roll, pitch and yaw, drift compensation) optical sensing platform. Specifications:

- Pixel size: 2 to 20 m (8 - 10 m typical)
- Swath width: 1.5 - 19 km
- Pixels/line of swath: 768 pixels (acquired data), 1024 pixels (resampled data)
- Spectral bands: up to 24 recorded bands are selected from 46 detector channels
- FOV: 92°
- IFOV at nadir: 2.1 x 3.0 mrad (acquired data), 2.1 x 2.1 mrad (resampled data)
- Data storage: Optical (WORM) disks, 5.25 inch, 325 MByte per side
- Data is normally provided corrected for atmospheric backscatter and geometric distortion.

Application: mineral exploration, agriculture and forestry mapping, environmental monitoring.²¹⁶⁵⁾

Spectral Range	Number of Channels	Wavelength Range	Band Pass Range
VNIR	32	0.49 - 1.09 μm	0.17 - 0.24 μm
SWIR	8	2.02 - 2.37 μm	0.43 - 0.44 μm
TIR	6	8.50 - 12.0 μm	0.55 - 0.59 μm

Table 596: AMSS spectral parameters

P.27 AOL (Airborne Oceanographic Lidar)

AOL is a NASA ²¹⁶⁶⁾ experimental instrument flown on NASA P-3B aircraft of GSFC Wallops Flight Facility (AOL was built by the AVCO Everett Corporation). Objective: to allow

²¹⁶⁵⁾“Airborne Multi-Spectral Scanner MK2,” brochure of GEOSCAN PTY, Ltd, Australia

investigation of the potential for an airborne laser sensor in the areas of altimetry, hydrography, and fluorosensing. AOL has been in use since 1977; it was upgraded many times to suit certain support requirements.²¹⁶⁷⁾ AOL was and is also used to test and support satellite sensor and algorithm development (such as CZCS, SeaWiFS, OCTS, EOS-Color, MERIS, MODIS).

AOL is a scanning laser radar system with a multispectral time-gated receiving capability. The system is designed to allow adjustments in most transmitter and receiver settings. The flexibility gives the AOL system a potential application in many areas of oceanography. AOL can be operated in either of two modes: temporal or fluorosensing mode. In the temporal mode, the sensor resolves the timing of the reflected laser pulse in 0.7 ns channels over a period of 250 ns. In the fluorosensing mode, laser stimulated fluorescence from water ice, or ground targets is spectrally resolved between 380 nm and 740 nm in 32 contiguous channels of 11.25 nm width. In either mode, the AOL also functions as a high precision laser altimeter measuring the range between the sensor and the surface. This range-measurement capability permits the AOL to conduct airborne surveys of topographic surfaces, including water and ice.

Applications: chlorophyll mapping experiments, oil spill detection, tracer dye, oceanic turbidity cell structure, water depth, laser backscatter investigations, etc.²¹⁶⁸⁾

Some program support services of AOL are: 1984 DOE/SEEP; 1985 DOE/SPREX; 1987 DOE/FLEX and DoD/BIOWATT; 1988/89 DOE SEEP; 1989 NSF/JGOFS/NABE; 1992 NSF/JGOFS/EQPAC; 1993 NSF/JGOFS; 1994 SeaWiFS validation; 1995 NSF/JGOFS Arabian Sea; 1997 NSF/JGOFS South Ocean; 1998 EOS-Color validation; 1999 NSF/JGOFS/NABE.

Transmitter: Wavelength Bandwidth Pulse width Pulse rate Peak output power (max) Beam divergence	Nitrogen laser with energy of 1 mJ 337.1 nm (oil film thickness measurements) 0.1 nm 10 ns ≤ 100 Hz 100 kW 4 mrad
Receiver: Bandwidth Spectral resolution (min) FOV	3500 - 8000 Å 11.25 nm 1-20 mrad, variable, vertical, and horizontal
Temporal resolution	8 - 150 ns, variable
Aircraft altitude Aircraft velocity	150 m 75 m/s

Table 597: Typical AOL operating parameters for oil fluorosensing mode

P.28 APDOR-95 (Airborne Polarimetric Doppler Radar)

The Microwave Remote Sensing Laboratory of the University of Massachusetts at Amherst and Quadrant Engineering Inc., Hadley, MA developed the 95 GHz radar system (W-band) with the objective of high-resolution cloud investigations (measurement of particle reflectivities, depolarization, Doppler-derived internal cloud radial velocities, cloud microphysical properties). APDOR-95 has been flown on a King Air aircraft of the University of Wyoming since October 1992, it was also part of WISP (Winter Icing and Storms Project) in February 1994.

2166) F. E. Hoge, "Oceanic and Terrestrial Lidar Measurements," Chapter 6 of 'Laser Remote Chemical Analysis,' R. M. Measures (Editor), John Wiley & Sons, 1988, pp. 409-503
2167) F. E. Hoge, R. N. Swift, "Oil film thickness measurement using airborne laser-induced water Raman backscatter," Applied Optics, October 1, 1980, Vol 19, No. 19, pp. 3269-3281
2168) F. E. Hoge, R. N. Swift, "Photosynthetic Accessory Pigments: Evidence for the Influence of Phycoerythrin on the Submarine Light Field," Remote Sensing Environment, 34, pp. 19-35, 1990

The instrument consists of:

- a 30 cm diameter lens antenna illuminated by a scalar feed horn, which provides integrated cross-polarized isolation of about 30 dB over the antenna footprint area
- a pulsed, 1.2 kW peak power transmitter consisting of an extended interaction amplifier that amplifies the output of an injection-locked amplifier, which is excited by a frequency-multiplied low-noise oscillator
- a dual-channel receiver with a 9 dB noise figure used to coherently detect vertically and horizontally polarized backscattered signals
- a switching subsystem consisting of seven latching circulator switches and an ortho-mode transducer, which is used to rapidly switch the polarization state of transmitted pulses
- a radar control and data acquisition subsystem, consisting of six A/D converters, signal processing cards and a computer. The processing cards compress the data before they are fed into the computer for storage and display functions

The data rate of the system depends on the complexity of the algorithm implemented on the real-time data processors. A typical imaging rate is 8 averaged profiles per second, when each profile is calculated from 100 independent profile samples containing 100 range gates. In this operating mode the data acquisition system records co- and cross-polarization reflectivity, Doppler velocity, and mean and standard deviation, for each range gate. ^{2169) 2170) 2171)}

The spatial resolution of the radar image is 30m x 10m x 30m at 1 km distance, established by a 0.7° antenna beamwidth, averaged along a 20m flight path and using 60 m transmit pulses. The effect of aircraft motion on the Doppler measurements is corrected by aircraft INS data in post-processing steps.

The APDOR-95 instrument on board the King Air is scheduled to participate in the Southern Cumulus Experiment in Florida during the summer of 1995.

Transmitter frequency	94.92 GHz (3 mm wave)	Antenna diameter	30 cm
Peak power	1.2 kW	Antenna gain	50 dB
Pulse duration	50 - 2,000 ns	Beamwidth	0.7°
PRF	10 Hz - 80 kHz	Far field distance	60 m
Receiver noise figure	9 dB	Polarization	V and H
Receiver dynamic range	80 dB	Receiver bandwidth	5 MHz
Receiver channels	V , I _v , Q _v , H , I _h , Q _h		
1st IF	1.2 GHz	2nd IF	120 MHz

Table 598: APDOR-95 system parameters

P.29 APE (Airborne Polar Experiment)

APE is a European instrument payload to be flown in several campaigns on the Russian stratospheric aircraft with the name of M-55 Geophysika. The first polar campaign, APE-1, was conducted in the winter of 1996/97 from Rovaniemi, Finland (six different flights were made on the M-55 Geophysika up to altitudes of 21 km). The APE-1 objectives were:

- 1) stratospheric chemistry - monitoring a variety of trace gases and aerosols in the polar stratosphere

- 2) study of ozone production and ozone loss mechanisms, study of the chemistry and microphysics of Polar Stratospheric Clouds (PSCs) and the role of aerosols in ozone depletion processes
- 3) comparison of measurements with the spaceborne GOME sensor on ERS-2 (under consideration).^{2172), 2173)}

APE considers in-situ and remote detection of the following trace gases: OCIO, NO_x, ClO, OH_x, O₃, HCl, and PSC particles, background and volcanic aerosols. The instrument payload on-board the Geophysika aircraft will be furnished by several western European and Russian laboratories.

Agency	Instrument	Species to be measured
CNR/IROE, RAL, SNCMP, NASA/LaRC	SAFIRE-A	O ₃ , H ₂ O, OH, HO ₂ , H ₂ O ₂ , HF, HCl, HOCl, HNO ₃ , HCN, CO, N ₂ O ₅ , ClO
CNR/IFA (Italy, U. of Mainz (Germany))	ARIAS	Aerosol refractive index, shape, in situ optical particle counter for particle size distribution
CNR/FISBAT (Italy)	GASCOD	O ₃ , NO ₂ , OCIO, BrO, ClO and NO
U. of Rome (Italy)	ABLE (Lidar)	Aerosols and PSCs
IKI, Cantonal Observatory (Neuchatel, Switzerland)	MAL (Lidar)	Aerosols, PSCs and PBL structures
CAO, Moscow	ECOC	O ₃ and partial pressure
CAO, Moscow	FLASH/ACH	Water vapor
CAO, CNR/FISBAT	FOZAN	O ₃
CAO	ACAP	Submicrometer particles
MISU, U. of Mainz, CNR/IFA	COPAS	Aerosol number concentrations (2nd campaign)

Table 599: Overview of APE instruments on first M-55 Geophysika campaign

The Geophysika M-55 is an operational dual turbofan aircraft, produced by Myasishchev Design Bureau, Moscow (multipurpose airborne platform not limited to stratospheric missions). M-55 can operate at ceiling altitudes of 21-22 km for flight durations of 5 to 6 hours with payloads of up to 1500 kg. The maximum cruise speed is about 750 km/h. The aircraft offers various bays for instrumentation. Aircraft power for payload: 60 kVA at 115 VAC and 3 kW at 27.5 VDC. Aircraft dimensions: length = 22.8 m, total wingspan = 37.5 m, maximum take-off mass = 24000 kg (see chapter P.96)

P.29.1 SAFIRE-A (Spectroscopy of the Atmosphere w. FIR Emission - Airborne)

SAFIRE-A²¹⁷⁴⁾ is an FTIR high-resolution radiometer designed and built by CNR/IROE of Florence, Italy in collaboration with RAL and QMW of UK, SNCMP of France, and NASA/LaRC, USA. The instrument observes atmospheric emission in the far infrared spectral region with an unapodized resolution of 0.004 cm⁻¹. The measurements are made utilizing the limb-sounding technique, to observe vertical profiles of stratospheric tracer species related to ozone chemistry, in particular the HO_x family. The instrument can be flown on a balloon platform or on a high-altitude aircraft.

The main parts of the instrument are the input optics (limb scanning system and telescope), the Fourier Transform Spectrometer and CODM (Cold Optics and Detector Module). The optical components as well as the electronics and recording system are assembled on an aluminum platform. The instrument is scheduled to be completed by early 1996.

The input radiation, collected by the limb-scanning mirror, is directed into a high-resolution, rapid-scanning Michelson polarizing interferometer. The output beam of the inter-

²¹⁷⁴⁾ Information provided by U. Cortesi and B. Carli of CNR/IROE, Florence, Italy

ferometer is condensed by an off-axis paraboloid into the cryostat containing the CODM. Inside the cryostat, cooled to 4 K, a polarizing beam divider creates two separate outputs of the instrument. Each beam passes through a very narrow band filter ($\sim 2 \text{ cm}^{-1}$ wide) before being detected by unstressed Ge:Ga elements. Different spectral bands are thus detectable on the two channels. In the first channel the priority species (OH, ozone, water vapor and molecular oxygen) are observed. In the second channel a filter wheel allows a selection of up to eight spectral bands, in which complementary species can be observed in successive flights (O_3 , H_2O , HCl , HF , OH , H_2O_2 , HO_2 , HOCl , HDO , ClO , N_2O , HNO_3 , HCN , CO , N_2O_5).

Type of Instrument	Polarizing Fourier Transform Interferometer
Instrument dimensions	1800 x 880 x 650 mm
Instrument mass	370 kg
Observed species	O_3 , H_2O , HCl , HF , OH , H_2O_2 , HO_2 , HOCl , HDO , ClO , N_2O , HNO_3 , HCN , CO , N_2O_5
Measurement time	30 seconds / interferogram; 7.5 - 11 minutes per limb sequence
Number of detectors	2
Spectral region	$80 - 160 \text{ cm}^{-1}$ baseline ($62.5 - 125 \text{ }\mu\text{m}$); $20 - 350 \text{ cm}^{-1}$ (future extension)
Spectral resolution	0.004 cm^{-1} unapodized $\rightarrow 1.5 \text{ nm}$ for $\lambda = 62.5 \text{ }\mu\text{m}$ and 6.25 nm for $\lambda = 125 \text{ }\mu\text{m}$
Detector bandwidth	2 cm^{-1} approximately
Vertical resolution	3 km
Limb step	1.5 km in tangent altitude
Pointing accuracy	0.1° from 20 km altitude; 0.02° from 40 km altitude
Spectral SNR	$> 250:1$
IFOV	1.4°

Table 600: SAFIRE/A instrument parameters

P.29.2 ARIAS (Airborne Remote-Sensing & In-Situ Aerosol Measuring System)

ARIAS consists of two complementary instruments, a MAS (Multiwavelength Aerosol Scatterometer) built and owned by CNR/IFA (Frascati, Italy; PI: A. Adriani), and a Forward Scattering Spectrometer Probe (owned by the University of Mainz, Germany; PI: S. Borrmann) commercially available at PMS Inc. (Boulder, CO) for in-situ measurements of aerosol particle sizes (optical particle counter). The objective of ARIAS is the study of stratospheric clouds and aerosols (particle size, distribution, composition, shape and phase) and the extension and location of clouds. ARIAS participated in SESAME (winter 1994/95) and is scheduled to participate in APE (winter 1996/97).

The MAS instrument measurement objectives are: particle refractive index, particle shape, spatial distribution, and layered structure in lee-wave induced PSCs. The MAS instrument (active device) uses the diode laser light backscattered by the atmosphere in aircraft proximity. It employs three wavelengths, polarized and simultaneously emitted, with polarized and depolarized detection channels (wavelengths: 660 nm, 780 nm, and 830 nm). The backscattered radiation is collected by an F/2 telescope with a 120 mm aperture. The telescope employs spherical mirrors with a lens corrector. The field of view (FOV) is 0.6 mrad. The backscattered light is collected by six receiving channels: three for light parallel to the laser diode polarization, two for the orthogonal polarized signals at 680 and 830 nm, and one for sky background measurements. The six detectors (SPCM-101-PQ by EGG, Canada) are avalanche photodiodes capable of operating in the photon counting mode. The instrument is controlled by a 8086 microcomputer. Measurement data along with housekeeping data are stored in mass memory.

Information about particle shape is obtained by measuring depolarization (changes in polarization between the emitted and backscattered light). The particle index of refraction is determined by detecting the backscattered light of the three wavelengths, which serves as input for a Mie-theory analysis. - The instrument mass is $\sim 25 \text{ kg}$, power consumption: 50 W.

Figure 429: Schematic layout of the MAS instrument

The **FSSP-300 (Forward Scattering Spectrometer Probe)** is an optical system using a laser beam in a high order multi-mode 5 mW He-Ne tube. The beam is focused to approximately 200 μm diameter using condensing optics with a 60 mm effective focal length. Particles passing through the laser beam in the sampling aperture scatter energy into the optics (see also chapter P.164 on PMS instruments). The instrument mass is approximately 30 kg.

- The FSSP-300 has been modified by the U. of Mainz for in-situ measurements of the stratosphere.
- Measurements of particles with size diameters between 0.4 - 23 μm by detecting light scattered by individual aerosol particles in the forward direction between the angles of 4° and 12° .
- No. of size channels: 31
- Resolution: 0.05 - 1.00 μm

Software development and participation in data analysis of FSSP-300 measurements is done by MPICH (Max Planck Institute of Chemistry) of Mainz.

Figure 430: Optical layout of the FSSP-300 instrument

P.29.3 GASCOD (Gas Absorption Spectrometer Correlating Optical Differences)

The Gascod instrument has been designed and built by CNR/FISBAT in Bologna, Italy (PI: G. Giovanelli). Gascod is a UV/VIS spectrometer which uses the combination of color light separation technique and holographic grating along with a diode array detector to collect

solar radiation backscattered by the atmosphere. The objective is to measure stratospheric trace gas concentrations using a solar absorption technique; the constituents O₃, NO₂, OClO, and BrO are observed in diffuse and direct mode, while CLO and NO are measured in the UV region only.²¹⁷⁵⁾

In August 1993 a ground-based version of GASCOD was installed at the Mount Cimone Observatory near Bologna, Italy, it is operational since then. As of 1994, a second instrument, GASCOD/A (airborne), has been under construction and scheduled to be completed in early 1996. This airborne instrument is specifically designed for measurements on stratospheric aircraft. The instrument consists of two major parts: the opto-mechanical assembly (mass of 46 kg, size: 385 x 480 x 405 mm), and the instrument electronics with a mass of about 16 kg. The system components are as follows:

- input optics
- spectrograph
- diode detector array
- instrument calibration device
- instrument controller and data recorder

GASCOD/A features a 90° off-axis parabolic mirror telescope as input optics. The objective is to view the zenith sky in a vertical direction; direct solar radiation can be viewed in a horizontal direction; in this case, a diffuser is placed in front of the aircraft's side window. - The custom-built spectrograph features a Jobin-Yvon 0.3 m holographic spherical diffraction grating (1200 grooves/mm, aberration limit of 50-100 µm on the focal plane, with protective buffers and an external band-pass filter wheel to reduce the stray light). The spectral dispersion is approximately 2.4 nm/mm at 300 nm and the resolution is 0.5 nm. The grating is moved by a stepper motor to examine the spectra in the region from 200 - 700 nm in intervals of 50-60 nm. An internal Hg lamp is used for wavelength calibration each time the stepper motor moves the grating.

The detector array (Hamamatsu multichannel device) consists of silicon MOS diodes, each measuring 50 mm x 2.5 mm. The array is cooled by an internal Peltier element to a temperature of 40° (±0.1°C). The intention is to reduce the dark current of the detector array to ~0.01 electrons/diode/s (which should result in a total current leakage of about 1 data number for 2-3 minutes of the sensor's integration time).

The instrument is monitored and controlled by a PC. All measured spectral data are unloaded and stored onto a solid-state hard disk. The system takes automatic and unattended spectral readings as per defined measurement cycles. Post-flight data analysis on the ground employs the DOAS technique for all data processing.

P.29.4 ABLE (Airborne Lidar Experiment)

The lidar is an instrument designed and developed by the University of Rome, Italy (PI:G. Fiocco). The initial objectives are the detection of the presence of PSCs (Polar Stratospheric Clouds) and aerosols. The instrument is scheduled to be completed in early 1996. ABLE can be used in a nadir or zenith pointing direction, depending on mission requirements.

Parameter	Value
Lidar instrument	Name: ABLE
Measurement technique	Incoherent backscatter
Observation direction	Nadir and zenith observation capability
Parameters or constituents measured	Aerosols (and aerosol sizes) and clouds
Measurement range	0 - 30 km
Vertical resolution	75 m
Measurement times (typically)	Every interval between 1-5 hrs (depending on flight time)

²¹⁷⁵⁾Information provided by G. Giovanelli of CNR/FISBAT

Parameter	Value
Laser type and transmitter wavelength	Nd:YAG: 1064 nm [double (532 nm) and tripple (355 nm) of frequency with harmonic generators]
Pulse repetition frequency	10 Hz
Laser energy/pulse, pulse width	100 mJ, 10 ns
Receiver size and configuration	30 cm diameter, Cassegrain telescope
Receiver FOV	1.5 mrad (full angle)
Receiver bandwidth	3 nm for for 532 nm and 355 nm
Detectors used	PMT (9813QB Thorn Emi)
Thermal control	Liquid cooling system
A/D converter	2-channel photon counting, 700 MHz max. counting rate
Instrument mass	270 kg
Research objectives/applications	2-D aerosol and boundary layer structures, clouds, cirrus, volcanic aerosols, PSCs (Polar Stratospheric Clouds)

Table 601: Specification of the ABLE instrument

P.29.5 MAL (Micro-Joule Airborne Lidar)

MAL is a compact and lightweight (10 kg) laser instrument developed by IKI of Moscow (PI: S. Pershin) and by the Cantonal Observatory of Neuchatel, Switzerland (PI: V. Mitev), with the objective to study PSCs (Polar Stratospheric Clouds), aerosols, and PBL structures.

The instrument consists of a transmitter/receiver module, an optical module, an electronic unit and a battery power supply. The laser transmitter is a pulsed diode GaAlAs laser emitting 1 μ J in 30 ms pulses at a wavelength of 880 nm. The optical system has a large collection cone to be able to receive the laser echoes. The optical receiver consists of a temperature-compensated SPAD (Single Photon Avalanche Diode), controlled by a circuit operating under temperature ranges from +20 to -60 °C. The background irradiance is reduced by an optical interference filter with a bandwidth of 4 nm (FWHM). The electronics unit consists of a time-of-flight counter, a programmable range-gate generator, the control logic and an I/O interface.²¹⁷⁶⁾

Measurement technique	Incoherent backscatter
Parameters or constituents measured	Aerosols and clouds
Measurement range	0 - 9 km ground-based 0 - 30 km for PSC from M-55 cruising altitude
Vertical resolution	15 m
Measurement times (typical)	1 hr - 5 hr (day and night)
Laser type and transmitter wavelength	GaAlAs: 880 nm
Pulse repetition frequency	10 kHz
Laser energy/pulse	~0.5 - 1 μ J
Pulse duration	30 ns
Transmitter FOV	4 x 2 mrad
Airborne platform of instrument	M-55 Geophysika
Receiver size and configuration	135 mm refractor telescope
Receiver FOV	~1.2 mrad (present version of detector) ~6 mrad (possible upgrading)
Detectors used	SPAD (Single Photon Avalanche Diode)
A/D converter	Single photon threshold counter
Instrument dimension	200 mm x 350 mm x 550 mm
Research objectives/applications	2-D aerosols and sub-visible cloud structures, PSC and stratospheric aerosols, PBL structure

Table 602: Instrument parameters of MAL

²¹⁷⁶⁾ Information provided by V. Yushkov of CAO, Moscow, and by V. Mitev of the Cantonal Observatory, Neuchatel

P.29.6 ECOC (Electrochemical Ozone Cell)

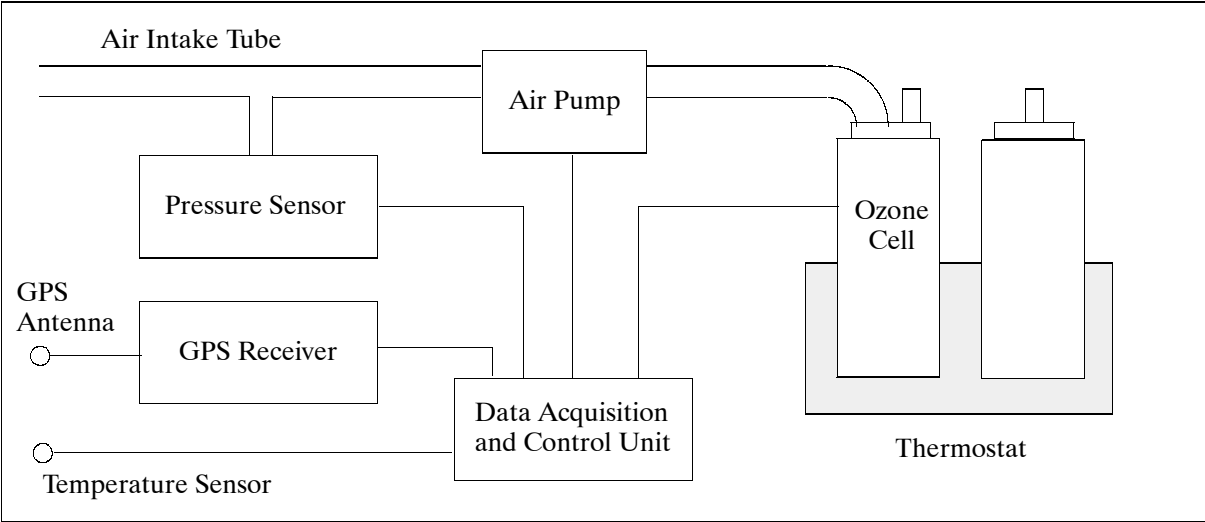

Figure 431: Schematic illustration of ECOC

ECOC is an instrument designed and developed by CAO (Central Aerological Observatory, PI: V. Galaktionov) of Moscow with the objective to measure ozone (partial pressure) in the troposphere and stratosphere. The instrument is an electrochemical cell employing a potassium water solution as electrolyte. The ozone, contained in an air sample, reacts with the KJ^+ ions, thereby shifting the balance of the electrochemical system and inducing an electric current in the outer circuit of the cell (two electrons per ozone molecule). The sample measurement time is 30 seconds, accuracy: 5%, pressure range: 5 - 107 hPa, temperature range: - 80 °C to + 50 °C, instrument size: 420 x 320 x 250 mm, instrument mass: 15 kg, power supply: 27V, power consumption: 25 W.

P.29.7 FLASH (Fluorescent Airborne Stratospheric Hygrometer)

An in-situ instrument of CAO (Moscow, PI: S. Merkulov) with the objective to observe water vapor in the upper troposphere and lower stratosphere. The measurement technique is based on photofragment fluorescence, using photodissociation at wavelengths below 137 nm, and subsequent fluorescent relaxation of the excited OH radical. The output signal is proportional to the water mixing ratio.

A coaxial optical scheme is used in the hygrometer. A mirror and quartz lens system are concentrically arranged around the lamp. The optical system analyzes an air sample; the results are measured by PMT-type detectors. In the hygrometer photodissociation is achieved by a glow-discharge hydrogen lamp and a hollow cathode with a photon flux up to $10^{14} s^{-1}$. The lamp is modulated by a square-wave input from a 1 kHz oscillator, which is also used for synchronous demodulation in order to increase the SNR ratio. The aspiration system of the hygrometer (including pump, valves, pipes, dryer) provides a flow rate of about 30 l/min for altitudes up to 20 km. The hygrometer is pylon-mounted below an aircraft wing to avoid contamination from the fuselage.

Parameter	FLASH	Frost Point ACH
Humidity range	1-100 ppmv	+30°C to - 60°C
Accuracy	10 % of reading	±0.5°C
Altitude range	8 - 25 km	0 - 10 km
Instrument size	100 cm x 18 cm diameter	18 cm x 25 cm x 40 cm
Instrument mass, power	8 kg, 100 W	8 kg, 60 W

Table 603: Operational characteristics of FLASH and ACH

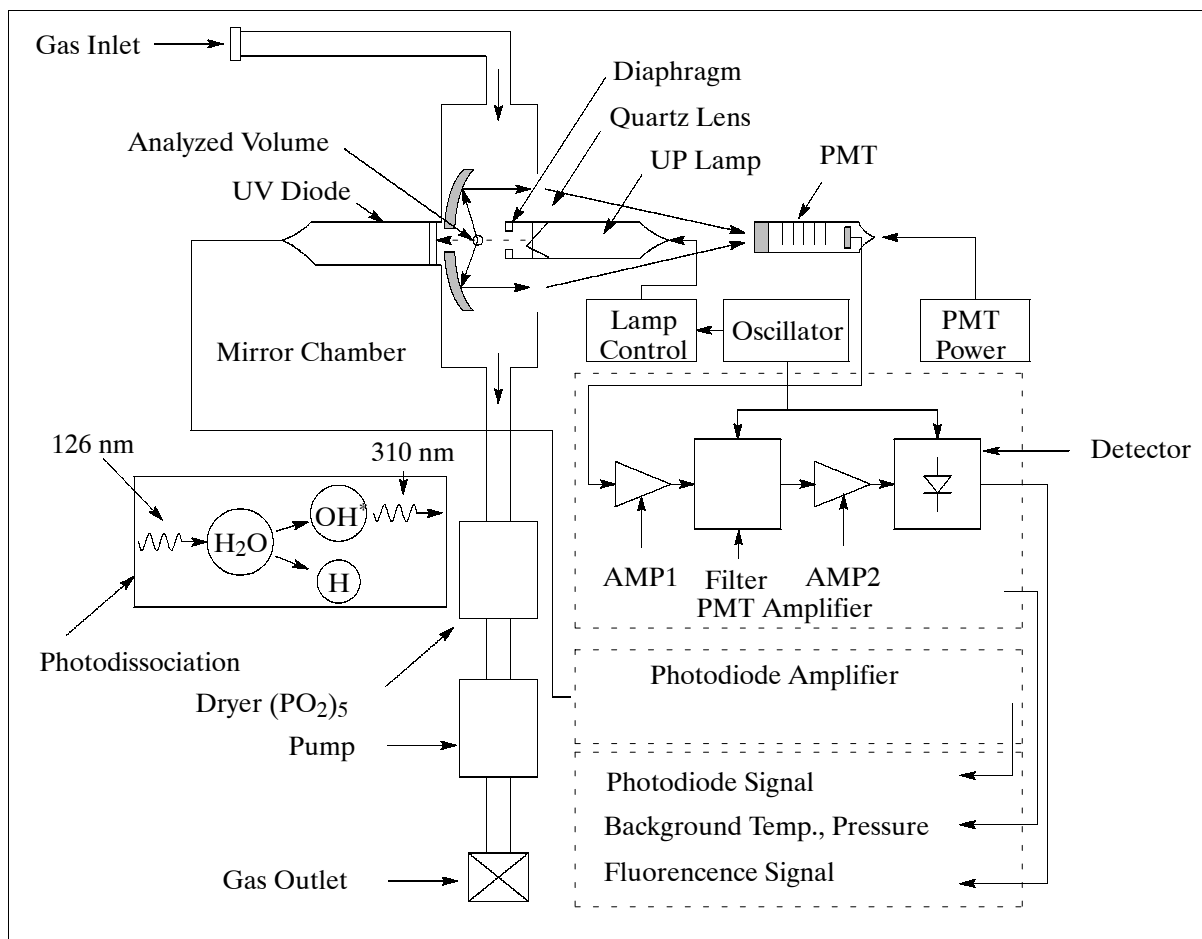

Figure 432: Schematic illustration of the FLASH instrument

P.29.8 ACH (Aircraft Condensation Hygrometer)

ACH is a CAO-developed in-situ instrument (PI: M. Mezrin). The objective is to measure tropospheric water vapor with the use of a condensation technique (phase equilibrium between the condensate on a mirror and the water vapor in the air). A constant condensate level on the mirror is provided through a feedback with the optical power-supply indicator of the refrigerator. The refrigerator control method provides high measurement stability, making it possible to determine the instant of maximum accuracy for the measurement of the equilibrium phase state.

The frost-point hygrometer ACH is an ‘absolute’ device which works up to altitudes of 10 km. On the other hand, FLASH is not an ‘absolute’ device and operates at altitudes normally above 8 km. Hence, FLASH will be coupled with ACH providing intercalibrations in the altitude range of 8 - 10 km.

P.29.9 ACAP (Airborne Counter of Aerosol Particles)

ACAP is a newly developed CAO (Moscow, PI: A. Ulanovsky) instrument for in-situ measurements of submicrometer particles in the stratosphere. A single particle counting technique is used to determine the aerosol particle concentration below 100 particles/cm³.

Optical system	Sideways scattering method
Light source	Halogen lamp
Particle diameter ranges	0.3, 0.4, 0.5, 0.6, 0.8, 1.0, and 2.0 μm
Flow rate	2 - 20 l/min

Particle concentration	0 - 10,000 particles/l
Counting loss	$\leq 5\%$ for 10,000 particles/l
Data output	RS 422 interface
Instrument dimensions	270 mm x 160 mm x 400 mm
Power supply; power consumption	115 AC, 400 Hz; 80 W

Table 604: Technical parameters of ACAP

Figure 433: Illustration of ACAP

P.29.10 FOZAN (Fast Ozone Analyzer)

FOZAN is an in-situ ozone sonde (PIs: V. Yushkov of CAO and T. Georgiadis of CNR/FIS-BAT, Italy) which employs a surface chemiluminescent technique (diffusion of ozone into a cover layer). A reaction takes place between the ozone and an organic dye which is integrated in the layer structure. The reaction generates an emission of light which is proportional to ozone in the air sample. This light is detected by a photomultiplier and converted into an analog signal.

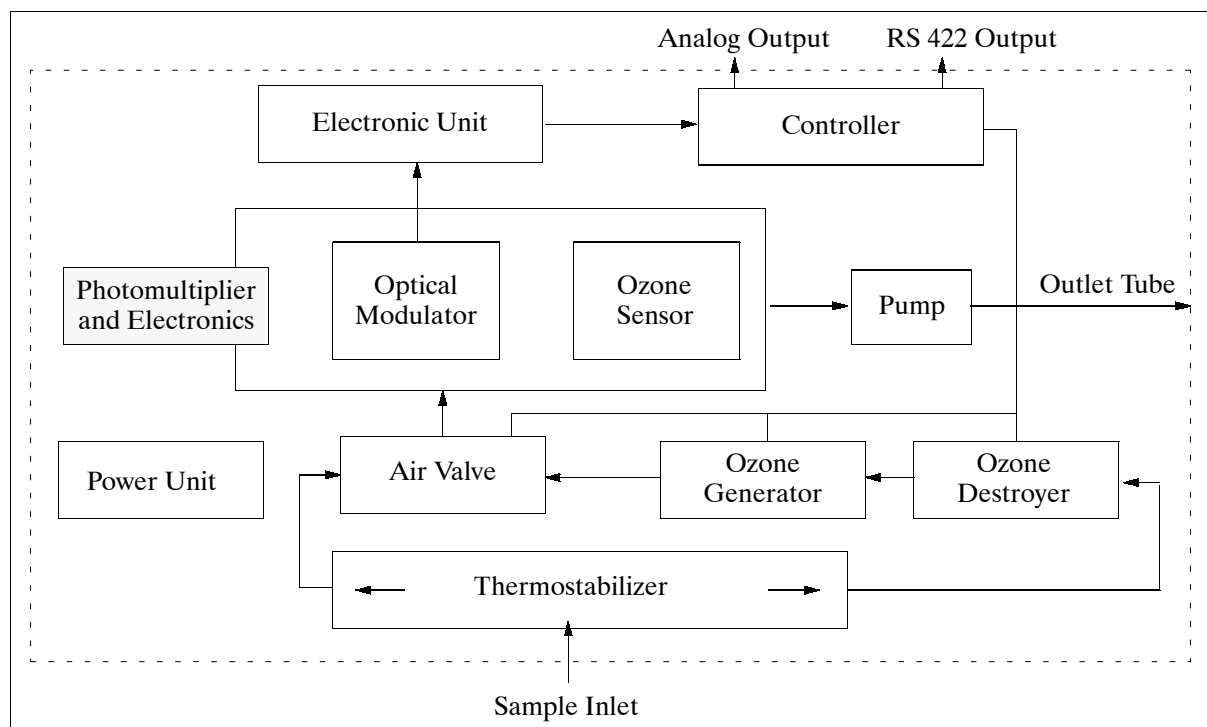

Figure 434: Schematic illustration of FOZAN

Self-calibration of the ozone sonde is done periodically with an internal ozone generator and ozone destroyer. The ozone destroyer provides a zero concentration reference for the ozone air sample while the ozone generator provides a known reference. A controller adjusts the measurement cycle and regulates the air valve operation.

Pressure range	5 - 107 kPa
Temperature range	-80 to +50°C
Partial ozone pressure	0 - 300 nbar
Sample measurement time	5 seconds
Automatic calibration period	5 - 10 minutes
Duration of calibration process	1 - 3 minutes
Instrument dimension	500 mm x 400 mm x 130 mm
Instrument mass, power supply, power consumption	10 kg, 115 VAC, 100 W

Table 605: Technical parameters of FOZAN

P.29.11 COPAS (Condensation Particle Detection System)

COPAS is an EU-funded instrument with the objective of in-situ measurements of stratospheric and tropospheric aerosol number concentrations. The instrument is being designed and developed by the U. of Stockholm (MISU), U. of Mainz, and by CNR/IFA, and will initially be flown on M-55 in the second APE campaign period in the antarctic winter of 1998.

COPAS detects aerosol particles down to 10 nm diameters. The instrument has three channels to sense sample air from three different inlets. Channel 1 heats the aerosol to 200°C permitting basic analysis with respect to volatility of the particulate material. The second channel is a CVI (Counterflow Virtual Impactor), a different instrument (see P.60), which separates particles by their inertia. CVI samples in this configuration only particles with a diameter > 1 µm. The third COPAS channel is a passive inlet for the purpose of sampling the ambient aerosol to yield the total aerosol concentration. - COPAS measurements in APE concentrate on lee wave mountain PSCs.²¹⁷⁷⁾

P.30 APEX (Airborne PRISM Experiment)

APEX is an airborne imaging spectrometer built in the framework of PRODEX (Programme développement d'expériences scientifiques), an ESA program with the support of EO-EP (Earth Observation - Envelop Program).^{2178) 2179) 2180) 2181)} It is based on a Swiss/Belgian initiative and designed as an airborne precursor simulator/testbed for future planned spaceborne imaging spectrometer missions (e.g., SPECTRA, CHRIS/PROBA, MERIS).²¹⁸²⁾ RSL (Remote Sensing Laboratory) of the University of Zürich is the instrument PI, while VITO (Flemish Institute for Technological Research) of Belgium is the CoI (Co-Investigator) in this constellation. The industrial consortium is composed out of joint Swiss/Belgian industries with the support of ESA EO-EP (detectors, calibration, tech-

²¹⁸²⁾ Note: In 1999, the PRISM (Processes Research by an Imaging Space Mission) instrument was considered the prime instrument of LSPIM (Land Surface Processes and Interactions Mission), an ESA core mission. In 2001, SPECTRA (Surface Processes and Ecosystems Changes Through Response Analysis) is the new name and successor of PRISM and LSPIM.

nical management). APEX is planned to be initially flown in 2003/04 for at least 5 years onwards. The instrument is defined as a pushbroom imager with the following capabilities (scientific requirements):

- A ground pixel resolution of of <5 m with about 1000 pixels in cross-track direction with a swath of 5 km depending on flight altitude.
- Spectral range from 400-2500 nm
- Up to 300 predefined bands, adapted to the specific mission and application
- A spectral sampling interval of <15 nm at a spectral sampling width <1.5 times the sampling interval
- Provision of calibrated data and a suite of user-oriented products up to fully geocoded and calibrated data.

Parameter	Value
Spectral coverage	400 - 2500 nm
Spectral bands	VIS: 140; SWIR: 145
Spectral sampling interval	400-1050 nm: < 5 nm; 1050-2500 nm: < 10 nm
Noise Equivalent Radiance Difference (NE _{DL})	11×10^{-5} to 5×10^{-5} (W/(m ² sr nm)) in the range: 1100-2500 nm
Spectral sampling width	<1.5 x spectral sampling interval
Center wavelength accuracy	>0.2 nm
Spectral sampling width accuracy	<0.02 x spectral sampling width
PSF (Point Spread Function)	<= 1.75 x sampling interval
Scanning mechanism	Pushbroom
FOV, IFOV	±14-20°, 0.48 - 0.70 mrad
GSD (Ground Sampling Distance)	3.7 m (at AGL of 7500 m)
Absolute radiometric calibration accuracy	<=2%
On-board storage capacity: online/offline	>50 GByte/>200 GByte
Dynamic range	12-16 bit
Positional knowledge	20% of the ground sampling distance
Attitude knowledge	20% of IFOV
Navigation system flight repeatability	±5% of FOV
Detector: number of pixels	VIS: 1024 spatial, 140 spectral SWIR: 1024 spatial, 145 spectral
Integration time	15-40 ms
Total instrument mass, power	100 kg, 27 VDC on aircraft
Source data rate	TBD

Table 606: Specification of APEX parameters

The instrument consists of an imaging spectrometer with an optimized spectrometer sensor design for the detection of land surface processes, a flexible aircraft integration scheme, a laboratory calibration home base, and a Processing and Archiving Facility (PAF) for the generation of level 1 - 3 data. A detailed calibration concept exists for APEX²¹⁸³⁾ including on-board calibration means (e.g., integrating sphere with spectral and radiometric standards), laboratory calibration, and reflectance based vicarious calibration approaches.

APEX uses two detector types to cover the spectral range, an Si CCD is used for VIS (450 - 950 nm), a cooled HgCdTe detector is used for SWIR (900 - 2500 nm).²¹⁸⁴⁾ The FEE (Front End Electronics) for the VIS detector is realized by using photo-capacitors and CCD read-out structures. The analog output signal of the CCD is sampled and converted to digital data by an ADC. - The HgCdTe detector is read out by a CMOS circuit. The array consists of a

number of addressable pixels using MOS transistors as switches, controlled by an x and y multiplexer.

The electronics unit consists of the video electronics unit, the framegrabber unit, the data storage unit and the user interface unit which incorporates four basic operating modes to control the APEX instrument.

- Mission preparation - before a data acquisition mission, all parameters and sequences are determined and stored in the system
- Calibration mode - the calibration sequence is initiated and the calibration data are stored
- Acquisition mode - the instrument stores the data coming from the detectors
- Standby mode - all the values stored or transferred into the instrument stay active but no acquisition is done.

Figure 435: Schematic illustration of the APEX instrument design

P.31 APMIR (Airborne Polarimetric Microwave Imaging Radiometer)

APMIR is an instrument designed and built at NRL (Naval Research Laboratory), Washington D.C. The objective is to measure microwave emission and reflection from the ocean surface for the deduction of surface wind speed and direction (the microwave emissions of sea surface vary with the degree of sea surface roughness). The wind direction is obtained from the relationship between the horizontal and vertical polarization characteristics of the received signal. For data analysis, the APMIR frequencies are useful beyond the measurement of ocean surface wind vectors. The APMIR observations will also be used to validate and calibrate various spaceborne instruments like SSMIS (Special Sensor Microwave Imager Sounder) flown on the DMSP series and WindSat on Coriolis.^{2185) 2186)}

The APMIR instrument consists of a number of passive microwave radiometers in the frequency range of 5.8 - 37 GHz. Four of the radiometers are fully polarimetric measuring the complex scattering matrix (four Stokes' parameters: T_v , T_h , T_u , and T_v), while the other radiometers measure the incoming radiation at two polarizations (T_v and T_h) of the receive channels. Provision for an additional channel at 91 GHz is being maintained.

²¹⁸⁵⁾<http://www.pxi.com/apmir/>

²¹⁸⁶⁾Information provided by Justin P. Bobak of NRL, Washington D. C.

The following nomenclature is used:

- T_v is the vertically polarized brightness temperature electric field, $T_v = |E_v|^2$
- T_h is the horizontally polarized brightness temperature, $T_h = |E_h|^2$
- T_U and T_V are the third and fourth Stokes parameters
- $T_U = 2 \operatorname{Re} (T_v T_h^*)$
- $T_V = 2 \operatorname{Im} (T_v T_h^*)$

Where $\operatorname{Re}()$ refers to the real part and $\operatorname{Im}()$ refers to the imaginary part of $()$. The “*” refers to the complex conjugate of the field (see also “polarization” in Glossary).

Frequency (GHz)	Polarization	Absolute accuracy (K) for T_v, T_h, T_U, T_V	NEDT (K) 100 ms integration time	Bandwidth (MHz)	Comments
5.8, 6.8, 7.8	T_v and T_h all channels	0.75, 0.75, 0.25, 0.25	0.2	125	The 6.8 channel matches WindSat
10.7	Polarimetric	0.75, 0.75, 0.25, 0.25	0.15	300	Matches WindSat radiometer channel
18.7	Polarimetric	0.75, 0.75, 0.25, 0.25	0.15	750	Matches WindSat and is switchable with 19.35 GHz
19.35	Polarimetric	0.75, 0.75, no spec., no spec.	0.15	750	Matches SSMIS (T_v, T_h), switchable with 18.7 GHz
22.235	T_v and T_h	0.75, 0.75, N/A, N/A	0.2	500	Matches SSMIS, switchable with 23.8 GHz
23.8	T_v and T_h	0.75, 0.75, N/A, N/A	0.2	500	Matches WindSat, switchable with 22.235 GHz
37.0	Polarimetric	0.75, 0.75, 0.25, 0.25	0.15	1400	Matches SSMIS, WindSat, SSMIS has T_v, T_h at 37.0

Table 607: APMIR instrument parameters

Radiometer type	Dicke switching mode, operated as total power radiometers
Scan motion parameters	Azimuth range: 360°; scan rate: 0-15 rpm; elevation range: 135°
Instrument sphere diameter	91 cm
Instrument size	91 cm x 152 cm x 214 cm (pallet structure)
Instrument mass	136 kg (sphere and contents), 500 kg (total, not including pallet)
Instrument power	1.5 kW (sphere), 3 kW (pallet total including sphere)
Instrument data rate	Up to 45 kbit/s

Table 608: Overview of instrument parameters

All APMIR radiometers are mounted into an aluminum sphere of about 91 cm in diameter. Internal (polarimetric) and external calibration sources are provided for the system. In the scanning configuration (available in 2002), the sphere continuously rotates through 360° during operation. The rate of rotation is variable from 0 to 15 rpm. There is the capability to change the elevation angle of the radiometer antennas from the nadir direction (0°) to 65° for the support of normal observation modes; in addition, the antennas can be elevated above the horizontal to view external calibration targets.

All channels are being measured simultaneously, the antennas view approximately the same area on the ground surface. The radiometers measure the full Stokes parameters at 10, 18, and 37 GHz, and the linearly polarized brightness temperatures (T_v, T_h) at 6 and 23 GHz. Typical IFOV values for the various frequencies are: 9.4° (6.8 GHz), 5.9° (10.7 GHz), 6.8° (18.7 GHz), 5.3° (23.8 GHz), and 6.0° (37 GHz). The system is being designed to make possible the estimation of wind direction within $\pm 20^\circ$ and wind speed to $\pm 2\text{m/s}$ or $\pm 20\%$ (which ever is greater).

The APMIR assembly is flown at altitudes ranging from 100 m to about 8 km. First flights are scheduled for spring 2001.

P.32 ARES (Airborne Remote Earth Sensing)

ARES is a mid-wave infrared (MWIR) hyperspectral imaging spectrometer designed/built and operated by Lockheed's Palo Alto Research Laboratory for the USAF remote sensing program office [the name ARES exists since 1992; however, the instrument has been operational as AIP (Airborne Instrument Program) since 1985]. The instrument is a combined spectrometer/radiometer, providing 75 spectral channels in the spectral range from 2.0 - 6.3 μm . A 2-D focal-plane array provides for simultaneous spectra formation over a spatial image of the spectrometer slit. When operated in a nadir or off-nadir stabilized pushbroom configuration, the spectrometer slit is oriented in a cross-track direction. Aircraft forward motion provides for the second spatial dimension, allowing the formation of 75 simultaneous (hyperspectral) images. The instrument is flown on a NASA/JSC WB-57F high-altitude research aircraft.²¹⁸⁷⁾

Optics		Detector Parameters	
Aperture	5 cm	2-D array	45 x 90 elements
Multielement	10.8 cm	Detector material	Si:In
Focal length imager	f1.9	Design	Hybrid w/Si CCD read-out structure
Spectrometer telescope	Focal reflective slit type	Spectral range	2-7 μm
Prism assembly	2-element Ge-MgO	Integration time	Selectable 10-80 Hz
Internal optics vacuum/cryo-cooled	77 K	A/D conversion	12 bit
Design features:	external scanning mirror	Data frame rates	10, 20, 40 or 80 Hz
Calibration sources (3)	external pointing mirror	Detector pitch	100 μm

Pointing & Tracking		System Parameters	
Sensor installation	Up- or Down-looking	Spectral coverage	2.0-6.3 μm spectrometer
Open-loop	Pre-program'd or joystick	Spectral resolution	25-70 nm
Closed-loop	Slaved or video tracker	Spectral filters	None, 2.21-2.26; 2.71-2.97; 3.72-3.84; 4.41-4.56 μm
Video track sources	TV cameras W&N FOV	Neutral Density filters	None; 0.34; 0.1; 0.01; 0.001
Pointing range	PtSi SWIR camera	IFOV (spatial)	1.17 mrad; slit: 360 mrad
	$\pm 90^\circ$ roll, 30° fwd, 20° Aft in pitch	FOV	$3.0^\circ \times 3.0^\circ$; $3.0^\circ \times$ scan/sweep
Scanning mirror	Sweep slit projection across target: range: $\pm 1.5^\circ$, rate: 0-6 $^\circ$ /s	Sensitivity	$\sim 1.0 \mu\text{W}/\text{cm}^2\text{-sr-}\mu\text{m}$
		Instrument mass	$\sim 200 \text{ kg}$

Table 609: Instrument characteristics of ARES

Applications: measurement of specular sunlight reflections from the tops of high-altitude clouds; mapping of surface thermal features (also detection of subsurface lava flow); multi-spectral imaging; measurement of atmospheric trace gases (H_2O , CO_2 , and CH_4) due to sunlight absorption, etc.

An IR/VIS dichroic beamsplitter separates and directs the IR signal into the main instrument, while visible light is passed through two TV/VIS band acquisition and tracking cameras. An IR/IR beamsplitter directs a portion of the incoming energy to a PtSi IR tracking camera, allowing observation and tracking of any object within the field of view by either the VIS cameras or in SWIR. An image-rotating 'K-mirror' allows the image to be rotated up to $\pm 90^\circ$ to provide any desired orientation of the spectrometer slit and scan. A fine-scan mirror allows the image to be scanned by the projection of the instrument's spectrometer slit.

Spectrometer Operation:

In the spectrometer mode, the mode select mirror is removed from the optical path (see Figure 437), allowing the incoming energy to enter the spectrometer telescope, which focuses on the edge of a 0.125 mm thick fused silica reflective slit. The resulting image is recolimated at the opposite side of the telescope, and reflected through a germanium/magne-

²¹⁸⁷⁾E. L. Jewett, K. D. Bishop, "An Airborne Mid-Wave Infrared Imaging Spectrometer for Atmospheric and Earth Science Remote Sensing Applications," internal Lockheed report provided by E. L. Jewett

sium oxide bi-prism assembly. The dispersed energy is then focused by the imaging lens onto the Si:In focal plane, resulting in a 2-D (spatial x spectral) image of the projection of the spectrometer slit.

To obtain spectra within the image area, the fine-scan mirror scans the projection of the spectrometer's slit across the image scene. A prism assembly is used to disperse the energy across the long dimension of the focal plane, resulting in a 45-pixel-long spatial image of the spectrometer slit; the dispersed 75 separate spectral channels cover the range from 2.0 - 6.3 μm . - Note: The 75 channels cover five of the six focal plane sections, each section is 15 x 45 pixels. The spectral bandwidths (20-70 nm) are a function of focal plane dimensions and prism dispersion. The FWHM for each band differs due to nonlinearity in the prism dispersion characteristics. At the shortwave end of the focal plane the bandwidth is ~ 21 nm; the maximum of 70 nm is at wavelength 4.05 μm , decreasing to 63 nm at wavelength 6.3 μm .

Figure 436: ARES sensor external optics

Radiometer Operation:

When ARES is operated as an imaging radiometer, the instrument is not 'hyperspectral' any more, it can form an image in only one spectral band at a time, with the band defined by selection of a bandpass filter. [It is possible to select filters fairly quickly (in the order of a second), but true simultaneous multispectral imaging is not possible]. - In the radiometer mode IR energy enters the primary telescope dewar (maintained at 77 K by liquid nitrogen) and passes through two commandable filter wheels, one containing neutral density filters to expand the instrument's useful signal range, and the other containing spectral filters. Both filter wheels have an open position allowing the option of no filtration.- From the filters, the energy is reflected from a two-position mode-select mirror through an imager and focused onto a 45 x 45 pixel sub-array of the sensor's Si:In focal plane. The focal plane mount is in contact with a liquid helium tank to reduce the operating temperature below that of liquid nitrogen. - With an individual pixel pitch of 1.17 mrad, the overall instrument FOV is 53 x 53 mrad, or approximately 3° x 3°.

ARES features one physical focal plane, an array of 45 x 90 active elements. It is electronically divided into six 45 x 15 sub-arrays, primarily to handle data output. The data rate at 80 Hz frame rate comes to 4.4 Mbit/s (max. rate for spectrometer operation plus housekeeping and aircraft navigation data), the same data rate (at 80 Hz frame rate) is maintained for the

radiometric instrument operation due to the recording concept of each focal plane section. All data are recorded on 14-track tape. The recording system was replaced with an 8 mm digital Exabyte system (end of 1994) reducing the maximum data rate to ~ 3.5 Mbit/s (due to the fact that only five focal planes instead of previously six must be recorded).

Figure 437: ARES schematic for radiometer and spectrometer mode operation

P.33 ARGUS (Two-Channel Atmospheric Tracer Instrument)

Argus, a 'two-eyed' sensor for upper tropospheric and stratospheric tracer measurements, is named after the hundred-eyed Greek giant, Argus Panoptes. The instrument was developed at NASA's Ames Research Center and is considered for the Perseus aircraft platform at altitudes up to 30 km. Argus is of ATLAS (Airborne Tunable Laser Absorption Spectrometer, see chapter P.38) heritage.²¹⁸⁸⁾

The tracer elements measured by Argus are N_2O (at $4.5 \mu\text{m}$) and CH_4 (at $3.3 \mu\text{m}$) at a sampled rate of 0.1 Hz. Argus is a two-channel TDL (Tunable-Diode-Laser) spectrometer

²¹⁸⁸⁾M. Loewenstein, "ARGUS: A New Instrument for PERSEUS A," The Perseus Data Link, Issue #3, Third Quarter 1993

operating in the second harmonic mode and employing sweep integration at a 10 Hz sweep rate. The combination of second harmonic spectroscopy and sweep integration provides great stability and excellent signal-to-noise ratio, and therefore high precision in the retrieval of stratospheric tracer fields. Direct fits (Marquardt-Levenberg algorithm) of the data to the second harmonic spectra are used to retrieve the tracer molecule number densities using the known spectral line parameters.

Figure 438: Schematic diagram of the ARGUS measurement concept

The instrument employs three processors, two for control of the individual channel lasers and one to manage overall data acquisition and storage. Each laser is current- and temperature-controlled on separate laser mounts inside the dewar. The lasers are sine-modulated at about 40 kHz. The 80 kHz second harmonic data are detected with phase-sensitive detection/integration electronics. The four InSb detectors, as well as two lasers, are mounted in the 1.8 liter capacity liquid nitrogen dewar.

A diagram of one optical channel of Argus is shown in Figure 438. Transfer optics convert an f/2 laser beam to a quasi-collimated f/40 beam which is injected into a 26.1 cm base path Herriott cell. The beam traverses the cell 72 times for a total path of 18.8 m. A beamsplitter provides a second beam that passes through a frequency marker cell to provide wave-number calibration for the second harmonic line fitting procedure. The marker cell contains a gas at low pressure providing several sharp, Doppler-broadened spectral lines of accurately known frequency.

Measurement accuracy:	3%
Measurement precision:	1%
Response time	10 s
Instrument mass:	23 kg
Instrument power:	65 W

P.34 ARL (Airborne Raman Lidar)

ARL is a sensor designed and built by GSFC and flown on a DC-8 aircraft since April 1994. Its objective is to measure the mixing ratio of methane and water vapor in the atmosphere above the aircraft; temperature and pressure are measured simultaneously. The instrument transmits a pulse of UV radiation into the atmosphere and analyses the Raman- and Rayleigh-scattered return signals. The characteristic Raman frequency shift of the incident radiation permits deduction of the concentration of Raman-active molecules by spectral analysis. ARL will be flown in the TOTE/VOTE campaign.²¹⁸⁹⁾

Measurement technique	Incoherent backscatter
Parameters or constituents measured	N ₂ , O ₂ , T, P, CH ₄ , H ₂ O
Measurement range (vertical)	Above aircraft up to 20 km for CH ₄ and H ₂ O, 40 km for T, P
Resolution	1 km vertical x 200 km horizontal for CH ₄ and H ₂ O 50 km horizontal for T and P
Response time	20 minutes for CH ₄ and H ₂ O, 5 minutes for T and P
Laser type and transmitter wavelengths	XeF excimer at 348, 351 and 353 nm
Pulse repetition frequency	200 Hz
Laser energy/pulse	300 mJ
Receiver size and configuration	40 cm diameter, Newtonian
Receiver FOV	Variable between 0.75 and 2.0 mrad
Receiver bandwidth	See Figure 439 (~5 nm)
Detectors used	PMT (Photomultiplier Tube)

2189)Information provided by W. S. Heaps of NASA/GSFC, Greenbelt, MD

P.35 ARMAR (Airborne Rain Mapping Radar)

ARMAR is an active microwave radar sensor operating at a frequency of 13.8 GHz. The instrument has been developed by NASA/JPL for the purpose of supporting future spaceborne rain radar systems, in particular the PR (Precipitation Radar) instrument of TRMM (Tropical Rainfall Measuring Mission, see A.31). ARMAR is installed on the Ames DC-8 aircraft and is operated by JPL. The sensor was completed in late 1991; the first airborne testing was in May 1992. Additional tests were completed in December 1992, and the system was successfully deployed during the TOGA/COARE campaign in the Western Pacific in early 1993.^{2190),2191)}

The primary design goal for ARMAR was to develop a system which matches the PR sensor of TRMM in both frequency and scanning geometry. ARMAR therefore operates at 13.8 GHz and has a cross-track scanning geometry as illustrated in Figure 440 (for spaceborne sensor and for algorithm development as well as for post-launch calibration of PR). A number of capabilities have been included on ARMAR which improve its ability to support PR and will allow it to serve as a testbed for future spaceborne systems.

Figure 440: ARMAR scanning geometry

For example, ARMAR has been designed to have a finer spatial resolution than PR so that specific topics such as the effect of partial beam filling can be studied. ARMAR is capable of making like-polarization, cross-polarization, or alternating dual-polarization measurements. ARMAR can also obtain a greater number of independent samples than PR by using frequency diversity, transmitting up to four slightly different frequencies. When using a single transmit frequency, ARMAR is coherent, providing Doppler information. For situations in which a high accuracy in Doppler measurement is required, the antenna can be pointed at nadir rather than scanned, allowing a substantially larger dwell time and improved Doppler resolution. While operating as a radar, a small fraction of time is spent measuring the brightness temperature in a radiometer mode at the same frequency and viewing geometry as the radar mode. Finally, ARMAR uses pulse compression to achieve the required range resolution.

²¹⁹⁰⁾Information provided by S. Durden of JPL

²¹⁹¹⁾S. Durden, et al., "ARMAR Observations During TOGA/COARE," Proceedings of IGARSS '94, Volume I, pp. 568-570

The ARMAR instrument is equipped with a mechanically scanned antenna (diameter = 0.41 m). Measurements are performed by looking in the nadir direction with a FOV of $\pm 20^\circ$.

Performance Characteristics: Range resolution (6 dB width) Surface cross-track resolution (12 km altitude) Swath width Frequency Polarizations	80 m 800 m 9 km 13.8 GHz HH, VV, HV, VH

Receiver Characteristics: System noise temperature Sample frequency ADC resolution	650 K 10 MHz 12 bits
Radiometer Characteristics: Bandwidth ΔT per pixel	40 MHz 1 K

Table 611: ARMAR system parameters

P.36 ASAS (Advanced Solid-State Array Spectroradiometer)

ASAS is a NASA airborne, off-nadir-pointing imaging spectroradiometer with the objective to acquire bidirectional radiance data from terrestrial targets. The original instrument has been modified for off-nadir pointing by GSFC in order to study the directional anisotropy of solar radiance reflected from terrestrial surfaces. As a consequence, ASAS is able to track and image a target site through a discrete sequence of fore-to-aft view directions from 45° forward to 45° aftward. The pointing capability was first utilized in 1987.²¹⁹²⁾

ASAS acquires data from 29 spectral bands in the range 455 - 871 nm with a resolution of approximately 15 nm. The ASAS optics features a f/1.4 objective lens with a 57.2 mm focal length for a 25° FOV. A diffraction grating, located between two prisms, disperses the received radiant energy into its wavelength spectrum (see Figure 441). The second prism directs the dispersed energy onto the focal plane.

A 512 x 32 element silicon CID (Charge Injection Device) detector array is located at the focal plane to generate digital image data. The first two rows of the array are blacked-out, with the remaining 29 rows intended for digital image data acquisition. The long dimension of the array is reserved for the spatial resolution of 512 cross-track ground elements. The cross-track spatial resolution is 4.25 m from an altitude of 5000 m.

As the aircraft flies forward, each row of the 512 elements is electronically scanned to generate 29 channels of digital data in pushbroom fashion. The channels are spatially registered and each channel corresponds to the spectral band of radiant energy incident on the element row (only 29 channels of the 32 were operable). The scan rate is selectable (3, 6, 12, 24, 48, or 64 frames/s). The quantization is 12 bit.

²¹⁹²⁾J. R. Irons, K. J. Ranson, D. L. Williams, R. R. Irish, F. G. Huegel, "An Off-Nadir-Pointing Imaging Spectroradiometer for Terrestrial Ecosystem Studies," IEEE Transactions on Geoscience and Remote Sensing, Vol. 29, No. 1, January 1991, pp. 66-74

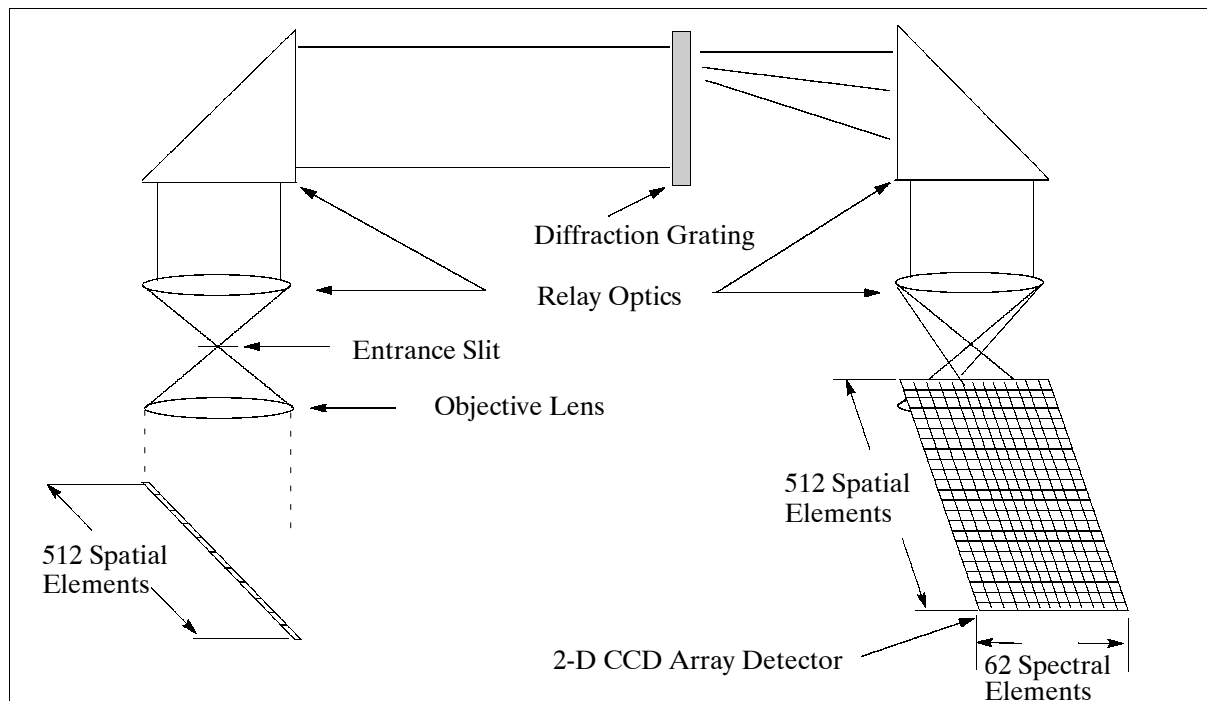

Figure 441: Schematic of the upgraded ASAS optical system

Multiangule data: The sensor FOV is tilted forward as the aircraft approaches the target site. The optical head is then rotated through a discrete sequence of fore-to-aft tilt angles as the aircraft flies over and then past the site. A typical sequence consists of seven angles from 45° forward to 45° aft in 15° increments.

ASAS upgrades in 1991/92 ²¹⁹³⁾

- A new tilting system for the optical head was installed to allow tilting angles up to 75° forward and up to 60° aft.
- The ASAS detector array subsystem was replaced. A CCD array was installed along with a new data acquisition system to accommodate the new array. The new array provides acquisition of data in 62 spectral bands ranging from 400 to 1060 nm with a spectral resolution of 11.5 nm.

The data of the ASAS sensor are being used for the development, testing, and validation of algorithms requiring multiangle data. Such algorithms are required for the EOS era.

History: The ASAS optics were originally part of the Scanning Imaging Spectroradiometer (SIS) of NASA/JSC in the early 1970's. SIS employed a vidicon detector for imaging. ASAS was created from SIS in 1981, when a CID detector array was incorporated in the optical system (NASA/JSC and the Naval Ocean System Center). ASAS was transferred to NASA/GSFC in 1984; the mounting bracket of the instrument was modified (gimbal mount) to permit off-nadir tilting (first utilized in 1987).

P37 ATHOS (Airborne Tropospheric Hydrogen Oxide Sensor)

ATHOS was designed and built at Pennsylvania State University (PI: H. Brune) with the objective to measure simultaneously OH and HO₂ with a laser-induced fluorescence technique by sampling ambient air at low pressure. The instrument consists of a) a laser system to generate the excitation radiation; b) an OH sampling chamber; c) fast, gated detector

²¹⁹³⁾J. Irons, "The Advanced Solid-State Array Spectroradiometer (ASAS)," *The Earth Observer*, Vol. 3., No. 7, 1991, pp. 31-35

and collection optics. Laser system: A diode-pumped Nd:YAG laser operated at 532 nm pumps an etalon-tuned prism dye laser. The dye laser has intracavity frequency doubling from 616 nm to 308 nm and a line width of 3 GHz. ATHOS is scheduled to fly for the first time in the NASA SUCCESS campaign in the spring of 1996 and can be used in subsequent campaigns in the NASA Atmospheric Effects of Aircraft Program (AEAP). Instrument mass: 400 kg.

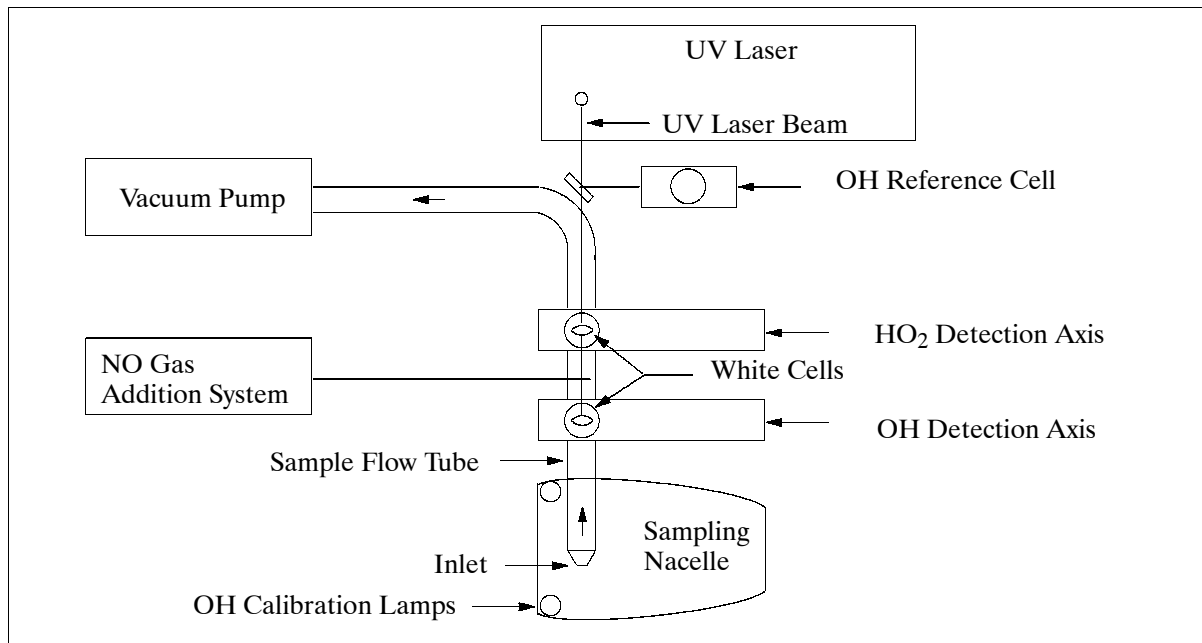

Figure 442: Conceptual arrangement of ATHOS

OH is both excited and detected at the transition wavelength near 308 nm. The ambient air is slowed from the aircraft speed to about 10 m/s in an aerodynamic nacelle, and then pulled into low-pressure detection chambers by a vacuum pump. Detection occurs in the detection chambers at the intersection of the airflow, the laser beams passed through multipass White cells, and the detector FOV. The laser has a 5 kHz repetition rate, with 35 ns pulses, and can be tuned on and off resonance with the OH transition to determine OH fluorescence and background signals. The detector is gated to detect the OH fluorescence after each laser pulse has cleared the detection cell. A reference cell containing OH indicates when the laser is on and off resonance with the OH transition. HO₂ is detected by adding NO inside the flow tube leading to the second detection chamber. The reaction of NO with HO₂ produces OH, which is detected by laser-induced fluorescence. An in-flight calibration system creates a known amount of OH outside the detection chamber inlet.²¹⁹⁴⁾

P.38 ATLAS (Airborne Tunable Laser Absorption Spectrometer)

ATLAS is a second-harmonic absorption spectrometer using a tunable diode laser of PbSnTe composition. The instrument is NASA-sponsored and has flown on ER-2 aircraft at Ames Research Center since 1987 for applications (in-situ measurements) in atmospheric chemistry.²¹⁹⁵⁾

Principle of operation: The instrument detects an infrared active target gas (e.g. N₂O, CH₄, CO, or O₃) by measuring the fractional absorption of the infrared beam from a tunable diode laser as it traverses a multipass White cell containing an atmospheric sample at ambi-

NASA/SSC also operates a sensor calibration lab. This lab is used to perform spectral, spatial, and radiometric calibrations on the instruments: CAMS, TIMS and ATLAS. Numerous calibrations are performed on sensors provided by outside customers.

P.40 Atmospheric Measurements on Commercial Airline Flights

The effect of man-made emissions on the atmosphere is a matter of growing concern to governments, the science community, to industry, to companies, and to many individuals. As of 1995 a number of initiatives are under way that call for an improved understanding of atmospheric processes. Airlines and aircraft builders are becoming ever more aware of the environmental impact of their large aircraft fleets on the atmosphere; some companies are willing and eager to cooperate with the science community and to share the burden of atmospheric data collection. It is felt by all parties concerned that commercial airlines with their global networks of service routes provide excellent platforms to carry a suite of atmospheric sensors for scientific evaluation.

P.40.1 MOZAIC (Measurement of Ozone by Airbus In-Service Aircraft)

MOZAIC is a European program, initiated in 1993 by EU scientists, it is funded by the EU, Airbus Industrie, airlines and scientific establishments with the objective to measure automatically atmospheric constituents on commercial airline flights over long periods (database over several years) for a better understanding of atmospheric processes. A secondary objective is to evaluate to some extent the impact of commercial aviation on the atmosphere. In the MOZAIC program, small, lightweight and automatic instruments are installed on selected A340 airliners to measure concentrations of ozone and water vapor in the atmosphere. The measurements are limited to ozone and water vapor because other instruments (NO_x , CO, CO_2 ,) are not yet available for routine in-service monitoring.²¹⁹⁸⁾

The five selected A340 aircraft are being flown by Air France, Austrian Airlines, Lufthansa and Sabena; there is practically coverage of five continents. The airlines carry the equipment free of charge. The first MOZAIC instrument set was flown on an Air France aircraft in April 1994 (regular service flights started in July 1994). Lufthansa took delivery of a MOZAIC-equipped A340 in November 1994. The fourth and fifth (final) instrument sets were installed on two A340-200 Austrian Airlines aircraft in March 1995.²¹⁹⁹⁾ - The scientific program coordinator is A. Marengo of CNRS/INSU (Laboratoire D'Aerologie, Toulouse), while Airbus Industrie coordinates the industrial side of the program. Sensor measurements are taken every 4 seconds during flights and annotated with aircraft navigation data.

The MOZAIC equipment is located in the A340 avionics bay, just below the cockpit. It consists of a PC for all operational functions of the sensors and for data storage (rack-mounted installation weighing 117 kg). All data are recorded onto a 'Bernoulli' disk (90 MByte), capable of storing the measurements of many flights. External air is introduced via an air inlet mounted below the flight deck on the left-hand side of the aircraft.

Data processing and verification/calibration is being conducted by the institutes of the respective instrument PIs. An aircraft MOZAIC disk change is planned at least every month. The processed data sets are transferred to Météo-France in Toulouse for long-term archiving (UNITREE system) and access by the user community.

A MOZAIC-II program has been submitted by CNRS for EU-funding (EU environment program) to continue the program beyond 1996. MOZAIC-II implies:

- Continuation of MOZAIC flights for another two years
- Installation of MOZAIC instruments into two more A340 aircraft (total of seven) for coverage of the Asia/Pacific region
- Development of new instruments to extend the range of species to be measured and upgrade the existing instruments
- Recording of engine parameters (to allow improved emission estimates).

²¹⁹⁸⁾“MOZAIC - Measurement of Ozone By Airbus In-Service Aircraft,” Airbus Industrie brochure, AI/T 800.0021/94, April 1994

²¹⁹⁹⁾MOZAIC NEWS, Number 2, June 1995 (printed by Airbus Industrie)

MOZAIC sensor complement:

- **Ozone Analyzer** (PI: A. Marenco, CNRS, France)²²⁰⁰⁾
The Ozone Analyzer (Thermo-Electron Model 49-103) is a classic UV Dasibi absorption instrument (ozone band at 254 nm) which is pressure and temperature corrected. The instrument features two channels and a short cycle analyzer (4 second cycle and respond time). The analyzer can be automatically calibrated using an internal ozone generator.
- **Water Vapor / Temperature Sensor** (PI: H. G. J. Smit, KfA Jülich, Germany)
A Vaisala humidity sensor, AD-FS-88, from AERODATA is being utilized. It is a compact sensing device for the measurement of the relative humidity and the temperature (Pt-100 element). Both parameters, with aircraft speed, static and pitot pressure, allow calculation of air humidity. The sensor is installed in a de-iced Rosemount housing outside the aircraft boundary layer. Preflight instrument calibration is performed against a Lyman α fluorescence hygrometer at KfA Jülich (environmental simulation chamber). The chamber permits the generation of atmospheric conditions (ozone and water vapor) which are relevant to the upper troposphere and the lower stratosphere.

Over 2200 MOZAIC flights from all five aircraft were reported by December 1995.

P.40.2 ACORN

ACORN (Airborne Composition Observations in the Region of the North Atlantic Corridor) is a program proposal as of 1995 (same institutes as for MOZAIC, plus others) to equip and utilize the Airbus-owned A340 flight test aircraft MSN 1 (Manufacturing Serial Number 1) also for intensive service periods in support of atmospheric research flights. The overall goal is to enhance observational capabilities with a suite of instruments (gas phase measurements of composition including several isotopic ratios and 'range of size resolved' aerosol measurements); specific objectives are:²²⁰¹⁾

- To determine cross-corridor contrasts in major emissions including the magnitude and spatial extent of the influence of aircraft emissions
- To distinguish between background aerosol properties and aerosol perturbed by aircraft emissions.

Phase I of the ACORN program is to last for three years (aircraft preparation plus a sampling period of two years in the main air corridor) with a start in early 1997. Phase II concentrates on scientific analysis and modeling activities for a period of two years (start in the year 2000).

A340 parameters:

- Range/duration: 13500 km/15.5 hours
- Cabin length: 23 m (available) plus cargo holds
- Maximum cruise altitude: 13.7 km (45,000 ft)

Note: The ACORN program was preceded by two proposed programs: AARGOS (A340 Atmospheric Research Global Observation System) and NEPONA (Nitrogen Oxide Emission and Photochemistry over the North Atlantic) that could not be funded by the EU due to budget limitations, in spite of high program ratings. ACORN is conceptually the same as the combined AARGOS/NEPONA programs of 1994.

P.40.3 CARIBIC

The acronym CARIBIC (Civil Aircraft for Remote-Sensing and In-Situ-Measurements in Troposphere and Lower Stratosphere Based on the Instrumentation Container Concept) defines a containerized atmospheric instrument package intended to be flown on long-distance commercial aircraft for the measurement of CO, aerosols and ozone. CARIBIC is a cooperative German pilot program with participation by the following institutions:²²⁰²⁾

- Max-Planck-Institut für Chemie, Mainz (MPICH, PI: P. Crutzen, CO monitoring and Whole Air Sampler)
- Institut für Troposphärenforschung, Leipzig (PI: J. Heintzenberg, aerosol measurements)
- Kernforschungszentrum Karlsruhe (KfK), Institut für Meteorologie und Klimafor-schung (PI: H. Fischer, ozone monitoring)

The system integrator is GFAS (Gesellschaft für Angewandte Systemtechnik) of Immenstaad, Germany. The program calls for proof-of-concept installations on LTU International Airways aircraft (Type: B767); initial flights started in January 1996. Phase 1 of the program is planned for the duration of one year with 15 intercontinental flights.

The objective of project CARIBIC is to demonstrate the logistics and services required for an affordable commercial airline atmospheric measurements program for scientific evaluation. The intent is to achieve eventually global coverage of data collection for the establishment of a long-term atmospheric database.

Container concept:

All instruments are mounted into a standard airline freight container (Type LD-4, volume of 5.5 m³) which is flown in the freight room of an aircraft. Outside air is required for measurement purposes. This in turn requires a small inlet mounting at the aircraft's fuselage and an air feed system into the container. For a survey flight (to flight destination and back), the instrument container is loaded into the freight bay (along with all other containers); the air intake is attached and the instruments are initialized for the round trip. After the round trip, the instrument container is unloaded and the instruments serviced by the parties concerned. The container and its instruments are eventually readied for a further survey flight. Since the unattended airline-container environment does not correspond to an attended and dedicated research flight, it is obvious that container instrument operation must be simple, rugged and automatic to survive the imponderabilities of the long-distance flight environment. - Safety regulations require the container to be furnished with temperature and smoke detectors for automatic deactivation of all instruments. In addition there is pilot remote control for container instrument deactivation in case of a sensed malfunction.

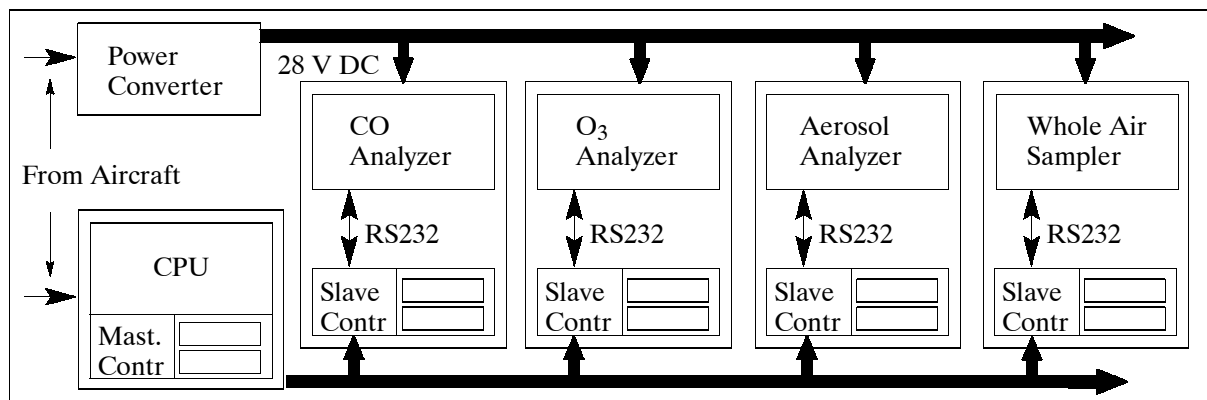

Figure 444: Controller system schematic of the CARIBIC payload

All instruments remain active throughout a service flight; however, the outside air intake is regulated in such a way that it occurs only above a flight altitude corresponding to a pressure

of ≤ 800 hPa (hecto-Pascal). Prevention of instrument contamination by ‘polluted air near the ground surface’ is the reason for this arbitrary measurement limit. - All instrument data (science, housekeeping data and navigation parameters) are recorded by a container master data controller (Figure 444).

Sensors: The initial sensor suite consists of three instruments and one WAS (Whole Air Sampler with 12 sample containers). The container concept allows an expansion to more sensors. While the current sensor suite consists only of in-situ instruments, there are studies underway to include also remote sensing devices sometime into the future.

OS-AP-M (Ozone Sonde Aircraft Platform Mid-altitude); KfK ozone sensor, instrument is built by GFAS)

The detection of ozone utilizes the method of surface chemiluminescence. In this scheme air is passed over a chemiluminescent plate causing the ozone molecules to diffuse into the coating of the plate and in turn generate a chemiluminescent reaction. The reaction sequence causes the emission of light (radiation) whose intensity is proportional to the ozone concentration. The intensity is measured and converted into an analog signal.

Pressure range of ozone detector	10 - 100 hPa (adjustable)
Measurement ranges	
Number	3
Range switching	Automatic
Range 1	0 - 1600 ppb
Range 2	0 - 800 ppb
Range 3	0 - 400 ppb
Instrument measurement rates	1/0.2/ or 0.1 Hz
Measurement limits	< 100 ppt ozon
Instrument power	1 kW max
Instrument mass	50 kg

Table 614: Instrument parameters of the ozone sonde

The ozone sonde controls pressure, flow rate and temperature in the ozone detector in order to provide reproducible measurements which are independent of aircraft speed and outside temperature. The instrument includes a calibration system along with an oxygen container (for internal/external calibration). The sensitivity of the calibration system is automatically checked before, during and after an aircraft flight.

The OS-AP-M instrument is rack-mounted (19 inch rack) along with a microcomputer which monitors and displays all instrument functions, such as:

- calibration and drift compensation
- flow, pressure and temperature monitoring
- automatic change of sensitivity ranges
- instrument status and initialization

RGA3 (Reduction Gas Analyzer),²²⁰³⁾ adapted by Max Planck Institut für Chemie, Mainz, PI: D. Scharffe. RGA3 is a commercially available instrument of Trace Analytical (Menlo Park, CA) for the measurement of CO. The instrument is an ultra-trace level gas detector capable of monitoring low ppbV concentrations of reducing (combustible) gases in a variety of sample matrices.

The instrument consists of a microprocessor-controlled gas chromatograph utilizing the method of reduction gas detection (RGD). This method is applied to CO of the inlet air, which is directed through a heated bed of mercury oxide (HgO). The general reaction of the gas is: $\text{CO} + \text{HgO} \rightarrow \text{CO}_2 + \text{Hg}\uparrow$ (vapor). The resultant mercury vapor (Hg) produced in the reaction is directly proportional to the inlet gas concentration; it is detected by a UV pho-

²²⁰³⁾Information provided by D. Scharffe of MPICCh, Mainz

tometer located immediately downstream of the reaction bed. Semi-continuous sampling rates of 2 minute intervals.

The instrument is equipped with the following service functions:

- An ‘independent slave’ computer and program (MPICh) offering fully automatic and unattended operation.
- Auto Cal. This feature enables RGA3 to calibrate itself at user-programmed intervals. The Auto Cal hardware consists of an air-actuated 4-port stream selector valve, which directs either sample or calibration gas flow to the instrument’s gas sampling valve.

Carrier Gas Purification Combustion filter type Analyzer flow rate Gases purified Absorption trap type	Metallic oxide 30 cc/min Air, N ₂ , He, Ar, O ₂ Molecular sieve
Gas Chromatograph Sampling hardware Column oven type Capacity Temperature range Temperature stability	4,6,8, or 10 port valves with external/internal sample volumes Isothermal mandrel heating Multiple 1/8 inch diameter columns up to 10 feet total length 40 - 300°C; (110°C analyzer temperature) ±0.1°C
RGD Detector Sensitivity Dynamic range	H ₂ < 5 ppb; CO < 1 ppb; Unsaturated He’s < 1ppb 5000 times minimum detectable quantity
Instrument mass	19 kg

Table 615: Specification of the RGA3 Reduction Gas Analyzer

WAS (Whole Air Sampler), the system was developed by Max Planck Institut für Chemie, Mainz, PI. C. A. M. Brenninkmeijer).

WAS is an automated system consisting of a tandem pumping system and 12 containers (each volume=22 liter, fill pressure=14-15 bar) for the collection of large air samples (approximately 300 liter at standard pressure). The primary intent and utilization of these air samples is laboratory-based stable isotope analysis (¹³C, ¹⁸O, ²H, ¹⁵N, etc.) of several important trace gases (CO₂, CH₄, CO, and N₂O). Larger air samples are in particular required for ¹⁴C analysis of CO.

CPC (Condensation Particle Counter), adapted by the Institut für Troposphärenforschung, Leipzig, for an external pressure of 200 mb, PI: J. Heintzenberg.

CPC is a commercially available instrument (Model 7610). It measures the number concentration of particles 0.014 µm in diameter and larger. The particles are detected by condensing n-butyl alcohol vapor (butanol) onto them, causing them to grow into droplets which are counted by an optical counter. Objective: measurement of aerosols in the atmosphere.²²⁰⁴⁾

Sample flow rate	1.41 liter/min	Vac. source minimum	18 inch Hg
Total exit flow rate	2.83 liter/min	Particle size	> 0.01 µm
Light source	laser diode	SNR	20:1 minimum
Instrument mass	4 kg	Instrument power	100//220 VAC, 50-60 Hz

Table 616: CPC instrument parameters

P.40.4 ASE (Automatic Air-Sampling Equipment)

ASE²²⁰⁵⁾ designates a Japanese trace gas measurement program which is conducted on commercial airline flights of JAL (Japan Airlines) on Boeing 747 aircraft. The cooperative

²²⁰⁴⁾Information provided by A. Wiedensohler, Institut für Troposphärenforschung, Leipzig, Germany

program is supported by the JAL Foundation, JAL, the Ministry of Transportation, and JMA (Meteorological Agency of Japan). The objective is to monitor carbon dioxide and methane concentrations at airline flight altitudes over a long period of time. The JMA/MRI/GRL (Japan Meteorological Agency / Meteorological Research Institute / Geochemical Research Laboratory) in Tsukuba is the institution functioning as the system integrator and scientific program coordinator; it also services the ASE and analyzes the sampled air.

Two ASE units (ASE-1 and ASE-2) were tested from October 1992 through April 1993; a final flight test occurred in April 1993 on a Boeing 747 (JA8127) aircraft on a flight from Narita airport, Japan, to Cairns in Australia. All operational procedures for system handling were also conducted and reported to CAB, the Civil Aviation Bureau of Japan. As a result the ASE system was licensed by CAB for Boeing 747 aircraft.

The ASE is a flask sampling system which collects riser duct air into twelve flasks of ASE-1 and ASE-2 with the use of a pump. The ASE system is installed in the R-2 life raft compartment, located above the main cabin ceiling of the aircraft. This compartment permits easy access and servicing of ASE after a flight. The handling concept requires removal of all flasks after a round trip for servicing by the parties concerned (MRI/GRL). The flasks are analyzed and eventually readied for a further survey flight. - The air in the riser duct originates from the engine bleed air, which is supplied to the cabin through the air-conditioning system. The air intake port for the sampling flasks is located upstream of the recirculating fan in the riser duct.

The main components of ASE-1 and ASE-2 are six sample flasks for each system, solenoid valves, pressure sensors, and a control unit (CPU with RAM and ROM). The measurement period of the system is pressure-controlled; whenever the pressure is < 600 mm Hg (corresponding to about 9 km altitude) samples are automatically collected in the prescribed intervals. A titanium cylinder with a volume of 1.9 liter is used for the collection of air samples. On a typical flight air samples are collected every 40 minutes (corresponding to a latitudinal range of about $4-5^{\circ}$). The sample air is filled into a flask by a bellows pump up to a pressure of 40 psia (2.8 bar). The maximum flask pressure indicates to the system a switch to the next flask (up to 12 flasks). A RAM in the ASE records the sampling times. Sampling is performed only on one leg of the flight (Sidney to Narita). The ASE sampling system operates without any crew member assistance during flight; this is an important functional requirement for measurement equipment on commercial aircraft.

Handling concept: After a sampling flight, the ASE units are unloaded and transported by JAL personnel to the MRI/GRL facility for analysis. After the measurements are conducted the ASE units are flushed with dry purified air and readied for the next sampling flight. Aircraft navigation data is provided separately by JAL for postflight mating/processing with the RAM data. Note: CAB-Japan regulations require total independence of ASE from flight/navigation systems. The ASE handling procedures are included in the maintenance manual of the aircraft.

All ASE measurements are put into a JMA long-term atmospheric database [WMO WDCGG (World Data Center for Greenhouse Gases) DATA REPORT] which is available to the research community after an initial exclusive access period by JMA researchers.

The operational period of ASE started in April 1993 with one monthly round-trip flight between Narita and Cairns (on JA8127). In July 1994 the ASE instrumentation was switched onto another aircraft and flight (JA8131), and is now flown twice a month between Narita, Japan and Sydney, Australia. The CAB of Japan requested in 1994 a change of ASE equipment installation in Boeing 747 aircraft - from the previous R-2 life raft location above the passenger cabin to a new location in the forward cargo compartment (closer to the pump).

2205) H. Matsueda, H. Inoue, "Measurements of trace gases in the upper atmosphere using airliner (Boeing 747)," JMA/MRI/GRL internal paper provided by H. Matsueda

ASE program recommendations and planning in 1994 call for observation of the Western Pacific region for at least 5 more years (open-ended long-term program). The objectives are to monitor trace gases such as CO₂ and CH₄ in the upper troposphere (comparison with global ground-level data) and to clarify a secular trend in the upper atmosphere over long time periods.

P.41 ATSS (Airborne Terrain Survey System)

The ATSS ²²⁰⁶⁾ research instrument package has been designed and developed by the Institute of Navigation of the University of Stuttgart, Germany, in collaboration with the Institute of Physical Geodesy of the Technical University of Darmstadt, Germany. The integrated instrument package consists of two different active surveying sensors, namely **AMAP** (Airborne Microwave Altimeter Platform) and the **ScaLARS** (Scanning Laser Altitude and Reflectance Sensor). Both sensors are complemented by an inertial navigation system (INS) for attitude (orientation) data, a DGPS for location data, and a recording system for all information gathering. The prototype ATSS instrument package was test flown (spring 1993 and summer 1994) on a DO-228 aircraft from DLR.

AMAP Parameters	
Transmitter center frequency	13.74 GHz
Transmitter wavelength	2.18 cm
Bandwidth	80 MHz
Sampling frequency	200 Hz - making an altitude measurement every 40 cm along the track
Data rate	3.2 kByte/s
Antenna	
Type	plane array (antenna size: 0.56 m x 0.40 m)
Gain	25 dB
Circular beam width	3.5°
Precision range measurement	≤ 10 cm
Signal impulse compression length ratio	1/1280
PN code length	16 μs
Transmitter power	10 W
ScaLARS Parameters	
Transmitter frequency	1 MHz and 10 MHz
Signal bandwidth	20 kHz
Sampling frequency	7.5 kHz
Sampling points	every 3-5 m along a 150 m diameter spiral in the along-track direction
Laser transmitter power	0.26 W
Laser wavelength	810 nm
Laser type	GaAlAs laser diode (CW)
Laser divergence	1.2 mrad
Scan rate	10 scans/s
Ranging beam deflection	±14° from nadir in flight direction, ±10° in the cross-track direction
Signal quantization	18 bit for range measurements, 12 bit intensity measurements
System Parameters	
Data rate	120 kByte/s
Average aircraft velocity	75 m/s
Aircraft altitude	500 m (above ground level)
GPS instrument	Trimble SSE (sampling rate of 0.5 second)
INS instrument	Lasernav II (sampling rate of 50 Hz, pitch, roll and yaw)
Instrument mass (total)	200 kg

Table 617: Specification of the ATSS instrument parameters

²²⁰⁶⁾U. Kälberer, "Topographic Mapping by an Airborne Microwave Altimeter Platform," Proceedings of the 1. International Airborne Remote Sensing Conference and Exhibition," Strasbourg, France, Volume II, September 12-15, 1994, pp. 43-51

The AMAP objective is the precise range measurement of ground surface profiles and features for topographic mapping surveys from airborne platforms. The signal measurement concept of the AMAP radar employs two modes: the FM/CW (Frequency Modulation/Continuous-wave) mode, known as 'frequency-modulated radar,' and the PN-code sequence transmission mode (the latter technique enlarges the measurement range and is similar to pulsed radar). The use of both modes offers increased performance values for the instrument. As of 1994 AMAP is only being operated in the PN-mode.

The objective ²²⁰⁷⁾ of the ScaLARS sensor is the imaging of terrain topography (range) as well as the measurement of the ground surface reflectance with high geometrical resolution. The instrument consists of an active laser ranging unit [transmitter, Schmidt-Cassegrain telescope ($f=270$ mm, aperture ratio = $1/1.4$), interference bandpass filter, receiver with APD detector, signal modulation and phase delay detection unit], an opto-mechanical Palmer scanner, and a digital data registration unit. Ranging is done by measuring the continuous wave multifrequency phase differences using a laser beam as a highly collimated carrier. Apart from the range data, the ScaLARS sensor also collects radiative intensity data which represents surface reflectance that is independent of lighting conditions.

Both sensors operate in parallel and look into the same nadir direction. The use of two independent surveying sensors provides simultaneous altitude measurement by an electromagnetic device (microwave altimeter) and an optical device (scanning laser altimeter) - the analysis of both signals results in a very precise topographic image. The radar altimeter has a footprint of 3° for each measurement; the laser altimeter, with an IFOV of 0.1° , scans a swath of $\pm 10^\circ$ on either side of the ground track. System upgrades are being considered for flight altitudes of 1000 m (above ground level) and for resolutions in the order of 5 cm.

P.41.1 ScaLARS-2 (Scanning Laser Altitude and Reflectance Sensor)

As of 1999, the Institute of Navigation of the University of Stuttgart offers an upgraded ScaLARS-2 instrument, a stand-alone version, containing all functional capabilities of the previous ATSS (Airborne Terrain Survey System) package with its upgrades. ScaLARS-2 consists of the following elements: scanner system, video system (CCD video camera, IMU), the navigation system, and the data acquisition system (up to 4.9 hours of continuous observation can be recorded on-board). All elements are integrated into a sensor head and a control/service rack. The main application of the instrument data is the generation of digital elevation models. Some of the upgrades are: ²²⁰⁸⁾

- Reduction of sensor head design (in size and mass)
- Redesign of range finder. The Cassegrain telescope and the co-axial Tx/Rx design were replaced by a parallel system layout with a new Achromat (80 mm aperture diameter) receiver optics.
- The laser transmitter laser power was increased from 0.26 W to 0.8 W
- The scan rate was increased to 20 Hz (using a smaller mirror)
- The laser beam deflection (scan angle) was increased with a capability to select between two ranges.
- The integration of a commercially available navigation system package improves the position accuracy and permits automatic data processing and evaluation.
- A CCD video camera (RGB output) was integrated into the sensor head permitting a parallel visual documentation of the ground swath.

ScaLARS-2 measures the range between sensor head and ground target by multifrequency phase comparison between the transmitted and echo laser signals. The multifrequency phase comparison method permits also the simultaneous measurement of surface reflectiv-

²²⁰⁷⁾ Ch. Hug, "The Scanning Laser Altitude and Reflectance Sensor, An Instrument for Efficient 3-D Terrain Survey," Proceedings of the ISPRS-Symposium 'Primary Data Acquisition and Evaluation,' September 12-16, 1994, Como, Italy,

²²⁰⁸⁾ Information provided by Ch. Hug of GeoLAS Consulting

ity, thus providing reflection imagery in the near-infrared, very suitable for surface type classifications. A spiral-type ground path pattern is generated by the superimposed cross-track motion of the laser beam and the forward motion of the aircraft. Two cross-track angles of $\pm 13.6^\circ$ or $\pm 19^\circ$ are available to suit a range of application requirements.

Laser type	CW (Continuous Wave) laser diode
Transmitter frequency, laser power	10 MHz, 1 MHz (sidetone frequencies), 0.8 W
Laser wavelength	812 nm
Maximum laser range, max flight altitude	750 m, 700 m
Range measuring method	Multifrequency phase comparison
Standard deviation of range	3 - 12 cm
Scan rate, sampling rate	0-20 Hz, 7.7 kHz
Scan mechanism used	nutating mirror
FOV in cross-track direction, along-track direction	$\pm 13.6^\circ$ or $\pm 19^\circ$; $\pm 9.7^\circ$ or $\pm 13.4^\circ$
Swath width at scan angle $\pm 13.6^\circ$; or $\pm 19^\circ$	340 m, or 480 m (700 m altitude)
Footprint diameter (at 700 m altitude) or IFOV	1.05 m (an elliptical pattern) or 1.5 mrad
Sampling distance in along-track direction	2.5 m (average) with 13.5 Hz scan rate
Sampling distance in cross-track direction	<2.5 m with a scan angle of $\pm 19^\circ$
Size of sensor head, mass of sensor head	50 cm x 85 cm x 50 cm, 56 kg
Navigation system	
Navigation system model	Applanx POS/AV 410 (with GPS receiver)
Position accuracy (postprocessing)	0.05 - 0.3 m
Roll and pitch error (postprocessing)	<0.008°

Table 618: Specification of the ScaLARS-2 instrument

P.42 AVIRIS (Airborne Visible/Infrared Imaging Spectrometer)

AVIRIS (of AIS heritage) is a NASA/JPL-developed/owned instrument operated by NASA/Ames Research Center (ARC) aboard an ER-2 aircraft. The instrument measures transmitted, reflected, and scattered solar energy from the Earth's surface and atmosphere in 224 channels over extended regions at high spatial resolutions. AVIRIS is regarded as the first operational hyperspectral instrument.²²⁰⁹⁾

Science objectives: AVIRIS radiance spectra are used to identify, measure and monitor constituents of the Earth's surface and atmosphere based on molecular absorption and particle scattering signatures. Research areas include: ecology, oceanography, geology, snow hydrology, cloud and atmospheric studies. AVIRIS data are also used for satellite calibration, modeling, algorithm development and validation. Research with AVIRIS is predominantly directed towards understanding processes related to the global environment and climate change.^{2210) 2211) 2212)}

AVIRIS was flown for the first time in 1986 (first airborne images), first science data in 1987, fully operational since 1989 [in June/July 1991 the instrument was flown over numerous European test sites in the framework of EMAC (European Multi-Sensor Airborne Campaign)]. AVIRIS uses scanning optics and a group of four spectrometers to image a 614 pixel swath width simultaneously in 224 contiguous spectral bands. A spatial image is built up through the scanner motion, which defines an image line 614 pixels wide perpendicular to the aircraft direction, and through the aircraft motion, which defines the length of the image frame. Sensor: optomechanical whiskbroom scanner (12 Hz) that uses line arrays of

Table 619: AVIRIS instrument parameters

AVIRIS is of modular construction, consisting of six optical subsystems and five electrical subsystems. The optical subsystems (a whiskbroom scanner, four spectrometers, and a calibration source) are coupled together through optical fibers.

Data: The recorded data set forms an image cube of which two axes represent spatial dimensions, and the third represents a spectral dimension (see Figure 361). The data recorder of AVIRIS was upgraded in 1992 (by a Metrum VLDS, 10 GByte storage capacity).

Figure 446: Illustration of the AVIRIS instrument

The general system performance of the instrument is continually being upgraded.²²¹³⁾²²¹⁴⁾ In addition the ground data system at JPL was modernized and its functionality expanded to handle the large data volumes of the sensor expediently and to provide data retrieval.

AVIRIS upgrades in 1994: New Lyot spectral calibration filters were installed in the AVIRIS calibrator in spring 1994 (improved spectral calibration). New focal planes with half the noise of the current focal planes will be installed by the end of 1994 with 12 bit digitization capability.

Further AVIRIS upgrades: In 1999 AVIRIS was outfitted with a dedicated INS/GPS receiver system mounted on the foreoptics that enables delivery of georectified AVIRIS data from the ER-2 platform. In addition, the baseline noise equivalent delta radiance (signal-to-noise) has been significantly improved for the spectral regions 650 to 1300 nm and 1900 to 2500 nm.²²¹⁵⁾

P.43 AWI Sensors

AWI ²²¹⁶⁾ ²²¹⁷⁾ (Alfred Wegener Institute for Polar and Marine Research, Bremerhaven, Germany) has been operating airborne sensors, among them line scanner systems on board its research aircraft (Polar 2 and Polar 4, both are DO 228 turbo-prop aircraft) since 1991. The imaging instruments are referred to as: **LSC** (Line Scan Camera), **IRLS** (Infrared Line Scanner), and **CLS** (Color Line Scanner); all instruments were designed and built at AWI. The IRLS instrument has been operational since early 1993, while the CLS sensor was added in 1995. The objective of all three sensor systems is the detailed observation of sea surface element characteristics (reflectance measurements) such as ice structures, nilas and open water distributions, surface roughness and temperature distribution, ice floe sizes, etc., and investigation of the physical processes at the atmosphere-ocean interface in polar regions (see REFLEX in ‘Survey of Campaigns’). Both aircraft are equipped with a complement of meteorological sensors, including pyranometers (two each for up/down) and navigational instruments (GPS, INS).

System Parameter	LSC	IRLS	CLS
Sensor detector	CCD 1024 pixels	Single IR sensor at 77 K	CCD 3 x 2048 pixels
Spectral coverage	0.4-1.1 μm	8-12 μm	0.4-0.48 μm , 0.48-0.58 μm , and 0.58-1.0 μm
Optics	8 mm lens, f/1.4	Rotating mirror, f/1.1	Small image (Nikon)
Scan angle (FOV)	$\pm 45^\circ$	$\pm 45^\circ$	$\pm 45^\circ$
IFOV	1.5 mrad	3.1 mrad	1.5 mrad
Time resolution	50 scans/s	50 scans/s	50 scans/s
Cross-track resolution	2 m (500 m height)	2 m (500 m height)	2 m (500 m height)
Along-track resolution	1.4 m (speed of 70 m/s)	1.4 m (speed of 70 m/s)	1.4 m (speed of 70 m/s)
Sensitivity	256 gray levels	0.1 K (25 K range)	3 x 256 levels
Quantities or parameters to be determined	Concentration of ice, nilas and open water, ice floe size, aerodynamic roughness, etc	Structural details of ice floes, surface temperature, ice types	Concentration of ice, nilas and open water, ice floe size, aerodynamic roughness, etc
Data rate	51.2 kbyte/s	25.6 kByte/s	153.6 kByte/s

Table 620: Technical parameters of AWI line scanners

P.43.1 PS100EL Laser Altimeter

A commercially-built scanning altimeter instrument by IBEO of Hamburg, Germany. The instrument is installed on Polar 2 of AWI with the objective to record the surface structure of ice floes. The distance measurement is based on the time-of-run technique of a laser beam as it reflects from a surface.

Parameter	Value	Parameter	Value
Laser source	laser diode	Receiver	Avalanche photodiode
Transmitter wavelength	905 nm	Receiver aperture	
Laser energy/pulse	100 mJ	Scan rate (selectable)	≤ 30 Hz
PRF	2 kHz	Operating altitude	300 - 1000 m
IFOV	2.4 mrad	Sensor size	650 x 640 x 650 mm
FOV (selectable)	0° to $\pm 20^\circ$	Sensor mass	70 kg
Range accuracy	< 10 cm	Power	28 VDC, 15 A

P.43.2 AWSR (Airborne Water Substance Radiometer)

AWSR is a dual-frequency microwave radiometer (passive device) that was designed and built by NOAA/ERL/ETL of Boulder, CO. The instrument was originally designed to fly in an upward-looking mode and to observe the downward-flowing atmospheric radiance at 23.87 and 31.65 GHz. When looking upward, a simple algorithm can be applied to the two radiance observations to derive the columnar amounts (above the aircraft) of water vapor and cloud liquid water. Such measurements of vapor and liquid can be applied to the validation of satellite observations, to the validation of meteorological models, and to fundamental studies of the spatial variability of water substances. When accompanied by in situ measurements of the profiles of temperature, water vapor, pressure, and cloud liquid density, measurements made during spiral ascents and descents of the aircraft can yield information on radiative transfer models. When accompanied by flight-level data of shortwave solar irradiance and by cloud liquid data, the AWSR data are valuable for climate research. Most recently (April to June 1995), AWSR, mounted on the NOAA WP-3P (ORION) aircraft, was operated during the joint VORTEX/ARM campaign in the Oklahoma region.²²¹⁸⁾

Parameter	23.87 GHz	31.65 GHz
Wavelength	12.6 mm	9.5 mm
Bandwidth	1000 MHz	1000 MHz
Temperature resolution	0.1 K	0.1 K
Absolute accuracy	2.0 K	2.0 K
Polarization	H	V
Integration time	1 s	1 s
Beamwidth	3.5° (coaxial alignment)	
Feed horn type	Pressure-compensating corrugated horn	
Instrument mass	100 kg	

Table 622: Instrument parameters of AWSR

Since its original deployment in 1992^{2219), 2220)} the instrument has been modified to look also downwards and to observe the emission from the ocean surface. The polarized response from the ocean surface can be used to infer both ocean wind speed and wind direction. In the downward-looking mode, the instrument was flown on a King Air C-90 during SCOPE in 1993²²²¹⁾ and will be flown on either a Twin Otter or a blimp during COPE in 1995

A single antenna accommodates both radiometric channels with equal beamwidths of 3.5°. The basic antenna design is that of a prime-focus partial paraboloid offset at an angle of 90° (focal length = 15.24 cm, the perimeter of the reflector is elliptical with a subtended aperture of 25.4 cm). A unique fairing has been incorporated into the antenna structure to optimize the aerodynamics and to minimize liquid build-up on the antenna surfaces.

P.44 B-Flux (Boundary-Layer Flux System)

B-Flux is a research instrument designed and built at the NOAA/ATDD (Atmospheric Turbulence and Diffusion Division) -Air Resources Laboratory in Oak Ridge, TN, with the ob-

jective to study boundary-layer fluxes. A major feature of B-Flux is its dependence on GPS to determine the full three-dimensional position velocity and attitude of the airplane at a Nyquist frequency of 5 Hz. B-Flux has been in development since 1990; it has been flown on a small experimental aircraft with the name of Long-EZ. The B-Flux system has been used in several boundary-layer experiments over land and open water, to determine mass, momentum, and energy transfers for a better understanding of the exchange mechanisms between the atmosphere and the surface. 2222) 2223)

2224) Note: μM =micromoles

ates on similar principles as commercial gust probes. It differs from these in being larger and in having four additional ports on the sphere. Ambient atmospheric pressure p_a is measured through these ports by a pair of sensors. A wide-range absolute sensor measures a slowly-varying reference pressure maintained by the pneumatic resistance-capacitance network. ²²²⁵⁾

The second sensor measures the small difference between this reference and the instantaneous atmospheric pressure (see Table 623). Dynamic pressure is determined from the pressure difference between the central port and the four p_a ports. The incident airflow direction, defined by angles α and β , of attack and sideslip, is determined as with commercial probes. The B-Flux probe mounts symmetrically on a boom, five cord lengths ahead of the closest wing.

All solid-state pressure and acceleration sensors have low mass, a broad frequency response, and high reliability. The central pressure port also serves as a temperature-sensor housing containing a microbead thermistor. Compensation is made for the 50ms^{-1} incident airflow. All signals except those from GPS receive anti-alias conditioning, beginning with four-pole Butterworth low-pass filters, which attenuate to half power at 30 Hz. The filtered signals are then sampled at 200 Hz by a 12-bit A/D converter, digitally filtered, and sub-sampled for recording. Normal recording rates of measurements are at 40 Hz and 1 Hz. On-board processing compresses the stored data. In addition to turbulent flux, the airplane is equipped to sample radiation fluxes and surface temperature.

The B-Flux instrument has been used under weakly-turbulent ocean and strongly-turbulent terrestrial boundary-layer conditions. Ocean data are typically obtained at 21 m altitude; terrestrial data flights are on the order of 40 m above ground. A variety of flight patterns are in use: typical flux lines are between 15 to 100 km long. A special ‘low and slow’ flight mode over the ocean provides flight patterns at 10 m above surface level at a speed of 50ms^{-1} . This very low altitude is necessary to sample small-scale transport structures, and it allows 3 km resolution in the flux measurement. ^{2226), 2227)}

Figure 447: A cross-sectional view of the B-Flux pressure sphere probe

The system participated in BOREAS in Saskatchewan (1993 and 1994) and in Alaska North-Slope campaigns (1993 through 1995). An over-water campaign off Monterey, CA

was flown in April 1995, along with several campaigns in the coastal environment of Cape Canaveral, FL in June and November 1995. Generally these flights were coordinated with other aircraft and with surface measurements of meteorological, hydrological, and biological characteristics.

A second, larger plane (Twin Otter) was purchased in 1995 and furnished with a second B-Flux instrument along with other equipment, including chemical sensors. The Twin Otter was flown in the SOS campaign in June 1995.

P.45 CAESAR

CAESAR²²²⁸) = CCD Airborne Experimental Scanner for Applications in Remote Sensing. CAESAR is a sensor developed and built by NLR (the Netherlands) and the Institute of Applied Physics (TU Delft). It is operated from NLR's Metro II laboratory aircraft.

Sensor: CAESAR is a single-lens triple CCD camera with filter sets in front of the CCD sensor arrays. A set of three cameras form the 9-channel down-looking module. A fourth camera is mounted as a 3-channel forward-looking module and is pointing up to 52° forward. Sensor type: Thomson CSF TH 7801; elements/channel: 1728; element size: 13 x 13 µm. CAESAR has been operational since 1988.

Advised Configurations	Land Mode	Special Land Mode	Sea Mode	Forward-looking Mode
Altitude	3 km	2 km	6 km	3 km
Integration time	7.5 ms	5 ms	40 ms	7.5 ms
Ground Speed	100 m/s	100 m/s	105 m/s	100 m/s

Table 624: Technical specifications of CAESAR

Applications: Measurement of water quality, coastal research, agricultural and forestry resource mapping, geo-botanical research (discrimination between chlorophyll, gelbstoff and other organic matter; shallow water depth mapping, bottom topography mapping), bi-directional reflectance measurements.

CAESAR can be operated in different basic modes:

- Land mode, using the three central channels of the down-looking module
- Special Land mode, using the three central channels of the down-looking module with a higher geometric resolution
- Sea mode, using all nine channels of the down-looking module
- Forward-looking mode, using all three channels of the forward-looking module

Spectral range: 400 - 1050 nm

Spectral resolution:

²²²⁸)“CAESAR CCD Airborne Experimental Scanner for Applications in Remote Sensing,” an NLR brochure

- 535-895 nm, land observation mode, three bands, 30-50 nm bandwidth
- 400-1050 nm, water observation mode, nine bands, 20-60 nm bandwidth.

Data: all channels are handled in parallel. Recorded raw CCD data and aircraft data are used to correct the CAESAR data radiometrically and geometrically. A quick-look facility is available.

P.46 CALS (Cloud and Aerosol Lidar System)

CALS is a NASA/GSFC autonomous lidar system that has been flown on high-altitude aircraft (the WB-57F and ER-2) since 1979. Objectives/applications: cloud and radiation studies, development of cloud remote sensing, provision of satellite ground truth measurements. The instrument is also referred to as CLS (Cloud Lidar System).²²²⁹⁾

The transmitter of the lidar system is a Nd:YAG laser with a nominal pulse energy of 50 mJ at the doubled wavelength of 532 nm and 100 mJ at 1064 nm. Backscattered light is collected by an 18 cm diameter Questar telescope and is split by a prism type polarization beamsplitter into parallel and perpendicular components. The instrument employs Avalanche Photo Diodes (APD) detectors. Two polarizations of the 532 nm signal and a single 1064 nm channel are detected. Data compression is performed by four decade logarithmic amplifiers. Data acquisition and storage is fully automatic. As part of the operational and data analysis procedures, the instrument is calibrated for the observed backscatter cross-section of the atmosphere and the signal depolarization.^{2230) 2231)}

The instrument was upgraded in the period of 1991-93; it currently features a new diode-pumped Nd:YAG laser with a total energy of 200 mJ and a pulse repetition rate of 20 Hz.

The instrument may be flown for periods of 9 hours with a 5 GByte data storage system. CALS provides the following measurement characteristics:

- Nadir viewing from 20 km altitude (on ER-2 aircraft)
- Profiling capability of all cloud and aerosol structures
- Resolutions: 7.5 m vertical and 20 m horizontal
- 532 nm and 1064 nm frequencies

Recent field experiments with CALS participation: FIRE Cirrus and STRATUS I (1986-87), COHMEX STORM Experiment (1986), FIRE Cirrus II (1991), ASTEX (1992), TOGA/COARE (1993), CEPEX (1993), MAST (1994), ARM CAS (1995), SCAR-B (1995), ARESE (1995)

P.47 CAMS (Calibrated Airborne Multispectral Scanner)

A NASA-sponsored instrument developed and operated at Stennis Space Center (Mississippi). CAMS is flown on a LearJet 23 (equipped with INS and GPS) at altitudes up to 12 km, the instrument became operational in 1987.²²³²

Channel	Detector	Bandwidth (μm)	NER (Sensitivity) mW/(cm ² str μm)

Optical parameters		Telescope: Dall Kirkham Aperture: f/2.8 Focal length: 267 mm NIR: dichroic bandpass SWIR: dichroic grating TIR: dichroic bandpass	

Table 626: Specification of the CAMS instrument

The CAMS instrument provides spectral coverage in six contiguous channels from 0.45 - 0.90 μm (VIS/NIR), plus two channels in the SWIR and one channel in the TIR range. An on-scanner integrating sphere provides calibration data for channels 1-8. A high-temperature blackbody (< 50 °C) and a low-temperature blackbody (> -10 °C) provide calibration data for channel 9.

P.48 CAR (Cloud Absorption Radiometer)

CAR²²³³) is a NASA/GSFC developed multiwavelength scanning radiometer for performing several functions, including determining the single scattering albedo of clouds at se-
²²³²)Information provided by B. A. Spiering of NASA/SSC

lected wavelengths in the visible and near-infrared, ²²³⁴⁾ ²²³⁵⁾ measuring the angular distributions of various surface types, ²²³⁶⁾ ²²³⁷⁾ ²²³⁸⁾ ²²³⁹⁾ and acquiring imagery of cloud and Earth surface features. ²²⁴⁰⁾ ²²⁴¹⁾ Because of its unique ability to measure both downwelling and upwelling radiance at 14 narrow spectral bands located in the atmospheric window regions of the UV, visible, and near-IR, the instrument is also used to study optical characteristics of aerosols. It has the potential to play a strong role in advancing remote measurement science, by combining multispectral and multi-angular data and therefore provide correlative data for satellite validation. The instrument was originally built in the early 1980s but has since undergone several modifications to enhance its capability.

CAR optical system	Non-dispersive type - consisting of a complex configuration of dichroic beam splitters and narrow-band interference filters
Dall-Kirkham (Cassegrain) telescope	12.4 cm diameter
IFOV	1° (17.5 mrad)
FOV	190° along the scan line and 1° along the plane's velocity vector
Detectors channels 1-2 channels 3-6 channels 7-8 channels 9-14 (filter wheel selected)	Enhanced hybrid silicon photodiodes operating at 308 K Hybrid silicon photodiodes operating at 308 K Germanium detectors operating at 255 K InSb cold-filtered detector cryogenically cooled
Scanner	Electromechanical scanning system
Scan cycle	600 ms
Calibration	Laboratory integrating sphere measurements before and after each research mission

Table 627: CAR instrument parameters

CAR has a 1° instantaneous field of view. In the normal mode of operation aboard an aircraft, the CAR views 190° of Earth-atmosphere scene around the starboard horizon. This configuration permits observations of both local zenith and nadir with as much as a 5° aircraft roll. In addition to the starboard viewing mode, the CAR instrument can now be rotated in-flight into three other viewing positions: downward-looking imaging mode, upward-looking imaging mode and a dedicated BRDF viewing mode.

The first eight channels of CAR (0.34-1.27 μm) are continuously and simultaneously sampled, while the ninth registered channel is selected from among the six spectral channels on a filter wheel (1.55–2.30 μm). The filter wheel can either cycle through all six spectral bands at a prescribed interval (usually changing filter every fifth scan line), or lock onto any one of the six spectral bands and sample it continuously. Since the scan rate of the radiometer is 1.67 Hz, each minute of flight duration results in 100 measurements of the angular intensity field for each of the first eight channels, and typically 12 measurements for each

Table 628: Spectral characteristics of the CAR instrument

The CAR was designed to operate from a position mounted on various aircraft. It was first operated from the tail gunner's position on a Douglas B-23 (1983-1984), later in a special nose cone on a Convair C-131A (1985-1998), and finally in the improved nose cone on a Convair CV-580 (1998-present). Instrument participation in campaigns: KOFSE (Kuwait Oil Fire Smoke Experiment), ASTEX, MAST, ARMCAS, SCAR, TARFOX, FIRE ACE, and SAFARI 2000.

P.49 CARABAS (Coherent All Radio Band Sensing)

CARABAS is a Swedish airborne experimental SAR instrument designed and built at FOA (National Defense Research Establishment, Linköping, Sweden), which operates in the lower part of the VHF-band. The objective is good penetration of vegetation/foliage and to some extent of the ground surface. The frequency band was chosen: 1) to reduce the image speckle level without sacrificing resolution, and 2) to obtain a system with diffraction-limited resolution (i.e. a system with a dimension of the resolution cell comparable to those of the wavelengths employed, to minimize the influence of speckle). A feasibility study started the project in 1985, the instrument was built and integrated during 1988-90 (except for the antenna system), initial test flights with CARABAS-I on a Rockwell Sabreliner were carried out during 1992, with the first major SAR campaign in October 1992.²²⁴²⁾ An upgraded CARABAS-II version is flown since 1996.

The original CARABAS-I antenna system consisted of two inflatable and flexible canvas sleeves (5.5 m in length) which were dragged behind the aircraft in flight. The design turned out to be problematic. - The new CARABAS-II system uses a new design with two antenna tubes which are mounted in front of the aircraft. The antenna works as a wideband dipole over the frequency range 20 - 90 MHz.

The SAR measurement concept is based on a stepped-frequency technique - instantaneous narrow-band signals are used while stepping through the required bandwidth. The scattering model used assumes that the reflectivity from a ground surface element is proportional

²²⁴²⁾ A. Gustavsson, P. O. Frörlind, H. Hellsten, T. Jonsson, B. Larsson, G. Stenström, "The Airborne VHF SAR System CARABAS," IGARSS '93, Vol. II, Kogakuin University, Tokyo, Japan, Aug. 18-21, 1993, pp. 558-562

to the scalar product between the ground surface normal and the aspect vector from the aircraft to that element. The inverse scattering problem consists of restructuring the reflectivity function with knowledge of all circular averages measured along the synthetic aperture. Derived signal processing algorithms have been applied on the acquired radar data to form images.

Aircraft	Rockwell Sabreliner
Nominal altitude	1500 - 6500 m
Nominal speed	100 m/s
Antenna	2 wideband dipoles
Polarization	Horizontal
Frequency	20 - 90 MHz
Number of frequencies, n	≤ 57
Frequency stepping factor	1.25 MHz
Pulse length	0.5 μ s
Receiver bandwidth	2.5 MHz
Peak power (transmitter)	1 kW
System PRF, PRF _s	10 kHz
Effective PRF, PRF _e	10/2/n kHz
Intermediate frequency (IF)	2.5 MHz
Digital sampling rate	10 MHz
Maximum slant range, R _{max}	7.5 km
Number of bits/real sample	12
Data rate	80 Mbit/s
Tape recorder capacity	107 Mbit/s
Cassette capacity	60 minutes

Table 629: System parameters of the CARABAS-I VHF SAR instrument

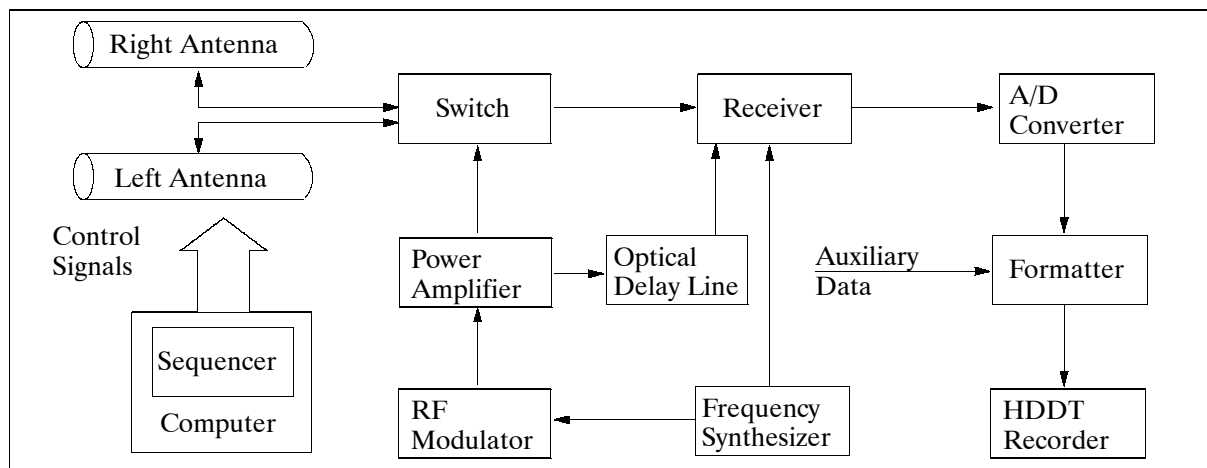

Figure 448: Functional block diagram of the CARABAS Radar electronics

Motion compensation algorithms have recently been included in the Fourier-Hankel processing scheme, and a spatial resolution of about 3 m by 3 m has been verified from a 5 m trihedral response when DGPS positioning methods were applied. An important parameter that has a great impact on resolution is the availability of signal bandwidth not severely disturbed by strong external radio sources. A lot of effort is being invested in techniques for filtering interfering radio sources in order to improve the resolution. ^{2243) 2244) 2245)}

CARABAS has imaged environments ranging from rain forests to deserts. Several campaigns have been joint efforts between FOA and MIT/LL under the sponsorship of ARPA.

²²⁴⁵⁾ Information provided by A. Gustavsson of FOA, Linköping, Sweden

The capability of foliage penetration for detection of concealed targets (using low frequencies) has been demonstrated.

CARABAS-II

An agreement between the Swedish government and Ericsson Microwave Systems AB (EMW) was signed in 1993 to develop the next generation of the CARABAS VHF-SAR concept (CARABAS-II) on a joint basis between FOA and EMW. The upgrade work was completed in 1996, the first flight was made in Oct. 1996. The main modifications of the new system involve the following: ^{2246) 2247) 2248) 2249)}

- A new rigid antenna system with de-icing and lightning protection. The 5 m long antennas are mounted in the nose of the aircraft, permitting normal aircraft operations.
- A considerable increase in mean transmitted power, in order to improve the SNR level in the SAR images
- Simultaneous signal registration in the two receivers from each antenna (avoidance of Doppler ambiguous sampling with the use of two parallel receiving channels). The receivers have 14 bit A/D converters.

Parameter	Value	Parameter	Value
Aircraft	Sabreliner	Receiver bandwidth	2 x 2 MHz (Rx)
Nominal altitude	1500-10,000 m	Transmitter peak power	500 W (Tx)
Nominal ground speed	100 m/s	System PRF, PRF _s	1-10 kHz
Flying conditions	IMC	Effective PRF, PRF _e	100 Hz - 10 kHz
Max. slant range	Programmable	Intermediate frequency	215.25 MHz (IF)
Full integration angle	120°, for 10 km AGL	Baseband center freq.	3.75 MHz
Full aperture length	60 km, for 10 km AGL	Tx notch	30 dB
Full integration time	500 s, for 10 km AGL	Rx notch depth	90 dB
Antenna	2 phased wideband dipoles	Tx & Rx notch BW	10 kHz
Radiation pattern	One side (backlobe < -15 dB)	Rx dynamic range	88 dB (spurious free)
Polarization	Horizontal	Digital sampling rate	2 x 5 MHz
Frequency	20-90 MHz	Number of bits	2 x 14
Nr. of frequencies	1-256	Data rate	160 Mbit/s
Freq. stepping factor	Programmable	Tape recorder max rate	240 Mbit/s
Pulse length, T _p	50% duty cycle	Cassette capacity	28 minutes recording

Table 630: Instrument parameters of CARABAS-II

The CARABAS-II is a fully coherent system, the direct signal synthesizer is used to generate the local oscillator signal for both, the transmitter and the two receivers. In the transmit chain, the local oscillator is used in the final mixing stage so that the arbitrary waveform generator signal is allocated to the selected carrier frequency. The FM chirp pulse is amplified to about 500 W. By the antenna selection network the signal is then fed to both left- and right-hand side antennas. In one of the feeders a delay line is inserted to give the phase shift needed to steer the beam to the selected side. Simultaneously, a -50 dB signal sample is taken from the power amplifier and used as a calibration signal. The receivers are trailing the transmitter while stepping across the band. The effective PRF is about 200 Hz when covering the full bandwidth.

P.50 CASI (Compact Airborne Spectrographic Imager)

CASI is a commercially available instrument (since 1989) of ITRES Research Limited of Calgary, Alberta, Canada. CASI is a lightweight spectrometer/multispectral pushbroom (CCD) imager system (of FLI heritage) for airborne remote sensing applications. It covers the visible and near infrared spectrum (0.400 - 1.0 μm) with 1.9 nm sample interval (288 spectral bands) and 512 spatial pixels. Quantization level = 12 bits. ^{2250) 2251)}

CASI consists of the sensor head, instrument control unit, power supply, power inverter, monitor and keyboard. The system is equipped with a data recorder (standard 8 mm video cassette tape recorder with a volume of about 1 GByte per cassette). Data are recorded at a maximum rate of 230 kByte/s. Operator-selectable band sets are based on the requirements of the application. There is quicklook capability in either grey-scale or pseudo color display. CASI can operate either as a multispectral imager or as a high-speed multipoint spectrometer with co-registered monochromatic imagery. In imaging mode, the spectral band configurations are defined interactively with a graphical user interface. In multispectrometer mode, high resolution spectra are recorded for the full spectral range of the instrument for up to 39 regularly spaced points in every data frame. CASI can be provided with optional roll correction and calibration systems.

Spectral coverage	400 - 1000 nm sampled by 288 detector elements, sampling interval = 1.9 nm, spectral resolution = 2.2 nm, FWHM at 650 nm
Spatial coverage	37.8° swath width, with standard lens; single camera gives 612 pixels, other lenses can be used to vary swath width, spatial resolution = 1.3 mrad (1.6 mrad)
Spectral mode	Up to 39 spectra of the full range are recorded with 2.9 nm resolution, from 101 adjacent look directions across the swath. A full-resolution image at a predetermined wavelength is also recorded to assist in track recovery.
Spatial mode	Spectral pixels are grouped to form up to 19 bands (19 pushbroom images each 512 pixels wide). The bandwidth and spectral position are under software control. The number of bands governs the integration time.
Spatial resolution	1.5 m (at an altitude of 1200 m above ground level, using a FOV of 37.8°)
Sensitivity	Depends on signal level
Integration times	30 ms, typical in spatial mode, 100 ms, typical in spectral mode
Digitization	12 bit
Detectors	612 by 576 element EEV UT104 array, 512 of the 612 elements are spatial image pixels, 288 of the 576 elements are spectral pixels (290 of the 578 storage pixels)
Foreoptics options	FOV-37.8° (standard), FOV-44.7° (custom-developed) IFOV - 1.3 mrad (for standard optics), IFOV = 1.6 mrad (for custom lens)
Optics	Reflection grating with f/2.8 optics
Data recording	Exabyte digital recording onto 8 mm tapes, 1.1 GByte/tape, 280 kbit/s recorded 1995: dual Exabyte tape drives with recording rates of ≥ 700 kByte
Power	3.9 A at 110 VAC (400W) or 20 A at 28 V (560W)
Weights	Total = 55 kg, head = 6 kg
Aircraft mountings	Designed for light aircraft
Navigation data	Integrated GPS receiver and vertical gyroscope (or INS or IMU), CASI imagery is in a GIS-format

Table 631: Specifications of the Compact Airborne Spectrographic Imager (CASI)

As of 1994 an incident light sensor (ILS) has been developed which samples downwelling irradiance simultaneously with CASI data acquisition. The objective is to facilitate the conversion of measured spectral radiances into measured spectral reflectance values. From the measured irradiance at the aircraft, the irradiance at ground level can be estimated. The sensor allows the deduction of the spectral reflectance of a scene on a pixel-by-pixel basis, taking into account standard atmospheric corrections. The ILS consists of a diffuser head

mounted in the aircraft roof which is fiber-optically connected to the spectrograph slit in the sensor head.

Some CASI owners/operators are:

G. A. Borstad & Associates, Sidney, B. C., Canada; Aerospace Image Production, Herrenburg, Germany; Geomatic Technologies Inc., St. John's, Newfoundland, Canada; Defense Research Establishment Suffield, Alberta, Canada; Freie Universität Berlin, Weltraum Institut, Berlin, Germany; Institute for Space & Terrestrial Science, York University, North York, Ontario, Canada; EG&G Energy Measurements Inc., Las Vegas, Nevada, SM Systems and Research Corp.; Natural Environmental Research Council (NERC), Swindon, UK; Institut Cartografie De Catalunya, Barcelona, Spain; NASDA, Tokyo, Japan; Atlantic Reconnaissance, Coventry, UK; Ariel Geomatics Inc., Dartmouth, Nova Scotia, Canada; Aquater, San Lorenzo, Italy. In 1999, a total of 17 CASI instruments are in use.

P.51 CASI-2 (Compact Airborne Spectrographic Imager - 2)

CASI-2 is a second generation instrument of ITRES Research Ltd with the objective to acquire VNIR multispectral/hyperspectral imagery from a variety of light aircraft platforms. The system components are: SHU (Sensor Head Unit), ICU (Instrument Control Unit), KBU (Keyboard Unit), VDU (Video Display Unit), and power supply. The instrument can be programmed to operate in any of three modes. Some design improvements include: a compact and power efficient instrument, reduced noise levels, and faster scanning rates.

Instrument type	Pushbroom imaging spectrograph
FOV, IFOV (spatial resolution)	37.8° cross-track (mode dependent), 0.077°
Number of pixels	512 (across-track)
Spectral range, max No of bands	400 - 1000 nm, 288
Spectral resolution	about 1.9 nm
Aperture	from f/2.8 to f/11 (all under automated control), 1 closed setting, 5 open settings
Dynamic range, SNR	4096:1 (12 bits quantization), about 480 (peak)
Maximum scan rate	333 lines/s
Calibration accuracy (absolute)	±2% in the range 470-800 nm, ±5% for 430-870 nm
Operating modes Spatial Hyperspectral Full frame	512 pixels (up to 19 programmable bands) Up to 511 programmable pixels, up to 288 bands 512 pixels, 288 bands
Data acquisition and processing Operator control Data recording Dat processing	Keyboard and real-time LCD display Digital helical scan drive (40 Gbit) or hard drive (9 Gbit) Display software, geometric correction software
Total instrument mass	30 kg
Instrument power	18-36 VDC, 4A (DC operation), 110/220 VAC (AC operation)

Table 632: Instrument parameters of CASI-2

The CASI-2 instrument, available as of 1999, comes with a variety of navigation options like IMU and GPS for geocorrection support. ^{2252) 2253)}

The SHU contains the fore-optics, slit and the reflective grating imaging spectrograph, and the thermoelectrically cooled CCD detector array (512 x 288). Optionally, an ILS (Incident Light Sensor) is provided to measure the downwelling irradiance for the selected operating configuration. Standardized post-processing techniques permit radiometric and geometric calibration of the recorded imagery.

P.52 Cast Eyes

Cast Eyes is an airborne stabilized optical sensor system built by the US Navy (Naval Air Warfare Center) in Point Mugu, CA and operated by its fleet on an EP-3E aircraft since 1992. The system offers high-resolution video images for surveillance and reconnaissance missions, it is utilized in particular for intelligence gathering (there is also some utilization in the war against drugs and narcotics).²²⁵⁴⁾

Typical ground image resolution is $> 10 \mu\text{rad}$ during the day and $> 50 \mu\text{rad}$ at night. This performance level is achieved by the following system features:

- Active stabilization of the optical line-of-sight (LOS)
- Passive vibration isolation
- A compact 20 to 120 inch (50 cm to 300 cm) diffraction-limited zoom telescope. The telescope provides motorized operator control of all system functions.

Background: Over the last 20 years the Naval Air Warfare Center has built a family of airborne optical systems, all based around the gimballed mirror technology. A different name is attached to each system/configuration for a particular customer, for better service support. The first system of this family of instruments was Cast Glance, completed in 1975. As of 1994 the three CASOS systems of table 633 are in the building phase; their primary use is for drug interdiction.

All optical systems are built in a modular fashion permitting operational adaptability for specific data collection requirements (assembly of a number of sensor types: color video, high-resolution B&W video, high-resolution electronic still video images (snapshots), low light level video for night-time applications, and various film cameras).

Instrument Name (No. of Instruments)	Customer	Telescope Aperture	Sensor Complement (No. of simultaneous op- erational sensors)	Aircraft Platform
Star Cast (1)	US Air Force	7 inch	Film/video (6)	C-135/130
Cast Glance (5)	US Navy	4 and 7 inch	Film/video (5)	P-3, C-135, Helos
Cast Light (1)	US Air Force	7 inch	Laser Range Finder (3)	C-135/130
Cast Eyes (2)	US Navy	4 inch	Video/still video (2)	EP-3E
Sea Glance (1)	US Navy	4 inch	Video (3)	Shipboard
CASOS (3)	US Customs	4 inch	Video (2)	P-3A

Table 633: Overview of surveillance instruments flown on US government aircraft

Cast Eyes optical station: the system contains a stabilized gimballed mirror that isolates the optical LOS from aircraft rotational motion and provides a means of steering the LOS for target tracking. Two rate-integrating gyros, one for elevation and one for azimuth, are mounted together in a two-axis gimbal system to form a stabilized platform. The mirror is attached to the gimbal system so that it rotates with the stabilized platform in one axis. In the other axis, the mirror rotates through a two-to-one angular reduction from the stabilized platform to compensate for the angular doubling effect of the mirror about the axis. The gyros sense the aircraft motion and send signals to the torquers, causing the mirror to be moved to compensate for the aircraft motion. - The LOS can be shared by multiple sensors simultaneously depending on the application. LOS pointing can be done by hand-controlled joystick, a video tracker, an acquisition sight, or by position pots on the control console. The system can also accept external pointing data.

The stabilized mirror receives radiation from the target through the aircraft optical window and reflects a 10 cm bundle of radiation to the zoom telescope via a folding mirror. The zoom is motorized and controlled from the operator's console, permitting focal length selections.

Aircraft tracking systems	GPS, INS		
Power requirements	120 VAC, 60-400 Hz / 28 VDC		
Mass (optical frame + operator's console)	210 kg		

Table 634: System parameters of Cast Eyes

In a typical operation a target of interest is observed by the acquisition sight operator (pilot in starboard seat). The pilot looks at the target with the acquisition sight, which then can be acquired on the WFOV (Wide Field of View) monitor by the console operator. The console operator takes control of the mirror by means of a thumb-controlled joystick and centers the target on the NFOV (Narrow Field of View) monitor. There are options of manual or automatic tracking of the video tracker and a number of acquisition aids. All telescope functions (zoom, focus, exposure lighted rectile. etc.) can be remotely controlled. The images obtained are of very high contrast.

Data: All video data is recorded in real-time (30 frame/s); data recording of the film camera varies from real-time 24 frame/s to 800 frame/s. The VHS recorders have a two hour recording capacity.

P.53 Chinese Airborne Instruments

P.53.1 CIS (Chinese Imaging Spectrometer)

CIS²²⁵⁵⁾ is an imaging spectrometer being developed and built by the Shanghai Institute of Technical Physics (SITP), Chinese Academy of Sciences (CAS), with the following objectives:

- to become acquainted with the key technologies in imaging spectrometry
- to develop and test an airborne sensor (along with the algorithms for data processing and interpretation); the airborne sensor serves as a prototype and testbed for the spaceborne sensor (research tool)
- to develop an engineering model of a spaceborne sensor
- to build a flight unit for spaceborne testing and operation on a polar orbiting platform.

Spectral/Optical Parameters				
Spectral Ranges	VNIR	SWIR	MWIR	TIR
Wavelength (μm)	0.4 - 1.04	2.0 - 2.48	3.55 - 3.95	10.5 - 12.5
No. of channels	64	24	1	2
Bandwidth (nm)	10	20	400	1000
Sensitivity	NEΔR ~ 1%	NEΔR ~ 2%	NEAT ~ 0.5 K	NEΔT ~ 0.5 K
IFOV (mrad)	1.2 x 3.6	1.2 x 1.8	1.2 x 1.2	1.2 x 1.2
Effective focal length (mm)	500	400	200	200
Detector element size (mm ²)	0.23 x 4	0.38 x 0.72	0.24 x 0.24	0.24 x 0.24
FOV	80°			
Quantization level	10 bit			
Aperture	200 mm			
Scan speed	6 rev/s			
Pixels per line	1226			
Sample rate	1.6 MHz			
Data rate	10 Mbit/s			

Table 635: Instrument specification of CIS (airborne prototype version)

The CIS airborne instrument employs the following functions:

- line scanning technique (45° scan mirror)
- a Cassegrain nonspherical telescope as primary optics
- parallel co-axis coupling of the dispersion system and the telescope
- multiband separation by co-axis splitter
- image transformation coupling with the use of bunched optical fibers
- VNIR dispersion with type III holographic concave grating
- SWIR dispersion by planar blaze grating
- 3-element mosaic filter/detection combination
- 64 element Si detector line array
- 24 element HgCdTe line array
- PC-based information processing system
- digital tape recording system with SCSI interface

The airborne engineering model (prototype) of CIS is in the test phase as of 1993. A spaceborne sensor CIS is considered for the turn of the century.

²²⁵⁵⁾ Zheng Qinbo, Zhang Zhimin, Zhang Baolong, Xu Xuerong, Feng Qi, Gu Gong, "Spaceborne Chinese Imaging Spectrometer," Proc. of the 5th ISCOPS, Shanghai, June 7-9, 1993

P.53.2 AMS (Airborne Multispectral Scanner)

AMS is a 19-channel instrument designed and built by SITP (no relation to Daedalus AMS). The scanner equally divides the spectrum from 0.46 - 1.1 μm into 16 bands. If required, such bands may be grouped to form channels compatible with TM, MSS (of Landsat) or HRV (of Spot). The AMS optics features a Kennedy scanner for high scanning efficiency of the ground. Applications for the instrument are mainly in the field of resource surveys.²²⁵⁶⁾

P.53.3 TIMS (Thermal Imaging Multispectral Scanner)

TIMS is a 7-band thermal infrared multispectral scanner developed and built by SITP. Its remote sensing applications are in the area of geological surveys. TIMS scans with a slant 45° rotating mirror. The main optical unit consists of a primary mirror and a collimating mirror. An infrared blaze grating with blaze wavelength of 9.0 μm is used as the dispersive element. The convergence unit is a specially designed Ge-lens with a FOV of 4.91° and $f/0.78$.

P.53.4 Prototype Scanner

This research instrument (image spectrometer development) co-uses the main optical unit of TIMS. A longwave pass filter separates the VIS range from the NIR range. In spectrometer I (0.46-1.1 μm), a concave holographic grating performs dispersing and converging functions. A special filter is used on the surface of the 32-element Si detector array to remove the higher order spectra. In spectrometer II (1.4-2.5 μm), the dispersive element is a plane blaze grating having a blaze wavelength of 1.6 μm . The grating sways back and forth between two positions synchronously with the scan line, and stays at each position for a scan line. In this way the 16 detector elements cover 32 bands.

P.53.5 MAIS (Modular Airborne Imaging Spectrometer)

The MAIS ²²⁵⁷⁾ instrument is designed, built and operated by the Shanghai Institute of Technical Physics (SITP) of the Academy of Sciences of China. The instrument is installed on a Citation S/II aircraft; the first flying tests with MAIS were conducted in November 1990. During the period September-October 1991, MAIS was also flown successfully in a joint Sino-Australian remote sensing campaign near Darwin and at several other test sites in Western Australia.

MAIS is a 71 channel imaging spectrometer with a spectral coverage from 0.44 μm to 11.8 μm . MAIS features a modular design; the optical system has four independent modules: the scanning unit, and three spectrometer modules for the different spectral ranges (separate calibration of each module is possible).

Applications: The instrument is being used for a number remote sensing applications by SITP for geological and environmental (pollution) surveys; some campaigns were conducted in Xinjiang and in the Quilian mountain area of the Gansu province, China.

As of 1993 the 64-channel prototype scanner is being built into the MAIS instrument.

Data: All video data is recorded in real-time (30 frame/s); data recording of the film cameras varies from real-time 24 frame/s to 800 frame/s. The VHS recorders have a two hour recording capacity.

P.53.6 CASSAR (Chinese Academy of Sciences SAR)

CASSAR was developed by the Electronics Institute of CAS and is operated by IRSA-CAS (Institute of Remote Sensing Applications of CAS), Beijing, China. The SAR instrument is flown on a Cessna Citation S2 aircraft along with other instruments (cameras: Wild RC10 and RC10A, an imaging spectrometer (MAIS), etc.).²²⁵⁸⁾

Application: flood control (disaster) monitoring, geological exploration, the possibility of vegetation discrimination is being considered.

The aircraft is equipped with a right- and a left-looking radar antenna mounted on platforms under the fuselage. The SAR instrument inside the plane may be switched in-flight to either one of these antennas, permitting a corresponding swath switch. The PRF is governed by the ground speed of the aircraft (V_g).

RF center frequency	9.375 GHz (X-band)
Wavelength	3.3 cm
IF bandwidth	30 MHz
Pulse repetition frequency (PRF)	6.4 V_g
Polarization	HH, VV, HV, VH, in-flight configurable
Looking modes	Left-side or right-side of track, in-flight changeable
Antenna gain	≥ 27 dB
Receiver noise	≤ 5 dB
Spatial resolution	10 m x 10 m (range x azimuth), independent of altitude

Table 638: Overview of Chinese scanners in the 1986-1990 Period

P.54 CHOPPY (Chopped Pyrgeometer)

CHOPPY is an airborne sensor measuring broadband infrared hemispherical irradiances of the atmosphere. The instrument consists of two radiometers - a target radiometer and a reference radiometer - using a specially developed mechanical chopper for signal modulation. In this setup, the reference radiometer is used to measure the radiation of the chopper,

which in turn serves as input to calculate the atmospheric radiation from the signal of the target radiometer. Important advantages of the chopped pyrgeometer are its insensitivity to temperature distribution inside the instrument and its fast response. CHOPPY was designed and built by DLR (Institut für Physik der Atmosphäre), it is operational since 1991 and flown on the Falcon 20 and other aircraft (pre-EUCREX campaign in January 1992, CIVEX in 1995). Applications: measurement of radiation fluxes in the atmosphere.²²⁵⁹⁾

Two instruments are installed in the aircraft, one pointing downward and one pointing upward for in situ measurements at flight level. Instrument parameters: spectral range = 4.0 - 100 μm ; measurement range = 0 - 600 W/m^2 ; measurement uncertainty of $\pm 2.3 \text{ W}/\text{m}^2$ with a blackbody irradiation of 430 W/m^2 ; FOV = 180° ; pyroelectric detectors with a special silver coating; sample rate = 12 Hz; power = 28 VDC, 7 A; instrument mass = 13 kg.

P.55 CHRISS (Compact High Resolution Imaging Spectrograph Sensor)

CHRISS is a commercially-developed and built-to-order high resolution hyperspectral imaging instrument by SAIC (Science Applications International Corporation of San Diego, CA) for SETS Technology Inc., Hawaii. The system was developed during 1991-92. There is one flight model of CHRISS with two different configurations; one is referred to as the IR&D (Internal Research and Development) prototype configuration, the second is called the SETS configuration. Both instrument configurations are flown (1993) on a light twin-engine aircraft (Piper Aztec).²²⁶⁰⁾ CHRISS consists of the following system components:

- a fixed focal length camera lens frontend
- an all-reflective imaging spectrograph to disperse and re-image the radiation ($\sim 10^\circ$ FOV).
- a CCD digital camera in the output plane of the spectrograph
- a video frame storage system
- a CCD TV color camera and SVHS tape recorder (for data correlation, processing)
- a GPS navigation system (aircraft)

CHRISS is a nadir-pointing CCD pushbroom 2-D imaging spectrometer with an all-reflective design, capable of imaging contiguously a spectral range from the ultraviolet to the infrared region with a conventional blazed diffraction grating. Images are acquired by a strip of n spatial elements (e.g., pixels in the cross-track direction) in many (simultaneous and contiguous) spectral bands, inherently registered - thereby forming an image frame, m image frames (in the flight direction) make up an image cube.

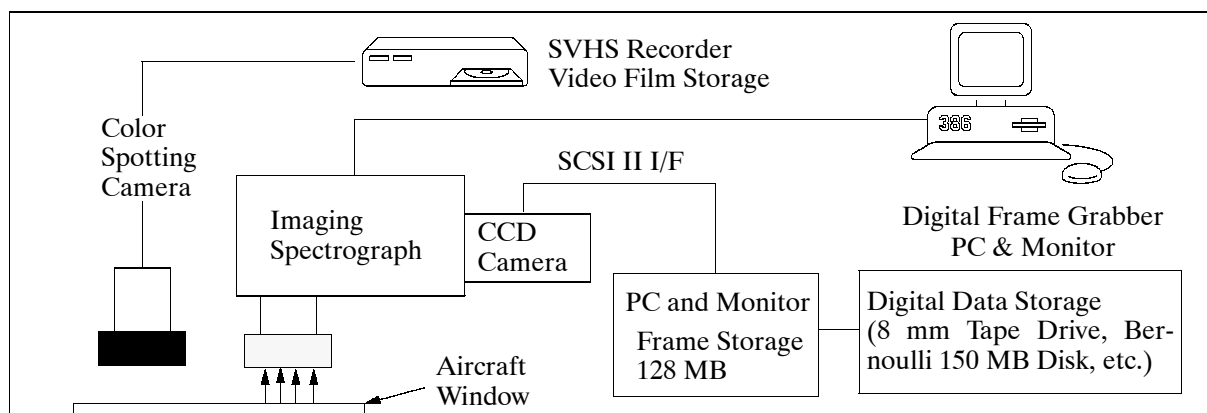

Figure 450: Flight data recording system of CHRISS

²²⁵⁹⁾ Information provided by P. Wendling of DLR

²²⁶⁰⁾ Courtesy of B. A. Speer of SAIC

The instrument is configurable with regard to spatial and spectral resolutions. Within the spatial dimension between 192 and 385 pixels may be chosen; in the spectral dimension the number of bands may range from 79 to 144. (Note: The active chip area of the CCD camera contains 385 spatial pixels x 288 spectral pixels; the spectral dimension is bisected with a quantization of 12 bit).

Spatial/spectral sampling varies according to the CCD camera format selected for a particular application. The CCD camera frame rate and noise characteristics can also be matched to the mission and platform to provide the optimum resolution and SNR. Frame rates are typically ≥ 30 frames per second. The spectrograph has a limiting blur of approximately 40 to 80 μm in the visible range, providing up to 385 channels (pixels) in the 20 mm slit plane. The spectrograph may be tuned to a range in the VIS/NIR from approximately 400 to 900 nm, consistent with blaze wavelength and a single octave spectral range. The instantaneous spectral range is tailored to the 7 mm spectral format of the spectrograph; grating dispersion is currently set to provide approximately 430 nm over the 7 mm format. Figure 450 depicts the system’s general arrangement. Table 639 summarizes the system parameters for the CHRISS SETS configuration.

Possible instrument applications: surveying for petroleum seepage, vegetation identification, forestry inventory surveys, ocean color monitoring, environmental monitoring.

Optical Parameters		Spectral Format	
First focal length	100 mm	Spectral range	430 - 860 nm
First focal ratio	f/4	Spectral channels ²²⁶²⁾	40
Spectrograph magnification	1.0	Image plane dispersion	63 nm/mm

Spatial channels ²²⁶¹⁾	192	Swath width	169 m
Spatial channel IFOV	44 μm	Integration time	21.32 ms

Table 639: CHRISS system parameter setup for the SETS configuration

P.56 CNC (Condensation Nucleus Counter)

CNR is an airborne instrument of the University of Denver, CO (PI: J. C. Wilson). The instrument became operational in the early 1980s, it is flown on ER-2 aircraft and has been utilized in the following campaigns/studies: Aerosol Climatic Effects Study, Stratosphere-Troposphere Exchange Project, Airborne Antarctic Ozone Experiment, and the Airborne Arctic Stratospheric Expedition (AASE). ²²⁶⁴⁾

CNC measures the number concentration of aerosol particles having diameters in the range of 0.02 to about 1.0 μm . The instrument operates at altitudes from 8 to 21.5 km.

The instrument functions by saturating the aerosol sample with warm alcohol vapor and then cooling the sample so that the alcohol vapor condenses on particles in the sample,

²²⁶¹⁾ Two 44 μm pixels are binned on-chip during readout to produce a single spatial pixel.
²²⁶²⁾ Two 44 μm spectral pixels are binned to produce a single 11 nm channel FWHM.
²²⁶³⁾ The CCD has 288 x 385 active area binned 2 spatial x 4 spectral (192 x 72). Forty (40) spectral channels are within the 7 nm spectral format and are used read out, the remaining 32 are dumped. Quantization is 12 bits per pixel; the data rate is 1.37 MByte/s.
²²⁶⁴⁾ Information provided by R. F. Pueschel of NASA/ARC

causing them to grow to sizes which can easily be detected by a simple optical particle counter.

Data quality: Laboratory studies have been made of the response of the instrument as a function of size and pressure. The precision of CNC has been checked in the lab and was found to be within a few percent of that implied by counting statistics.

P.57 CRL Radar/Radiometer

The instrument is a combined radar/radiometer system which was designed and built in the late 1970's (first flown in 1981) by CRL (Communications Research Laboratory) of Tokyo, Japan. Objectives: remote sensing of precipitation (rain) from an aircraft, research instrument for a future spaceborne rain scatterometer.²²⁶⁵⁾ -After several years of testing and experimenting at CRL in Japan (for both rain and ocean measurements) the instrument was sent to NASA for joint research between CRL and NASA/GSFC.²²⁶⁶⁾

- 1985-86: instrument on board the P-3A aircraft of GSFC/WFF
- 1988-89: instrument on board the T-39 aircraft of GSFC/WFF (flights over deep convection regions). For this experiment the system was modified (better sensitivity, spatial resolution and range window)
- 1990: instrument on board the DC-8 aircraft with several other instruments for the observation of tropical storms. For this experiment the system was modified to measure the cross-polarized signal at X-band.²²⁶⁷⁾
- 1991: instrument on board the T-39, participation in the CaPE experiment over Florida.
- 1994: the instrument is under modification for continuous ground-based rain observation at GSFC/WFF.²²⁶⁸⁾

Parameter	X-band	K _a -band
Type	Null balancing Dicke type	
Antenna	Commonly used with rain-scatterometer	
Local frequency	9.86 GHz	34.21 GHz
IF band width	100 MHz	
Polarization	H or V	
Noise figure	6 dB	
Integration time	0.25 s (aircraft); 0.5, 1 and 3 s (ground)	
Temperature resolution	0.5 K (aircraft)	
Absolute accuracy	±2 K	±3 K
Dynamic range	50-400 K	
Modulation frequency	440 Hz	
Calibration (aircraft)	Hot: 400 K; Cold: 300 K	
Calibration (ground)	Hot: 400 K; Cold: 80 K	

Table 640: Characteristics of the microwave radiometer

The system consists of an X-band rain-scatterometer, a X-band microwave radiometer, a K_a-band rain scatterometer, and a K_a-band microwave radiometer. The antenna and feeder subsystems for each frequency band are commonly used for the rain-scatterometer and the radiometer. The circulator of each frequency band works as the transmit-receive switch.

Table 641: Characteristics of the airborne rain-scatterometer

P.58 C-SCAT (C-band Scatterometer)

C-SCAT is a NASA-sponsored instrument, designed and built by the Microwave Remote Sensing Laboratory of the University of Massachusetts at Amherst.²²⁶⁹ Objective: measurement of wind speed over ocean surfaces and ocean surface reflectivity (also referred to as the normalized Radar Cross-Section (NRCS)). The instrument became operational in 1990 and participated in a number of campaigns such as SWADE (1991, ARC C-130B aircraft), ERS-1 underflight experiments on NOAA P3 aircraft, and TOGA/COARE (1992/93).

C-SCAT is a vertically polarized C-band pulsed scatterometer utilizing a microstrip patch phased antenna array, which is mounted underneath the fuselage of an aircraft. The main lobe of this antenna is a pencil beam with an approximate beamwidth of 5° that can be frequency-steered from 20° to 50° off-nadir (incidence) by changing the transmit frequency from 5.70 GHz to 4.98 GHz, respectively. During operation, the antenna is mechanically rotated in azimuth at ~ 30 rpm; the incidence angle is electronically selected. Thus, C-SCAT performs a conical scan of the sea surface, thereby providing full azimuthal coverage with respect to the surface wind direction.

²²⁶⁹J. Carswell, R. McIntosh, "Backscatter from the Ocean Surface under low Wind Conditions," Proceedings of IGARSS '94, Volume I, pp. 562-564

P.59 C-STAR (Conically-Scanning Two-Look Airborne Radiometer)

C-STAR is a passive radiometer with a parallel measuring capability of two footprints (fore and aft) from an aircraft. It is designed and built by NASA/MSFC with the objective to measure ocean surface winds and to serve as research tool for future spaceborne sensors. First test flights with C-STAR are planned on ER-2 for spring 1996. The instrument is to evaluate combinations of different radiometric measurement techniques for wind vector retrievals.²²⁷⁰⁾

Frequency	37.1 GHz
IF bandwidth	900 MHz
Half-power beamwidth	7.5°
Temperature resolution	0.1 K
Integration time	0.125 s
Scan pattern	conical
FOV	±45° (both fore and aft ports of the aircraft)
Scan angle	53° from nadir
Scan rate	6 rotations per minute
Radial separation between feed pairs	45°
Surface footprint size from 20 km AGL	7.3 km x 4.4 km
Total number of data samples per scan	52 per channel
Total number of calibration samples per scan	8 per channel per load

Table 642: C-STAR instrument parameters

Figure 451: Scan pattern configuration of C-STAR

C-STAR has two pairs of 37 GHz feedhorns, all pointing into the same footprint, providing two pairs of polarized look configurations. Both pairs of look configurations scan in a circular pattern underneath the aircraft with a 53° incidence angle at all points of the scan. Data are collected simultaneously from all channels (or feedhorns) as they point through the forward porthole and alternately through the aft porthole. The periodic instrument swing from forward to aft porthole provides a two-look combination.

Both feedhorn pairs of the instrument collect data in V and H polarized channels. However, the field of view of the second feedhorn pair is rotated by an angle of 45° with respect to the

²²⁷⁰⁾Information provided by R. E. Hood of NASA/MSFC

field of view of the first pair configuration. The intent is to investigate the phase correlation of the V and H radiation fields (i.e. to find the combination of viewing directions and polarizations that most accurately determine ocean surface wind speed and direction). - C-STAR will also be used for measuring anisotropic effects of other passive radiometer signatures.

P.60 CVI (Counterflow Virtual Impactor)

CVI is an in situ cloud-droplet sampler that inertially separates cloud droplets and ice crystals larger than a certain size (radius of about 2 μm) from the surrounding air and injects them into a slowly moving stream of dry, heated, and particle-free air. Water vapor and residue particles left behind by the evaporated cloud elements are subsequently sensed and sampled by other subsystems operating downstream from the CVI, providing such derived information as: the light scattering coefficient, mass concentration number, size distribution, amount of liquid water associated with the cloud droplets, and the chemical composition of the residue particles. This in turn allows determination of the spatial and temporal distribution of the sampled cloud, as well as a derivation of the solute mass concentration of cloud droplets. The flow rate adjustment of the probe allows size-selective cloud droplet sampling.^{2271), 2272), 2273), 2274)}

The CVI instrument design is a cooperative venture of MISU (Meteorological Institute of Stockholm University) and the University of Washington in Seattle. The first CVI was flown aboard a Falcon aircraft in the MIZEX-84 campaign (study of the microphysics and chemistry of clouds). Several sensor versions have been operated since then in other campaigns (ICE). As of 1995 plans call for CVI to participate in STREAM and APE (Airborne Polar Experiment) in the winter of 1996/97.

P.61 C/X-SAR

C/X-SAR^{2275) 2276) 2277) 2278)} is a CCRS-developed (Ottawa, Canada) airborne radar sensor system aboard a Convair 580 aircraft. Navigation units: UNS (Universal Navigation System) flight management system, INS, GPS (Ashtech Z12), OMEGA VLF/GPS, DME (Distance Measurement Equipment) 42. - Note: C/X-SAR was developed originally by MacDonald Dettwiler under contract to CCRS. - C/X-SAR is used as a research tool for a wide range of applications, including the support of numerous campaigns throughout the world [AGRISCATT, CEAREX, LEWEX, LIMEX, MAESTRO-1, RENE, SAREX-92, SWADE, GlobeSAR'93 (a large training and preparatory program for Radarsat)]. There are also contractual flight assignments for individual customers with specific needs. The aircraft and instrument system is being operated for CCRS under contract by industry (Innotech Aviation Ltd. with Intera Technologies Ltd.).

Maximum line rate 39/s				
Number of grey levels 16				
Full header annotation, time and position blocks				
slant range or ground range corrected		Azimuth-compressed 7 looks		
4096 8-bit pixels per range line		1 channel per Radar		

Table 643: Technical specifications of C/X-SAR

Since the commissioning of the C- and X-band SARs, in 1986 and 1988, respectively, the C/X-SAR system has undergone several upgrades, including improvements in real-time processing, more flexible imaging geometries, navigation, motion compensation processing, and a data recording unit. Interferometric experiments with the C-band radar were conducted, resulting in a multimode operational capability, namely: ²²⁷⁹⁾

- repeat-track interferometry (combined SAR images from separate repeat passes, using a single SAR antenna, since 1989)
- across-track interferometry (INSAR capability, using a dual-antenna receive configuration in the across-track direction- DTEs can be obtained in a single pass, since 1991)
- along-track interferometry (INSAR capability, using a dual-antenna receive configuration in the along-track direction, since 1993)

²²⁷⁹⁾Information brochure provided by L. Gray of CCRS, Ottawa, Canada

Applications: imaging of terrain, ocean or ice scenes, monitoring of resources (renewable such as agriculture and forestry, or nonrenewable such as geological resources), stereo imaging (part of special applications, different incidence angles are used to create parallax for targets; however, the stereo imaging capability is not being used by CCRS). Preparatory support for the spaceborne Radarsat sensor. C/X-SAR features:

- Mapping to the left or right of the aircraft
- Slant range or ground range representation
- Radiometric corrections in range for all geometries and all terrain types
- Video monitoring and recording of real-time imagery
- C- and X-band receivers, each with dual channel receivers
- Digital motion compensation across the swath
- Three-axis antenna stabilization
- Variable range-dependent gain for different applications (e.g. ocean, land)
- Radar and navigation parameter logging
- Built-in test equipment for receiver calibration
- Operation in three selectable modes: nadir, narrow swath, and wide swath
- Since 1993 the C/X SAR instruments can be configured in three different ways to perform special SAR imaging functions. The original configuration uses the two radars as synchronized, C- and X-band polarization diversity SARs. Two additional experimental configurations have been added: C-band polarimetry and C-band interferometry.

Figure 452: Geometries of C/X-SAR standard operating modes

The C/X-SAR instruments are computer-controlled and use identical algorithms to generate the specified configurations. These specifications include: the desired imaging function (dual frequency, polarization diversity, polarimetry, interferometry, etc.), the desired analysis objective, the scene contents, and the predetermined targets of interest within a scene.

The two radars (of C/X-SAR) are constrained to operate in the same imaging geometry by the commonality of the antenna drive system and are constrained to operate at the same pulse repetition frequency (synchronized) by the common image data recording system. All other parameters can be adjusted independently. - The signal data are processed in real-

time to 7-look, 6 m resolution image data and stored on high-density digital tape for post-flight processing. Data rates: each channel of each SAR is digitized at 37.5 MHz (high resolution mode) or at 10 MHz (wide swath mode); the maximum PRF (Pulse Repetition Frequency) is 383 Hz. The C-band polarimetric operations mode preempts the parallel operation of the X-band SAR.

In 1996, the C/X-SAR on the CV-580 aircraft was transferred to Environment Canada which continues to operate the facility. Part of the transfer agreement is that CCRS may continue to use the C/X-SAR system for internal Earth observation research purposes.²²⁸⁰⁾ - In 1995, NRC (Natural Resources Canada), of which CCRS is a branch, underwent a restructuring in which the airborne program was terminated. This resulted in a transfer of the C/X-SAR system to Environment Canada.

P.62 D2P (Delay/Doppler Phase-monopulse Radar)

D2P is a JHU/APL designed, built, and operated airborne radar instrument sponsored by NASA's Instrument Incubator Program. The goal of this project is to demonstrate the use of two enhancements to satellite radar altimetry and to reduce the risk to a future flight program that would employ an enhanced altimeter.²²⁸¹⁾

The underlying concepts behind the D2P radar altimeter are those employed by the TOPEX/Poseidon and GFO (Geosat Follow-On) satellite altimeters (E.21 and E.9). The altimeters flown on these spacecraft are capable of measuring the distance between the satellite and the mean ocean surface with a precision of 2-3 cm. The D2P radar differs from those instruments in two ways:

- Pulse-to-pulse coherence and full Doppler processing to allow for measurement of the along-track position of the range measurement
- Use of two antennas and two receiver channels that allow for measurement of the across-track angle of the range measurement.

The pulse-to-pulse coherence allows for a group of pulses to be Doppler processed so that the backscattered energy is separated into contributions that each represent a different along-track position of the scattering surface. This allows for an improvement in the resolution of the altimeter measurement. This is useful in ocean applications near coastlines, in the observation of smaller ocean features, and in solid surface altimetry such as ground ice applications. The second antenna and receiver channel allow for an angle measurement to accompany the range measurement.

The two enhancements provide accurate altimetry over the ice sheets of Greenland and Antarctica and contribute valuable data to an analysis of the ice mass balance as part of global climate change studies. The coherent processing constrains each range measurement to a known position in the along-track direction. The phase-monopulse angle measurement determines the across-track position of the measurement area. The range measurement therefore corresponds to a known position on the ice surface. A conventional radar altimeter must infer the position of the measurement and this inference represents a significant source of error.

The first two test flights with the D2P instrument were conducted in the spring of 2000 (March 30 and April 3) on a Navy P3 aircraft operated by NRL (Naval Research Laboratory). Further demonstrations of the D2P radar over the ice sheets of southern Greenland were performed in June 2000 (conducted from Goose, Bay, Canada). Several auxiliary measurements with various (standard GPS, DGPS, nadir-looking video, IMU) instruments

P.63 Daedalus Instruments (Digital Multispectral Scanner)

Commercially available instrument package of Daedalus Enterprises of Ann Arbor, Michigan, USA. As of 1995 Daedalus has delivered over 85 instruments/systems to its customers into 24 countries.²²⁸²⁾

P.63.1 ATM (Airborne Thematic Mapper)

ATM and ATMX (extended) systems are the most widely used airborne line-scanners in the world.

Note: the ATMX (AADS1278) is designed for higher altitude applications and special spectrometer configurations that require additional collecting aperture to achieve a higher sensitivity than is provided by the standard ATM (AADS1268) system. The electronics include all the ATM features; the scan head is designed to interface to the ATM, TIMS, or AOCL.

History: Daedalus built the AADS1260 sensor model from 1976 to 1982. This instrument preceded the era of the TM sensor on Landsat. The AADS1260 instrument enables users to emulate the spectral bands of the Landsat-4 MSS sensor from an airborne platform. The four channels of the MSS satellite are obtained by combining 7 of the 11 channels contained in the AADS1260 airborne multispectral system.

The AADS1268 was given the acronym “ATM” (Airborne Thematic Mapper); it was developed to match the Landsat TM sensor bands. This instrument (AADS1268) includes spectral channels that match six of the seven bands contained in the Landsat TM, and four additional visible and NIR channels. The thermal band (channel 6 of TM) was broadened for airborne operations. The spectral match of bands enables users to compare and complement data from both systems. The ATM now covers channels of Landsat MSS, TM and of Spot (HRV).

ATM (AADS1268) is an opto-mechanical linescanner with 8 bit data quantization. The ATMX (AADS1278) is similar but has a large collecting aperture and can be configured for 10 bit data quantization on selected channels. The total mass of the system is about 200 kg.

The AADS1280 scanner is a one-of-a-kind instrument built in 1978 for NASA for the purpose of crop classification. It then became the property of DGGTN (Direction General de Geografica del Territorio Nacional) of Mexico to detect poppy crops. The instrument is flown on a LearJet 35 aircraft.

5	0.95 - 1.06	0.11

Table 648: Spectral channels of the AADS1280 scanner

P.63.2 Analog Bispectral Instruments

The following instruments are in this category: AADS1220, AADS1221, and AADS1230.

AADS1220 (Dual Channel Terrain Surveillance Scanner)

This passive sensor uses TIR (Thermal Infrared) line scan techniques for wide-area day/night monitoring of land and water surfaces of interest. The system senses and records relative temperature differentials of objects in the target area and translates the resultant signal differences into a near photo-quality black and white image (on-board film recorder).

The two-channel design offers “hot spot” and fire detection capabilities. By combining the two detector signals, it is possible to create a high resolution image (MCT detector) with a very sensitive hot spot or fire detection capability (InSb detector).

Applications: Environmental monitoring, energy loss detection, geological explorations, forest fire monitoring, volcanology, etc.

- Operating wavelengths 3.0 - 5.5 μm , and 8.0 - 13.0 μm
- Aperture 12.7 cm
- Focal length 15.2 cm
- Optical aperture (effective) f/2
- Scan rate 160 scans/s
- TFOV 87° 20'
- Gated FOV 77° 20'
- IFOV 1.7 mrad
- Temperature resolution 0.2 °C
- Velocity/height ratio 0.26 radians/s
- Roll correction total: $\pm 10^\circ$, unvignetted $\pm 5^\circ$

AADS1221 (Maritime Surveillance Scanner)

The AADS1221 IR/UV instrument is a proven and operational sensor [being offered by SSC (Swedish Space Corporation) as a licensee of Daedalus, see P.140] for monitoring oil slicks (spreading of oil and measurement of the relative thickness of the oil film), in support of cleanup operations.

The IR/UV instrument is used at close range to obtain high-resolution imagery. The passive sensor measures reflected radiation (in IR and UV bands) from the sea surface. A mirror scanning normal to the aircraft flight direction allows for mapping line by line, yielding images 400 m wide from a 300 m flight altitude, with a ground resolution of a few meters.

The IR/UV signals are presented in real-time on a split-screen format color TV monitor. There is support for quicklook documentation, data recording, air-to-ground image transfer, a provision for SLAR instrumentation (Ericsson, see P.140.1), and camera instrumentation.

- Operating wavelengths 0.32 - 0.38 μm (UV), and 8.5 - 14 μm (IR)
- System sensitivity $\text{NE}\Delta\text{R} \leq 0.06\%$ (UV), $\text{NE}\Delta\text{T} \leq 0.2^\circ\text{C}$ (IR)
- IFOV 5 mrad
- TFOV 87°
- Scan rate 160 scans/s
- Velocity/height ratio 0.4 radians/s
- Roll correction output signal for: $\pm 10^\circ$

AA2000 is identical to AADS1221 except that it includes an image printer to allow it to be operated as a ‘stand-alone’ system.

AADS1230 (Dual Channel Quantitative Infrared Scanner)

- Operating wavelengths 0.35 - 13.0 μm
- Aperture 12.7 cm

- Focal length 15.2 cm
- Optical aperture (effective) f/2
- Scan rate 80 scans/s
- TFOV 87° 20'
- Gated FOV 77° 20'
- IFOV 2.5 mrad
- Temperature resolution 0.2 °C
- Velocity/height ratio 0.2 radians/s
- Roll correction total: $\pm 10^\circ$, unvignetted $\pm 5^\circ$

With regard to the AADS1230, 1220, 1221, and AA2000 systems, Daedalus offers optional detectors to fill the two ports. The customer can thus acquire combinations of 3.0-5.5 μm , 0.4-1.1 μm , and 0.32-0.38 μm (UV). Normally these systems are operated with one thermal detector plus one UV detector (for oil spill monitoring).

P.63.3 Analog and Digital Bispectral/Multispectral Instruments

The following instruments are in this category: AADS1250 and AA3500.

- AADS1250 (Eleven Channel Analog Multispectral System)

The system consists of a dual optical path single aperture scanner permitting simultaneous acquisition of 10 channels of calibrated reflected data in the spectral region of 0.38 - 1.10 μm , and one channel of calibrated infrared data in the 3.0-14.0 μm region. The system specifications correspond to those of the AADS1220 instrument.

- AA3500 = Airborne Bispectral Scanner (ABS)

ABS is a dual optical port, bispectral scanner consisting of a compact scan head with one or two detectors, and an electronics package. ABS provides 12-bit digital precision and a broad dynamic range with interchangeable detectors for a wide range of applications plus continuous video monitoring and operator control. Standard 8 mm digital tape recorder.

The system performs simultaneous scanning for TIR and a second spectral region: either SWIR, VNIR, or UV. Dual blackbody reference sources permit calibration of the TIR channel.

Applications: ABS collects data for applications as diverse as geological mapping, vegetation studies, pollution monitoring, maritime surveillance, heat loss detection, etc.

Spectral ranges (2 available)	TIR + (8.5-12.5 μm),	MWIR or (3.0-5.5μm)	VNIR or (0.4-1.1μm)	UV (0.32-0.38 μm)
IFOV	2.5 (1.25 or 5.0 optional) mrad			
FOV	86°			
Scan rates	100, 50, 25, 12.5, 6.25 scans/s (operator selectable)			
Velocity/Height ratio (V/H)	0.25 radians/s at 100 scans/s			
Roll correction	± 15° of roll correction (automatic)			
Navigation data interface	Data: date, time, ground speed, latitude, longitude			
Power requirements	28±3 VDC, 40 A continuous			
Mass of instrument	81 kg

P.63.4 AOCI (Airborne Ocean Color Imager Spectrometer)

AOCI²²⁸³) is a sensor developed under NASA contract in response to user requests to emulate the spectral and radiometric characteristics of the spaceborne CZCS (Coastal Zone Color Scanner) on the Nimbus-7 satellite (launched in 1978) to expand the possibilities of biological oceanography. The CZCS instrument failed in 1986 on Nimbus-7, SeaWiFS (see B.8.2) was the next NASA sensor to continue ocean color monitoring (other spaceborne sensors in this category are OCTS on ADEOS with a launch in August 1996 and MERIS on ENVISAT-1 (see D.9) with a launch in 2001).

Application: AOCI is a prime tool in oceanographic research for the study of biomass, chlorophyll, fishery management, pollution detection, and for the investigation of aquatic ecosystems for a wide variety of applications.

²²⁸³) R. C. Wrigley, R. E. Slye, S. A. Klooster, R. S. Freedman, M. Carle, L. F. McGregor, "The Airborne Ocean Color Imager: System Description and Image Processing," Journal of Imaging Science and Technology, Vol. 36, No. 5, Sept./Oct. 1992, pp. 423-430

Owners/operators of AOCI instruments: NASA/Ames Research Center, Moffett Field, CA, on ER-2 aircraft; Telespazio S. P. A., Rome, Italy on Partenavia aircraft.

Note: The NASA/Ames AOCI is actually the reconfigured AADS1278 (ATMX) instrument to meet special support/application requirements.

Table 653: Spectral/radiometric characteristics of CZCS, AOCI and SeaWiFS sensors²²⁸⁴⁾

The AOCI system was developed from the AADS1278 system. The AADS1278 optics system consists of a rotating scan mirror, a telescope, folding optics, and a field stop. A new AOCI spectrometer section replaces the original TM spectrometer section of the AADS1268. Note: Bands number 9 and 10 of the AOCI provide 8-bit quantization, the rest 10-bit quantization.

IFOV(spatial resolution) at 12.5 km altitude	31 m
No. of pixels per scan line	716
Scan rate	6.25, 12.5, 25 scan/s
Quantization level	10 bit (for band 1-8), 8-bit (for band 9-10)

Table 654: Geometric characteristics of the AOCI instrument

P.63.5 AMS (Airborne Multispectral Scanner)

The AMS (AA3600) is a dual-port system which records up to six spectral channels simultaneously directly onto digital tape. The standard configuration offers a dual element thermal-infrared detector and an 8-channel VNIR spectrometer for choice from 10 spectral bands. Applications: mapping of chlorophyll in bodies of water, geologic mapping, suspended sediment and temperature conditions, forest inventory and crop vigor studies.

AMS Systems	Aircraft
EG&G Energy Measurements Inc. (EG&G); Las Vegas, NV, USA	Cessna Citation II
Geoscan GmbH, Hildesheim, Germany	Cessna 404

Table 655: Owners/Operators of AMS systems

²²⁸⁴⁾SeaWiFS band centers and band widths (at full width, half maximum) are given in nanometers, the SNRs use radiances expected at the top of the atmosphere.

Spectral Channels	Channel Width (μm)
UV channel (optional with 5.0 mrad IFOV)	0.32 - 0.38 (oil spill detection)
VNIR spectrometer	0.42 - 0.45
	0.45 - 0.52
	0.52 - 0.60
	0.60 - 0.63
	0.63 - 0.69
	0.69 - 0.75
	0.76 - 0.90
	0.91 - 1.05
IR channels	3.0 - 5.50
	8.50 - 12.5
Geometric Parameters	
IFOV	2.5 mrad (1.25 optional)
FOV	86°
Scan rates (scans/s)	6.25, 12.5, 25, 50, 100
Roll correction	$\pm 15^\circ$
Quantization level	8 or 12 bit

Table 656: Spectral and geometric characteristics of the AMS instrument

P.63.6 TIMS (Thermal Infrared Multispectral Scanner)

TIMS is a digital airborne scanner (specified by JPL, developed by Daedalus) and an optional imaging spectrometer for the AADS 1278 system (ATMX), since 1981. TIMS provides six spectral bands in the thermal infrared region for geological applications.

A unique version of the TIMS with a larger collecting area was built for NASA/SSC (on LearJet 23 aircraft) and is designated AADS1285. The TIMS instrument is occasionally installed on the Ames C-130 or ER-2 aircraft for specific project support.

Applications: monitoring spectral emittance from geologic materials (rock type discrimination, geological mapping, oil/mineral surveys, etc.). Since TIMS has on-board blackbody calibration sources, its use has been extended to surface temperature mapping and thermal inertia studies.

Channel	Detector	Spectral Region (μm)	NE Δ T (Sensitivity)
1	HgCdTe	8.2 - 8.6	$\leq 0.3^\circ\text{C}$
2	HgCdTe	8.6 - 9.0	$\leq 0.3^\circ\text{C}$
3	HgCdTe	9.0 - 9.4	$\leq 0.3^\circ\text{C}$
4	HgCdTe	9.40 - 10.2	$\leq 0.3^\circ\text{C}$
5	HgCdTe	12.2 - 11.2	$\leq 0.3^\circ\text{C}$
6	HgCdTe	11.2 - 12.6	$\leq 0.3^\circ\text{C}$
Geometric Parameters			
FOV		86° (80° for SSC TIMS)	
IFOV		2.5 mrad	
Ground resolution		7.6 m (at 3000 m altitude)	
Pixels/scan line		714 (638 for SSC TIMS)	
Swath width		4.8 km (at 3000 m altitude)	
Scan rates (selectable)		6.25, 12.5 and 25 scans/s (7.3, 8.7, 12, 25 for SSC TIMS)

P.63.7 Wildfire

Wildfire is a Daedalus development for NASA (1987) with the objective to measure fires, as well as terrestrial and atmospheric parameters. The instrument is an optical spectrometer for the ATMx system. Wildfire provides 50 channels in the infrared region. It has capabilities for infrared studies of geological and volcanic features as well as for environmental applications (PI: J. Brass and J. Arvesen at Ames).

Spectrometer	Spectral Range (μm)	No. of Channels	Band Width (μm)
1	1.15 - 1.55	8	0.05
2	1.55 - 2.35	16	0.05
3	3.00 - 5.40	16	0.15
4	8.20 - 12.7	10	0.40 - 0.50

Table 659: Spectral coverage of the Wildfire instrument

Owners/operators of Wildfire: NASA/Ames Research Center, Moffett Field, CA, on ER-2 aircraft. The Wildfire instrument no longer exists (as of 1993), according to J. Myers of NASA/Ames; it was converted into the MAS [MODIS Airborne Simulator].

P.63.8 MIVIS (Multispectral Infrared and Visible Spectrometer)

Figure 453: Schematic layout of MIVIS optics

MIVIS is a new Daedalus hyperspectral spectrometer system for geologic and environmental investigations. The first instrument delivery with a 102-channel configuration took place in fall 1993 for operational use. MIVIS has the following features:

- a large area scan mirror for increased energy gathering power (the SNR performance is maximized for low-level sensor outputs)
- a common field stop design to ensure co-registration of all channels in the described configuration (providing spatially and spectrally coregistered images)

- a four-port spectrometer assembly with spectral coverage in the VIS, NIR, SWIR, and TIR regions
- 12 bit quantization (touch panel for operator interaction)
- Scan rates of 25, 16.7, 12.5, 8.3, and 6.25 scans/second (operator selectable)
- Aircraft roll correction. The output data is corrected for up to $\pm 15^\circ$ of aircraft roll
- VLDS tape recorder system, 10.4 GB capacity
- Reference sources: two controllable field-filling blackbody calibration sources
- PAS (Position & Attitude sensor); an integrated GPS receiver (roll, pitch and heading sensors)
- a companion digital image processing system known as MIDAS (Multispectral Interactive Data Analysis System)
- MIVIS instrument mass = 209 kg (100 kg scan head; 109 kg electronics)

Spectrometer	Spectral Range (μm)	No. of Channels	Band Width (μm)
1	0.433 - 0.833	20	0.02
2	1.15 - 1.55	8	0.05
3	2.00 - 2.50	64	0.008
4	8.200 - 12.70	10	0.40 - 0.50
Total = 102 channels, expandable to 128 channels			

Table 660: Example of a MIVIS spectral coverage

Owners/operators of MIVIS: Consiglio Nazionale Delle Ricerche (CNR), Rome, Italy; on Casa 212 aircraft.

P.63.9 MAS (MODIS Airborne Simulator)

MAS is a 50 channel modified spectrometer based on the AADS1278 scanner. The instrument was built by Daedalus for NASA/Ames Research Center and GSFC for an airborne simulator of the MODIS instrument (initial flights of MAS in 1992).²²⁸⁵ The system is being flown on the NASA ER-2 aircraft. MAS utilizes four detector arrays to simultaneously acquire data in the spectral range from 0.55 to 14.4 μm , with band widths from 0.033 μm to 0.587 μm (hyperspectral imaging). Of the 50 MAS channels, 19 have corresponding channels on MODIS (EOS sensor). MAS is designed for the measurement of biological and physical processes and atmospheric temperature sounding.²²⁸⁶

Spectral channels	50
Output channels	50 channels at 16-bits
IFOV	2.5 mrad
Spatial resolution (ground)	50 m (at 20 km spacecraft altitude)
Total scan angle (FOV)	85.92 $^\circ$
Swath width	37 km at 20 km altitude
Pixel/scan line	716
Scan rate	6.25, scan lines/s
Roll correction	$\pm 3.5^\circ$
Data rate	1.78 GByte/hr (since 1998)
Instrument mass	96 kg

Table 661: MAS sensor parameters

The optical system of MAS is composed of a complex configuration of dichroic beam splitters, collimating mirrors, folding mirrors, diffraction gratings, filters, lenses, and detector arrays. The scanner consists of a motor driven rotating mirror and the blackbodies. Radio-

²²⁸⁵) M. D. King, D. Herring, "The MODIS Airborne Simulator (MAS)," The Earth Observer, Vol. 4, No. 6, 1992, pp. 15-19, the paper provides a historical background of MAS

²²⁸⁶) M. D. King, et al., "Airborne Scanning Spectrometer for Remote Sensing of Cloud, Aerosol, Water Vapor and Surface Properties," Journal of Atmospheric and Oceanic Technology, submitted in April 1995

metric calibration of the shortwave ($< 2.5 \mu\text{m}$) channels is obtained by observing laboratory standard integrating sphere sources on the ground before and after missions, while calibration of the IR channels is performed in flight by viewing two on-board blackbody sources once every scan. Instrument participation in campaigns: ARM CAS, ASTEX, BOREAS, MAST, SCAR, TOGA/COARE, CEPEX, ARESE, TARFOX, SUCCESS, FIRE ACE, and SAFARI 2000.

Table 662: Spectral coverage of the MAS instrument

P.63.10 AHS (Airborne Hyperspectral Scanner)

The AHS spectrometer is a commercially available Daedalus derivative development of the Wildfire and MAS instruments and an extension of the ATM and ATMx series. Applications: geologic mapping, land use studies, mineral exploration, agricultural crop studies, pollution assessment, volcanology, oceanography, forest inventory and fire management. AHS has been operational since 1994.

Spectral range	0.440 - 12.70 μm (coverage of VIS, NIR, SWIR, MWIR, and TIR regions)
Spectral channels	48 contiguous bands (the output product is an image cube)
Bandwidth	0.20 - 1.5 μm
IFOV, FOV	2.5 mrad, 86°
Scan rates	25, 16.7, 12.5, 8.3, or 6.25 scans per second, operator selectable
Aircraft roll correction	Output data automatically corrected for up to $\pm 15^\circ$ of aircraft roll
Data quantization	12 bit
Data rate	2 MByte/s (maximum rate for 48 channels at 25 scans/s)
Data recorder	Metrum buffered VLDS with VHS cartridge, 10.4 GByte capacity
Recording time/tape	80 minutes minimum
Image real-time display	9" CRT (755 pixels in continuous moving window, RS-170/CCIR output)
Calibration sources	Two controllable field-filling blackbody reference sources
Power requirements	28 ± 3 VDC, 55 amps continuous
Instrument mass	Scan head = 100 kg, electronics = 109 kg
Navigation interface	Integrated GPS receiver, roll and pitch sensors

Table 663: AHS instrument parameters

Figure 454: Illustration of the MAS instrument

The system design of the electro-optical hyperspectral instrument is focused on maximizing SNR performance for low-level sensor outputs while capturing a very large dynamic range. All operator interaction with the AHS system is through a touch panel display with menu provision, permitting channel selection and all monitor and control functions. 2287) 2288)

P.63.11 ADC (Airborne Digital Camera)

The ADC²²⁸⁹⁾ panchromatic instrument with the designation AA 455 is a new Daedalus camera (1995) with the objective to acquire contiguous sequential images of the ground from an aircraft platform. The ADC is made up of three modules: 1) the camera head with lens, 2) the camera head control chassis, and 3) a system control and recording chassis packaged within a 'lunchbox' style computer. - Owners/operators of ADC: James W. Sewall Company, Daedalus Enterprises, Inc.

Spectral range	400-700 nm is standard, extended response to 1000 nm is also provided
Camera resolution	2020 x 2044 (detector array) scene pixels
Ground coverage	~ 1.2 km x 1.2 km at 1700 m AGL, IFOV ≈ 0.35 mrad
Frame rate	10-40 s, operator selectable in 2 second increments
Frame trigger	Internal timer, external signal: 100 ms pulsewidth minimum, or manual
Lens aperture control	Operator adjustable lens, f/2.8 - f/22 for 24 mm lens
Camera shutter control	1/200, 1/100, 1/50, 1/25 second, operator selectable
Output media, capacity	8 mm tape cartridge, ~ 1200 frames/110 m tape cartridge
Data annotation	Text input through keyboard is inserted into output data
Operator I/F control	Keyboard input; instrument status and acquired images are displayed on an LCD screen

2289) Information provided by G. England of Daedalus Enterprises, Inc., Ann Arbor, MI

GPS	Position data is automatically correlated to frame acquisition time
Instrument mass, power	22 kg, 120 VAC @ ~300 W. An inverter is provided for 28 VDC

Table 664: Specification of the ADC instrument

P.64 DARMS (Digital Aerial Right-of-Way Monitoring System)

DARMS is a NASA-funded aerial photography-based system which has been developed under NASA's EOCAP (Earth Observation Commercial Applications Program) by J. W. Sewall Company of Old Town, Maine, by NASA/SSC, Mississippi, and is operated by Panhandle Eastern Corporation of Houston, Texas. The objective is to provide a system in an AM/FM/GIS (Automatic Mapping/Facilities Management/Geographic Information System) environment for the purpose of cost-efficient pipeline monitoring, in particular with regard to safety standards and regulations. Operation of the DARMS system for commercial pipeline surveys started in 1992. A second generation DARMS prototype was in the testing phase at the end of 1994.²²⁹⁰⁾

DARMS consists of the following major components: a Kodak Megaplug camera head (CCD array), digital camera interface, camera controller, frame grabber, video monitor, a PC, and an 8 mm Exabyte 8500 tape recorder for data storage. The system is designed to be operated in small aircraft; operator controls by the pilot are limited to a few commands.

Typical pipeline surveys require swaths in the order of 1 km for the determination of dwelling densities and other potential hazards along the path of a pipeline. - The image data are annotated in real-time with GPS and navigation data.

Lens compatibility	C-mount, 2/3"	Aircraft speed (typical)	150 knots (75 m/s)
Lens focal length	16-28 mm	Flight altitude	2 - 4 km
IFOV (pixel size)	0.24-0.42 mrad	GPS	
FOV (swath width)	1 km	Data quantization	8 bit
Frame overlap	70%	Video output	RS-170
CCD array	2048 x 2048	Data frame format	2048 x 2048
Spectral range	0.4 - 0.7 μ m	Instrument power	110 VAC, 300W
Frame exposure time	1 ms	Instrument mass	35 kg
Flight monitor	RS-170, 9"		

Table 665: Parameters of the DARMS instrument

P.65 Deimos

Deimos is a dual-channel passive microwave radiometer operating at 23.8 and 50.3 GHz, equivalent to channels 1 and 3 of the temperature sounding component of AMSU-A which will fly on the NOAA-K, -L, -M POES satellite series. It was developed by the UKMO Remote Sensing Instrumentation branch at Farnborough and first flown on the UKMO C-130 Hercules in 1995 (MACSI campaign in Finland). The purpose of Deimos is to extend the validation of radiative transfer models by UKMO to AMSU-A frequencies, specifically through clear air, liquid water and ice clouds and precipitation, and to verify surface emissivity models notably for ice and wind-roughened oceans.²²⁹¹⁾

Deimos is housed in a general-purpose downward-facing aperture bay in the floor of the C-130. The detected polarizations (which rotate with the scan angle) are selected using a ferrite rotator and are chosen to be H and V at +35° scan angle.

²²⁹⁰⁾ M. A. Jadcowski, R. J. Birk, R. L. Wilson, "Aerial CCD Camera System for Pipeline Right-of-Way Management," Proceedings of the 1st International Airborne Remote Sensing Conference and Exhibition, Strasbourg, France, September 12-15, 1994, Volume II, pp. 225-235

²²⁹¹⁾ Information provided by D. C. Jones of UKMO at Farnborough, UK

Parameter	23.8 GHz	50.3 GHz
Radiometer type	total power	
IF bandwidth	10 - 135 MHz double side bands	10 - 90 MHz double side bands
Temperature resolution	0.5 K	0.5 K
Integration time	50 ms	
Polarization	H and V at 35° scan angle	
Calibration system	internal calibration targets: one at ambient, one at 60°C	
Instrument mounting location	underside of C-130	
Beamwidth (FOV) @ 3 dB	10°	
Footprint at 1 km altitude (3dB)	175 m at nadir	
Antenna type	plane mirror with quasi-optic feed-through to 2 feedhorns	
Scan direction	along-track	
Scan mirror positions	-5° to + 35° in 10° steps, down only, 2 calibration views	
Scan period	3 s	

Table 666: Parameters of the Deimos instrument

P.66 DLR Lidar Instruments

As of 1995, DLR/IPA (Institute of Atmospheric Physics) and DLR/IOE (Institute of Optoelectronics) have five operational airborne lidar systems that are used intermittently for a number of research applications, including studies/demonstrations of the usefulness of spaceborne backscatter lidars. The sensor is considered as part of an airborne test program for the ESA spaceborne ATLID (ATmospheric LIDar) sensor.

- 1) **ALEX** = Aerosol Lidar Experiment (see table 667). ALEX is a nadir-looking, three-wavelength Nd:YAG sensor. The instrument participated in the ELAC 1990 campaign.

Parameter	Description
Lidar instrument	ALEX = Aerosol Lidar Experiment , operational at DLR/IPA since 1979, (PI: W. Renger)
Measurement technique	Incoherent backscatter
Parameters or constituents measured	Aerosols and clouds
Measurement range	0 - 30 km
Vertical resolution	3 m - 12 m
Frequency of measurement (typically)	4 - 5 periods of 2 weeks per year
Measurement times (typically)	1 hr - 10 hr, day and night
Laser type and transmitter wavelength	Nd:YAG: 1064 nm, 532 nm, and 354 nm
Pulse repetition frequency	5 - 10 Hz
Laser energy/pulse	500 mJ at 1064 nm; 150 mJ at 532 nm; 70 mJ at 354 nm
Airborne platform of instrument	Falcon 20, DO 228, and Transall
Receiver size and configuration	35 cm diameter, Cassegrain telescope
Receiver FOV	1.5 mrad (full angle)
Receiver bandwidth	10 nm for 1064 nm frequency, 0.5 nm for 532 nm and 1.5 nm for 354 nm frequency
Detectors used	PMT (R928 Hamamatsu)
A/D converter	APD (1064) 4-channel, 10 MHz, 12 bit
Research objectives/applications	2-D aerosol and boundary layer structures, clouds, cirrus, volcanic aerosols, PSCs (Polar Stratospheric Clouds)

Table 667: Specification of the ALEX instrument 2292) 2293)

- 2) **OLEX** = Ozone-Aerosol Lidar Experiment

2292) J. Fischer, W. Cordes, A. Schmitz-Pfeiffer, W. Renger, P. Mörl, "Detection of Cloud Top Height from Backscattered Radiances within the Oxygen A Band - Part 2: Measurements," JAS, Vol. 30, 1991, pp. 1260-1267

2293) M. Kästner, K. T. Kriebel, R. Meerkötter, W. Renger, G. H. Ruppertsberg, P. Wendling, "Comparison of Cirrus Height and Optical Depth Derived from Satellite and Aircraft Measurements", submitted to Monthly Weather Review, Florida State University, Tallahassee, 1992

Lidar instrument	OLEX = Ozone-Aerosol Lidar Experiment ; operational at DLR/IPA since 1990 (PI: W. Renger)
Measurement technique	Incoherent backscatter
Parameters or constituents measured	Ozone, aerosols and clouds
Measurement range	0 - 30 km
Vertical resolution	15 m range bins, ozone: 500 - 1000 m
Frequency of measurement (typically)	3 - 4 periods of 2 week campaigns per year
Measurement times (typically)	1 hr - 10 hr, day and night
Laser type and transmitter wavelength	Nd:YAG: 532 nm, and 354 nm; XeCl: 308 nm
Pulse repetition frequency	5 - 10 Hz
Laser energy/pulse	150 mJ at 532 nm; 70 mJ at 354 nm; 150 mJ at 308 nm
Airborne platform of instrument	Transall (BMVg)
Receiver size and configuration	35 cm diameter, Cassegrain telescope
Receiver FOV	1.5 mrad (full angle)
Receiver bandwidth	0.5 nm for 532 nm frequency, 1.5 nm for 354 nm and 1 nm for 308 nm frequency
Detectors used	PMT (R928 Hamamatsu)
A/D converter	12-bit, 10 Hz, 4-channel
Research objectives/applications	2-D distributions of volcanic aerosols, PSCs (Polar Stratospheric Clouds) and ozone in the stratosphere

Table 668: Specification of the OLEX instrument ²²⁹⁴⁾ ²²⁹⁵⁾

- 3) **H₂O-DIAL = Water Vapor Differential Absorption Lidar** (see table 669). The system is based on an injection-seeded OPO (Optical Parametric Oscillator) for online and offline measurements. ²²⁹⁶⁾ ²²⁹⁷⁾

Parameter	Description
Lidar instrument	H₂O-DIAL = Water Vapor Differential Absorption Lidar ; operational at DLR/IPA since 1988 (PI: G. Ehret)
Measurement technique	Differential absorption lidar
Parameters or constituents measured	Water vapor, aerosols and clouds
Measurement range	0 - 10 km
Vertical resolution	10 - 15 m for aerosols, 100 - 500 m for water vapor
Frequency of measurement (typically)	for one week periods about five times per year
Measurement times (typically)	1 hr - 3 hr, day and night
Laser type and transmitter wavelength	Injection-seeded OPO, 730-935 nm
Pulse repetition frequency	10 Hz
Laser energy/pulse	30-40 mJ at 724 nm
Airborne platform of instrument	Falcon 20, NCAR Electra, DO-228
Receiver size and configuration	35 cm diameter, Cassegrain telescope
Receiver FOV	1 - 3 mrad adjustable
Receiver bandwidth	0.6 nm
Detectors used	PMT (R928 Hamamatsu), APD
A/D converter	Transiac 20, 10 MHz
Total instrument mass	240 kg
Research objectives/applications	2-D distributions of water vapor and aerosols, boundary layer and cloud top heights, cirrus clouds

Table 669: Specification of the H₂O-DIAL instrument

- 4) **Microlidar** (see table 670). Microlidar is a diode-pumped Nd:YAG laser with a high repetition rate. The sensor is considered as part of an airborne test program for the ESA spaceborne ATLID sensor.^{2298),2299),2300)}

Lidar instrument	Microlidar ; operational at DLR/IOE since 1988 (PI: Ch. Werner)
Measurement technique	Incoherent backscatter, 4 channels
Parameters or constituents measured	Dense clouds, especially under multiple scattering conditions
Measurement range	0 - 10 km
Vertical resolution	1.5 m
Frequency of measurement (typically)	2 - 3 periods of 1 week each per year
Measurement times (typically)	1 hr - 4 hr, day and night
Laser type and transmitter wavelength	Nd:YAG: 1064 nm
Pulse repetition frequency	10 Hz
Laser energy/pulse	1.5 - 4 mJ (tunable)
Airborne platform of instrument	Falcon 20
Receiver size and configuration	14 cm diameter, Cassegrain telescope
Receiver FOV	6 mrad (full angle); 18 mrad (separate detection of multiple scattering)
Detectors used	4 APD photodiodes
A/D converter	2 x Philips 10-bit, 100 MHz, 2-channel
Research objectives/applications	Distributions of dense clouds, cirrus; dense fog (ground based)

Table 670: Specification of the Microlidar instrument

- 5) **ADOLAR** = Airborne Doppler Lidar. ADOLAR is a short-range conical scanning continuous-wave CO₂ Doppler lidar for the measurement of small-scale wind phenomena. The sensor is also considered as a testbed for open questions concerning airborne Doppler lidar (e.g. housekeeping data, signal processing, ground return).²³⁰¹⁾

Parameter	Description
Lidar instrument	ADOLAR , operational at DLR/IOE since 1994 (PI: S. Rahm)
Measurement technique	Coherent Doppler
Parameters or constituents measured	3-dimensional wind
Measurement range	50-300 m
Vertical resolution	50-300 m
Frequency of measurement (typical)	1-2 periods of 1 week per year
Measurement times (typical)	1-3 hr, day and night
Laser type and transmitter wavelength	CO ₂ , 10.59 µm
Laser power	3 W
Repetition rate of data system	3-10 Hz (tunable)
Airborne platform of instrument	Falcon 20
Receiver size and configuration	15 cm diameter, Dall-Kirkham off-axis telescope
Detectors used	Liquid nitrogen cooled MCT
A/D converter	Sensorlab, 240 MHz, 2 channel, 8 bit
Scan mode	Conical with the axis pointing downward, full cone angle 60°
Research objectives/applications	3-dimension small scan wind, tested for signal processing

P.67 DMSV (Digital Multi-Spectral Video)

The DMSV instrument is a four CCD array video camera imaging system with interchangeable narrow-band filters, designed and built by SpecTerra Systems Pty, Ltd, of Perth, Western Australia. The objective is to obtain airborne imagery for environmental assessment (vegetation conditions, discrimination of vegetation types, study of soils, phytoplankton, blossoming algae, etc.). DMSV is a powerful tool for a range of applications, such as monitoring agriculture, forestry and marine environments.²³⁰²⁾

Four CCIR (PAL)-format CCD cameras	
CCD array dimensions	578 lines of 740 pixels per line
IFOV (12 mm lenses)	0.7 mrad
FOV (12 mm lenses)	31° x 24° (along-track x cross-track)
Spectral range	0.4 - 0.9 µm
Four 25 nm band-pass interference filters, centered at:	0.45, 0.55, 0.65, and 0.75 µm, 25 nm FWHM
Data rate	Typically 500 kByte/s, function of I/O device
Dimension (camera head)	205 x 210 x 320 mm
Instrument mass	12.5 kg
Instrument power	24 volts DC, 6 A max., or 115/230 V AC

Table 672: DMSV instrument parameters

DMSV consists of a camera head and a control and data acquisition system (CADAS). The four cameras in the DMSV camera head are arranged in a square with lens centers 90 mm apart. A computer-controlled aperture-adjustment mechanism insures proper operation between camera radiometric responses over the full range of aperture settings. Integration time (shutter speed) of the cameras may be adjusted by the operator. Focal length of lenses may be either 12.0 or 25.0 mm. The CADAS consists of a single-board PC, with a 4-channel digital frame grabber, a 4 MByte RAM, and at least 540 MByte disk storage. The system features real-time display and integrated image enhancement and analysis software. DMSV has been operational since 1992; as of early 1995 there are at least six instruments in use; the New South Wales Government and the US Army CRREL (Ft. Belvoir, MD) are among the instrument operators.

P.68 DOAS (Differential Optical Absorption Spectroscopy)

DOAS is a measurement technique, whereby any known difference in absorbency is used to determine the concentration of a gas.^{2303), 2304), 2305), 2306)}

DOAS is also the name of two spectrographs that employ the DOAS measurement technique. The first performs measurements in the VIS region (DOAS-VIS), and is owned by the Institute of Environmental Physics of the University of Heidelberg. The second instrument measures in the UV region (DOAS-UV) and is owned by MPI for Chemistry (MPICh), Mainz. Both DOAS spectrographs were used in ground-based experiments on

different sites (Kiruna, Sweden; Sondre Stromfjord, Greenland); depending on mission objectives, they are also flown on a C160 Transall (since January 1991) aircraft along with other sensors MIPAS-FT, OLEX, Aerosol Experiment and TRITIUM) in European campaigns [EASOE from Dec. 1991 to March 1992, CHEOPS III Jan./Feb. 1990, etc.]. The objective is to measure trace gas profiles in the stratosphere (O_3 , O_4 , NO_2 , NO_3 , $OCIO$).

Background: An experimental ground-based DOAS-UV and VIS spectrograph arrangement was installed at KfA Jülich in 1978, Germany (measurement of atmospheric CH_2O , O_3 , and NO_2).

DOAS Sensors

The instrument package consists of the following elements: entrance optics (vessel-mounted), a quartz fiber bundle conducting the light to the spectrograph, the spectrograph, and a diode array detector. The entrance optics feature a zenith-oriented lens (25 mm diameter, focal length = 50 mm, $f/2$) which focuses the light into the fiber bundle. Zenith scattered light is measured with an aperture of 1.1° . Measurement calibration is with a halogen lamp. The fiber bundle splits into two exit branches that are connected to the DOAS-VIS and DOAS-UV spectrographs, respectively (tandem operation of both instruments).

The fiber exit for the **DOAS-VIS** spectrograph forms a 2.5 mm by 60 μm entrance slit ($f/2.2$); a concave grating is used for light dispersion (a long path filter is integrated into the light path). The spectrograph is thermally controlled to a temperature of $30 \pm 0.1^\circ C$ for optical stability. Radiation (light) detection is done in a 1024-element diode array detector (evacuated to $< 8 \times 10^{-4}$ mbar and cooled to $-67^\circ C$). DOAS-VIS is operated at a wavelength range of 362 - 680 nm; the spectral resolution (FWHM) is 1.2 nm. Signal integration times range from a few seconds to 5 minutes.

The **DOAS-UV** Czerny-Turner spectrograph (Digikrom instrument) is operated in the spectral region from 320 to 420 nm with a spectral resolution of 0.3 nm. The instrument is thermally stabilized, equipped with diode array detectors, and is designed to identify and measure ozone, nitrogen dioxide, chlorine dioxide and bromide monoxide. Slant columns of these species are derived in a first step. Height distributions at least for ozone and nitrogen dioxide are being considered in a further step of analysis. While the instrument is mainly used for zenith scattered sunlight collection, it may also be used for nighttime moonlight observations which allow the measurement of O_3 , NO_2 , and $OCIO$.

P.69 DOE Airborne Instruments in ARM Program

The US Department of Energy (DOE) and the Strategic Environmental R&D Program (SERDP) are sponsoring and developing four airborne instruments for use on Unmanned Aerospace Vehicles (UAVs) such as PERSEUS. The research activities are considered as part of the ARM (Atmospheric Radiation Measurement) program for atmospheric modeling. Major measurement objectives are: radiation balance determination at the tropopause, flux profiles through the troposphere, cloud top properties, and upper tropospheric water vapor profiles.

All instruments will be integrated into the UAV payload by Sandia National Laboratories, Livermore, CA with the instrument developers serving as PIs and mentors. The scientific data will be made available both to the ARM Science Team as well as to the general scientific community.

P.69.1 MPIR (Multispectral Pushbroom Imaging Radiometer)

MPIR is being designed and built at the Sandia National Laboratories in Albuquerque NM (PI: G. Phipps). Objective: investigation of radiation/cloud interactions. First test flights with MPIR are planned for 1996.

The instrument offers nine spectral bands between 0.62 and 11.3 μm with wavelengths chosen for the retrieval of cloud reflectivity, cloud droplet phase (ice/water) and size. An objective is also to provide radiometric calibration for spaceborne sensors such as AVHRR. MPIR generates multispectral images by using linear CCD detector arrays in a pushbroom imaging arrangement. Each band of MPIR is independent, with its own detector array, filter, all reflective optics, and electronics. The detector and optics package for each of the nine bands is being designed as a modular unit that can be interchanged with any of the other detector units. To change wavelengths one simply exchanges the detector modules. This design method thus allows not only cloud radiometry, but also such applications as crop assessment, detection of environmental contaminations, etc.²³⁰⁷⁾

Instrument calibration: a mix of pre-, post-flight and on-board calibration will be used to attain calibration goals of 1% in the thermal and 3% in the visible spectrum.

Spectral bands (μm)	0.62 - 0.67; 0.86 - 0.90; 1.36 - 1.39; 1.58 - 1.64; 2.11 - 2.22; 3.55 - 3.93; 6.54 - 6.99; 8.40 - 8.70; 10.3 - 11.3
Linear detector arrays (9) with LN_2 cooling	256 elements per array
Detector material	Si < 1 μm InGaAs up to 2.2 μm InSb up to 3.9 μm HgCdTe from 6.5 to 11.3 μm
FOV	80°
IFOV	6 mrad at FOV center, 8 mrad at FOV edge
Output	2 samples per second
Quantization	12 bit
Data rate	55 kbit/s

Table 673: Specification Parameters of the MPIR instrument

P.69.2 CDL (Cloud Detection Lidar)

CDL is an active instrument developed at the Lawrence Livermore National Laboratories (LLNL) in Livermore, CA. CDL is a small backscatter lidar for detecting and profiling thin cirrus clouds and for accurate determination of cloud top altitudes. The instrument is intended to fly on small UAVs, such as PERSEUS. Initial test flights were conducted (PI: A. Ledebuhr) on board a manned aircraft in 1995. The first UAV flight is scheduled for spring 1996.

Measurement technique	Incoherent backscatter
Parameters or constituents measured	Cirrus clouds, cloud top heights
Measurement range (height)	15 km
Vertical resolution	100 m
Laser type and transmitter wavelength	Nd:YLF: 1.053 μm
PRF (Pulse Repetition Frequency)	5 kHz
Pulse length	20 ns
Beam divergence	80 μrad
Laser output energy/pulse	50 μJ
Output aperture	20 cm
Receiver: Aperture Transmission Filter FWHM FOV Overlap FOV with laser	20 cm 23% 0.2 nm 100 μrad 0.93
Detector: Type Quantum efficiency Maximum count rate Dark current	Geiger made Si APD 2.1.% 20 M counts/s 250 - 500 counts/s
Instrument mass	~ 30 kg

Table 674: CDL instrument parameters

²³⁰⁷⁾Information provided by J. Vitko of Sandia National Laboratories, Livermore, CA

Figure 455: Illustration of the CDL instrument

Energy source: A Nd:YLF micro-pulse laser, providing 50 μJ per pulse at a 5 kHz repetition rate, allows for a fully eye-safe design with sensitivities comparable to large single-pulse lidars. The telescope is of a Dall-Kirkham design with an f/number of 25. CDL has a full aperture narrowband filter and a detector mounted at the prime focus of the primary optics. Instrument requirements call for an in-flight control capability to operate CDL in either nadir- or zenith-viewing mode.

P.69.3 HONER (Hemispherical Optimized Net-flux Radiometer)

HONER is under development at the Los Alamos National Laboratories (LANL), Los Alamos, NM (PI: P. La Delfe). The objective is to make high-accuracy net radiative flux measurements for climate modeling. Test flights are planned for 1996.

The net flux is the difference between up- and down-welling radiation. The knowledge of the net flux between two altitudes represents the heating rate of that layer. However, the quantity (net flux) is difficult to measure since it is the difference of two large numbers. HONER uses a novel optical differencing technique to measure this net flux directly.

The HONER measurement technique is based on an optical integrating sphere with two apertures: one looking downward and the other upward. The radiation through each aperture is chopped at the same frequency, but out of phase, and then is incident on filtered pyroelectric detectors. Pyroelectric detectors have the intrinsic property of being sensitive only to the AC (Alternating Current) component of the signal. Hence, if the phase difference between the chopped upward and downward radiation is 180° , then HONER gives a direct measure of the net flux. If the phase difference is selected to be 90° , then HONER measures the absolute fluxes (in quadrature). With the HONER measurement principle net fluxes should be obtainable with an accuracy of 3%.

In practice, HONER consists of two integrating spheres. The instrument provides broadband, hemispherical flux and net flux measurements of both solar and thermal fluxes. HONER offers in-flight calibration with two calibration sources (blackbodies in IR and lamp/small integrating sphere combinations in the solar portions of the spectrum).

Spectral ranges (total broadband)	< 0.3 - 4 μm , and 4 - > 50 μm
FOV	> 170° (upward and downward)
Net flux accuracy	3%
<ul style="list-style-type: none"> • Optical differencing for common mode rejection • Direct difference measurements between upwelling and downwelling fluxes • Frequency and phase multiplexed optical signals for continuous, simultaneous data acquisition and calibration • Material absorption filtering for stability. Additional spectral channels can easily be added. • Insensitive to drift • In-flight conversion from differential mode to simultaneous measurement of upwelling and downwelling fluxes • Low production cost 	

Table 675: Specification parameters and features of HONER

P.69.4 UAV-AERI (UAV Atmospheric Emitted Radiance Interferometer)

The instrument is a miniaturized version of existing ground-based AERIs that are utilized for DOE climate programs [one is operational at the U. of Wisconsin, the other at DOE's Cloud and Radiation Testbed (CART) site in north/central Oklahoma]. As of 1995, the UAV-AERI sensor is being developed and built at CIMSS of the University of Wisconsin, Madison (PI: H. Revercomb). The objective is to provide contributions to the study of radiative properties in various fields:

- Atmospheric spectroscopy
- Cloud microphysics and radiative transfer modeling
- Atmospheric chemistry (direct observations of radiatively active trace gases)
- Spectral radiative forcing of dynamic processes

UAV-AERI measures up- and down-welling radiances over a spectral range from 3 to 25 μm with a spectral resolution of 0.5 cm^{-1} or better and with a spatial footprint of 1 km diameter from 10 km altitudes.

The instrument will be available for flight in 1996. UAV-AERI uses a modified commercial Michelson interferometer (repackaged for small UAV); calibration sources are provided to ensure the required radiometric accuracy. Instrument mass < 30 kg, power < 100 W.

P.70 DO-SAR (Dornier SAR)

The DO-SAR instrument was developed and built by Dornier (DASA) during the period 1986-89 and became operational in 1989. The objective is to gain SAR sensor experience with respect to high-resolution imaging technology. The instrument has been flown since then on DO 228 and Transall aircraft.

The main features of the instrument are:²³⁰⁸⁾

- high resolution and MTI (Moved Target Indication) capability
- multifrequency and multipolarization capability (simultaneous operation)
- interferometric SAR modes in C-band and X-band (azimuth and elevation)
- programmable chirp signals and pseudo-noise coding

The operational frequencies are 3.2, 5.3 and 9.6 GHz, representing centimeter wavelengths, and 35 GHz, representing millimeter wavelengths. An inertial measurement unit within the antenna mount is used for motion compensation. The measured radar echo data is augmented by parallel measurements of a GPS receiver, a barometer, and by autofocus techniques. The correction of the flight path end velocity is done in real time by the on-

²³⁰⁸⁾ Information provided by B. Fritsch and P. Röber of Dornier

board computer. The swath width depends on the number of selected modes (parallel operation) and the desired resolution. The swath width is limited to 10 km by the tape recorder data rate of 100 Mbit/s.

Parameter	S-band	C-band	X-band	Ka-band
Center frequency	3.2 GHz	5.3 GHz	9.6 GHz	35 GHz
Wavelength	9.4 cm	5.6 cm	3.1 cm	8.5 mm
Polarization	VV, VH, HH, HV	VV, VH, HH, HV	VV, VH, HH, HV	VV
Transmitter peak power	2 kW	1 kW	2 kW	1 kW
Interferometric modes	azimuth basis = 0.6 m; elevation basis = 1 m			
Bandwidth	50, 100, 200, or 400 MHz			
Pulse repetition rate	1.5, 3.0, or 6.0 kHz			
Resolution	< 1 m for 4 looks			
Quantization	8 bit (I and Q)			
Number of samples	1024, 2048, or 4096			
Data rate	100 Mbit/s			
Swath width	300 m - 10 km (depending on altitude)			
Operating altitude	100 m - 4 km			
Incidence angle range	30° - 89°			
Pulse generation	programmable (digital signal generator)			
Operating modes	a maximum of 4 different radar modes can be supported (data limited) example: C-band (VV+HH)+ Ka-band (VV+VV) or: C-band (VV+VH+HH+HV)			
Positioning	integrated GPS			
Motion compensation	integrated INS, GPS and barometer, supported by autofocus			
Image processing	integrated online multilook SAR processor, programmable SAR ground processor, SAR processing software for UNIX			
Storage media	Ampex DCRSi cassette for raw radar data, video-8-cassette recorder for video data, DAT-cassette for online-processed SAR images, CCT for ground processed SAR images, diskettes for INS- and GPS-data, diskettes for log- and system files			

Table 676: Specification of the DO-SAR instrument

Five antenna platforms/configurations are available for DO-SAR:

- 1) An X-band reflector antenna together with a C-band reflector antenna (only for Trans-all aircraft operation)
- 2) X-band reflector antenna / X-band reflector antenna - one on top of the other (dual polarized)
- 3) C-band reflector antenna / C-band reflector antenna - one on top of the other (dual polarized)
- 4) S-band reflector antenna (dual polarized)
- 5) Three slotted waveguide array antennas for cross-track and along-track interferometric applications. This configuration can only be mounted on a DO-228 aircraft. One of these antennas is mounted in the first door, and two in the second door. The Ka-band antenna is mounted in the second door as well. Furthermore, a C-band reflector antenna is mounted in the tailboard of the aircraft.

The equipment of the S-, C-, X-, and Ka-band radars, the data unit/recorders, and the SAR processor are installed in the aircraft cabin.

P.71 DPA (Digital Photogrammetric Assembly)

DPA is a stereo and multispectral high-resolution imaging and evaluation system, designed and developed by DASA/MBB of Ottobrunn, under the sponsorship of the German military (Office for Military Technology and Procurement, Koblenz). The objective is the provision of airborne photogrammetric and multispectral imagery for mapping applications.

DPA is a parallel development to MOMS-02 (a spaceborne sensor); both instruments employ the same basic design concept and technology. DPA has been operational since the end of 1992.²³⁰⁹⁾

The airborne DPA camera system consists of a stereo module and a multispectral module. The stereo module is in fact a wide-angle optoelectronic three-line scanner, consisting of three linear array CCD sensors, and arranged in the across-track direction with respect to the focal plane(s) of one or more permanently opened lenses. The sensors continuously scan the swath width during flight, thereby producing three overlapping image strips, each taken from a different viewing angle.²³¹⁰⁾

The evaluation of the three image strips is effected by means of image matching processes and of a special bundle adjustment, called model reconstruction. The results gained from the adjustment process are the camera's parameters of exterior orientation in so-called up-date points and the 3-D coordinates of the object points used in the adjustment process plus their accuracies.

The optics module of the DPA camera features a double lens design with the stereo module (three linear arrays, A, B and C, are arranged in each focal plane), and a multispectral module (four spectral lenses (S) with exchangeable filters). The sensors of the spectral channels cover the same target area as the nadir-pointing CCD array B of the stereo module. The high resolution of 12000 pixels/line at the wide-angle swath of the stereo module is obtained with the double-lens arrangement (Leica), in a process also referred to as 'optical bottoming'.

The camera is radiometrically and geometrically calibrated. Radiometric correction of the imagery is performed online during image recording, compensating for the nonuniformities of the sensor elements and of the lenses.

Figure 456: The Stereo recording principle of the three-line DPA camera

Permanently linked to the optics module is an IMU sensor packet containing a turn-rate gyro and an accelerometer for position and attitude determination of the camera at each

²³⁰⁹⁾ A. Kaltenecker, F. Müller, O. Hoffmann, "Digital Photogrammetric Assembly (DPA) - An Airborne Stereo and Multispectral Imaging and Evaluation System," Proceedings of the 1st International Airborne Remote Sensing Conference and Exhibition, Strasbourg, September 12-15, 1994, Volume II, pp. 117-127

scanning line. The DPA is mounted onto a stabilized platform. A GPS receiver is planned for a future upgrade. There is a software package that includes the evaluation programs specific for DPA (three-line imagery evaluation steps). The DPA system is planned to be commercially available starting in 1995/1996.

Stereo Module		Spectral Module	
CCD arrays	Fairchild (each with 6000 detectors)	High-performance lenses	Leica, Heerbrugg, Switzerland
Focal length	80 mm	Focal length	40 mm
Three imaging lines (A,B,C)	12000 pixels/line	Four imaging lines (S1, S2, S3, S4)	6000 pixels/line
FOV	$\pm 37^\circ$	FOV	$\pm 37^\circ$
I FOV	0.125 mrad	I FOV	0.250 mrad
Spectral range	515 - 780 nm	Spectral ranges	440 - 525 nm 520 - 600 nm 610 - 685 nm 770 - 890 nm
Convergence angle	$\pm 25^\circ$		
System Parameters			
Data quantization		12 bit/pixel	
Data recording		8 bit/pixel	
HDDT recorder		Model DCRSi, Ampex	
Data rate		103 Mbit/s or 210 Mbit/s (user selectable)	
Aircraft altitude above ground level		1 - 10 km	
Instrument mass		200 kg (minimum, depending on DPA options)	

Table 677: Instrument parameters of DPA

P.72 DRA-SAR (Defense Research Agency SAR)

Two SAR instruments (one X-band and one C-band) developed by DRA (Defense Research Agency) at Malvern, UK. The two SARs are installed on different aircraft. The X-band system has been operational since 1983, the C-band system became operational in 1993. Both Radar systems are used for research into information extraction from images, targets and background. They are both available for civil use, the principal field in the civil context is the development of tools for remote sensing. ²³¹¹⁾ ²³¹²⁾

SAR Image processing

SAR data processing of the DRA-SAR instruments is performed on the ground. The facilities at DRA include a real-time rate programmable processor based on the parallel Meiko CS-1 computer (2.5 Gflop/s) providing in effect real-time focused, linear, image formation.

The image formation algorithms developed at DRA include features for SAR image auto-focussing and phase correction. There are also a number of tools for image interpretation such as:

- Despeckling
- Intensity segmentation
- Target change detection
- Target super-resolution
- Clutter simulation
- Texture segmentation and classification

Note: the algorithms are available under license from DRA for implementation on neural networks or on single- and multi-processors. As of 1995 the C-band SAR has been fitted

²³¹¹⁾Information received from C. J. Oliver of DRA, Malvern

with an additional top antenna to allow studies involving vertical interferometric 3-D imaging.

Parameter	C-band SAR	X-band SAR
RF center frequency	5.7 GHz	9.65 GHz
Wavelength	5.3 cm	3.1 cm
IF center frequency	300 MHz	300 MHz
System bandwidth	90 MHz	100 & 500 MHz selectable
SAW chirp signal bandwidth	N/A	100 MHz low resolution
Expanded pulse length	5-12 μ s	5 μ s
Compressed (analog) pulse length	N/A	10 ns
Digital chirp signal bandwidth	90 MHz	500 MHz high resolution
Operating range	< 10 km	10 to > 50 km
Swath width	6 km	1 - 6 km
Number of range samples	4096	4096
Range sampling interval	1.5 m	0.3 - 1.5 m
Azimuth sampling interval	> 3/16	> 3/16
Azimuth sampling rate	adjustable	adjustable
Flight altitude	< 3.5 km	< 14 km
Angle of incidence (from grazing)	0 - 70°	0 - 30°
Antenna gain	19.9 dB	35 dB
Antenna 3 dB beamwidth, azimuth elevation	8° 24°	1° 10°
Transmit peak power	9.4 W	50 kW
Receive noise	8.5 dB	8.5 dB
Nominal PRF (Pulse Repetition Frequency)	10 kHz	1 kHz
Quantization (bit/sample, I & Q)	16	16
Sampling rate (MHz)	adjustable	adjustable
Nominal data rate on high density DCRS	107 Mbit/s	107 Mbit/s
Maximum recording time per tape	60 min	60 min
Spatial resolution, range x azimuth	2.2 m x 0.3 m	0.4 m x 0.2 m
Number of statistically independent looks	1	1
Radiometric distortion	1 in 10000	1 in 10000
Polarization	full	HH
Along-track velocity	62 m/s	200 m/s

Table 678: Specification of the DRA-SAR instruments

The current X-band SAR system will be replaced by a new radar system in 1996 and flown on board a BAC1-11 500 series aircraft. The new X-band system is called **ESR** (Enhanced Surveillance Radar). It is fully programmable and can mimic existing radars and future potential systems. The antenna can be fully scanned by 360°. ESR offers MTD (Moving Target Detection), stripmap and spotlight SAR modes of operation, and full polarimetric capabilities. ²³¹³⁾

P.73 Dual Polarized 37 GHz Radiometer

A passive NASA/GSFC instrument flown on a C-130 aircraft at the Wallops Flight Facility and operational since 1992. Objective: measurements of canopy characteristics (fractional ground cover, water content, and structural attributes, e. g., foliage and woody stems). ²³¹⁴⁾

The instrument employs noise injection with null balance for measuring the antenna energy. Dual-polarized (H and V) coincident observations are performed; the center frequency is 37 GHz; the bandwidth 800 MHz; the 3 dB beamwidth is 6°, with a beam efficiency of 90%. The temperature sensitivity is 1 K. The instrument may be also be mounted on a truck.

²³¹³⁾Information provided by R. D. Edwards of DRA, Great Malvern, UK

²³¹⁴⁾Information provided by B. J. Choudhury of NASA/GSFC

P.74 DUTSCAT (DUT Airborne Radar Scatterometer)

The airborne radar scatterometer DUTSCAT²³¹⁵⁾ is an instrument for measuring radar backscatter from the Earth's surface. It operates in six frequencies between 1 and 18 GHz. DUTSCAT was developed by the Laboratory for Telecommunications and Remote Sensing Technology of the Electrical Engineering Department of the Delft University of Technology (DUT) in cooperation with NLR, it is owned by BCRS. DUTSCAT is installed in a Beechcraft Queen Air research aircraft of NLR.

Parameter	Specification
Radar type	Coherent pulse radar
Frequencies	1.2, 3.3, 5.3, 9.65, 13.7, and 17.25 GHz
Pulse repetition frequency	78.125 kHz
Pulse width	100 ns
Peak power	250 mW
Operating range	50 - 1920 m
Polarization	VV and HH
Incidence angle	0 - 80 °
Data acquisition	8 bits 40 M-samples/s
Output	A-scan 5 scans/frequency
Aircraft speed	110 knots

Table 679: DUTSCAT specifications

The DUTSCAT system uses a 0.9 m diameter parabolic dish antenna mounted on a support structure and protected by a radome. The high-frequency parts of the radar (transmitters/receivers) are mounted in the support structure. DUTSCAT can be tilted between 0-80° from vertical, looking to the left of the aircraft flight direction.

The facility has been used since November 1983 for investigations of land and sea in a single-frequency mode. Since August 1986 the instrument has been operational in its six-frequency configuration.

The scatterometer data are recorded in a digital format on magnetic tape. Aircraft position, attitude, speed and altitude data are recorded on the same tape simultaneously.

P.75 EDOP (ER-2 Doppler Radar)

EDOP is a NASA-sponsored X-band Doppler instrument designed and developed by GSFC and nose-mounted into the ARC ER-2 aircraft; it has been operational since September 1993. The instrument has two antennas: one nadir-pointing with pitch stabilization, the other forward pointing. The EDOP system collected its first reflectivity data in the CAMEX campaign during September/October 1993; Doppler measurements were taken during subsequent flights. Objectives: measurement of the vertical structure of air motions and precipitation in mesoscale convective systems; development of combined passive microwave/radar algorithms for precipitation estimation (related to the TRMM mission (U.183) PR (Precipitation Radar) sensor development and GEWEX).²³¹⁶⁾

EDOP measures high resolution time-height sections of reflectivity and vertical hydrometeor velocity (and vertical air motion when the hydrometeor fall speed and aircraft motions are removed). The forward beam measures in addition the linear depolarization ratio (LDR), which provides orientation information of the hydrometeors (i.e. the canting angle), hydrometeor phase, size, etc. The dual beam geometry has advantages over a single

²³¹⁵⁾ "DUTSCAT - Airborne Radar Scatterometer," NLR/TU Delft, brochure

²³¹⁶⁾ G. Heymsfield, NASA/GSFC, "TOGA/COARE Mission Plan," NASA paper, November 1992, pp. 51-54

beam. Horizontal air motions along the aircraft track can be calculated by using the displacement of the aircraft to provide dual Doppler velocities (forward and nadir looks) at a particular altitude.

EDOP has been designed as a turn-key system with real-time processing on board the aircraft. The R/F system consists of a coherent frequency synthesizer which generates the transmitted and local-oscillator frequencies used in the system, a pulse modulator (PIN diode) which converts the transmitted frequency into a 0.25 - 2.0 μ s pulse signal, a high gain 20 kW Traveling Wave Tube Amplifier (TWTA) which is coupled through the duplexer to the antenna, and the receiver, which is comprised of a low-noise (~ 2 dB) GaAs preamplifier, mixer, IF amplifier and synchronous detectors for each of the antennas. The composite system generates a nadir oriented beam with a co-polarized receiver and a 35° forward-directed beam with co- and cross-polarized receivers. The antenna gain consists of two separate offset-fed parabolic antennas with tri-mode feed horns mounted in the nose radome of the ER-2. The two beams operate simultaneously from a single transmitter.

Center frequency	9.6 GHz (X-band)	Antenna diameter	0.76 m
Peak power	20 kW	Antenna beamwidth	2.9°
Duty cycle	0.01 max.	First sidelobe level	≤ 30 dB
Pulse length	0.25, 1.0 ms	Cross-polarization level	≤ 38 dB
PRF	2200, 4400	Receiver dynamic range	110 dB
No. of Doppler channels	2	No. of logarithmic reflectivity channels	3
Nadir beam: transmit polarization received polarization	horizontal co-polarized	Forward beam: transmit polarization received polarization	vertical co-polarization and cross-polarization

Table 680: Specification of the EDOP instrument

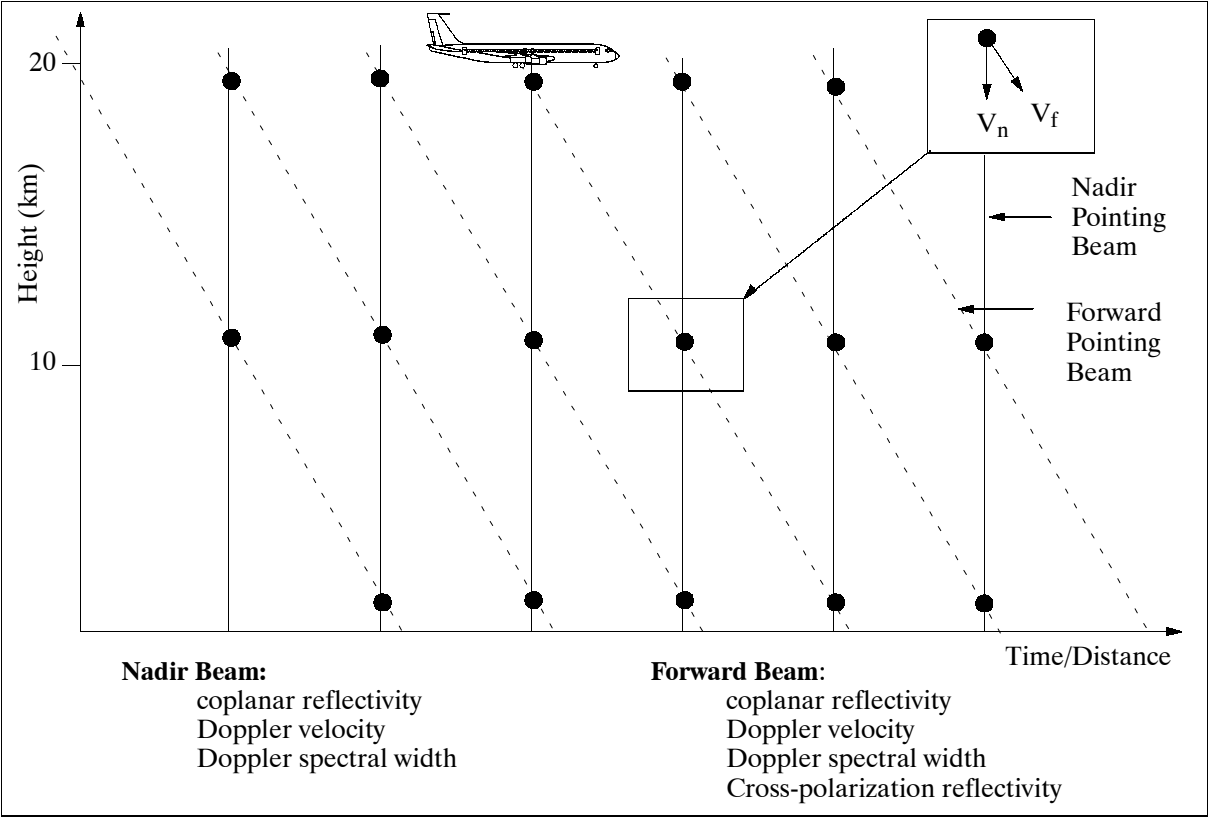

Figure 457: Measurement geometries of EDOP

The system obtains high vertical resolution profiles (37.5 m spacing) of radar reflectivity, vertical velocity, Doppler spectral width, and linear depolarization ratio (forward beam

only). The antenna footprint on the ground is about 1.2 km in diameter (with a 2.9° beam-width) for flight altitudes of 20 km.

EDOP is furnished with a real-time processor to accommodate the very high data and processing rates required by the system's 4400 Hz pulse repetition frequency, the four linear and three logarithmic analog output channels, and the 0.25 μ s range resolution. The input data rate is 56 MByte/s, the processing rate required to calculate reflectivity, Doppler velocity, and spectral width at 0.1 s intervals (440 pulses) and 900 range gates is 380 MFLOPS. The data system also provides automatic gain control to achieve > 100 dB dynamic range.

P.76 ELDORA/ASTRAIA

The ELDORA^{2317),2318)} (ELectra DOppler Radar) / ASTRAIA (Analyse Stereoscopique par Radar Aeroporte sur Electra) is an X-band, dual beam, airborne Doppler radar jointly built by NCAR (Boulder, CO) and by CRPE, Paris (France). Background: The initial designs of ELDORA by NCAR and of ASTRAIA by CRPE began in 1984. The efforts of both parties were combined in 1988 to jointly develop a single airborne radar system. NCAR provided the transmitter receiver, signal processor, data system, and aircraft; CRPE provided the antenna/rotodome and the intermediate frequency signal processor. Development of the instrument was largely completed in 1991. A first test of a complete, but simplified radar occurred in 1991. In June 1992, two complete radars were tested in the lab, each using a three frequency, stepped waveform. Flight testing occurred until the end of 1992, and in January/February 1993 support was provided for the first TOGA/COARE experiment. ELDORA was upgraded in 1994 to meet system design goals. A field program was conducted in late 1994 to evaluate the upgrades.

Scientific objectives: measurement of storm structures and kinematics (radial velocity and reflectivity) to an accuracy level allowing the derivation of thermodynamic properties of the storm (buoyancy, heat transport, water transport). These measurements are required over large domains, over remote domains, and at high enough sampling densities to resolve the important scales of motion and structure.

Measurement requirements:

- Temporal and spatial data sampling needs range greatly for different types of clouds. For a large storm system, e.g. hurricanes and mesoscale convective systems, the spatial resolution requires 0.5 - 0.8 km in the horizontal and 0.3 - 0.4 km in the vertical direction with measurements completed in a few seconds.
- Observation of isolated cumulonimbi requires measurements each 0.3 km in the horizontal and vertical plane with measurements completed in about 3 minutes.
- For small cumulus clouds requirements call for a spatial resolution of 0.1 km in both planes in a time frame of about 1 minute.
- Stratiform cloud systems require resolutions slightly lower than those of cumulonimbus systems.
- Measurement accuracy for radial velocities: ± 0.3 - 0.5 m/s and for reflectivities within ± 1 - 1.5 dBZ (note: Z is the radar reflectivity factor using a meteorological radar intensity scale).

The ELDORA/ASTRAIA design features a dual-beam, fore-aft scanning technique permitting the radar (two complete radar systems) to collect dual Doppler information in flight. The scan pattern enables collection of dual fore- and aft-pointing Doppler velocity data; the analysis of this data provides 2-D wind fields on observation surfaces passing through the storm. The instrument makes use of a complex transmitted waveform which

2317) P. H. Hildebrand, J. Testud, "ELDORA/ASTRAIA Capabilities for TOGA COARE," paper provided by P. H. Hildebrand

2318) P. H. Hildebrand, C. A. Walther, Ch. Frush, J. Testud, "The ELDORA/ASTRAIA Airborne Doppler Weather Radar: Goals Design, and First Field Tests," submitted Nov. 4, 1993 to Proceedings of IEEE

consists of 3 - 5 different frequencies. In addition the radar transmits a shorter pulse than is needed in the output data sample. These data are averaged in the digital signal processor to provide the required additional samples.

Parameter	Design Goal	Actual
Wavelength	3.2 cm	3.2 cm
Transmit frequency (X-band)	9.2 - 9.8 GHz	9.2 - 9.8 GHz
Beamwidth	1.8° circular	1.8° circular
Antenna gain	40 dB	38.75 dB, 38.7 dB
Polarization (antenna vertical))	horizontal	horizontal
Sidelobes	-35 dB	-35 dB
Beam tilt angle (fore or aft)	15 - 19°	15-19°
Antenna spin axis parallel to	aircraft heading	aircraft heading
Antenna rotation rate	0-144°	0-84°
Dwell time	7-50 ms	10-50 ms
Rotational sampling rate	1°	1°
Peak transmit power	35 - 50 kW	35 - 50 kW
Minimum detectable signal at 10 km	-12 dBZ	-12 dBZ
Receiver bandwidth	0.5 - 8 MHz	2.0 MHz
Receiver temperature at antenna	< 600 K	< 600 K
Pulse repetition frequency	2000 - 5000 Hz	2000-3000 Hz
Unambiguous range	20 - 90 km	20-90 km
Unambiguous velocity	13 - 24 m/s	13-24 m/s
Number of radars	2 (one fore, one aft)	2
Number of transmit frequencies per Radar	2-5	2-4
Pulse chip length	0.1 - 3.0 μ s	0.1-3 μ s
Range averaging	1 - 4 chips	1-4 chip
Total gate length	0.015 - 1.2 km	0.015 - 1.2 km
Elevation step	1°	1°
Along-track beam spacing	0.3 - 1.0 km	0.5-1.2 km

Table 681: ELDORA radar performance characteristics

Figure 458: Schematic illustration of the fore-aft scan technique (FAST)

The radar consists of five major functional blocks: the RF signal generator/receiver unit, the high power amplifiers, the signal processor, the antenna/rotodome system, and the radar control equipment. The two 35 kW peak power traveling wave tube amplifiers are driven by a common synthesizer (a high-precision 10 MHz crystal oscillator). The synthesizer generates all the needed reference frequencies for the fore and aft radar transmitters. The 60

MHz intermediate frequency (IF) is generated by the RF signal generation hardware and is used by the receivers, the IF signal processors, the master timing module, and the digitizers. The transmitted signal consists of pulses which contain sub-pulses, or chips, for each of the three to five separate transmitted frequencies. The pulses can be transmitted at staggered intervals in order to assist with range-velocity ambiguity reduction. - The transmitted signal passes through a dual channel rotary joint to separate fore and aft antennas which are mounted in the rotodome. The rotodome spins about the aircraft's longitudinal axis at a rate of 20 - 40 rpm to provide the required scanning motion.

Calibration of the received signals must include calibration of the high and low channel A/D converters for each frequency and for each radar. Thus for TOGA/COARE, with three transmitted frequencies per radar, a total of 12 calibrations must be monitored.

P.77 EMIRAD (Electromagnetics Institute Radiometer)

EMIRAD is an airborne, multifrequency passive radiometer system designed and built by the Electromagnetics Institute (EMI) of the Technical University of Denmark. EMIRAD became operational in 1980. Applications: EMIRAD has been used for several sea-ice missions in the high Arctic and for measuring oil pollution on sea surfaces in different European waters. EMIRAD is comprised of the following systems:²³¹⁹⁾

- an imaging multifrequency antenna
- receivers at 5, 17, and 34 GHz
- digital processing and control units
- digital tape recorders
- real-time false color display

The antenna is based on an offset 1 m aperture parabolic reflector scanning sinusoidally around the vertical axis, and illuminated by three microwave horns pointing upwards along that very axis. The antenna can be configured for horizontal and vertical polarization - individually for each channel. The beam efficiency is in excess of 95%; the sidelobe level below -30 dB, and the cross-polarization level is below -23 dB in the maximum scan range of $\pm 25^\circ$.

The antenna and the receivers are mounted on a cargo pallet, which is positioned on the loading ramp of a Hercules C-130 aircraft. The ramp is closed during take-off, landing and transit, but lowered to its horizontal position when measurements are to be carried out. Thus, the antenna has an unobstructed view of the scene below the tail of the aircraft. The ground speed of the aircraft is 140 knots during operation when the ramp is open.

Radiometer type	Noise-injection with microwave front-end temperature stabilized to 40°C		
Frequency	5 GHz	17 GHz	34 GHz
RF bandwidth	500 MHz	1 GHz	1 GHz
Noise figure	4.5 dB	5 dB	5 dB
Integration time	8 ms		
Sensitivity	1 K		
Polarization	H or V	H and V	H or V
Angle of incidence	41°	54°	50°
Footprint (1000 m)	160 x 248 m	47 x 73 m	24 x 37 m
Antenna type	Off-set parabolic reflector viewed by 3 vertical horns		
Scan angle	$\pm 12.5^\circ$ for 1000 m altitude; $\pm 25^\circ$ for 2000 m altitude		
Scan speed	1.0 Hz		
Scan pattern	sinusoidal		
Swath width	500 m for 1000 m altitude, 2000 m for 2000 m altitude		
Aperture	1 m		

Table 682: EMIRAD characteristics

²³¹⁹⁾Information provided by N. Skou of the Technical University of Denmark, Lyngby, Denmark

The radiometer system is designed to give contiguous ground coverage down to a flight altitude of 1000 m. In the past the radiometer system has been used in two imaging modes: 2000 m altitude with $\pm 25^\circ$ scan giving a swath of 2000 m; and 1000 m altitude with $\pm 12.5^\circ$ scan giving a 500 m swath (and a better ground resolution than in the 2000 m mode).

EMIRAD is provided with an operator's console, including a digital processing and control unit and the CCT recorders. Navigational data from the aircraft INS is recorded onto the CCT along with the measured radiometric data. The console also provides a real-time false color display system for in-flight monitoring of the radiometer data, and a TV monitor and video cassette recorder both connected to a TV camera mounted on the antenna pallet. The TV camera has a FOV comparable to that of the antenna, which gives valuable visible support to the task of data interpretation.

P.78 EMISAR (Electromagnetics Institute SAR)

EMISAR is an airborne SAR instrument designed and built by the Electromagnetics Institute (EMI) of the Technical University of Denmark at Lyngby, Denmark. A single polarization C-band system has been flown since 1989, including a full-resolution, full swath on-board real-time processor and display. As of 1994 the instrument has been upgraded for dual-frequency polarimetric operation. The C-band polarimetric SAR was completed in 1993; the L-band polarimetric SAR was completed end of 1994.

EMISAR is installed and flown on a Gulfstream G-3 aircraft of the Danish Air Force (maximum altitude of about 14 km). The cruising speed is 480 knots (~ 250 m/s). The platform is equipped with GPS and INS navigation systems. EMISAR is expected to fly also on other aircraft as part of the JRC EARSEC initiative.

The spatial resolution of the system is in-flight programmable; the finest resolution being 1.5 m (2 m with side lobe suppression). The system records 8192 complex range samples, hence, the swath width is approximately equal to the defined pixel spacing times 8192. The recording geometry can be programmed in-flight; it is possible to cover incidence angles in the range of 20° to 80° . The system includes motion compensation correction.

System Parameter	C-band	L-band
RF center frequency	5.3 GHz	1.25 GHz
System bandwidth	100 MHz	100 MHz
Polarization	Quad-polarization	Quad-polarization
Maximum pulse length	20 μ s	20 μ s
Antenna gain	27 dB	18 dB
Azimuth 3 dB beamwidth	2.7°	10°
Elevation pattern width	30°	42°
Transmitted peak power	2 kW	6 kW
Received noise	1.5 dB	1.5 dB
System loss	4 dB	4 dB
Quantization (bits/channel I+Q)	8+8	8+8
PSLR (Peak Side Lobe Ratio)	30 dB	30 dB
ISLR (Integrated Side Lobe Ratio)	25 dB	25 dB
Spatial resolution	2 m x 2 m	2 m x 2 m
Cross polarization ratio	30 dB	35 dB
Range pixel spacing (m)	1.5 x N	1.5 x N
Azimuth pixel spacing (m)	programmable	programmable
Azimuth presummer	programmable	programmable
Tape recorder rate	240 Mbit/s (shared)	
Range 10 dB SNR, $\sigma = -10\text{dB(m}^2\text{)}$	80 km	64 km
Flight altitude	> 12 km	

Table 683: Technical specifications of EMISAR

The antennas are dual-polarized microstrip antennas designed to have a modified cosec-squared radiation pattern for optimum illumination of the ground. The design aims at low side lobes and high polarization discrimination. The antenna is mounted in a pod attached under the fuselage of the aircraft and is 3-axis stabilized. An INS is mounted to the pod to sense aircraft movement.

EMISAR features internal calibration loops. Just before and after mapping a scene, pulses with the same coding as the transmitted pulses can be routed through all units of the radar except the antenna. Thus, the complex transfer function of practically the complete radar is measured and the results are used to correct the echo data recorded in between calibrations. Stability between calibrations is enhanced by temperature control of the analog units of the radar.

The system²³²⁰⁾ was financed by the Thomas B. Thrige Foundation, the Technical University of Denmark, the Danish Technical Research Council, and by the (then) European Economic Community.

P.79 EOS (Opto-Electronic Scanner)

EOS is an experimental multispectral camera system, based entirely on solid-state technology, that was developed in 1977 by MBB (Munich, sponsored by BMFT under contract to DFVLR) and test-flown in the spring 1978 on a DO-28 aircraft (Skyservant) of DFVLR, Oberpfaffenhofen. The EOS instrument consisted of the camera/ scanner subsystem (objective: Leitz ELMARIT-R, f-24 mm), an electronic module, PCM interface, an operator interface, an oscillograph, and a HDDT (Ampex AR 1700) recorder. EOS featured a self-scanning (pushbroom) linear CCD line scanner (silicon CCD 121 of Fairchild Co.), thus providing ground surface imagery. The photosensitive CCD line array contained 1728 elements (pixels, pixel size = 13 μm); spectral range of detector array = 0.47 - 1.0 μm (VNIR) with six spectral channels: 0.475 - 0.530 μm , 0.535 - 0.585 μm , 0.580 - 0.630 μm , 0.640 - 0.685 μm , 0.675 - 0.730 μm , and 0.75 - 1.0 μm . Sampling rate = 80 Hz; data quantization = 8 bit, FOV=50°, data rate = 1.1 Mbit/s. The real-time A/D conversion of the signals permitted data recording onto the HDDT recorder.

First test flights in spring 1978 were conducted at altitudes of 1-1.2 km above ground at aircraft speeds of 170 - 210 km/h, providing ground swaths of 1 to 1.2 km. Resolutions of 1.8 m x 2.4 m were obtained. The success of the airborne imagery of EOS, its subsequent processing, and the potential of CCD technology in remote sensing, led to the development of the spaceborne MOMS sensor program. **The EOS sensor represents probably the first civil airborne implementation of the then new solid-state CCD technology.** ^{2321) 2322) 2323)}

P.80 ER-2 High-Altitude Aircraft Program

Two ER-2 ('Earth Resources' or 'Extended Range') survey aircraft are operated by NASA's Ames Research Center (ARC) in Moffett Field, California. The ER-2s are flown from various deployment sites in support of scientific airborne missions (national and international campaigns).

The ER-2 is the modern successor of the 1950's vintage U-2 aircraft (developed and built by Lockheed). ARC has operated two U-2s since 1971, when they were phased out of opera-

²³²⁰⁾ Information provided by S. N. Madsen and N. Skou of the Electromagnetics Institute of the Technical University of Denmark

²³²¹⁾ O. Hofmann, P. Seige, "Erste Erprobungsergebnisse mit der experimentellen optoelectronischen Kamera von MBB," *Bildmessung und Luftbildwesen*, Vol. 47, No. 2, 1979, pp. 33-40

²³²³⁾ O. Hofmann, "Digitale Aufnahmetechnik," *Bildmessung und Luftbildwesen*, Vol. 50, Heft 1, 1982, pp. 16-32

tion and replaced by three ER-2s. The ER-2 is a versatile aircraft for multiple mission work. It is approximately 30% larger than the U-2 for increased payload capacity [four large pressurized experiment compartments and a high-capacity AC/DC electrical system). Flying at altitudes of 70,000 feet (21 km), the ER-2 operates above 95% of the Earth's atmosphere and yields an effective horizon of almost 500 km.²³²⁴⁾

Aircraft parameters: single jet engine, single seat aircraft; payload mass 1179 kg (max); speed ~ 210 m/s (410 knots); range: 2200-3000 nm; flight duration: 6.5-8 hours.

Telemetry data: A local-area telemetry system exists between the aircraft and ARC for data rates of up to 1.2 Mbit/s. - A new real-time data link called **STARLink** (Satellite Telemetry and Return Link) is under development and planned to be operational by the end of 1995. STARLink is capable of providing global coverage by using TDRSS data links. The STARLink concept offers online data rates of up to 137 Mbit/s per channel from the ER-2 to the investigators. In addition the system can provide up to 200 kbit/s of data from the investigators to the aircraft (forward link). The STARLink architecture is made up of three major elements: the airborne element, the TDRSS elements, and the ground-station element at ARC.

As of 1995 more than one hundred different sensors and experiments have been flown aboard the ER-2. Some of these sensors are part of the regular ARC inventory and are used by various investigators from all NASA centers, other government agencies and universities; other sensors are flown on a particular mission(s) in support of experimental work (test of concept, etc.) for an investigator. - The ER-2 high-altitude missions involve collecting data in three principal areas: atmospheric data within the stratosphere, Earth and celestial observations using electronic sensors, and thirdly, photographic data acquisition. Some examples:

Figure 459: Illustration of the ER-2 aircraft

- 1) Atmospheric investigations:
 - Measuring the levels of fluorocarbons, hydrocarbons and other atmospheric constituents capable of interacting with and degrading the Earth's ozone layer. The ER-2 was

²³²⁴⁾Information provided by J. Myers of ARC

deployed to Punta Arenas, Chile during August/September 1987 in order to conduct atmospheric experiments in the ozone hole discovered over the Antarctic.

- Studying the dynamics of pollutants moving from the troposphere to the stratosphere and the resulting changes in atmospheric chemistry. Measuring these phenomena was accomplished from an operational base in Darwin, Australia.
- Direct observations of severe thunderstorms using lasers, infrared and microwave scanners, spectrometers and electric field antennas.
- Sampling and identifying volcanic dust plumes injected into the upper atmosphere from the volcanic eruptions of El Cichon in Mexico and Mount St. Helens in Washington state.

2) Earth and celestial observations:

- Simulating, prior to launch, the spatial and spectral characteristics of the scanners aboard Landsat 1 through 5.
- Measuring background microwave radiation in intergalactic space predicted by the “Big Bang” theory. The magnitude variations in the measurements were used to determine the velocity and direction of our own galaxy.
- Defining the spectral bands for measuring food productivity and pollution in the world’s oceans through data flights with the Ocean Color Scanner. These flights were important in developing the CZCS instrument on Nimbus 7. Currently (1990’s) the Airborne Ocean Color Imager (AOCI, see P.63.4) is collecting data on board the ER-2 and will provide design information for next generation instruments.
- Defining the concept, and proving the feasibility, of registering day and night thermal imagery to measure the heat capacity of the Earth’s surface. Input for HCMM (see A.18).
- Directly observing forest fires and controlled burns using a multispectral scanner to image thermal emissions from the fire. The resulting imagery is transmitted in real-time to firefighting personnel for fire management and containment. Also, smoke plume constituents are collected and evaluated for their role in changing the radiation balance of the Earth’s atmosphere.

P.81 ERASME (Etude Radar des Sols et des Mers)

ERASME is a FM/CW dual-frequency (C- and X-band) scatterometer of CNRS/CETP (Vélizy, France). It is a research tool with the objective to monitor simultaneously vegetation and soil responses with the radar backscattering technique; it also intended to be used for calibration of other airborne and spaceborne radar instruments. ERASME is a forward-looking radar instrument with a large elevation beam width ($\pm 10^\circ$ at 3 dB) and a narrow azimuth beam ($\pm 2^\circ$) providing the capability to observe the same surface target area over a large range of incidence angles during a single pass.

ERASME^{2325), 2326)} was initially built (1983) as a side-looking C-band FM/CW radar; it was rebuilt/enhanced in 1988 as a forward-looking C-band and X-band radar instrument with two direct noncoherent polarization configurations (HH and VV) providing the capability of simultaneous vegetation and soil monitoring. ERASME is flown on helicopters and

²³²⁵⁾ M. Bénallégue, O. Taconet, et al., “Evaluation of Calibration Methods for an Helicopter-borne Microwave Scatterometer,” paper accepted by International Journal of Remote Sensing, 1994

²³²⁶⁾ R. Bernard et al., “Data Processing and Calibration for an Airborne Scatterometer,” IEEE Transactions on Geoscience and Remote Sensing, Vol. GE-24, No. 5, September 1986, pp. 709-716

small aircraft; it was utilized in the following airborne campaigns: AGRISCATT-88, SA-REX-92, and MAC-Europe.

Measurement technique	Forward-looking FM/CW radar scatterometer
Operational frequencies	C-band (5.35 GHz), X-band (9.65 GHz)
Polarization	HH, VV
Transmitted power	11.2 dBm at C-band (13 mW) 20 dBm at X-band (100 mW)
Modulation	Sawtooth, 3 ms period of reception
Modulation ramp bandwidth	23°: 203 MHz, range resolution = 0.97 m 38°: 150 MHz, range resolution = 1.30 m
Transmitting antennas	Gain: CH 13.1, CV 12.3, XH 12.5, XV 11.9 C and X apertures: ± 18.5 in elevation, $\pm 16^\circ$ in azimuth
Altimeter antenna	Scalar horn, nadir-looking
Internal calibration	Bulk acoustic wave device at C-band corresponding to a 300 m two-way travel time
Signal processing	Five FFT analyzer 512 points, 3 ms synchronization, waveform bandwidth 100 kHz, frequency resolution 0.5 kHz, local oscillator 23°: 150 kHz; 38°: 120 kHz
Acquisition	LSI 11/23 CCT tape recorder; 8 analog lines for aircraft sensors (clock, pitch, roll, etc.)
Nominal flight altitude	350 m

Table 684: ERASME instrument characteristics

The transmitting and receiving C- and X-band antennas are planar dipole arrays. The transmitting antennas are quasi-isotropic (coverage: $\pm 16^\circ$ in elevation and $\pm 18.5^\circ$ in azimuth). Nonsymmetrical receiving antennas are employed for both frequencies. The on-board data processing employs FFT analysis, which is performed on each ramp of the sawtooth waveform, 64 consecutive power spectra being averaged to obtain one radar sample in 0.2 second intervals.

Internal in-flight calibration is performed using a delay line to monitor continuously the radar's electronics stability. External instrument calibration uses corner reflectors (absolute calibration accuracy within 1 dB).

P.82 ERIM Airborne Instruments

ERIM (Environmental Research Institute of Michigan) is an independent institute in Ann Arbor, Michigan, providing a wide range of remote sensing services to its user community (governmental agencies like DoD, NASA, NOAA, the public sector, and private industry). It also is actively engaged in advanced remote sensor design, usually in cooperation with other agencies.

P.82.1 M-5 (Michigan-5 Imager)

Background: The pioneer airborne instrument of spatially-registered multispectral scanners is M-5, developed by the Willow Run Laboratories of the University of Michigan.²³²⁷⁾²³²⁸⁾ The M-5 whiskbroom scanner is based on solid-state technology, and developed around an optomechanical scanning system called the S-5 (built by HRB Singer for the US Army). The S-5 had two optical channels (not registered) and recorded its data on film. From 1963 to 1965, two of these instruments were flown in tandem, each in a DeHavilland Beaver aircraft, to obtain four unregistered bands (selectable from UV through LWIR).

²³²⁷⁾ Information provided by B. Horvath of ERIM, who operated the M-5 imager and analyzed the data.

²³²⁸⁾ Note: In 1973 the Willow Run Laboratories team separated from the University of Michigan and became ERIM (Environmental Research Institute of Michigan)

From June 1963 through June 1964, around-the-clock (every 4 to 6 hours) imagery was collected once a month over a local fifty mile flight path, selected for natural and cultural diversity. These data were manually analyzed to form the initial basis for an understanding of day-night-seasonal spectral imaging phenomena. The M-5 instrument provided support of the developing ERTS (Landsat) program, in particular for the design of MSS (Multispectral Scanner).

M-5 instrument: A rotating mirror alternately scans the FOV of two parabolic mirror telescopes in the cross-track direction, the motion of the aircraft generates the second component of the spatial scan. At the focus of each of the telescopes, either filtered detectors or a spectrometer-detector combination convert the narrow spectral band radiation into electrical signals which are amplified and recorded on tape.

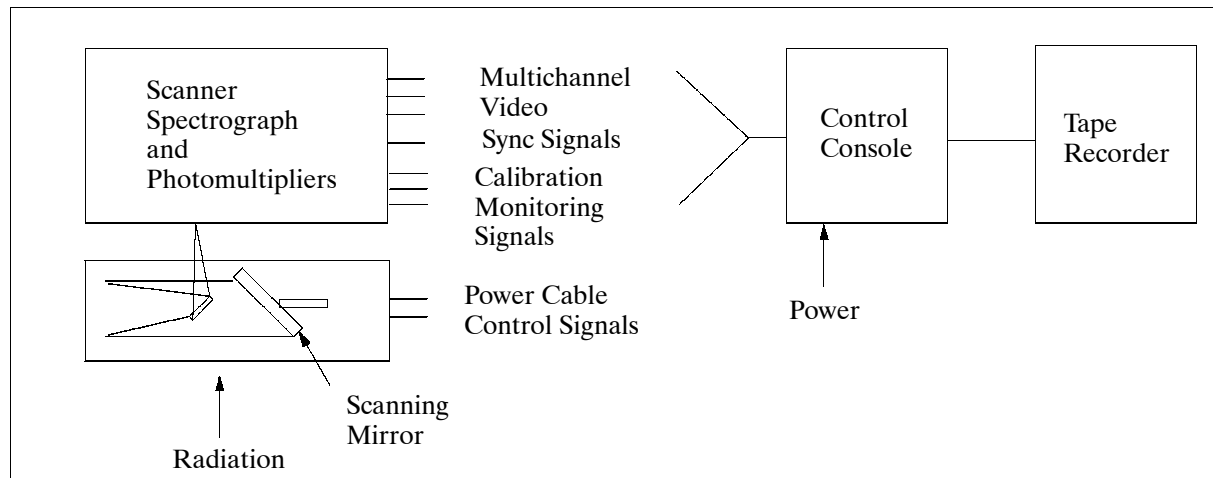

Figure 460: Schematic of the M-5 multispectral scanner system

The spectral range of the scanning system extends from 0.32 to 14 μm . Two scanners with two telescopes each were used, generating four sets of data. The first set in the VIS range (0.4 - 1.0 μm) contained 12 spectral channels. The second set contained three channels: 1.0-1.4 μm , 1.5-1.9 μm , 2.0-2.6 μm from a filtered three-element InAs detector. The third set consists of three channels: 1.0-1.4 μm , 2.0-2.6 μm , and 4.5-5.5 μm (all with InSb detectors). The fourth set has a single channel in the range 8-14 μm with mercury-doped germanium detector. Either of the three element detectors may be replaced by a photomultiplier detector, operating in the UV range from 0.32-0.38 μm .²³²⁹⁾

P.82.2 M-7 (Mapper Multispectral Testbed)

The M-7 multispectral sensor was developed by ERIM for NASA and DoD in 1971/72 to provide airborne imagery and to support research in the application of remote sensing. [Note: the 'M' in the sensor name stands for 'Michigan,' from the time when ERIM was still part of the University of Michigan; the term 'testbed' refers to the fact that instrument configuration is regularly changed to meet customer needs and to keep the technology to state-of-the-art]. The sensor and aircraft instrumentation experienced various upgrades during the 70's and 80's including: digital recording of data, increasing the number of spectral bands from 12 to 16, utilization of a radar altimeter, installation of an IMU for sensor attitude information, and the use of LORAN-C and GPS positioning systems. - The following upgrades of the system were completed and demonstrated in the summer of 1993:

- Increase of the wavelength bands from the original 15 to a total of 31 bands in the spectral range from 0.35 to 12.5 μm .

²³²⁹⁾R. E. Marshall, N. Thomson, F. Thomson, F. Kriegler, "Use of Multispectral Recognition Techniques for Conducting Rapid, Wide-Area Wheat Surveys," Proceedings of the Sixth International Symposium on Remote Sensing of Environment, Ann Arbor, Michigan, Vol. I, Oct. 13-16, 1969, pp. 3-20

- Installation of a Laser Inertial Navigation System (LINS, from Honeywell, H-770) and dual Trimble 4000 GPS receivers for differential mode operation (DGPS).²³³⁰⁾

These upgrades were the result of user needs for high-quality, calibrated and spatially registered multispectral imagery in map coordinates. Both navigation systems (LINS and DGPS) are integrated into a MMSS (Motion Measurement Subsystem); both LINS data and the multispectral imagery are precision time-tagged using the GPS clock reference. Modified software in the LINS allows access not only to the real-time navigation solution, but also to all raw accelerometer and gyro signals and compensation coefficients for subsequent post-processing on the ground.

[Post-processing consists of first developing the differential GPS (DGPS) solution, and then iteratively processing the LINS/DGPS data through a 61-state Kalman filter. This combines the best qualities of the LINS navigation data (short-term precision) with those of the DGPS data (long-term accuracy) to produce an optimized total (six degrees of freedom) navigation solution for use by the M-7 mapper camera model for image reconstruction.]

M-7 applications include terrain and topographic mapping, multipass stereo imaging and simulation of imagery from broad-area, fine-spatial resolution spaceborne sensors [Landsat (TM), Spot (HRV), etc.]. The overall M-7 system provides a capability to accomplish precision image correction, orthorectification, geocoding and multi-pass mosaics. ERIM provides its services of data collection and processing on a contractual basis to any customer (past customers have been: NASA, DoD, USGS, Department of Agriculture, state and local governments, and some private companies (making oil and geological surveys).

Figure 461: Typical spectrometer band responses and geometrical relations

The M-7 mapper is an optomechanical imaging spectrometer; the design features four clearly-defined detector regions. A common aperture and a 12.7 cm diameter 45° scan mirror are used to collect radiation for all four detector positions.[Note: the term ‘position’ means ‘optical port’ for a particular detector type covering a particular spectral range]. Two-dimensional detector arrays (CCDs) are used in positions 1 and 3, which requires special geometrical preprocessing to de-rotate the array pixels and to bring all spectral bands to

²³³⁰⁾D. C. Carmer, R. Horvath, D. P. Rice, J. W. Sisak, “M-7 Mapper Multispectral Testbed,” paper presented at the Second Thematic Conference on Remote Sensing for Marine and Coastal Environments, New Orleans, LA, January 31, - February 2., 1994

the location of a common reference band, usually to the one of the spectrometer bands in position 4.

The four detector positions are achieved by folding out the obscured center region of the Dall-Kirkham telescope (position 1); a dichroic reflector in this folded-out path (position 2); the output of the telescope (position 3), and a dichroic reflector in the telescope output (position 4).

Figure 462: M-7 optical-mechanical layout

The spectrometer in position 4 is comprised of an entrance aperture, a collimating lens, the prism, a re-imaging lens and a fiber-optic coupler that distributes incoming radiation to the detectors. Typically each individual segment of the fiber optic coupler is terminated in a cap mounted over a photomultiplier tube (PMT) or Si APD detector. - Six-element detector arrays (dewar-mounted) are in positions 1 and 3. The arrays are comprised of two rows of three elements each with individual filters supported in a small frame mounted to the dewar's cold finger. Because of the refractive optics used to focus radiation onto the detectors, the spacing of each element from the dewar's window was specified to assure optimum simultaneous focussing.

A dichroic reflector at position 2 reflects radiation from 0.35 to 1.0 μm and transmits from 2.8 to 14 μm . This, in combination with a choice of UV, VIS or NIR band limiting filters offers considerable configuration flexibility for narrow or broad spectral bands. Instead of adding blue, green and red bands in the data processing to achieve a panchromatic image, direct collection capability of panchromatic imagery is provided by the choice of a properly specified broadband filter.

Position	Detector Arrangement	Spectral Bands at FWHM (μm)	
1) Folded from central ob- scuration in primary telescope (6 bands in MWIR and TIR)	Dewar with detector array (2 x 3)	3.3 - 4.4	8.7 - 9.2

P.82.3 P-3/SAR (ERIM/Navy Sensor)

P-3/SAR^{2331),2332),2333)} is a high-resolution multifrequency polarimetric imaging SAR jointly developed for the US Government by the Naval Air Warfare Center, Aircraft Division (NAWC/AD) and the Environmental Research Institute of Michigan (ERIM). In addition, ERIM and NAWC/AD are continually upgrading the SAR system to meet new imaging research objectives. The P-3/SAR system is jointly owned and operated by ERIM and NAWC/AD, and is installed on a US Navy P-3A Orion aircraft. The sensor is a multi-mode SAR operating at X-, C-, and L-band. In addition, ERIM is developing and integrating for the Advanced Research Projects Agency (ARPA) a polarimetric Ultra Wideband (UWB) frequency mode (200-900 MHz), to be operational in the summer of 1994. This new frequency mode is intended to support future foliage and ground penetration experiments/applications. Developed between 1985-87, the system has been operational since 1988 and has logged over 2000 hours of data collection (1993) worldwide, including flights in the USA, Canada, Caribbean, Europe, Africa, Greenland and the Pacific.

²³³¹⁾ Information provided by M. Dudzik and P. Wagner of ERIM

²³³²⁾ A. R. Ochedlick, K. Birny, P. Cho, C. Duke, S. K. Krasznay, J. Evans-Morgis, J. S. Verdi, "A Description of the NADC SAR Facility and Examples of Observations and Measurements," CH2971-0/91/000-1785, © 1991 IEEE

²³³³⁾ R. Sullivan, A. Nichols, R. Rawson, "Polarimetric X/L/C-band SAR," Proc. IEEE Radar Conference, Ann Arbor, Michigan, 1998, pp. 9-14

Key operational features of the P-3/SAR system are:

- X-, C-, and L-band modes of operation
 - Stripmap mode: a pushbroom mode with the antenna pointed 90° (broadside) to the line of sight (looking either left or right), imaging a continuous strip with a swath range of either 4.9 km or 9.8 km in the slant plane.
 - Spotlight mode: a mode in which the antenna is pointed 45° forward of broadside at a predetermined spot while the aircraft flies past until the antenna is pointing 45° aft of broadside. This mode allows data to be collected with a spot diameter of 1.5 km in L-band (significantly smaller spots are collected at X- and C-band) through a range of 90° in aspect angle variations.
 - Dragging spot mode: this is a variation of the spotlight mode in which the antenna rotation is slowed for a few seconds during its rotation to increase the spot size of the area imaged in azimuth.
 - Circle mode: this is a variation of the stripmap mode in which the antenna is fixed broadside and aimed at a point on the ground; the aircraft flies in a circle around that point allowing the area to be imaged at all aspect angles.
 - Displaced Phase Center (DPC) mode: this is a variation of the stripmap mode in either X- or C-band using two antennas to measure the radial position by observing a target from the same point in space at different times (lags).
- The UWB mode operates in the stripmap mode with a fixed incidence angle imaging a continuous strip with a recorded swath range of approximately 1 km.
- Pass-to-pass single frequency, full polarimetric imaging in all frequencies.
- Simultaneous imaging at X-, C- and L-band with selectable polarizations.
- Pass-to-pass UWB and X-, C-, L-band imaging capability.

There are three separate antenna or antenna combinations for the P-3/SAR system. The tri-band antenna is comprised of a dual horn feed dish for the X- and C-band with a cross dipole array for the L-band. This antenna is mounted in the belly radome just aft of the wings. The tri-band is capable of operating in all but the DPC and the UWB modes. In addition, imaging incidence angles can be selected from 20° - 70° depending on the frequency, mode and altitude. The DPC antenna consists of two, dual frequency (X- and C-band) quadridge horns mounted side-by-side. DPC operations require this antenna be mounted in place of the tri-band antenna in the belly radome. The UWB antenna is a one meter quadridge horn mounted in the magnetic anomaly detection (MAD) boom, located at the tail of the P-3 aircraft.

Figure 463: Some data collection modes of ERIM sensors

Parameter	X-band	C-band	L-band	UWB
Wavelength	3.2 cm	5.7 cm	24.0 cm	1.5 - 0.31 m
Center frequency	9.35 GHz	5.30 GHz	1.28 GHz	350 MHz
Polarization	VV, VH, HH, HV	VV, VH, HH, HV	VV, VH, HH, HV	VV, VH, HH, HV
Peak transmit power	1.5 kW	1.4 kW	5.0 kW	1.0

Circle	1-3	1-4	2	6	65/5
Displaced Phase Center	1-2	1-4	1	1	98.3
Ultra Wideband	1	1-4	TBD	TBD	TBD

Table 688: Modes of operation of the P-3/SAR instrument ²³³⁴⁾

Applications include: sea ice and frozen terrain studies (Alaska, Greenland and Norway); seasonal forest studies (Maine), wave refraction, shelf break behavior, current-wave interactions, and sub-mesoscale features (North Sea, Gulf Stream and continental shelf); high wind studies (NASA windshear); buried object detection (29-Palms and Yuma Proving Grounds); foliage penetration for search and rescue (Duke Forest, NC and Maine); environmental monitoring and disaster relief (Kenya, Mississippi River and Florida Everglades).

P.82.4 DCS (Data Collection System)

DCS is a variable resolution interferometric SAR imaging system developed and operated jointly by ERIM and the USAF Wright Laboratory. The instrument is installed on an ERIM-owned Convair 580 turbo prop aircraft (CV-580) and can operate at either X-band (polarimetric) or Ku-band (VV polarization). The system has been operational since 1987; as such the DCS is considered the first single-pass interferometric fine resolution SAR in the world. ^{2335) 2336)}

The DCS contains the following subsystems: the radar sensor subsystem, the antenna controller/pedestal, the A/D conversion and recording subsystem, motion compensation, and the in-flight monitor and control subsystem.

²³³⁴⁾Note: 'PRESUM' refers to the number of pulses that are summed together to allow increased data recording

²³³⁵⁾M. A. DiMango, W. T. Hanna, L. A. Andersen, "The Data Collection System (DCS) Airborne Platform," Proceedings of the 1st International Airborne Remote Sensing Conference and Exhibition, Volume II, Strasbourg September 12-15, 1994, pp. 22-31

²³³⁶⁾Information provided by D. Ager of ERIM

The sensor subsystem is made up of the transmitter, a dual-channel receiver, transmit/receive exciters, and a timing generator. The dual-channel receiver allows the DCS to receive all polarizations on each channel since the channels are time-multiplexed. The subsystem employs a transmit-then-receive technique where a linear chirp pulse waveform is used to achieve the required range resolution. Because the signal is pulse-to-pulse coherent, azimuth resolution is obtained through the processing of the signal phase history over the length of the synthetic aperture. The received signal is dechirped via mixing with a delayed replica of the transmitted signal so that the range delay is encoded into the IF frequency.

The antenna subsystem consists of the antenna pedestal and an antenna package - there are four antenna assembly mounted on the pedestal, a side-by-side pair and an over/under pair. The antenna pointing capability is from 5° to 78° in elevation (90° would be nadir pointing), and $\pm 165^\circ$ in the azimuth direction (0° is in flight direction). The four-antenna configuration permits the collection of displaced phase-centered imagery (using the side-by-side antenna pair) and interferometric imagery (using the over/under antenna pair on a pass to pass basis).

Note: 'displaced phase center' implies that there are two physical antenna apertures displaced along the flight track. Interferometrics implies that there are two physical antenna apertures displaced in range. A radar operating with a displaced phase center has the capability for enhanced clutter rejection (which is useful for moving target detection), while a radar operating with interferometrics can provide accurate height determination of the ground surface.

The motion compensation subsystem offers two motion measurements, from IMU and from DGPS. The combination of both instruments provides accurate determination of aircraft position in real-time.

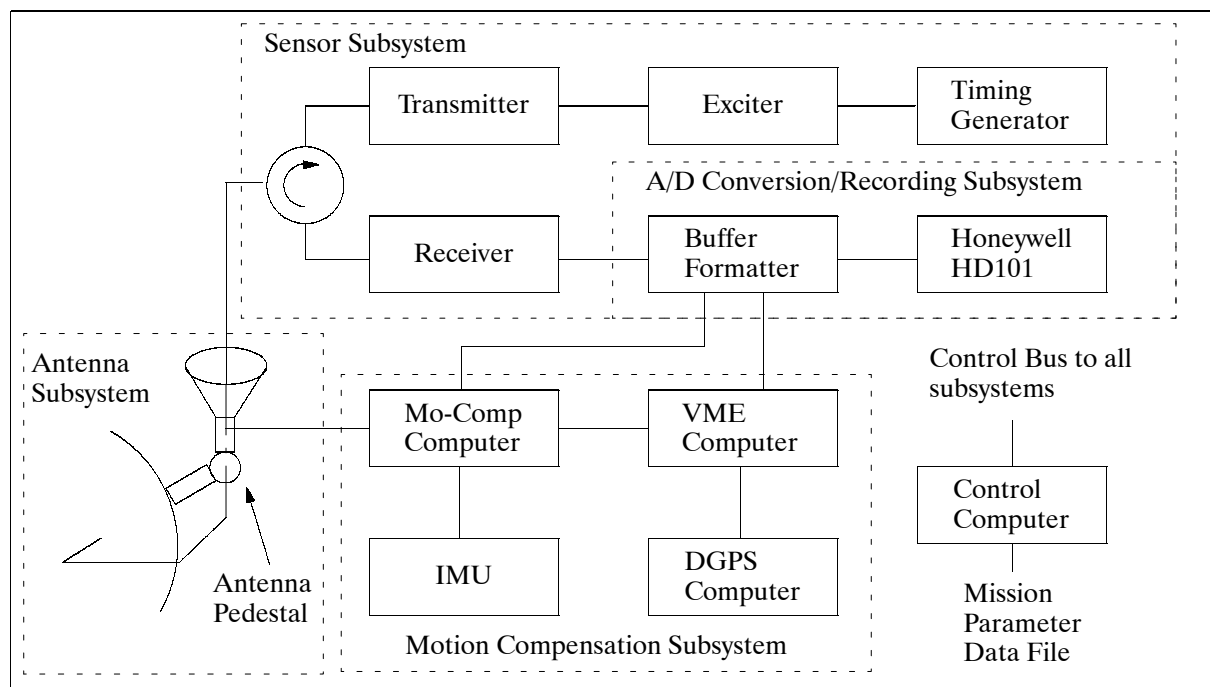

Figure 464: DCS block diagram

The A/D conversion and recording subsystem contains a buffer/formatter and a high-density tape recorder. The buffer/formatter is capable of digitizing either 1, 4 or 8 channels of data from the receiver. The recorder is capable of recording video and auxiliary data at a rate of 114 Mbit/s.

The radar collection modes are: stripmap, spotlight, dragging spot mode, circle mode, etc. (for definition of these modes see P.82.3 (P-3/SAR)). X-band and Ku-band data collection is mutually exclusive.

Operational bands	X-band	Ku-band
Center Frequency, wavelength	9.66 GHz, 3.2 cm	14.96 GHz, 0.5 cm
Polarization	VV, HH, VH, HV	VV
Antenna		
Azimuth beamwidth	6.25°	3.8°
Elevation beamwidth	5.25°	3.3°
Antenna pointing angle	± 165° off the aircraft nose	
Peak transmit power	1 - 1.5 kW	
Variable pulse width	2-100 µs (in 0.03 µs steps)	
Variable waveform	direct digital synthesis	
Effective PRF	1953 or 3906 Hz/channel	
A/D sampling rate	6 bits at 90 MHz	
Data window	variable 2 to 100 µs	
Samples/pulse	4096	
Operating altitude	2.5 - 7.5 km	
Platform, endurance,	Convair CV-580, 6 hours	
Nominal ground speed	70 - 140 m/s	
Processed scene size	approximately 1500 x 1500 cells	
Scene center pointing accuracy	approximately 10 - 20 m	
Maximum slant range	30 km	
Spatial resolution	classified	
Swath width	between 0.5 and 1.7 km	
Data rate	96 Mbit/s	
Data recording	high density tape (current recording capability of 114 Mbit/s)	

Table 689: Parameter definition of the DCS instrument

Applications: studies and demonstration in the following areas: target detection and identification, intelligent weapons, automatic target recognition, polarization diversity, interferometric mapping, training and keys development (generation/collection of radar signatures of various target to help image interpreters train themselves to identify certain targets, target types, or target phenomenology), RCS reduction (study of how to reduce a target's apparent radar cross section), coherent change detection, clutter characterization, etc.

P.82.5 IFSARE (Interferometric SAR for digital terrain elevation data)

The IFSARE^{2337), 2338)} instrument is the product of a cooperative research program of ERIM and JPL (funded by ARPA) with the objective to provide a highly accurate elevation mapping SAR instrument using single-pass interferometric technology. The IFSARE program started in May 1993; it was preceded by an extensive proof-of-concept phase (IFSAR) from 1992-93 and draws on ERIM's extensive DCS and JPL's TOPSAR processing experience. In this setup, ERIM has been developing the interferometric radar and auxiliary data processor, while JPL provided the image formation and DTE (Digital Terrain Elevation) processor. The IFSARE development program was completed in fall 1994, followed by a test and evaluation period in the first half of 1995. IFSARE is installed on an ERIM Lear-Jet-36 aircraft.

The design of this instrument implies new and improved remote sensing technologies and sensor data processing capabilities with the ultimate aim to provide a means of quickly gen-

²³³⁷⁾H. W. Klimach, G. T. Sos, "High Performance Interferometric SAR - Description and Capabilities," Proceedings of the 1st International Airborne and Remote Sensing Conference and Exhibition, September 12-15, 1994, Strasbourg, France, Volume III, pp. 697-710

²³³⁸⁾Information provided by D. Ager of ERIM

erating accurate terrain elevation data over large areas to meet the demands of a large user community - the applications are for military use, environmental monitoring and in particular for map-making purposes.

The radar interferometer is formed by a spatially-separated dual-antenna design providing the capability to relate the signals from both antennas in such a way that signal phase differences can be detected. The IFSARE system is divided into sensor and processor segments. The sensor segment consists of a dual-channel SAR, an inertial measurement unit (IMU) and a GPS system located on board the aircraft (LearJet 36). A second ground-based GPS provides DGPS data within a ground range of 200 km from the collection site. The processor segment consists of position/attitude, image formation, and digital terrain elevation processors.

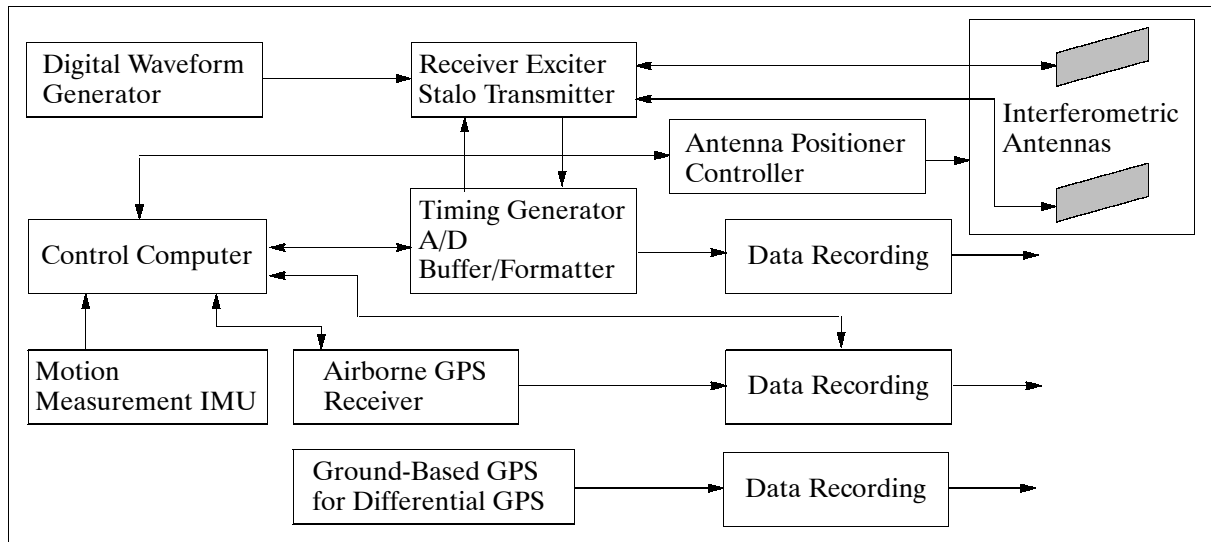

Figure 465: Schematic illustration of IFSARE sensor segment

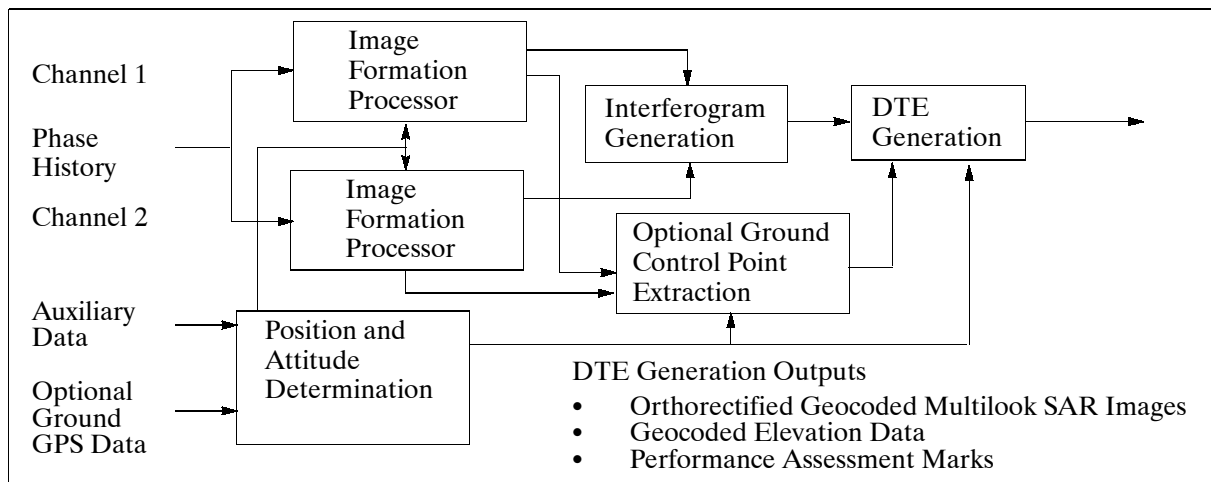

Figure 466: Functional diagram of the IFSARE ground processing segment

Two antennas (slotted waveguide) are mounted on a rigid structure that controls the antenna baseline separation (~ 1 m; effective azimuth beamwidth of $\sim 2^\circ$, elevation beamwidth of $\sim 30^\circ$). This rigid baseline assembly is attached to a gimbal that orients the antenna bore-sight in azimuth and pitch normal to the swath to be mapped. The IMU is rigidly attached to the antennas. The antenna/IMU assembly is fastened to the airframe through the azimuth and pitch gimbals and covered with a specially-designed radome. - The motions of IFSARE are measured by GPS and IMU as the instrument moves in its flight path. This information

is recorded on 8 mm tape recorder and later combined in the position/attitude processor to precisely reconstruct the actual path of the antenna phase centers.

Parameter	Normal Swath	Narrow Swath	Wide Swath
Frequency	9.5 GHz (X-band)		
Polarization	HH		
RF bandwidth	67.5 MHz	135 MHz	42.2 MHz
Transmit PRF	1200 Hz	1200 Hz	1200 Hz
Ground swath width	10 km	5 km	16.6 km
Near range	15.3 km	7.65 km	14.7 km
Far range	22.8 km	11.4 km	27.6 km
Flight altitude	12.2 km	6.1 km	12.2 km
Data collection coverage	> 100 km ² /min	> 50 km ² /min	> 164 km ² /min
Processing rate (% of real-time)	40	40	40
Slant range resolution	2.5 m	1.25 m	4 m
Nominal ground resolution	3 m	1.6 m	5 m
Number of looks	3.5	2	7

Horizontal position accuracy	2 m	1 m	3 m
Available post spacing	5, 10 m	5, 10 m	10 m
Data rate	107 Mbit/s		
Data recorder	DCRSi Ampex		
Status (end of 1994)	flight test version	future extension	future extension

Table 690: Estimated IFSARE performance parameters

The processing segment generates DTE products from the collected interferometric SAR phase histories, motion and auxiliary data. The position/attitude determination processor combines the highly accurate motion data with airborne and ground-based GPS data to generate all needed information to align the radar signals for proper focusing during the image formation process. A Kalman filtering process produces a full bandwidth motion history which is more accurate than either the high-frequency IMU data or the low-frequency DGPS data alone. These algorithms also determine the location of the radar data with respect to local and global coordinate systems. Full system performance is maintained as long as the ground GPS receiver is within 200 km of the collection site.

The image formation processor compares the received signal phase histories in two SAR images. Interferograms are then generated from these images by the DTE processor and used with motion data to generate elevation data. Points on the ground are geocoded by geometrically combining the relative range, along-track position and depression angle of the radar antennas with the absolute position and attitude of the aircraft. The output products are both DTE and geolocated, and orthorectified radar imagery at the selected pass spacing. The outputs are provided as a 2-D grid of elevation values or radar imagery samples in the WGS-84 (World Geodetic System - 1984) coordinate system.

P.83 EROS Digital Imagery and Photographic Products

The USGS (US Geological Survey) EROS Data Center at Sioux Falls, South Dakota serves as the archive and product distribution facility for NASA/Ames aircraft-acquired digital imagery and photography. Digital imagery is available to users on CCTs.²³³⁹⁾

The Airborne Science and Applications Program (ASAP) has acquired photographic data over much of the coterminous US, Alaska, and Hawaii. Since 1971 NASA U-2 and ER-2 high altitude aircraft have employed sophisticated aerial mapping cameras of different for-

²³³⁹⁾Paper provided by Jeff Myers of NASA/Ames Research Center

mats and focal lengths for obtaining high-resolution photography for Earth observation and science applications. Additionally, the C-130-B aircraft acquires mapping camera photography at medium altitudes during its digital data acquisition missions. This NASA acquired photography comprises an archive of over 500,000 frames. These data are accessible through a geographically referenced data base that allows users to specify a study area and select frames of photography by film emulsion, format, and scale. Photographic products available through the EROS Data Center include 1:1 transparency reproductions and 1x, 2x, 3x, and 4x paper print enlargements of any frame selected. Film formats include 9 x 9 inch photography taken with six and twelve inch focal length lenses and 9 x 18 inch photography taken with 24 inch focal length lenses.

P.83.1 Airborne Science and Applications Program (ASAP)

The NASA ASAP is supported by three ER-2 high altitude Earth Resources Survey aircraft. These aircraft are operated by the High Altitude Missions Branch at NASA/Ames Research Center, Moffett Field, CA. The ERS-2s are used as readily deployable high altitude sensor platforms to collect remote sensing and in situ data on Earth resources, celestial phenomena, atmospheric dynamics, and oceanic processes. Additionally, these aircraft are used for electronic sensor research and development and satellite investigative support.

The ERS-2s are flown from various deployment sites in support of scientific research sponsored by NASA and other federal, state, university, and industry investigators. Data are collected from deployment sites in Kansas, Texas, Virginia, Florida, and Alaska. Cooperative international scientific projects have deployed the aircraft to sites in Great Britain, Australia, Chile, and Norway.

P.84 E-SAR (Experimental SAR)

E-SAR is an airborne SAR system designed and built by DLR/IRF (Institute of Radio Frequency Technology) at Oberpfaffenhofen, Germany. The instrument is installed aboard a DO 228 aircraft and is used as a research tool to elaborate SAR-related problems in particular in the areas of system performance and data analysis. E-SAR has been flown in many campaigns since the beginning of 1989 in preparatory support of spaceborne sensors such as AMI (of ERS-1), X-SAR (on SIR-C/X-SAR).²³⁴⁰⁾

E-SAR is a multi-channel SAR system with the following functional capabilities:²³⁴¹⁾

- Flexible multi-channel SAR system
- Operational modes in X-band in horizontal or vertical polarization; the instrument has dual-polarization capability (VV, VH) in C-band and is fully polarimetric in P- and L-band.
- High-resolution imaging (up to 0.5 m resolution in azimuth)
- Along- and across-track interferometry
- Real-time SAR processing
- Innovative imaging modes (SAR tomography, polarimetric repeat-pass SAR interferometry).

The system platform is equipped with an AEROcontrol II Precision Air Navigation and Positioning System (CCNS4 of IGI). The maximum operating altitude is 6000 m. The maximum cruising speed is 400 km/h.

Applications: imaging of all surface types, flat or mountainous terrain, ocean or ice surfaces; monitoring resources (agriculture, forestry, etc.) or urban growth. There are also contractual flight assignments for individual customers with specific needs.

Slant range resolution	2.50 m (high)	4.50 m (medium)
Radar segment compatibility	X-C-L-(P)	X-C-L-P

Table 692: Swath modes and slant range resolution of E-SAR

Operating geometry: The nominal ground speed for SAR operation is 85 m/s (about 306 km/h). The radar is capable of mapping in two swath modes: narrow and wide mode. The optimum altitude for SAR operation is 3500 m. The depression angles of the antennas can be varied either mechanically (C- and X-band) or electronically (L-band) within a range of 30-45°, the P-band is fixed to 35°. The off-nadir (look) angles typically range from 25-65°. There is compensation for aircraft motion in order to obtain good image quality.

A single digital conversion and recording system is used to record the SAR raw data on SONY SD-1 high density cassettes formatted in the SAR 580 format. In addition there is on-board real time SAR quicklook processing.

The ground system consists of the following units:

- Radar raw data transcription from HDDC to Exabyte
- Standard SAR processing to CEOS level 1 b3 (i.e. geocoded imagery).

Typical image sizes are: 3 km x 10 km for narrow swath width and 5 km x 10 km for wide swath width. Larger areas are possible.

P.85 E-SLAR (Experimental Side-Looking Airborne Radar)

E-SLAR²³⁴²⁾ is an experimental DLR system (of the type: real aperture radar) designed and built by IRF (Institute of Radio Frequency Technology) at Oberpfaffenhofen, Germany. The initial version was built in 1976 and redesigned and improved as a research tool ever since. The original instrument provided a single-frequency X-band SLAR capability; the

²³⁴²⁾F. Witte, "The Archimedes IIa experiment: remote sensing of oil spills in the North Sea," International Journal of Remote Sensing, 1991, Vol. 12, No. 4, pp. 809-821

current (1995) 2nd generation E-SLAR version offers two front-ends, a Ka-band for the study of radar backscatter at different frequencies, and an X-band system. The current instrument is flown on a DO 228 aircraft.

Parameter	X-band	Ka-band
Transmitter/Receiver		
Frequency	9.39 GHz	35 GHz
Peak power (short pulse)	23.0 kW	20 kW
Peak power (long pulse)	19.5 kW	
PRF (recorded)	43 Hz	43 Hz
Pulse width	60 ns/280 ns	60 ns
IF center frequency	60 MHz	60 MHz
IF amplifier bandwidth	16 MHz	15 MHz
IF dynamic range	70 dB	80 dB
Noise figure	8.6 dB	< 10 dB
Antenna		
Antenna gain	29.5 dB	33 dB
3 dB beam width	Az. = 0.53°, El. = 45°	Az. = 0.5°, El. = 20°
Polarization	linear, VV	linear, VV
Antenna length	3.6 m	1.2 m
Data Recording	Videocassette recorder (VCR)	
Digital	8 bit	
Word length	60 min (on one cassette)	
Recording time		
Quicklook	512 x 512 pixels	
Rolling map	b/w TV monitor	
Display		
Operating Conditions	1000 - 3000 m	
Altitude	about 150 knots	
Airspeed	3 - 15 km	
Swath width	22°	
Depression angle	Incidence angle: 10° 40° 65°	
Resolution (short pulse, altitude = 1000 m)	Azimuth (m): 53.3° 14.4° 10.2°	
	Elevation (m): 9.1° 11.8° 21.4°	

Table 693: Technical parameters of the E-SLAR

The X-band antenna is a slotted waveguide antenna of 3.6 m length. It provides vertical polarization and is fed from one end. The Ka-band antenna is a reflector type and vertically polarized. The signal is detected by an incoherent rectifier in both transmitter/receiver units (X-band/Ka-band); the output from each receiver is a unipolar video signal.

E-SLAR is provided with an on-board data recording system, operator controls and monitoring, and a quicklook capability.

Applications: detection of oil slicks on water surfaces, land use monitoring (tropical rain forest, flood surveys, etc.).

P.86 ESMR (Electronically Scanned Microwave Radiometer)

ESMR is a NASA/GSFC passive sensor. ²³⁴³⁾ The instrument measures the upwelling thermal microwave radiation emitted by the Earth’s surface and atmosphere at a frequency of 19.35 GHz (1.55 cm wavelength). It is a cross-track imager scanning an angular swath of ±50° in 39 steps. ESMR is usually flown on a DC-8 aircraft at altitudes of 10-12 km. Its beam width is 3°, the polarization is horizontal with the electric vector parallel to the direction of flight. The temperature sensitivity of this sensor is about 2 K, the calibration accuracy is about ↓5 K. The main application of ESMR is to provide microwave images for precipitation and sea ice studies. ESMR took part in the TOGA/COARE mission in early 1993.

²³⁴³⁾Information provided by J. R. Wang of GSFC

P.87 ESTAR (Electronically Steered Thinned Array Radiometer)

A research airborne synthetic aperture microwave radiometer^{2344),2345),2346)} (a passive instrument), developed by NASA/GSFC and the Microwave Remote Sensing Laboratory of the University of Massachusetts at Amherst, with the objective to improve the spatial resolution of spaceborne passive microwave imagers, in other words, to apply microwave interferometry to an Earth remote sensing problem. The instrument is a 1.4 GHz (L-band) radiometer suitable for the remote sensing of soil moisture and ocean salinity. ESTAR uses Fourier synthesis to derive high-resolution images from a minimum number of antenna elements. The concept is borrowed from radio astronomy where it is commonly used to obtain high-resolution stellar images by synthesizing very large apertures from a few relatively small antennas.

Center Frequency	1.4 GHz (L-band)
Bandwidth	25 MHz
Polarization	horizontal (for ESTAR-A), vertical (for ESTAR-B)
Resolution along-track	$\pm 4^\circ$
Resolution cross-track	$\pm 3^\circ$
Swath width	$\pm 45^\circ$
Integration time	0.25 s
Platform	NASA/ARC C-130 and NASA WFF P-3
Data	15 correlator outputs + housekeeping data

Table 694: Specification of the ESTAR instrument

The ESTAR prototype has been flown aboard NASA Wallops aircraft (P-3) in the summer of 1988 and thereafter. The instrument consists of five antenna elements and a bank of 10 correlators that cross-correlate all possible pairs of antennas. The antennas are deployed along a line and are spaced at certain integer multiples of half the RF wavelengths so that the set of all cross-correlations generates every half-wavelength spacing up to a maximum spacing, while sampling each one as few times as possible. The configuration is referred to as a minimum redundancy linear array.

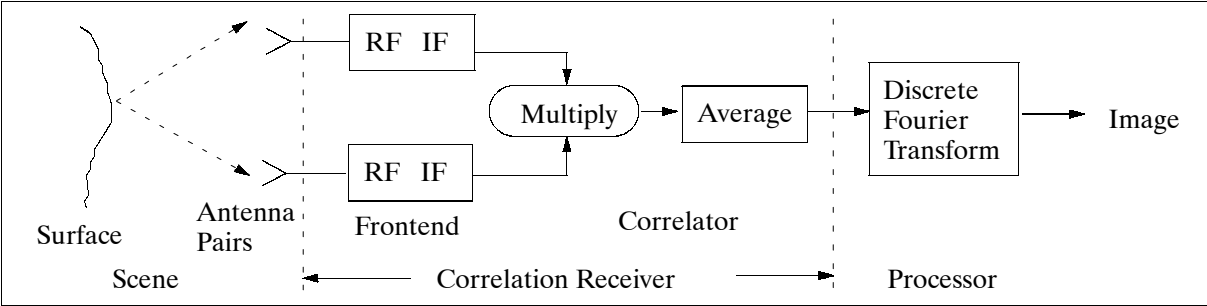

Figure 467: Schematic illustration of ESTAR signal processing

The ESTAR prototype is a hybrid instrument (5-element L-band interferometer) which uses real aperture antennas to obtain resolution along-track (with stick antennas) and employs aperture synthesis to obtain resolution across-track. The array of stick antennas is oriented with their axes pointed in the direction of motion. The stick antennas produce a fan beam which is narrow in the along-track direction and broad in the cross-track direction.

2344) C. S. Ruf, C. T. Swift, A. B. Tanner, D. M. Le Vine, "Interferometric Synthetic Aperture Microwave Radiometry for the Remote Sensing of the Earth," IEEE Transactions on Geoscience and Remote Sensing, Vol. 26, No. 5, September 1988, pp. 597-611

2345) D. M. Le Vine, M. Kao, A. B. Tanner, C. T. Swift, A. Griffis, "Initial Results in the Development of a Synthetic Aperture Microwave Radiometer," IEEE Transactions on Geoscience and Remote Sensing, Vol. 28, No. 4, July 1990, pp. 614-619

2346) D. M. Le Vine, T. T. Wilheit, R. E. Murphy, C. T. Swift, "A Multifrequency Microwave Radiometer of the Future," IEEE Transactions on Geoscience and Remote Sensing, Vol. 27, No. 2, March 1989, pp. 193-199

The fan beam is swept along the surface as the sensor moves and provides resolution along-track. Resolution across-track is achieved using aperture synthesis (which divides the swath into small cigar-shaped resolution cells) by detecting the signal from pairs of the stick antennas with a correlation receiver. All correlation pairs are measured simultaneously.

Figure 468: Schematic elements of the ESTAR prototype sensor

An imaging radiometer maps the brightness temperature distribution over a given field of view (FOV). Real aperture radiometers do this by scanning their antenna - either mechanically or electrically - across the FOV. The resolution of the image is consequently determined by the beamwidth of the antenna.

Interferometric imaging radiometers (like ESTAR), on the other hand, generate an image indirectly by measuring the Fourier transform of the brightness temperature distribution over the FOV. This measurement, which is referred to as the visibility function, is inverse Fourier-transformed by the user to form an image.

At each antenna an RF frontend amplifies and mixes the received signal down to an intermediate frequency (IF). At the IF a 10-way complex cross-correlator then generates the visibility samples by correlating all antenna pair combinations. Each correlator consists of two multipliers - one produces the in-phase component by multiplying the IF signals directly, the other produces the quadrature component by multiplying one IF with a 90° shifted version of the other IF. In all there are 21 analog signals which are low pass filtered, sampled by an A/D converter every quarter second and sent to the computer.

The raw data produced by ESTAR is a set of complex cross-correlation voltages measured between various pairs of antennas in the array. Each data point is a sample of the visibility function and is a measure of a spatial harmonic in the brightness temperature scene. The spatial harmonic depends on the spacing between a given antenna pair. If the elements are spaced at every integer multiple of one half of an RF wavelength, $\lambda/2$, then the resulting visibility samples are sufficient to reconstruct an image through a 180° field of view. The largest spacing, or baseline, determines the spatial resolution of the imager. The key feature of a thinned array is that all the required baselines are obtained with fewer antennas than there

are spacings. The ESTAR prototype in Figure 468, for example, simultaneously measures visibility at eight contiguous cross-track spacings with just five antennas.

The ESTAR²³⁴⁷⁾ instrument was also calibrated by several methods on the ground and in further test flights in the summer of 1989. Models have been developed that relate temperatures to the color in the images. The demonstration of the aperture synthesis (microwave interferometry) technique for remote sensing is regarded as promising and may be utilized in future spaceborne systems.

As of 1993 there are two instruments, ESTAR-A (H polarization) and ESTAR-B (V polarization, the latter being a 2nd generation radiometer developed to improve on the performance of ESTAR-A).²³⁴⁸⁾

P.88 FAST

FAST (Frequency-modulated Absorption Spectroscopy by Tunable diode lasers) is a dual-channel spectrometer designed and developed at MPICH (Max-Planck-Institut für Chemie) of Mainz, Germany (PI: H. Fischer) with the objective to measure atmospheric trace gases such as CO, N₂O, CH₄, OCS. The instrument design is based on the TDLAS (Tunable Diode Laser Absorption Spectrometer) measurement technique using a TTFM (Two-Tone Frequency Modulation) method for signal detection at about 12 MHz. The first instrument was completed in 1991 and has been upgraded and improved continuously since then. - Campaign participation of FAST in SAFARI '92 (on a DC-3 aircraft) in southern Africa; STREAM-I (1993) operated from Kiruna, Sweden; STREAM-II (1994) operated from Amsterdam, Holland; and STREAM-II (1995) operated from Kiruna Sweden; instrument intercomparison campaigns in Scotland in May 1991 and in Denmark in August 1993. Further STREAM-III campaigns are scheduled for 1996 and 1997.²³⁴⁹⁾

The in-situ measurement technique makes use of the existence of rotational-vibrational molecule transitions in the mid IR spectrum and monitors a single absorption line. The light source is provided by a lead-chalkogenide diode laser. The air, measured continuously, is taken from outside the aircraft and pumped through a multi-reflection cell. Two species can be measured simultaneously. Multiplexing is achieved using a dichroic optical element and a mechanical chopper which blocks each beam alternately. A control program on a dedicated digital signal processor allows the registration of the full absorption line shape at ms intervals; parallel data reduction occurs with the use of a multiple linear regression algorithm. Gas exchange through the compact multireflection cell (2.7 l volume, total path of 53 cm) takes place in ~200 ms, which determines the instrument response time.

The optical module layout is mounted on two boards, one on top of the other. The two diode lasers are embedded in liquid nitrogen cooled dewars. Repetition rate of 20-50 Hz for the mechanical chopper. The detector material is HgCdTe.

P.89 FIRS-2 (Far Infrared Spectrometer)

FIRS-2 is a balloon-borne instrument of the Smithsonian Astrophysical Observatory, Cambridge, MA (PIs: K. V. Chance, W. A. Traub). The objective is the simultaneous measurement of stratospheric trace gas families (profiles) using the Fourier Transform spectrometer emission technique in limb-scanning geometry. The following species can be identified

2347) A. B. Tanner, C. T. Swift, "Calibration of a Synthetic Aperture Radiometer," IEEE Transactions on Geoscience and Remote Sensing, Vol. 31, No. 1, January 1993, pp. 257-267

2348) P. W. Gaiser, C. T. Swift, D. M. LeVine, "L-band Synthetic Aperture Radiometers for Earth Remote Sensing," Proceedings of IGARSS '94, Volume II, pp. 1311-1313

2349) F. G. Wienhold, T. Zenker, G. W. Harris, "A dual channel two tone frequency modulation tunable diode laser spectrometer for ground-based and airborne trace gas measurements," SPIE, Vol. 2112, 1994, pp. 31-44

in the spectra: CO₂, O₂, O₃, H₂O, HDO, OH, HO₂, H₂O₂, HF, HCl, HOCl, HBr, HOBr, N₂O, NO₂, HNO₃, HCN, CO. Isotopic variants of species: ¹⁶O¹⁸O, ¹⁶O¹⁸O¹⁶O, ¹⁸O¹⁶O¹⁶O, and ¹⁷O¹⁶O¹⁶O can also be detected.

FIRS-2 is of FIRS-1 heritage which was on six balloon flights between 1979-1983 (1-channel instrument in TIR from 210 - 80 cm⁻¹). FIRS-2 has been operational since 1987; it was on a total of nine balloon flights as of the beginning of 1995. Flight sites: three from Palestine, TX, five from Fort Sumner, NM, one from Daggett, CA. FIRS-2 flew also on a NASA DC-8 aircraft (13 flights, 140 hours of data, average altitude of 11 km) in the 1992 AASE-II campaign.²³⁵⁰

The FIRS-2 spectrometer is a high-resolution instrument operating in two TIR spectral regions: TIR₁ from 14 - 25 μm (700 - 400 cm⁻¹) and TIR₂ from 48 - 125 μm (210 - 80 cm⁻¹). It is designed as a dual input/output system to utilize all of the light entering the spectrometer from the telescope. The two inputs to the system are the sky (via telescope) and a 77 K black-body surface. The signals at the two outputs are the out-of-phase linear combinations of the interferograms of the two input sources.

Interferometer	
Aperture	45 cm ² (7.6 cm beam diameter)
Number of simultaneous bandpasses	2
Scan time per interferogram	180 s
Unapodized spectral resolution	0.0040 cm ⁻¹
Spectral resolution after apodization	0.0080 cm ⁻¹
Etendue in TIR ₁ channel (14 - 25 μm)	1.7 x 10 ⁻³ cm ² sr
Etendue in TIR ₂ channel (48 - 125 μm)	3.4 x 10 ⁻³ cm ² sr
Telescope: off-axis (no obscuring secondary) design, primary mirror	20 cm diameter, focal l.= 175 cm
FOV	0.22°
Height resolution (nominal -3° elevation, altitude dependent)	1.3 km (TIR ₁ in limb scan)
Scanner (view of sky range)	+45° to -7° in elevation
Detectors (both detectors are cooled to liquid helium temperature)	Cu:Ge (14 - 25 μm) range Ge:Ga (48 - 125 μm) range
Instrument calibration (with ambient-temperature BB reference)	280 K (nominal, is monitored)
Instrument mass (total)	250 kg
Instrument power	200 W

Table 695: Instrument parameters of FIRS-2

Scanner control concept: the telescope azimuth is controlled to an accuracy of ±2° by orienting the gondola with a magnetometer-controlled servo system (JPL built). The azimuth is independently measured with a magnetometer which automatically compensates for the magnetic field of the gondola. The elevation angle is controlled to within ↓0.02° by referencing the telescope elevation to a single axis stabilized platform which uses a gyroscope as a short-term inertial reference and an inclinometer to correct for offsets and long-term drifts in the gyroscope. This corresponds to 0.14 km accuracy at 25 km tangent height.

Sky spectra from the various elevation angles are recorded and in ground-processing is inverted to produce species abundance profiles with an altitude resolution of about half the scale height. One observation cycle - containing one blackbody spectrum, one cold space spectrum (looking upward), and six spectra observing toward the limb at the selected tangent heights for both spectral regions - takes about 48 minutes. FIRS-2 can cover a wide range of altitudes (15-40 km) and can be operated during the entire diurnal cycle.

The total data rate of FIRS-2 is 64 kbit/s (of this the TIR₁ region takes 3 kByte/s and the TIR₂ region 1 kByte/s). The interferometer normally scans at 12,000 HeNe fringes/s, while the TIR₁ region is sampled every 10 fringes (1200 samples/s) and the TIR₂ region every 30 fringes (400 samples/s).

²³⁵⁰) Information provided by K. V. Chance of the Smithsonian Astrophysical Observatory, Cambridge, MA.

P.90 FIRSC (Far Infrared Sensor for Cirrus)

FIRSC is a NASA-sponsored airborne FTS (Fourier Transform Spectrometer) instrument, developed in a multi-institutional effort by LaRC, Queen Mary and Westfield College. The objective is to measure the upwelling radiance across the entire submillimeter-wave region (0.1 -1.0 mm) with a spectral resolution of 0.1 cm⁻¹, and to monitor cirrus particles (sizes and characteristics). 2351) 2352)

The instrument operates as a polarization-sensitive Martin-Puplett interferometer. 2353) The configuration provides for two separate outputs which are obtained by reflection/transmission by the polarizer element (P) at the focus of the f/4 lens in the cold optics of the detector dewar. This enables two spectral channels to be separately optimized to span the range between 10 - 140 cm⁻¹. The lower range from 10 to 65 cm⁻¹ (or 10 to 35 cm⁻¹) is being sensed with a Ge bolometer cooled to 0.3 K. The range from 80 to 140 cm⁻¹ is sensed with an unstressed Ge:Ga photodetector cooled to 4.2 K.

The bolometer is a composite element with a 3 mm diameter sapphire substrate to support the radiation-absorbing niobium bismuth film and Ge temperature sensor. Table 697 summarizes the bolometer parameters for both channels, with the bolometer parameters optimized for the different passband options.

The instrument is controlled by a Pentium CPU based Compact PCI computer consisting of the processor board, SCSI controller, (data is recorded on optical disk), motor controller for the linear motor mirror drive and viewing mirror step motor (rotation to view scene or calibration sources), a GPS receiver, a multi-channel 16 bit ADC board, and an image capture board. For non-autonomous operation the system uses Labview-based software for instrument control.

Each channel is sampled by drive encoder triggering at 4 mm 8 μm (OP) increments (10 encoder pulses, 2x oversampling) for a total of 12,500 points for each channel. During a typical flight, about 1.5 hours of data is acquired, amounting to about 0.25 GByte of data. Along with each scan the system also records a TIFF digital image of the nadir cloud scene and also logs GPS time, track and position data.

Initial engineering flights of FIRSC were made in 1998 using a NASA Wallops T-39 Sabreliner. The 1999 flights employ a commercially-leased Lear 24C aircraft operated by Flight International.

Parameter	Value
Spectral bands	Band 1: 10-65 cm ⁻¹ (1000-154 μm) Band 2: 80-135 cm ⁻¹ (125-75 μm)
Spectral resolution	Band 1, 2: 0.1 cm ⁻¹ (10 nm), double-sided interferogram
FOV	0.03 rad
Footprint	<1 km
Input aperture	5.4 cm diameter
Scan time	4 s
Max. optical path difference	± 5 cm
Max. mirror stroke	± 2.5 cm
Mirror scan velocity	1.25 cm/s (10 cm/s max)
Detectors	Band 1: bolometer @ 0.3 K Band 2: Ge:Ga photodiode @ 4 K
Single scan NEΔT	About 1 K rms at 20 cm ⁻¹

P.91 FISH (Fast In-Situ Stratospheric Hygrometer)

FISH is a Lyman- α fluorescence hygrometer developed by the Institute of Atmospheric Chemistry at the Forschungszentrum Jülich, Germany. Objective: Measurement of water vapor mixing ratios in the stratosphere (profiles). The in-situ detection scheme utilizes Lyman- α photons at a wavelength of 121.6 nm to photodissociate water vapor and produce excited OH molecules, which emit photons that are detected by a PMT (Photo Multiplier Tube) detector.^{2354), 2355)}

The instrument is mounted within an insulated pressure tank for temperature stability. The entire flow system is vacuum-sealed. The fluorescent cell consists of the following elements: Lyman- α light source, quartz plate, VUV (Vacuum UV) diodes A and B, interference filter, and PMT detector. An RF-excited lamp is used as Lyman- α source. The instrument performs measurements in three modes according to the position of a quartz plate (acting as a window for near-UV and visible light and as a mirror for Lyman- α radiation). In position 1, the Lyman- α flux passes through the cell. Thus the PMT detects the fluorescence signal while VUV diode A measures the Lyman- α flux across the instrument, providing H₂O absorption measurements at high mixing ratios for calibration. In position 2 of the quartz plate, the flux is directed to VUV diode B, monitoring the Lyman- α flux at the fluorescence volume. Background PMT counts can be measured in position 3 of the quartz plate. A cycle of three measurements takes about 3 seconds. Instrument ground calibration at stratospheric H₂O mixing ratios and pressure is performed using a humidity generator controlled by a frost-point hygrometer.

The first version of FISH was flown on balloons (several flights); a test flight was conducted in southern France in November 1990. In addition an aircraft instrument version was built with an improved temporal resolution of 3 seconds (measurement of one cycle) and a precision of 0.2 ppmv. The latter FISH instrument was initially flown on the DLR Falcon in March 1995. Instrument mass = 85 kg (balloon), = 40 kg (aircraft). FISH is scheduled to participate in two STREAM campaigns (spring 1996, and winter/spring 1997) and in CHORUS in 1998.

P.92 FLASH (FOA Laser Airborne Sounder for Hydrography)

FLASH is a Swedish airborne depth-sounding lidar system, owned and operated by FOA, providing data from water surfaces for charting purposes. The instrument is flown on a helicopter (Boeing Vertol); first trials of a prototype and demonstrator were conducted in 1989. Two operational systems were assembled in 1993 based on experiences with FLASH and

²³⁵⁴⁾Information provided by C. Schiller of the Forschungszentrum Jülich, Germany

²³⁵⁵⁾U. Mörschel, E. Klein, D. Kley, U. Schmidt, "A New Balloon Borne Stratospheric Hygrometer," Proceedings 10th ESA Symposium on European Rocket and Balloon Programmes and Related Research, Mandelieu-Cannes, France, May 27-31, 1991, ESA SP-317, pp. 201-205

were to be ready for use in 1994. The two new systems are called Hawk Eye; they are manufactured by SAAB Combitech (Sweden) in cooperation with FOA.^{2356),2357)}

The FLASH system consists of a sensor platform (transceiver/scanner), a signal handling module, a data processing/storage system (computer), a navigation module, and a power supply. The transceiver unit is made up of a laser head, the optical receiver, and the receiver electronics unit. The scanner is programmable, enabling the beam to search the water surface in different patterns. The FOV can be altered from 5 to 50 mrad. The signal extraction unit converts the received signal into digital form, and extracts the depth value in real-time for on-board display. The computer controls the system and handles the data. The lidar data are stored on magnetic tape along with a number of system parameters and navigation data. The navigation module employs a GPS receiver for differential positioning.

The laser is a frequency-doubled Nd:YAG laser with emission wavelengths of 532 and 1064 nm. The pulse length is approximately 7 ns. Laser beam divergence is automatically controlled via a beam expander to values between 2 - 10 mrad to allow studies of the horizontal resolution of bottom features close to the surface. The longer infrared wavelength (1064 nm) is used to measure the slant range to the water surface (the wavelength of 1064 can penetrate the surface only a few centimeters). The resolution in slant range measurements is ~8 cm. The IR beam is also used for discrimination between reflected signals. The short wavelength (green) beam of 532 nm is used for water penetration measurements.

The IR and green beams are swept by the scanner. The programmable scanner offers a wide range of system performance optimization and utility with regard to selectable scan patterns and to spot densities. - Typical altitudes for operating the system are in the range of 200 - 500 m above ground. The water depth that typically can be reached depends on water quality and is given by the formula:

$D_{\max} \approx 4 K$, where K = diffuse attenuation coefficient (1/m)

The footprint on the water surface can be altered by changing the laser beamwidth within the range: $\Phi_{\text{Laser}} \approx 1 - 10$ mrad.

Mirror diameter	280 mm
Receiver aperture	200 mm
Beam nadir angles	$\pm 25^\circ$ (lateral), -15° (backward), 25° (forward)
Sensor angle encoders	0.005° resolution
Vertical gyro accuracy	$\pm 0.3^\circ$
Rate gyro resolution	0.025°/s
Digital servo-loops sampling frequency	1 kHz
Scanner mass	24.6 kg

Table 698: FLASH scanner characteristics

P.93 FLI (Fluorescence Line Imager)

The FLI (also known as Programmable Multispectral Imager, PMI) is an airborne imaging spectrometer developed for the Canadian Department of Fisheries and Oceans (built by Moniteq Ltd and Itres Ltd.). The instrument was in operation by Moniteq, of Concorde, Ontario, from 1984 - 1990. Objectives: imaging ocean chlorophyll fluorescence and spectral reflectance changes in water caused by phytoplankton in the sea. Note: the instrument has also been operated in missions for applications related to water quality and aquatic vegeta-

tion monitoring, as well as over land. There was support for a campaign in Germany in 1986 to monitor spectral reflectance from forests as part of a forest damage survey.^{2358),2359)}

The imaging spectrometer makes use of a 2-D multi-element array of detectors (CCD push-broom technology) in the focal plane of a dispersive optical system. The system can operate in two modes.

- Spatial mode: high spatial resolution mapping in 8 selectable spectral bands.
- Spectral mode: high spectral resolution mapping in 288 spectral bands (spatial resolution is reduced to 40 look directions).

Spectral coverage	430 - 800 nm using 288 detector elements, pixel size = 1.3 nm, spectral resolution = 2.5 nm
Spatial coverage	70° swath with five cameras having a total of 1925 detectors, pixel size = 0.65 mrad, spatial resolution = 1.3 mrad
Spectral mode	Spectra are recorded from 40 different directions across the swath (8 per camera). The band width and look direction are under software control.
Spatial mode	Spectral pixels are grouped into a pushbroom image about 1900 pixels wide in each of eight spectral bands. The bandwidth and spectral position are under software control.
Sensitivity	Maximum 1800:1 SNR for a band of 16 detector elements at full signal
Integration time	40 ms minimum, typically 90 ms in spatial mode, 150 ms in spectral mode
Digitization	12 bits on chip, summation to 16 bit readout
Detectors	Five 385 by 576 element EEV P8600 arrays. Half of the area is used for frame storage
Optics	Transmission grating with f/1.4 Nikon lenses
Data recording	Bell and Howell 14-track high-density tape drive 8 by 875 kbit/s recorded
Weights	Head = 70 kg, data acquisition = 26 kg, recorder extra, cooling unit = 41 kg
Power	Head and acquisition = 450 W, cooling unit up to 1 kW
Aircraft mountings	DC-3, Falcon Fan-jet, Cessna 402, Piper Navajo, DO 228, Twin Pioneer

Table 699: Specifications of the Fluorescence Line Imager

The system comprises five separate optical camera modules, aligned to provide a field-of-view (FOV) of about 70°, with 1925 detector elements and 1.3 mrad resolution (IFOV). Each module has a silicon diode array of 385 elements across track by 288 elements along-track. The spectral response is from 430 - 805 nm, all wavelengths are accessible in steps of 1.3 nm, the spectral resolution is 2.5 nm.

P.94 FOLPEN (Foliage Penetration VHF Impulse SAR)

SRI International of Menlo Park, CA²³⁶⁰⁾ operates two fixed-wing VHF impulse SAR systems with foliage penetration capability, designated: FOLPEN-I and FOLPEN-II. The instruments have been operational since December 1990 and are currently used for target detection hidden under foliage.

The system provides on-board real-time image display (1024 x 1024 pixels) and data recording onto optical disk (1.6 MByte/s data rate); the aircraft is equipped with GPS.

The FOLPEN antenna consists of two phased arrays, one on each wing for the transmit and receive functions. The array elements are loaded dipoles designed to suppress reflections and to be relatively flat from 100 - 500 MHz. The sampling rate in I&Q on FOLPEN-I is 500 MHz, on FOLPEN-II it is 250 MHz. The swath width is 3 km maximum, depending on altitude.

²³⁶⁰⁾Information provided by R. S. Vickers of SRI International

Frequency	100 - 500 MHz in two bands (VHF/UHF-band SAR)
Bandwidth	200 MHz per band
Pulse Repetition Frequency (PRF)	200 Hz
Pulse width	5 ns
Polarization	HH
Resolution	1 m x 1 m
Coverage	500 km ² /hr at a flight altitude of 3 km
Surveying altitudes	300 m to 3.5 km
Average power	5 W
Instrument mass	115 kg

Table 700: FOLPEN parameter specification

P.94.1 GPR (Ground Penetrating Radar)

GPR is a helicopter-borne ground penetrating radar profiler of SRI International. The current system (1993) is an upgrade of previous systems built for special-purpose client applications over the past 20 years. The first system was flown for ice penetration studies in 1974. As of 1993 SRI has two operating systems installed in helicopters.

GPR is capable of detecting targets buried up to a few meters in favorable soils, up to 1 m in most soils. Deeper penetration requires a change in antennas. At mid-range frequencies the ground swath is approximately equal to the altitude - nominally 15 m. As in all GPR systems, performance is severely limited in high-loss soils, such as wet clay or silt.

Frequency range	200 - 1000 MHz (VHF/UHF profiler)
PRF	200 MHz
Pulse width	5 ns
Polarization	not applicable
Vertical resolution	0.5 m
Average power	1 W
Survey speed	up to 60 knots
Survey altitude	15 m (above ground)

Table 701: Specification parameters of SRI-GPR

P.95 FTVHSI (Fourier Transform Visible Hyperspectral Imager)

The FTVHSI airborne instrument is a design/development of Kestrel Corporation of Albuquerque, NM. The objective is the provision of a commercial high (spectral/spatial) resolution imager for a variety of environmental applications. First flight tests with FTVHSI were conducted in late 1995. The downward-pointing instrument consists of three major subsystems: the optical subsystem, the line-of-sight instrumentation, and the data management subsystem.²³⁶¹⁾

The optical subsystem employs an all-refractive optical design and a Sagnac interferometer which produces the spatially modulated interferogram. The concept of the FTS technique is illustrated in Figure 387 on page 1260. The optics are designed to operate with a large-format silicon-detector CCD array with a full frame readout. Images are acquired simultaneously during the common integration time in all spectral bands with each pushbroom swath. The 2-D CCD array collects images of 1 pixel (along-track) by 512 pixels (across-track) spatially with 256 channels of spectral information for each of the 512 spatial pixels. An image cube is formed by assembling the contiguous pushbroom stripes (or frames) pro-

²³⁶¹⁾Information provided by L. J. Otten of Kestrel Corporation

duced by the forward motion of the aircraft to create the second spatial dimension of data. An internal calibration source and local downwelling spectra are recorded with every frame of data to retain radiometric accuracy. Kestrel is flying the FTVHSI instrument in a Cessna TU-206 aircraft at an altitude of normally 2 km AGL. The corresponding velocity/altitude ratio amounts to about 30 scans/s (or frames/s) for contiguous strips of imagery.

Parameter	Value	Parameter	Value
Spectral range	440 - 1150 nm	CCD detector array	1024 x 1024 binned to 512 x 512
No. of spectral bands	256	Quantization	12 bit
Spectral resolution	≤ 5 nm	Frame rate	7.5/s, 15/s,30/s, 60/s
Spatial resolution (2-D)	0.8 mrad (IFOV)	Data rate	15 MByte/s (for 30/s)
FOV	15°	Instrument mass	205 kg

Table 702: System parameters of FTVHSI

The line-of-sight instrumentation provides a means of converting the images into a GIS-referenced coordinate system. The instrumentation consists of a 3-axis attitude indicator and a color scene camera, which contains the hyperspectral image scene by taking snapshots at about 20 second intervals. Both are aligned with FTVHSI. A Trimble GPS receiver provides location data. GIS geo-referencing with location accuracy of about 50 m rms is obtained in post-processing analysis.

The data management subsystem monitors and controls the instrument and provides for source data recording onto the on-board disk array recorder.

P.96 Geophysika M-55 Stratospheric Aircraft

Figure 469: The Geophysika M-55 aircraft model

The Russian ²³⁶²⁾ stratospheric subsonic aircraft was designed and developed by the Myasishchev Design Bureau, Moscow. The aircraft serves as a multipurpose instrument platform for ecological monitoring, providing ceiling altitudes of 21-22 km for flight durations of up to 6.5 hours with payloads of up to 1500 kg. The aircraft is equipped with two Perm

²³⁶²⁾Information provided by F. Orlandini, Rome, Italy, as general agent for Myasishchev D. B.

Aviadvigatel engines (fuselage-mounted, dual turbofan) providing a total thrust of 19,000 kg. The Geophysika M-55 aircraft is of 'M-17 Stratosphera' heritage; it was originally developed for the Russian Defense Ministry; the prototype Geophysika made its first test flight in August 1988. The aircraft is being employed for the Russian stratospheric measurement program as well as for the Italian APE (Airborne Polar Experiment) research program. As of 1994 four M-55 aircraft have been built; they are commercially available for a wide range of applications.

Performance characteristics: crew = 1; cruise speed = 750 km/h; takeoff mass = 24,000 kg; payload mass = 1500 - 2000 kg; payload power = 60 kVA at 115 VAC and 3 kW at 27.5 VDC. Aircraft dimensions: length = 22.8 m, total wingspan = 37.5 m.

P.97 GER Corporation Instruments

GER (Geophysical & Environmental Research Corporation of Millbrook New York) is a commercial builder of remote sensing imaging spectrometers [ASTER Simulator (custom-built), DAIS-2815, DAIS-7915, DAIS-16115, GERIS, etc.]. Recording data rates vary from 300 kByte/s to 32 MByte/s depending on instrument and recording device.

P.97.1 AAS (Airborne ASTER Simulator)

The AAS or simply ASTER simulator is an airborne instrument developed by GER Corporation of Millbrook, NY for the 'JAPEX Geoscience Institute (JGI) in Tokyo' for algorithm verification of ASTER (Advanced Spaceborne Thermal Emission and Reflection Radiometer) on the EOS/AM-1 payload. The ASTER simulator has been in operation since 1991. 2363) 2364)

bands were chosen to investigate their utility in this region for geological and environmental remote sensing.

A 3-axis gyroscope is attached to the scanner housing to measure the aircraft's attitude. Aircraft position is determined by a GPS receiver. The on-board computer has a display monitor for quicklooks. Recording media: IBM 3480 compatible cartridge recorder (12 inch, 18 track parallel), 200 MB capacity/tape, up to 10 tapes for autoloading.

The spectrometer optics separate the incident radiation into 24 distinct spectral bands using dichoric beamsplitters and gratings to eliminate interband registration errors. The VNIR detector plane has two silicon detectors adjoining each other. Their outputs are electronically combined and recorded as a single data channel. A 3-element InSb array is mounted in the MWIR detector plane. The output from each element is recorded separately. A 12-element HgCdTe array is mounted in each of the TIR detector planes (each 12-element HgCdTe array is composed of two 6-element arrays adjoining each other). One set measures radiation between 8.0-10.4 μm ; the other set measures radiation between 9.6-12.0 μm . A total of 24 channels of data are produced and recorded. Four spectral bands (9.6-10.4 μm) are recorded twice. The two outputs for each of these four bands may be digitally combined during ground processing.

Table 705: Specification of the DAIS-2815 instrument

P.97.3 DAIS-7915 (Digital Airborne Imaging Spectrometer)

DAIS²³⁶⁵) is a 79-channel/15 bit quantization opto-mechanical scanner built by GER (Geophysical Environmental Research Corporation) of Milbrook, NY and funded by the European Community (Joint Research Centre, Ispra, Italy) and DLR. DAIS covers the spectral range from visible to thermal infrared wavelengths at variable spatial resolutions from 5-15 m for flight altitudes of 1500-4500 m AGL. The system is integrated and operated by DLR/IOE (Institute of Optoelectronics). DAIS-7915 has flown since mid-1994. DAIS is accessible through DLR to serve EARSEC (European Airborne Remote Sensing Capabilities), as well as for other contractual applications worldwide.

Applications: environmental monitoring of land and marine ecosystems, vegetation stress research, agriculture and forestry resource mapping, geological mapping, mineral exploration and provision of data for geographic information systems.

Spectral Parameters

		SWIR	> 80
		MWIR/TIR	> 80

Table 706: DAIS-7915 instrument spectral ranges and system parameters

The DAIS-7915 system consists of an optoelectronic module (OM) and an electronic module (EM). The OM houses the Kennedy scanner with scan motor, encoder, two blackbody

²³⁶⁵) S. H. Chang, M. J. Westfield, F. Lehmann, D. Oertel, R. Richter, "79-channel Airborne Imaging Spectrometer," GER/DLR paper

radiation sources, a folding mirror assembly, telescope, gyros, beam splitters, grating spectrometers, detector assemblies and preamplifiers. The EM includes the data acquisition module and control electronics, the blackbody controller and the power supply/distribution units. The mass of OM is 172 kg; the mass of EM is 100 kg.

Image data are measured with a radiometric resolution of 15 bits/pixel and coregistered bands. Housekeeping data are recorded as channel 80. Selectable IFOV: 3.3 (2.5, or 5.0 optional) mrad. The TFOV = 64-78° depending on the size of the aircraft hatch. Pixels per line = 512.

System performance: SNR = 100-300 (VNIR), and SNR = 20-50 (SWIR), for a 30% ground albedo and a solar zenith angle of 45°.

Data storage: on-board IBM-compatible STK cartridge; data rates = 3.2 Mbit/s (for a 6 Hz scan rate) to 12.8 Mbit/s (for a 24 Hz scan rate). The selected scan rate depends on aircraft altitude and speed.

In 1998 the DAIS-7915 instrument of DLR was selected by ESA in preparation of LSPIM (Land Surface Processes and Interactions Mission), a spaceborne project. The intent is to demonstrate the potential and capabilities of imaging spectrometry for the quantitative retrieval of physical parameters such as surface temperature and leaf area index. The DAISEX campaigns in 1999 were a preparatory program initiative in this regard.

P.97.4 DAIS-16115 (Digital Airborne Imaging Spectrometer)

DAIS-16115 is a GER imaging spectrometer of 161 channels at 15 bit quantization. All spectrometer channels are spatially registered (image cube). Applications: geological, environmental, ecological and marine life monitoring.

Spectrometer	Spectral Range (μm)	No. of Bands	Bandwidth (nm)	SNR
1 (VNIR)	0.4 - 1.0	76	8	> 200

Table 707: Specification of the DAIS-16115 imaging spectrometer

P.97.5 GER-63 Channel Scanner

GER-63 is an airborne 63-channel imaging spectrometer designed for environmental studies and acquisition of spectral information pertinent for geological studies. A Kennedy-type scanner is used to acquire the images, which are formed at the entrance slit to the spectrometer. Note: The instrument was sometimes also referred to by the names of GERIS or AIS).

Spectrometer	Spectral Range (μm)	No. of Bands	Bandwidth (nm)	Detector
1 (VNIR)	0.4 - 1.0	24	25	Si
2 (SWIR1)	1.5 - 2.0	4	125	PbS
3 (SWIR2)	2.0 - 2.5	29	17.2	PbS
4 (TIR)	8.0 - 12.5	6	750	HgCdTe

Table 708: Specification of the GERIS imaging spectrometer

P.97.6 DAIS-3715 (Digital Airborne Imaging Spectrometer)

GER has designed and built a multipurpose scanner (hyperspectral imaging spectrometer) that acquires high-resolution images in 37 wave bands in the spectral range from 0.4 μm to 12 μm. The objective is to provide a commercial instrument for a wide range of applications such as: detection and mapping of oils spills, soil and water contamination, stressed vegetation, natural hazard mitigation, emergency response, agricultural management, and urban planning. Adjustable apertures, scan rates, and number of pixels per line allow a wide range of ground resolution cells to be acquired under different conditions of air speed and aircraft altitude. The instrument has been operational since spring 1995 ²³⁶⁶⁾

The Kennedy-type scanner is coupled to custom spectrometers and modular electronic subsystems. The scanner module consists of the scanner shock mount, the image acquisition optics (rotating polygonal mirror, 60° folding mirrors, 15° folding mirrors, and parabolic mirror), gyroscopic encoder, polygonal-mirror-drive motor, mirror speed encoder, and reference blackbodies. The gyroscopic recorder records the amount of aircraft roll during the recording of each pixel, allowing for correction of geometric distortions. The motor of the rotating mirror is adjustable, through the mirror speed encoder, for different scan rates, hence for different air speeds, aircraft altitudes, and spatial resolution requirements. The reference blackbodies are viewed every scan line, and are used as a thermal baseline to calibrate the thermal data channels.

Spectral Parameters		
Spectral Range (μm)	Number of Bands	Bandwidth (nm)
0.36 - 1.0	32 (contiguous, hyperspectral)	20
1.0 - 2.0	1	1000
2.175 - 2.35	2 (there is a small gap between the bands, due to detector construction)	50
3.0 - 5.0	1	2000
8.0 - 12.0	1	4000
General System Parameters		
FOV	±45°	
IFOV	5 mrad	
Data quantization	15 bit	
Recording system	Exabyte (SCSI)	

Table 709: DAIS-3715 instrument parameters

The spectrometer module is composed of the aperture, beam splitters, focusing optics and collimators for each spectral range, and detectors. There are three spectrometers with separate detectors for each spectral range (note: the spectral ranges from 1-2 μm and 3-5 μm do not employ dispersing elements, they are separated by dichroic filters). There are a total of 37 spectral bands recorded simultaneously with complete co-registration, making the instrument ‘hyperspectral’.

The computer and image display module features a Sun workstation with an 8 mm Exabyte tape drive, giving the operator the full functional range of services (quicklooks, control of instrument and recorder, etc.). GPS data are recorded and display simultaneously on the imagery, along with a map graticule.

P.98 Harvard Atmospheric Chemistry Instruments

During the past 15 years Harvard University has been developing instrumentation for the measurement of trace species in the stratosphere. One aspect of this research has been to improve understanding of stratospheric ozone depletion.

²³⁶⁶⁾S. H. Chang, B. M. Sorensen, T. D. Rubin, “A General Purpose Scanner for Airborne Remote Sensing,” Proceedings of the 1st International Airborne Remote Sensing Conference and Exhibition,” Strasbourg, France, September 12-15, 1994, Volume II, pp. 155-158

P98.1 OH/HO₂ Instrument

The OH/HO₂ instrument was designed and developed in the laboratory of professor J. G. Anderson. The objective is to measure OH and HO₂ in the altitude region of 8 to 25 km (PIs: J. G. Anderson, P. Wennberg, T. Hanisco). The instrument consists of a high repetition rate pulsed dye laser pumped with a pair of Q-switched diode pumped YLF (Yttrium Lithium Fluoride) solid-state lasers, a detection axis to detect laser-induced fluorescence at 309 nm, and NO gas addition system to convert HO₂ to OH. The OH/HO₂ instrument was test-flown on ER-2 aircraft in the fall of 1992 and participated in SPADE in the spring of 1993.

Principle of operation: OH is detected by direct laser-induced fluorescence in the (O-1) band of the $^2\Sigma^+ - ^2\Pi$ electronic transition. The instrument produces a frequency-tunable laser light at a wavelength of 282 nm. An on-board frequency reference cell is used by a computer to lock the laser to the appropriate wavelength. Measurement of the signal is then made by tuning the laser on and off resonance with the OH transition. Stratospheric air is channeled into the instrument using a double-ducted system that both maintains laminar flow through the detection region and slows the flow from the free-stream velocity (at about 200 m/s) to 40 m/s. The laser light is beam-split and directed to two detection axes where it passes through the stratospheric air into a multipass White cell. Fluorescence from OH, centered at 309 nm, is detected orthogonal to both the flow and the laser propagation using a filtered PMT (Photo Multiplier Tube) assembly. Optical stability is checked periodically by exchanging the 309 nm filter with a filter centered at 302 nm where Raman scattering of N₂ is observed. HO₂ is measured as OH after chemical titration with nitric oxide: HO₂ + NO → OH + NO₂. Variation of added NO density and flow velocity help to analyze the titration kinetics. Ancillary measurements of ozone and water vapor are made to diagnose potential photochemical interfaces.

P98.2 ClO/BrO Instrument

A dual-axis resonance fluorescence instrument (PIs: J. G. Anderson, R. C. Cohen). Objective: to measure ClO and BrO from 10 to 25 km in altitude on board remotely-piloted aircraft. A predecessor of this instrument (PIs: J. G. Anderson, R. Stimpfle) was flown in AASE (1987-1994), AAOE SPADE, and ASHOE/MAESA campaigns.

The instrument consists of an NO gas addition system and a resonance fluorescence detection system of Cl and Br atoms, respectively. A 5 cm x 5 cm inlet samples air from the free stream. Laminar flow in the sampling duct is maintained at velocities of 20-80 m/s, insuring that the walls of the instrument have a negligible effect on the measurement. The Vacuum Ultraviolet (VUV) radiation produced in a low pressure plasma discharge lamp is used to induce resonance scattering in Cl and Br atoms within the flow sample. The radicals ClO and BrO are chemically converted to Cl and Br, respectively, by addition of NO and the rapid reaction $XO + NO \rightarrow X + NO_2$.

P98.3 H₂O Instrument

A photofragment fluorescence hygrometer instrument for the measurement of water vapor in the stratosphere (PIs: J. G. Anderson, E. Hints). Water vapor, the primary driver of convection, and ozone, in addition to being radiatively important, can be used to identify regions of deep convection. This is due to a steep gradient in the lower stratosphere. The instrument was test flown on the ER-2 aircraft (nose) in 1992 and flew in 1993 during the CEPEX and SPADE campaigns, it is being considered for future flights on PERSEUS A. Participation in the STRAT campaign (1995-97, flying on ER-2). Note: The combination of the H₂O and O₃ instruments flew on the ER-2 aircraft under the designation **WOX** (Water Ozone Experiment) in CEPEX.²³⁶⁷⁾

The water vapor instrument uses the technique of photofragment fluorescence combined with dual-path absorption to measure water vapor concentrations ranging from 10¹³ to 10¹⁶

molecules/cm³ at pressures from 50 to 500 mb. The detection scheme utilizes Lyman-alpha photons at a wavelength of 121.6 nm to photo-dissociate water vapor and produce excited OH molecules which emit photons that are detected by a PMT (Photo Multiplier Tube) near 314 nm. Dual-path absorption measurements (path length is 9.2 cm), which provide a self-consistent check in the laboratory, are carried out during the ascent and descent part of each flight of the aircraft to verify the fluorescence calibration. In-flight diagnostic measurements, such those made after periodically changing the air flow velocity, confirm that the water vapor is not contaminated by the walls of the instrument.

Laboratory calibration: A stable water vapor concentration is provided by an air flow established by a 0.5 SLM (Standard Liters per Minute) flow controller bubbled through water and premixed with a flow of air from a larger flow controller. The mixture is then fed into the fast flow system through a loop injector. The water vapor concentration in the flow tube can be measured by absorption down the center of the flow tube, and for water vapor concentration $\geq 2 \times 10^{14}$ by the dual-path absorption measurement that is part of the flight instrument.

In-flight calibration: A vacuum photodiode, positioned across the duct from the lamp, serves as a beam flux monitor of Lyman-alpha emission. A doughnut-shaped VUV (Vacuum UV) spherical mirror surrounds the photodiode and focuses the Lyman-alpha radiation back across the duct to a second photodiode. In the presence of sufficient water vapor, the two diode measurements provide a dual-path absorption measurement, independent of the lamp intensity. This absorption measurement made simultaneously with fluorescence provides an in-flight check of the instrument calibration.

P.98.4 O₃ Instrument

An absorption instrument with the objective to measure ozone in the altitude region between 10 and 25 km (PIs: J. G. Anderson, E. Hintsa, E. Weinstock). The instrument consists of an absorption cell, an ozone scrubber, and a stabilized 254 nm light source.

The instrument determines ozone concentrations by measuring the absorption of 253.7 nm radiation. Ambient air is alternately drawn through a scrubber that chemically removes ozone and through a Teflon inlet tube. With ozone scrubbed air flowing through the detection cell, the reference signal (I_0) is determined. The ozone signal (I) is determined with ambient air flowing through the cell. Ozone concentration is then determined with ambient air flowing through the cell. The ozone concentration is then determined by Beer's law, where σ is the cross section and λ is the path length.

Figure 470: Schematic arrangement of the ozone instrument

P.98.5 ClONO₂ Instrument

The instrument consists of a heater to thermally dissociate ClONO₂ into ClO and NO₂ fragments. The gas addition of NO is used to titrate the ClO fragment, and the Cl produced is detected by resonance fluorescence. The NO₂ fragment is simultaneously detected by laser-induced fluorescence. A ClONO₂ instrument is currently (1995) under development to fly on the ER-2 during the STRAT campaign with test flights in June 1995 (PIs: J. G. Anderson, R. Cohen). The objective is to measure ClONO₂ from 15 to 25 km to help understand the partitioning of inorganic chlorine in the stratosphere.

P.98.6 NO/NO_y Instrument

The objective is to measure NO/NO_y in the region between 12 and 25 km using a lightweight design suitable for use on remote pilotless aircraft (PI: S. C. Wofsy).²³⁶⁸ The detection scheme utilized is chemiluminescence of NO with O₃, where NO_y is reduced to NO by H₂ over gold at 300 °C, with photon counting at wavelengths longer than 625 nm. The measurement period is 1 second with ±5 ppt. The lightweight design includes operation at ambient pressure, allowing a small roots pump, replacing a large vacuum pump, to move a large volume of sample (2l/s). A new cell design has been implemented that rapidly mixes reagent O₃ with the sample just upstream of the cell, to eliminate artifacts associated with incomplete mixing. The instrument is calibrated by adding known flows of NO, NO₂, or other species to the sample; the null signal is determined by frequently switching the reagent ozone flow to a reaction volume, where the sample NO is tritrated to NO₂, out of view of the photomultiplier.

P.98.7 CO₂ Instrument

A Harvard-developed instrument for measuring CO₂ in the stratosphere with high precision (±0.05 ppm) and accuracy (±0.1 ppm). (PI: S. C. Wofsy). The measurement period is 2 s. The instrument measures absorption of light at 4.26 μm wavelength (IR) in a 12 cm cell maintained at 340 torr, and compares this value to absorption in an identical cell containing a reference gas with known concentration of CO₂. Calibration is maintained by filling the sample cell with three different standard mixtures at frequent intervals during the flight. Stability and high precision are obtained by carefully regulating temperatures and pressures throughout the instrument. Accuracy is determined by comparing primary and secondary standards to archival standards at the Scripps Institution for Oceanography.

P.99 HELISCAT (Helicopter Scatterometer)

HELISCAT is a microwave (five-frequency) polarimetric scatterometer designed and built at the Institute of Oceanography of the University of Hamburg, Germany. Objectives: simultaneous measurement of multifrequency and polarimetric radar signatures of water, land, and ice surfaces. The first prototype of the scatterometer without the S-band channel was flown aboard a Cessna 207 aircraft in 1989; since 1990 in the HELISCAT version. The instrument was flown in a number of small campaigns in the German Bight of the North Sea and off the Dutch coast (LOTREX, SAXON-FPN, MAST-2, MAC-Europe, SIR-C/X-SAR underflights, etc.).²³⁶⁹

The instrument offers quasi-simultaneous operation in all frequency bands and polarization modes. The duration of one measurement cycle for all polarizations is 100 μs. The antenna is aft-looking and can be tilted mechanically such that the incidence angle on the ground can vary between 23°-65°. This angle can be changed by the operator during flight.

²³⁶⁸) Information provided by S. Wofsy of Harvard University

²³⁶⁹) HELISCAT Technical Report by V. R. Wismann, Institute for Applied Remote Sensing, Hamburg

The scatterometer footprint is monitored by a CCD video camera which is mounted on the antenna pedestal. The RF-part of HELISCAT consists of five pulsed superheterodyne Doppler scatterometers, one for each microwave channel. Phase-locked oscillators (PLO) are used to generate the radar signals for the transmitters and to act as local oscillators (LO) of the receiver. The transmitter RF signals are pulsed by PIN diode single-pole-single-throw switches (SPST) and then combined by a bandpass multiplexer. A small portion of the transmitter signal is coupled to a short-circuit delay line; the reflected signal acts as an internal calibration signal. External calibration is performed using reference calibration targets, i.e. corner reflectors on the ground. - HELISCAT operates in a beam-limited mode; this implies that the footprint size depends on the antenna beamwidth, the incidence angle, and the flight altitude.

Radar band	L	S	C	X	Ku
Frequency (GHz)	1.0	2.4	5.3	10.0	15.0
Wavelength (cm)	30.0	12.5	5.7	3.0	2.0
Transmitter output power (mW)	150	100	40	10	10
Antenna beamwidth ($^{\circ}$, 2-way half power)	13.6	5.6	2.5	1.4	0.9
Antenna type	96 cm parabolic dish (aft-looking,)				
Antenna feed	logarithmic, dual polarizations				
Polarization	VV, HH, HV, VH				
Incidence angle	23° - 65°				
PRF (Pulse Repetition Frequency)	40 kHz				
Footprint size,(m), flight altitude = 150 m					
Incidence angle = 23° , (cross/along track)	38.9/42.3	15.9/17.3	7.1/7.7	4.0/4.3	2.6/2.8
Incidence angle = 45°	50.6/72.6	20.8/29.4	9.3/13.1	5.2/7.3	3.3/4.7
Incidence angle = 65°	84.6/214	34.7/83.1	15.5/36.3	8.7/20.5	5.5/13.2
Data rate	409.6 kByte/s				
Instrument platform	DASA/MBB Helicopter, BO-105				
Operational altitudes	150 - 1000 m				
Altitude measurement	Collins ALT-50 Radar Altimeter (Helicopter provided)				
Antenna attitude measurement	Sperry VG-14-H Vertical Gyro				
Navigation	Magnavox MX 4200 D Differential GPS				
Helicopter ground speed; endurance	50 m/s; 2.5 hrs				
Mass microwave rack; mass operator rack	55kg; 90 kg				
Instrument power consumption	700 VA @ 28 VDC provided by the helicopter				

Table 710: Specification of the HELISCAT instrument

The measured data of the HELISCAT receiver are sampled at 10 kHz per channel and subsequently Fourier-transformed by using a 1024 points FFT. The Doppler spectrum of the backscattered radar signal is integrated over frequency, yielding the backscattered radar power. Finally, the radar data at the five frequencies and four polarizations are merged with navigation data (antenna attitude, helicopter altitude and position) to one data set for further analysis.

P100 HIS (High-Resolution Interferometer Sounder)

The HIS ^{2370), 2371), 2372)} instrument is an airborne Michelson-type Fourier Transform Spectrometer that was developed (from 1983-85) by the Cooperative Institute for Meteorological Satellite Studies (CIMSS) of the University of Wisconsin at Madison (sponsored by

²³⁷⁰⁾ "High-Resolution Interferometer Sounder (HIS) Phase II," A Report from the Cooperative Institute for Meteorological Satellite Studies, University of Wisconsin-Madison, October 1988

²³⁷¹⁾ H. E. Revercomb, et al, "Radiometric calibration of IR Fourier transform spectrometers: solution to a problem with the High-Resolution Interferometer Sounder," Applied Optics, Vol. 27, No. 15, August 1, 1988, pp. 3210-3218

²³⁷²⁾ W. L. Smith, R. E. Revercomb, et al., "GHIS - The GOES High Resolution Interferometer Sounder," Journal of Applied Meteorology, Vol. 29, No. 12, December 1990, pp. 1189-1204

NASA/GSFC and NOAA). Objectives: atmospheric temperature and humidity sounding; high vertical measurement of the thermal emission spectrum; exploring the use of high-resolution IR spectra for retrieving a variety of surface and weather-related variables with high precision ($\sim 1\%$). The primary focus is on the retrieval of temperature and water vapor profiles with high spectral resolution ($\lambda/\Delta\lambda = 2000$) and high radiometric precision ($0.1 - 0.2^\circ\text{C}$ rms noise equivalent temperature).

HIS is a nadir-looking instrument that is flown on ER-2 aircraft. The three spectral bands, covering most of the region from 3.6 to $16.4\ \mu\text{m}$, are split inside a single liquid helium dewar, which contains three sets of bandpass cold filters, focussing optics, and arsenic-doped silicon detectors. The preamplifiers are external and operate near the ambient pod temperature of about $260\ \text{K}$. The gain of each channel is fixed, the signals are digitized with a 16 bit A/D converter. On-board numerical filtering is used to reduce the sample rate from the HeNe Laser rate by factors of 14, 8, and 8 in bands I, II, and III.

Absolute instrument calibration at each wave number is provided by viewing two high-emissive blackbodies that are temperature-controlled to $300\ \text{K}$ and to about $240\ \text{K}$. The noise-equivalent temperature and calibration accuracy are approximately $0.1\text{-}0.2^\circ\text{C}$ and $0.5 - 1.0^\circ\text{C}$ over much of the spectrum. HIS calibration observations of the two on-board reference blackbodies are made every two minutes. Each group of HIS interferograms consists of two cold blackbody views, two hot blackbody views, and six Earth views from each scan direction of the mirror.

Parameter	Value	
Spectral ranges:		
Band I	$590 - 1070\ (\text{cm}^{-1})$	$9.3 - 16.4\ (\mu\text{m})$
Band II	$1040 - 1930\ (\text{cm}^{-1})$	$5.1 - 9.6\ (\mu\text{m})$
Band III	$2070 - 2750\ (\text{cm}^{-1})$	$3.6 - 4.63\ (\mu\text{m})$
Spectral resolution		
Band I	$0.5\ \text{cm}^{-1}$	$(2\ \text{nm})$
Band II	$1\ \text{cm}^{-1}$	$(1\ \text{nm})$
Band III	$1\ \text{cm}^{-1}$	$(1\ \text{nm})$
FOV (Telescope)	$100\ \text{mrad}$	
FOV (Interferometer)	$30\ \text{mrad}$	
Blackbody reference sources		
Emissivity	> 0.998	
Aperture diameter	$1.5\ \text{cm}$	
Temperature stability	$\pm 0.1\ \text{K}$	
Auto-aligned interferometer	modified Bomem BBDA2.1	
Beamsplitter		
Substrate	KCl	
Coatings ($1/4\lambda$ at $3.3\ \mu\text{m}$)	Ge + Sb_2S_3	
Maximum delay (double-sided, (cm)		
Band I (hardware limit = ± 2.0)	± 1.8	
Bands II and III (limited by data system)	$+1.2, -0.8$	
Michelson mirror optical scan rate	$0.6 - 1.0\ \text{cm/s}$	
Aperture stop (at interferometer exit window)		
Diameter	$4.1\ \text{cm}$	
Central obscuration area fraction	0.17	
Area	$10.8\ \text{cm}^2$	
Area-solid angle product	$0.0076\ \text{cm}^2\ \text{sr}$	
Detectors		
Type	Arsenic-doped silicon	
Diameter	$0.16\ \text{cm}$	
Temperature	$6\ \text{K}$	
Ground resolution (for $20\ \text{km}$ altitude)	$2\ \text{to}\ 4\ \text{km}$ (approximately)	

Table 711: Characteristics of the HIS instrument

The Bomem Michelson interferometer (developed by Bomem Inc. of Quebec, Canada) provides double-sided interferograms from both scan directions. Its auto-alignment system makes it possible to operate in the ambient thermal environment of the pod and in very

close proximity to the aircraft jet engine. The optical bench is shock-mounted to damp high frequency vibration; the interferometer is evacuated to protect the beamsplitter during descent.

HIS has been flown on many flights and participated in the following campaigns/projects: Kitt Peak (April 1986), COHMEX (June-July 1986), FIRE-I (October-November 1986), Pacific Ocean (May 1991), CAPE (July-August 1991), SERON (August 1991), FIRE-II (November-December 1991), STORM-FEST (February-March 1992), CAMEX I (September-October 1993), ASHOE (March - November 1994), OTIS (January 1995), and CAMEX II (September 1995). The HIS instrument has also been adapted to function as a ground-based temperature and water vapor profiler.

HIS²³⁷³⁾ is being used as a research tool for a number of applications, such as: estimation of cloud radiative properties in the infrared region (spectral emissivity and reflectivity), cross-validation of the spectral correction algorithm applied by other spaceborne sensors (such as HIRS, AVHRR, and ERBE).²³⁷⁴⁾ Observations with HIS have already made significant contributions to validating and improving line-by-line radiative transfer models. A long-term conceptual study program is underway at CIMSS (funded by NOAA, NASA, and EU-METSAT) called GHIS (Geostationary HIS). The objective is to investigate the utility of an interferometer sounder for future weather satellites, based on the experiences gained with HIS.

P.101 HRSC (High-Resolution Stereo Camera)

HRSC is a DLR instrument developed at the Institute of Space Sensor Technology and Planetary Exploration in Berlin-Adlershof. Its main part (i.e. the sensor electronics) was built at DLR, whereas the entire camera was built and assembled at DASA/Dornier. Originally, the camera technology was developed to be flown on the Russian Mars 96 space mission, along with WAOSS (Wide-Angle Optoelectronic Stereo Scanner). However, the Mars-96 satellite launch (November 17, 1996) from Baikonur failed to obtain a Mars orbit. - In addition to the space-qualified version of HRSC, an engineering model (EM) and a qualifying model (QM) were built. They have been flown on DLR and other aircraft (DO-228, Falcon, Cessna Caravan 208) for Earth observation applications since Feb. 1997. The qualifying model is now referred to as HRSC-A (HRSC-Airborne), while the EM instrument is named as HRSC-A/RMK (HRSC-Airborne RMK). Both of these systems are mounted on a Carl Zeiss T-AS stabilizing platform in their in-flight configurations. Both systems are multispectral stereo cameras (three-line pushbroom type), providing a wide range of surveying capabilities for photogrammetric and environmental applications.^{2375) 2376) 2377) 2378)}

A completely automatic photogrammetric and cartographic processing procedure including digital image matching, digital terrain model (DTM) and ortho-image generation, mosaicking and merging of multispectral data has been developed at DLR Berlin-Adlershof in cooperation with the Technical University of Berlin (TUB).

P101.1 HRSC-A (High-Resolution Stereo Camera - Airborne)

The HRSC instrument is a compact mono-block device consisting of camera head, electronic modules, and interface boards in one unit. The along-track stereo imaging system is based on multiple CCD-lines, mounted on a focal plate and using single optics, operating in pushbroom mode, and taking images simultaneously in the forward-, nadir- and backward-pointing direction of the ground track. ²³⁷⁹⁾

Instrument optics Focal length	Zeiss Apo-Tessar (dispersive), aperture=175 mm, f/5.6 175 mm (153 mm) Note: HRSC-A/RMK specific parameters are put into brackets
TFOV	36.0° x 11.8° (43° x 13.4°)
Detector type	Thompson THK 7808B (silicon), pixel pitch: 7 µm x 7 µm
Nr. of CCD detector lines	9
Pixels per CCD line, pixel size	5184, 7 µm x 7 µm
Stereo angles (center lines)	±18.9°, ±12.8°, (±22.1°, ±14.9°)
Radiometric resolution	10 bits, reduced to 8 bits
Spectral resolution (five bands) in nm	395-485 (blue), 484-576 (green), 729-777 (red), 920-1020 (NIR), 585-765 (nadir/stereo/photometry)
Readout frequency	450 lines/s (maximum)
Instrument mass	32 kg (16 kg)
Data rate	10 MByte/s
Instrument stabilization	Carl Zeiss T-AS stabilizing platform, IMU fixed to the camera, DGPS (Applanix position and orientation system)
Data recording	Sony high-speed tape recorder, capacity: 100 GByte/tape
Flight navigation	PC and GPS
Flight parameters (typical for Cessna 208)	3500 m AGL (6000 m max), speed = 250 km/s

Table 712: Parameters of HRSC-A and (HRSC-A/RMK) instruments

The detector array of HRSC-A features nine line detectors mounted parallel to the focal plane of the instrument, acquiring imagery in parallel by the forward motion of the aircraft. Four of the nine CCD line arrays are furnished with filters for the acquisition of multispectral imagery. Five of the nine line arrays are used for stereo imaging: the nadir, forward, and aft stereo lines for classical triple stereo and additionally, the forward and aft photometry lines are used to improve the stereo performance especially in urban areas. The absolute location accuracy obtained of the imagery is ±20 cm in range and ±25 cm in position. A typical pixel size in the along-track direction is 15 cm (at an aircraft speed of 250 km/h) from 3500 m AGL, the swath width for this altitude is 725 m, resulting in a pixel size of 14 cm in the cross-track direction. - Calibration: There is no on-board calibration system. Cloud measurements are used for flat-field corrections.

Sensor line No and band designation	Filter color	Wavelength center and / range (nm)	Bandwidth (nm)	Center line of view (from nadir)
5 Stereo forward	PAN	675±90 / 585-765	180	18.9°
4 Infrared forward	Infrared	750±20 / 730-770	40	15.9°
3 Photometry forward	PAN	675±90 / 585-765	180	12.8°
2 Blue forward	Blue	440±45 / 395-485	90	3.3°

P.101.2 HRSC-A/RMK (High-Resolution Stereo Camera - Airborne/RMK)

The instrument consists essentially of the sensor part of the HRSC-A with some additional optomechanical and electronic interfaces. It can easily be adapted to the Carl Zeiss RMK TOP 15 or TOP 30 system by replacing the conventional film box (T-MC) with the digital HRSC-A/RMK sensor unit.

Explanation for instrument mass difference (HRSC-A/RMK vs HRSC/A): The camera head electronics used for both cameras are nearly identical. For HRSC-A the optics and other structural elements are included in the mass figure; for the HRSC-A/RMK, however, they are not included. - The HRSC-A/RMK configuration was initially thought to be a simple and quick solution. However, better results in imagery have been achieved with the HRSC-A instrument. Therefore, since mid 1997, all observation requests have been realized with HRSC-A.

Figure 471: Observation configuration of the HRSC-A instrument

P.102 HUT (Helsinki University of Technology) Instruments

The LST (Laboratory of Space Technology) of HUT was established in 1988 with the objective to provide a university-level education in remote sensing, space-flight instrumentation and space research. Since then, a number of instrument were built and flown at HUT. Here are some of them. In 1994, LST acquired a Short SC-7 Skyvan turboprop aircraft. It serves as the main platform for LST's remote sensing instrumentation. The aircraft is equipped with a navigation system (DGPS, a new GPS receiver was installed in 1999 providing attitude data), a data location system (use of GPS time signal), and a motion video system (target imagery is displayed at a monitoring panel).²³⁸⁰⁾

P.102.1 HUTRAD (Helsinki University of Technology Radiometer)

The HUTRAD microwave radiometer system is accommodated on board the Skyvan aircraft of HUT and consists of two subsystems:

- The nonimaging subsystem (six frequencies between 6.8 and 94 GHz)

²³⁸⁰⁾ M. Hallikainen, "Development of Sensors and Methods for Remote Sensing of Northern Areas by HUT Laboratory of Space Technology," IEEE Geoscience and Remote Sensing, Dec. 1999, pp. 6-12

- The imaging subsystem (93 GHz)

P.102.1.1 Nonimaging Subsystem of HUTRAD

The instrument (ESA funding) objective is to provide validation of the spaceborne system concept (and to prepare for the operational algorithms) for MIMR (Multifrequency Imaging Microwave Radiometer) to be flown on METOP missions starting in 2002 (see G.2.1). Hence, the main technical characteristics of HUTRAD and MIMR are identical (there is a slight difference in channel 6 with 94 GHz vs 89 GHz, but this is of no consequence with regard to the measured results). Six frequencies are used with vertically and horizontally polarized radiation measured at each frequency. - A video camera is used in parallel to the nonimaging subsystem to record the target area. The instrument (complete system configuration) is scheduled to start flight tests in April 1996; partial configurations of the instrument were already flown before. ²³⁸¹⁾

Subsystem	Non-Imaging						Imaging
	Low-Frequency Unit			High-Frequency Unit			
Receiver channel No.	1	2	3	4	5	6	7
Center frequency (GHz)	6.8	10.65	18.7	23.8	36.5	94	93

In-flight display	Brighness temperature, H&V data, Video image						

Table 714: Parameters of the HUTRAD nonimaging subsystem

The nonimaging receivers are calibrated on the ground before and after a measurement flight by using two calibration targets that consist of absorbing material. One of the targets is kept at ambient temperature, the other target is cooled to 77 K using liquid nitrogen.

Background: The design and development of HUTRAD, as an airborne nonimaging radiometer system for concept validation of a future spaceborne imaging radiometer (MIMR), was guided by two factors, money and operational versus research use. An airborne imaging MIMR-type radiometer would simply cost substantially more to design and to build than a nonimaging radiometer. Also, an imaging MIMR-type radiometer would require a larger aircraft with corresponding expenses in operations. Hence, the solution of a nonimaging multifrequency instrument in combination with an existing one-frequency imaging instrument is considered adequate.

P.102.1.2 Imaging Subsystem of HUTRAD

The imaging 93 GHz sensor measures brightness temperatures (V and H polarizations). Its real-time display includes an image of the brightness temperature and a synchronized video target image.

²³⁸¹⁾Information provided by M. Hallikainen of HUT

Parameter	Value	Parameter	Value
Scan angle	Adjustable up to 70°	Look direction	Backward along-track
In-flight calibration	Hot and cold load	Sampling overlap	Adjustable
Additional equipment	Video camera	Mechanical stabilization	Optional: active stabilization

Table 715: Parameters of the HUTRAD imaging subsystem

The imaging subsystem also has two calibration targets for inflight calibration. One is at ambient temperature, the other is cooled to 77 K with liquid nitrogen. In addition the receiver is calibrated on the ground before and after each flight. - The imaging subsystem can be accommodated on board a Skyvan aircraft as well as on a Bell JetRanger helicopter. It was initially flown in April 1995.

Figure 472: HUTRAD imaging subsystem illustration

P.102.2 HUTSCAT (Helsinki University of Technology Scatterometer)

HUTSCAT is an active dual-frequency radar sensor designed and developed at the Helsinki University of Technology. The instrument measures the backscattering properties of a target with a range resolution of 0.65 m. The real-time ranging capability is obtained by performing a Fast Fourier Transform (FFT) to the received time-domain signal (the HUT, can identify the backscattering sources within a distributed target, like forests).

Measurements^{2382),2383),2384)} are made simultaneously in eight channels (VV, HH, HV, and VH polarization modes at 5.4 GHz and at 9.8 GHz). HUTSCAT has been operational since 1988 and flies as a research tool on a helicopter (Bell 206 Jet Ranger) with the objective to monitor forests, sea ice, and snow; HUTSCAT is also being used for the development of algorithms for data interpretation from spaceborne radars. The application in Finland with the most potential is forest survey for estimating forest inventory and characteristics.

2382) M. Hallikainen et al., "A Helicopter-Borne Eight-Channel Ranging Scatterometer for Remote Sensing: Part I: System Description," IEEE Transactions on Geoscience and Remote Sensing, Vol. 31 No. 1, January 1993, pp. 161-169

2383) J. Hyypä, M. Hallikainen, "Development of a Helicopter-Borne 8-Channel Ranging Scatterometer," HUT, Laboratory of Space Technology Report 4, July 1991

2384) J. Hyypä, "Development and feasibility of airborne ranging radar to forest assessment," doctoral dissertation at HUT, Finland, November 1993

HUTSCAT provides two microwave configurations - one for ranging and the other for backscattering measurements. Two antennas are used for ranging to achieve a better isolation between the transmitter and receiver. For backscattering measurements the scatterometer employs a single antenna for each frequency. The system measures the radar return spectrum for eight channels in 16.6 ms, which corresponds to an along-track distance of 0.33 m (helicopter speed 20 m/s).

Parameter	Value
Center frequency	5.4 GHz (C-band) and 9.8 GHz (X-band)
Modulation type	FM-CW
Modulation bandwidth	300 MHz
Polarization modes	HH, VV, HV, and VH
Antenna type	Parabolic with ring-loaded dipole-disk feed
Antenna size (diameter)	75 cm (5.4 GHz); 36 cm (9.8 GHz)
Incidence angle	1. Mechanically adjustable support: 0-45° off nadir 2. Electrically adjustable support: 0-60° off nadir
Antenna look direction	Across flight track
Pitch angle compensation (slow)	Max. 10° (preset prior to take-off)
Radar control	PC
Data storage	Cartridge tape unit (60 MByte) Bernoulli box disk drive (44 MByte) Floppy disk drive (1.2 Mbyte)
Stored data	Radar return versus range Fourier spectra Time domain signal
Calibration methods	Internal (delay time) External (active radar calibrator)
Additional equipment	Video camera (synchronized to radar)
Signal Processing Parameters	
Modulation frequency	60 Hz
Number of samples in each FFT	1024
Sampling frequency (one channel)	160 kHz
Range resolution	0.65 m
A/D converter	12 bit
Data rate (data recording)	80 kByte/s

Table 716: Technical parameters of HUTSCAT

P.102.3 HUTSLAR (HUT Side-Looking Airborne Radar)

The HUTSLAR real aperture radar was designed and built at the Helsinki University of Technology (HUT) and became operational in 1988. Initial on-board signal processing of HUTSLAR was partially performed in analog form, the data storage system was equipped with an analog video tape recorder. This system was replaced in 1993 by an all digital system.²³⁸⁵⁾

Applications: Mapping of sea ice, forests and oil spills. In Finland the monitoring of sea ice conditions is useful maritime information. The data of HUTSLAR are used in combination with HUTSCAT and with satellite data.

Operational frequency	9.445 GHz (X-band), $\lambda = 3.174$ cm
Polarization	Vertical (VV)
Antenna beam width	0.5° (horizontal)
Peak power output	4 kW
Pulse repetition frequency	45 - 450 Hz (depending on flight speed)
Pulse width	0.5 μ s
Resolution	75 x 75 m (approximately) at 8.6 km

Table 717: Technical specification of the HUTSLAR instrument

²³⁸⁵⁾Information provided by P. Ahola of HUT

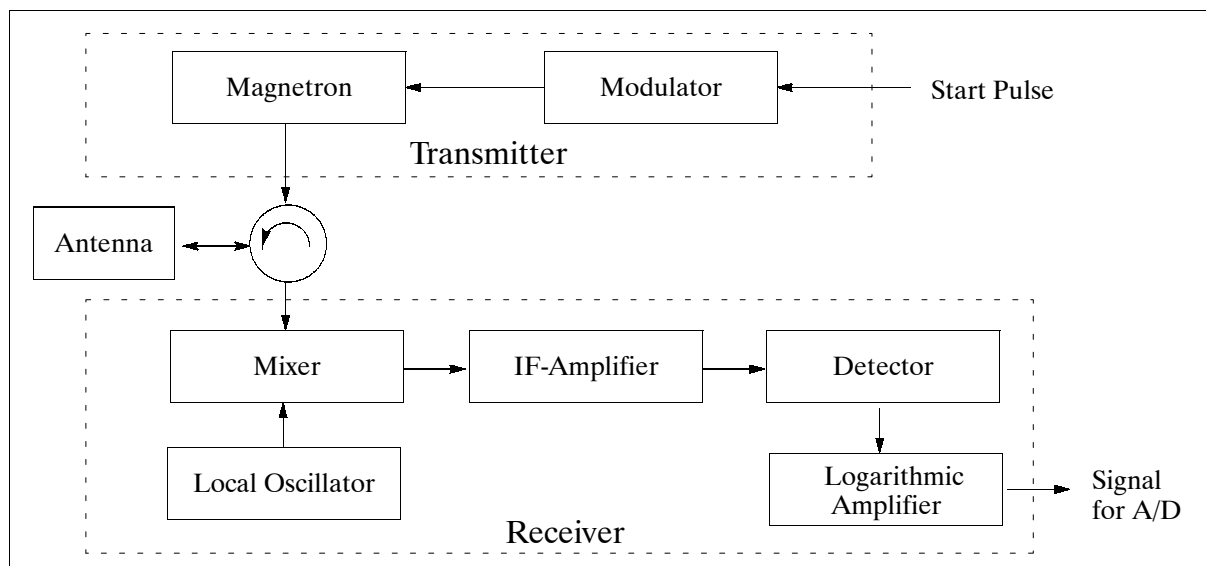

Figure 473: Schematic Blockdiagram of the HUTSLAR Instrument

The HUTSLAR transmitter/receiver signals are incoherent. The transmitter sends 256 pulses/s (constant count, PRF is dependent on air speed); the received echo pulse is digitized at a sample rate of 2 MHz providing a spatial resolution of 75 m. Slanrange resolution is achieved by a narrow horizontal beam of the antenna (beam width = $0.86^\circ \times 80^\circ$) and is 87 m at a range of 10 km (167 m at a range of 19 km). HUTSLAR uses a slotted waveguide antenna of 2m length in flight path direction.

HUTSLAR was initially flown on a helicopter (flight altitudes of 1 km). Current plans (1993) call for an aircraft mounting in order to eliminate yaw-axis vibration of the helicopter. A GPS system is also being considered (as input for better data processing).

P.102.4 MINISCAT

MINISCAT is an active single-frequency HUT scatterometer (a reduced version of HUTSCAT, which participated in the Arctic-91 campaign.²³⁸⁶) The sensor is a nonimaging FM-CW radar using a digital signal processor and Fast Fourier Transform processing. The instrument is flown on a helicopter.

The principle of operation is comparable to HUTSCAT. The main differences are:

- MINISCAT is a single-frequency (5.3 GHz) scatterometer
- MINISCAT has two ranging modes with resolutions of 0.31 m and 0.62 m
- MINISCAT is a lightweight version of HUTSCAT

Applications: MINISCAT is a research tool at HUT, it is also used for the measurement of stand profiles of forest canopies to produce stem volume estimates.

Center frequency	5.3 GHz
Sweep bandwidth	300/600 MHz
Modulation type	FM-CW
Range resolution	31/62 cm
Distance range	10 - 75 m / 10 - 150 m
Polarization modes	HH, VV, HV, VH
Antenna type	75 cm parabolic antenna with ring-loaded dipole disk feed
Calibration capability	External and internal

P.103 HYDICE (Hyperspectral Digital Imagery Collection Experiment)

HYDICE is an instrument of NRL (Naval Research Laboratory - Congressionally funded initiative) with the objective to advance the technology and to demonstrate the utility of hyperspectral imaging (participating agencies: EPA, DOE, USDA, USGS, NOAA, NASA, and US Army Corps of Engineers). HYDICE was built by Hughes Danbury Optical Systems Inc., Danbury, CT, USA. The instrument was completed in 1994. ERIM (Ann Arbor, MI) was awarded the HYDICE operations by NRL. In the fall of 1994 HYDICE was installed on an ERIM CV 580 aircraft and flown along with the DCS SAR instrument.²³⁸⁷⁾

Optics system	Paul Baker fore-optics, Schmidt double-pass bi-prism spectrometer
Aperture diameter	27 mm
Objective lens	f/3.0
IFOV, (FOV)	0.5 mrad, (8.94°)
Spectral coverage	0.4 - 2.5 µm, contiguous
Nr. of spectral channels	206
Bandwidth (FWHM)	7.6 - 14.9 nm
Integration mode	Simultaneous
Integration time	1.0 -42.5 ms
Frame time	8.3 - 50 ms
Readout time	7.3 ms
Quantization	12 bit
Polarization	< 3%
Pixel size	40 x 40 µm
Array size	320 x 210 pixels
Nr. of pixels per line	312 pixels
Detector array (SBRC)	320 x 210 element InSb
Mass of instrument	176 kg
Power of instrument	1700 W
Aircraft	CV-580 (the sensor is mounted outside the pressure hull)
Velocity/Height (V/H) ratio	0.028 radians/s (0.01 - 0.06, selectable)
Altitude	8 - 10 km
Pointing	±1° of nadir
Orientation	±1° of ground track
SNR (at 5% albedo)	250-280 in VNIR (0.4-1.0 µm) 100-107 in SWIR (1.0-1.9 µm) 50-58 in MWIR (1.9-2.5 µm)

Table 719: HYDICE instrument specifications

HYDICE is a 206 channel imaging spectrometer in the spectral range from 0.4 - 2.5 µm (VNIR/SWIR/MWIR) that employs the CCD pushbroom technique with a single detector array for coverage of the entire spectral region (full spectral range contiguous sampling). The instrument requirements call for a high SNR and high resolutions (spatial and spectral) of the imaging data.^{2388) 2389) 2390) 2391)}

The on-board system provides tape recording of all data (data rate of 45 Mbit/s), and a quicklook display. The aircraft is equipped with INS and GPS to provide navigation data for the engineering telemetry record.

Program objective: demonstrate the utility of hyperspectral imaging through the acquisition and analysis of high-quality hyperspectral data. - Civil applications are in the following fields:

- Agriculture: crop analysis, pest control, stress analysis

Figure 474: Schematic view of the HYDICE instrument

- Forestry: monitoring of inventory, habitat mapping, pest control, reforestation
- Environment: monitoring of toxic waste, acid rain, air pollution, eutrophication, soil conservation, water pollution
- Resource management: land use, mineral identification
- Mapping: area classification, bathymetry, wetlands, critical habitats
- Disaster management: damage assessment, search and rescue support
- Law enforcement: a host of applications

P.104 HyMap (Hyperspectral Mapper)

HyMap is a nadir-viewing imaging instrument family designed and developed by Integrated Spectronics Pty Ltd, Baulkham Hills, NSW Australia. The system offers rapid and efficient wide-area imaging, in particular for mineral exploration and environmental monitoring applications. It can be flown on a variety of light unpressurized aircraft. The fully enclosed instrument is mounted onto a three-axis gyro-stabilized platform. ^{2392) 2393)}

The following general capabilities (range of options) are provided to suit customer needs:

- A spectral coverage VIS, NIR, SWIR, MIR, TIR
- Spectral bands between 100 - 200
- Spectral bandwidth generally in the 10-20 nm range

²³⁹²⁾ T. Cocks, R. Jensen, et al., "The HyMap Airborne Hyperspectral Sensor: The System, Calibration and Performance," 1st EARSel Workshop on Imaging Spectroscopy, University of Zürich, Switzerland, Oct. 6-8, 1998, pp. 37-42

²³⁹³⁾ <http://www.intspec.com/>

- Spatial resolutions between 3-10 m
- FOV (Field of View) between 60-70°
- SNR >500:1
- Operational altitudes of instrument between 1.5-5 km AGL
- Provision of three-axis gyro-stabilized platform
- Calibration facility, pre-processing software

The HyMap instrument of HyVista Corporation, with typical performance characteristics, has the following configuration.

The design concept is modular, featuring a whiskbroom (opto-mechanical) scanner with a two-facets scan mirror. The optomechanical subsystem features an off-axes parabola telescope with an aperture diameter of 10 cm. Each spectral region is furnished with its own spectrometer module. The four spectrometer units cover a spectral range of 450 - 2500 nm in 126 bands; each unit provides 32 spectral bands while the VIS has 30 bands. The VIS module includes a silicon detector line array operated at ambient temperature. The NIR and SWIR modules use InSb detectors cooled to 77 K by liquid nitrogen.

Spectrometer Module	Spectral range (µm)	Bandwidth across module	Average sampling interval
VIS	0.45 - 0.89	15-16 nm	15 nm
NIR	0.89 - 1.35	15-16 nm	15 nm
SWIR1	1.40 - 1.80	15-16 nm	13 nm
SWIR2	1.95 - 2.48	18-20 nm	17 nm
Spatial resolution IFOV	2.5 mrad along track; 2.0 mrad across track		
FOV	60° (512 pixels across track)		
Swath	2.3 km at 5 m IFOV (along-track); 4.6 km at 10 m IFOV (along-track)		
Aircraft altitudes	1500 - 5000 m AGL		

Table 720: HyMap instrument parameters

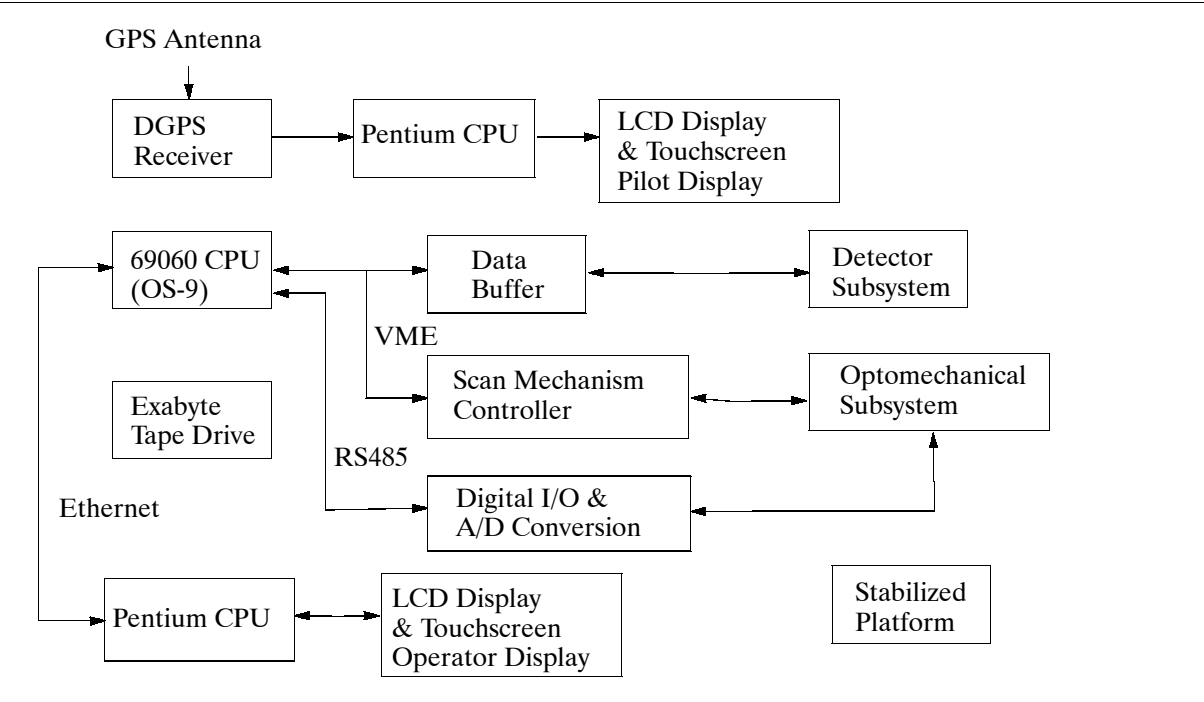

Figure 475: Block diagram of the HyMap instrument major subsystems

Calibration includes an on-board reference lamp and a shutter synchronized to scan-line readouts for dark current monitoring. In the laboratory calibration, a monochromator and

QI light source are used to illuminate the field stop of the collimator. During a spectral calibration sequence, the monochromator is scanned in wavelength and the sensor records the signal levels at each wavelength. - Band-to-band registration of the instrument is within 0.1 of a pixel.

The stabilization platform of Zeiss-Jena (SM2000) provides $\pm 5^\circ$ of pitch and roll correction. The yaw can be offset to $\pm 20^\circ$ with $\pm 8^\circ$ of stabilization provided. The platform provides a residual nadir pointing error of less than 1° and reduces the aircraft motion effects by a factor ranging from 10:1 to 30:1. - The residual motion effects on the imagery are corrected by the use of an IMU (C-Migets) fixed to the scanner.

The first HyMap instrument was introduced in 1997 and operated by Integrated Spectronics (support of several campaigns). Other instruments are operated at: 1) Anglo American plc Company, Johannesburg, South Africa, and 2) ESSI (Earth Search Sciences Inc.), Kalispell, MT, USA (2 instruments).

P.105 IFSAR (Interferometric SAR)

IFSAR is a Ku-band two-antenna elevation (across-track) interferometer designed and built at Sandia National Laboratories (SNL), Albuquerque, NM. The system has been operational since October 1993 and is used as a research platform (with much experimentation and modification) for the development of interferometric SAR methods, algorithms, and hardware. The objective is the generation of high-resolution digital terrain data.²³⁹⁴⁾

IFSAR is flown on board a Twin Otter (DeHavilland) aircraft. The two antennas are stabilized against aircraft motion by a single three-axis gimbal which is housed inside a radome on the aircraft underside. The radar system performs real-time motion compensation, collects two channels of radar returns for IFSAR processing and performs real-time image formation on one of the channels. Navigation consists of an on-board GPS-aided inertial measurement unit. The navigation system provide real-time motion compensation signals to the radar, provides real-time position and error information to the pilots, and collects GPS data for ground processing with carrier-phase techniques.²³⁹⁵⁾

Parameter	Nominal	Minimum	Maximum
Center frequency (GHz)	15.0	14.7	15.3
Incidence angle	45°	0.0°	55.0°
Elevation antenna separation (baseline)	0.330 m		
Range to scene center	5 km	3.5 km	15 km
Noise-equivalent clutter cross section	-35 dB	-45 dB	
Transmit power	650 W		650 W
Ground swath width	1500 m		
Range resolution (azimuth resolution)	1.0 m (1.0 m)		10 m (10 m)
Number of looks in range (azimuth)	9 (9)		
Antenna beamwidth in elevation (azimuth)	15.0° (5.0°)		

Table 721: Parameter Specification of IFSAR

The interferometer baseline is formed by alternately transmitting and receiving on the upper and lower halves of the antenna system (single transmitter and receiver chain, switching at twice the azimuth sample rate). This mode of operation enhances the effective distance between the two antennas at the cost of a reduction in SNR as measured for a single antenna. The system uses a pair of custom offset-dish antennas to maximize the antenna gain and

²³⁹⁴⁾ Information provided by W. H. Hensley, Sandia National Laboratories, Albuquerque, NM

²³⁹⁵⁾ D. L. Bickel, W. H. Hensley, "Interferometric SAR Phase Difference Calibration: Methods and Results," IGARSS '94 Proceedings, pp. 2259-2262

minimize phase errors introduced by the antenna system. The antennas are mounted on a common gimbal which is stabilized against aircraft roll, pitch and yaw. The antenna system is either operated in spotlight mode (where the antenna pair is always pointed at a specific spot on the ground), or in strip-map mode (generating a straight line along the ground). The phase centers of the two antennas are separated by 0.33 m.

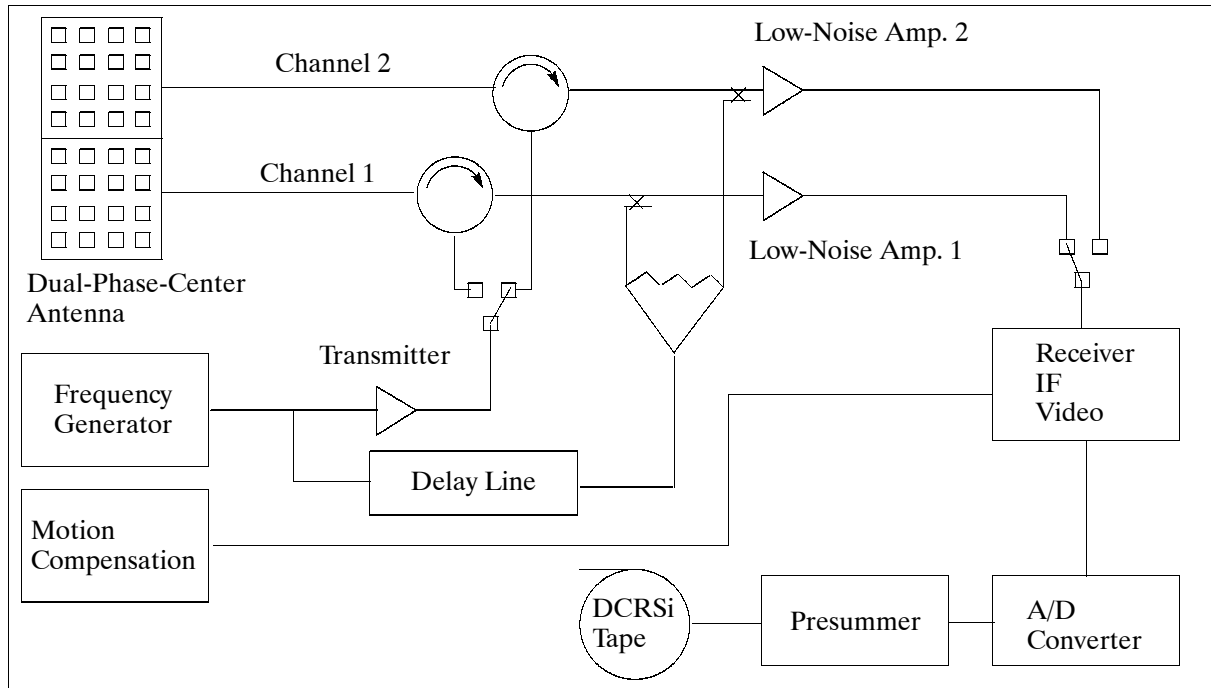

Figure 476: Two-channel IFSAR system design

The basic ground processing steps for digital terrain elevation data are as follows:

- Generation of accurate antenna position and attitude measurements using GPS carrier-phase techniques
- Formation of images from the upper and lower antennas
- Multilook processing and phase-difference computation
- Removal of flat-Earth phase in range and removal of azimuth phase tilt due to offset sampling
- Phase unwrapping
- Z- and Y-position estimation
- Y-axis gridding
- Registration into selected geographic coordinate system

P.106 IKI RAN Airborne Sensors

The Space Research Institute (IKI) of the Russian Academy of Sciences (RAN), Moscow, developed an airborne sensor payload which is flown on a Tupolev-134 CX aircraft. Principal areas of application are: oceanography, ecology, meteorology, environmental resource monitoring, etc. The Tupolev aircraft parameter are: altitude range = 0.5-10 km; operating altitude = 2-3 km AGL; operating speed = 500 km/hr; flight duration = 3-3.5 hr.²³⁹⁶

Background: From 1986 to 1992 IKI operated a Tupolev-134 CX aircraft conducting regular observational campaigns (mostly) in Russia for several months during each year. In 1992 the Tupolev participated in the JUSREX campaign. Basic sensors of the Tupolev were NIT, MKF-6 and NAMR. The computational equipment consisted of two IBM PCs (AT-286 and

²³⁹⁶Information provided by Yu. Kravtsov of IKI RAN, Moscow

an i486 with a streamer tape recorder). The navigational system employed regular inertial navigation (and Loran during JUSREX). As of 1995 IKI must rent Tupolev aircraft from commercial owners, such as NPO Vzlet in Zhukovski and Aeroflot Aviaotryad in Voronezh.

Sensor complement:

P.106.1 NIT (Side-looking Airborne Real Aperture Radar)

NIT (meaning ‘thread’ or ‘filament’ in Russian) is a SLAR-type radar; it is a principal payload instrument of the Tupolev and was built by in the early 1980s with the objective of sea surface and land surface monitoring. NIT employs two cylinder antennas (6 m in length and 44 cm in diameter), which are mounted on either side of the aircraft, allowing the simultaneous observation of two parallel swaths. The antennas are used alternatively for transmitting and receiving HH and VV signals (the receivers can be switched to receive cross-polarized HV and VH signals).²³⁹⁷⁾

Parameter	Value	Parameter	Value
Frequency	13.3 GHz (Ku-band)	Antenna look angles	72-84° (from nadir)
Wavelength	2.25 cm	Antenna polarization	VV, HH, VH, HV
Peak power	60 kW	Swath width (each side)	15 km (for 2 km AGL)
Pulse width	110 ns	Distance betw. swaths	12.4 km (for 2 km AGL)
PRF	2 kHz	Pixel size	25 x 25 m, (2 km AGL)
Data rate	4 kbit/s	Quantization	16 bit

Table 722: Parameter specification of NIT

P.106.2 MKF-6 (Multispectral Camera)

MKF-6 is a camera built by Carl Zeiss, Jena; first operation of this IKF sensor was on Soyus-22 in 1976, afterwards on Salyut-6 and -7 (see L.4). MKF-6 operates in 6 spectral bands.: 0.46-0.50 μm , 0.52-0.56 μm , 0.58-0.62 μm , 0.64-0.68 μm , 0.7-0.74 μm , 0.79-0.89 μm . Number of lenses = 6; focal length = 125 mm; weight of camera = 73 kg; power = 100 W; FOV=40.5°.

P.106.3 NAMR (Nadir-looking Airborne Multichannel Radiometer)

An IKI-developed instrument complex which has been flown since 1990. The objective of NAMR is the measurement of sea surface temperatures and the deduction of wind direction and speed (by the variation of the thermal radiation over azimuthal angles relative to the wind by a few degrees Kelvin). The NAMR radiometric complex includes the following instruments: polarimetric K-band and Ka-band radiometers, as well as an S-band radiometer. The K/Ka-band polarimeters measure the brightness temperature at four linear polarizations separated by 45° angles; the S-band and IR-band instruments are common Dicke-type radiometers.

Instrument	K-band	Ka-band	S-band	IR-band
Frequency	20 GHz	37 GHz	3.6 GHz	
Wavelength	1.5 cm	0.8 cm	8 cm	8-12 μm
Radiometric sensitivity	0.15 K	0.15 K	0.1 K	0.05 K
Radiometer bandwidth	2 GHz	2 x 700 MHz	200 MHz	
Antenna type	Corrugated conical horn		Pyramidal horn	Optical lens
Antenna size	18 cm x 28 cm	14.5 cm x 23 cm	30 x 38 x 76 cm	
Antenna beamwidth	9°	9°	15°	9°
Input waveguide diameter	11 mm	6 mm		

Table 723: NAMR complex parameter specification

²³⁹⁷⁾ A. V. Smirnow, “Polarimetric radar imagery of the ocean at grazing angles under atmospheric conditions of variable stability,” IGARSS’94 Digest, Pasadena, CA, August 8-12, 1994, pp. 805-807

P.106.4 Delta-K Spectrometer

The instrument is a dual-frequency scatterometer of IKI, first flown in 1981 with the objective to measure surface-wave spatial spectra. This implies simultaneous active sensing of the sea surface at two closely-spaced microwave frequencies along with correlation processing of the reflected signals. By changing the frequencies f_1 and f_2 one can obtain the modulated spectrum of the backscattered cross section from the intensities of various $\Delta f = f_1 - f_2$ resonance peaks; Δf is changed discretely from 5 to 50 MHz corresponding to the wave numbers from 0.072 to 0.33 rad/m.

Parameter	Value	Parameter	Value
Frequencies	7.45 - 7.55 GHz	Receiver dynamic range	50 dB
Transmitter power	0.28 W	Frequency bandwidth	5-50 MHz
Polarization	VV	Number of channels	16
Antenna diagram	10°	Receiver noise figure	4 dB

Table 724: Delta-K Spectrometer parameters

P.106.5 IKIRAD (IKI Radiometer)

IKIRAD refers to a radiometric instrument complex which was designed/developed by IKI RAN. The complex was completed in 1992 and flown aboard an Antonov (AN-12) aircraft. The modularity of the complex permits single instruments or all instruments to be installed on a number of different research aircraft or on research vessels. Designations of instruments in Table 725:

- R-11W (Radiometer with 11 cm wavelength and waveguide input)
- RP-1.5 WA (Radiometer/Polarimeter with 1.5 cm wavelength, waveguide input, the 'A' stands for the fact that radiometers are included in aircraft-laboratory equipment). Polarimeters RP-1.5WA and RP-0.8WA measure differences between H and V polarizations.
- R-18C (Radiometer with 18 cm wavelength and coaxial input)
- R-8CS (the 'S' stands for the fact that shipborne instrumentation is used)

Instrument	R-11W	RP-1.5 WA	R-0.8WS	RP-0.8 WA	R-18C	R-8CS	R-21WA	R-18W
Wavelength	11 cm	1.5 cm	0.8 cm	0.8 cm	18 cm	8 cm	21 cm	18 cm
Frequency (GHz)	2.73	20	34.75	34.75	1.66	3.475	1.43	1.66
Sensitivity	0.1 K	0.07 K	0.07 K	0.05 K	0.1 K	0.07 K	0.1 K	0.1 K
Antenna type	Pyramidal horn	Corrugated conical horn			Pyramidal horn with waveguide to coaxial adapter			
Antenna size		18x28 cm	14.5x27	14.5 x 23	40x30x75	40x30x75		
Power (DC)	27 VDC	27 VDC	27 VDC	27 VDC	220 V, 50 Hz, 27 VDC			

Table 725: IKIRAD complex parameter specification

P.106.6 K-band Dual-frequency Atmospheric Radiometer

The objective of this IKI radiometer is to measure the total column water content in the atmosphere. The technique employed is to measure simultaneously the brightness temperatures differences at two frequencies and the absolute temperatures at the same frequencies. The sensor has been operational since 1992.

Parameter	Value
Frequencies	20.20 and 22.235 GHz (K-band)
Fluctuation sensitivity (integration time: 1 s)	0.09 K
Microwave input waveguide diameter	11 mm
Antenna type; size	Corrugated horn; 14.5 cm x 23 cm
Microwave unit size; mass	45 cm x 20 cm x 18 cm; 6 kg
Low-frequency unit size; mass	36 cm x 36 cm x 18 cm; 4 kg
Supply voltage and power	220 V, 50 Hz, 50 W 27 VDC, 1.2 A
Microwave unit	
Low-frequency unit	

Table 726: Parameter definition of K-band radiometer

P.106.7 Multipolarization K- and Ka-band Polarimeters

The instruments RPM-1.5 WA (Radiometer/Polarimeter/Multipolarization, 1.5 cm wavelength, Waveguide, Airborne) and RPM-0.8 WA (Radiometer/Polarimeter/Multipolarization, 0.8 cm wavelength, Waveguide, Airborne) are intended for the determination of the first, second, and third Stokes parameters of partially polarized microwave emission. The polarization plane of the electromagnetic wave is rotated step by step by means of a ferrite gyrator. The antenna used is a corrugated conical horn. The sensors have been operational since 1992.

Instrument	RPM-1.5 WA	RPM-0.8WA
Frequency	19.5 GHz (K-band)	34.5 GHz (Ka-band)
Wavelength	1.5 cm	0.8 cm
Fluctuation sensitivity (integration time: 1 s)	0.05 K	0.07 K
Measurement modes	a) Simultaneous processing of two signals with orthogonal polarizations b) Simultaneous processing of two pairs of orthogonal polarizations at 45° angles c) Polarization scanning, consecutive processing of 13 polarization plane directions with 15° increments	
Polarization accuracy	2°	
Power, voltage	30 W, 220V, 50 Hz

P.107 INGARA (Australian Airborne Imaging Radar System)

Ingara²³⁹⁸) is a technology demonstrator instrument of the Defense Science and Technology Organization in Adelaide, Australia. The objectives are to evaluate airborne multimode radar technology, such as SAR and moving target indicators for the Australian Defense Forces, and to provide the scientific and remote sensing community access to an in-country imaging radar sensor for assessment. The Ingara system first flew in March and June 1993 (demonstration of stripmode SAR operation with a 12 km imaging swath and 3 m spatial resolution). As of 1994, the instrument is undergoing further development and evaluation until the end of 1995. Ingara is an Australian Aboriginal word for 'long way,' in the initial program phase (up to the end of 1993) the instrument was called AuSAR. Applications include land use monitoring, natural disaster mapping, resource assessment, and future digital elevation mapping for the generation of topographic maps.

The current radar hardware can sample 4096 range samples at 50 MHz to acquire the echo from a 12 km wide swath. A 36 km wide swath is acquired as three independent 12 sub-

²³⁹⁸)N. J. S. Stacy, M. P. Burgess, "INGARA: The Australian Airborne Imaging Radar System," Proceedings of IGARSS '94, Volume IV, pp. 2240-2242

swaths sampled in an interlaced fashion. The radar antenna is designed to illuminate a 48 km wide swath when the aircraft is flying at 3 km altitude.

Figure 477: INGARA data acquisition geometries

The following extended functionality is planned for the end of 1995:

- operational modes: stripmap SAR, spotlight SAR, squint SAR, and moving target indicator
- upgrade of acquisition hardware to 2000 Hz PRF (for moving target indicator mode)
- enhancement of R/T processor to accommodate the additional modes
- real-time data link transmission from the aircraft to the ground
- integration of a GPS receiver system for location data
- GIS software for image data interpretation and extraction (ground facility)
- interferometric SAR mode capability with the installation of a second antenna.

Radar frequency	9.375 GHz (X-band)	Antenna size	1.46 m x 0.16 m
Polarization	HH	Data quantization	8 bit I and Q
Transmit waveform	FM chirp, 8 ms, 48 MHz	Max. raw data rate	4 MByte/s
PRF	190 - 400 MHz	Incidence angles, θ	$60^\circ - 86^\circ$
Peak transmit power	1 kW	R/T signal processor	CSPI SuperCard-2XL and SuperCard-4XL
Stripmode mapping Resolution Swath width	3 m (4 looks) 12 km, 24 km, 36 km	Sensitivity	$\sigma_0 < -35$ dB (3 m resolution, 4 looks and 24 km standoff)
Swath standoff distance	5 km - 36 km	Aircraft platform	Dakota C47
Operating altitude	3 km	Aircraft speed	70 m/s

P.108 ISM (Infrared Imaging Spectrometer)

ISM is a French airborne spectrometer developed by DESPA of the Paris/Meudon observatory, as part of a planetary mission, in collaboration with IAS. CESR (Centre d'Etude Spa-

tiale des Rayonnements) realized an airborne version of the instrument on the ARAT (Atmospheric Research and Remote Sensing Aircraft). The first test flight occurred in 1991.

ISM operates in the NIR and MWIR portion of the spectrum; it provides 128 spectral channels between 0.8 and 3.2 μm . Objectives: geology, clouds, ice and snow, vegetation (i.e. forest and agricultural), with special emphasis on the Mid-Wavelength Infrared (MWIR) region for canopy chemistry (lignin, nitrogen, cellulose) analysis.^{2399),2400)}

ISM employs an electro-mechanical scanner design [scan mirror located in front of the collecting aperture, (whiskbroom principle)] that projects the entire spectrum of a resolved element onto two CCD arrays. The spectrometer provides a fixed grating system which measures the radiation wavelengths in three ranges. The optical system features a dichroic blade and beam splitters for wavelength selection. ISM has two 64 PbS detectors located in parallel rows, providing acquisitions with 128 contiguous spectral bands. The detection system is cooled by passive cryogenics. ISM provides internal calibration from an incandescent lamp.

Spectral coverage	0.80 - 1.6 μm (64 bands of 12.5 nm bandwidth) 1.6 - 3.2 μm (64 bands of 25 nm bandwidth)

P.109 Japanese Airborne Sensors in the TRMM/ADEOS-II Programs

P.109.1 AMR (Airborne Microwave Radiometer)

AMR is a NASDA-developed profiling instrument (to be completed in spring 1995) in the ADEOS-II/AMSR preparatory program with the following basic objectives:

- to confirm the AMSR (spaceborne sensor of ADEOS-II) design specifications with respect to selected frequencies and bandwidths
- to provide early data for the development of retrieval algorithms
- to calibrate and validate the AMSR data with underflight experiments (after ADEOS-II launch)
- to promote the scientific use of microwave radiometer data

Applications (same as AMSR of ADEOS-II mission): atmospheric water vapor, cloud and precipitation liquid water, sea surface temperature, sea ice concentration.

P.109.2 AMSS (Advanced MultiSpectral Scanner)

AMSS is a NASDA-developed instrument (to be completed in spring 1995) in the ADEOS-II/GLI preparatory program with the following basic objectives: ²⁴⁰¹⁾

- to confirm the GLI (spaceborne sensor of ADEOS-II) design specifications
- to provide early data for the development of retrieval algorithms
- to calibrate and validate the spaceborne GLI data with underflight experiments
- to use AMSS as a research tool for future instrument development

Configuration	Region	Bandwidth	Sampling rate	No. of Bands
Case 1	400 - 800 nm	10 nm	5 ns	80
	800 - 1000 nm	10 nm	10 ns	41

P.109.3 CAMPR (CRL Airborne Multiparameter Precipitation Radar)

The CAMPR instrument is part of the NASDA/EOC TRMM preparatory program; it is under development by CRL (Communications Research Laboratory, a division of the Ministry of Posts and Telecommunications of Japan) and will be completed in 1995 (including instrument test and integration). The objectives of CAMPR are to collect data, to test radar precipitation retrieval algorithms, to obtain ‘ground truth’ information in parallel (under-flights) to the spaceborne TRMM instrument (PR) for data product verification, and to employ CAMPR as a research tool for the development of future advanced spaceborne rain radar instruments. CAMPR will be flown and operated by CRL on a Super King Air B-200 (Beechcraft Co.) at altitudes between 5 - 8 km. Instrument algorithm development and data processing is a cooperative research activity by CRL and NASDA.²⁴⁰²⁾

Frequency	13.8 GHz (Ku-band)
Polarization	VV, VH, HH, HV (pulse-by-pulse switching)
Antenna Type Aperture Beamwidth Antenna scan	Two slotted waveguide array antennas 82 cm (along-track) x 36 cm (cross-track) 1.9° (along-track) x 4.5° (cross-track) $\pm 80^\circ$, electrical (motor) drive
Transmitter Type Peak power PRF Pulse width (τ)	TWTA (Traveling Wave Tube Amplifier) > 2 kW 2 kHz, 4 kHz, or 8 kHz 2 μ s, 1 μ s, or 0.5 μ s
Receiver Dynamic range Noise figure	> 70 dB < 8 dB
Data processing Operation modes Video sampling rate A/D conversion	Integration mode (total rec. power, mean Doppler velocity and variance) I/Q mode (I/Q signal recording) 1/ τ or 2/ τ 12 bit
Range resolution Cross-range resolution	75 m, 150 m, or 300 m (switchable) Depends on the range; typically 200 m

Table 733: CAMPR system parameters ²⁴⁰³⁾

Joint tests of CAMPR with JPL's ARMAR instrument are anticipated. The development and operation of CAMPR in parallel to ARMAR was considered necessary by NASDA for reasons of independent testing capabilities in Japan. CAMPR has some advantages over ARMAR: a) the wide scan angle provides better wind estimates, and b) CAMPR has two receivers, enabling the simultaneous reception of HH/HV or VV/VH signals. The CAMPR design adopted a non-pulse-compression system, which simplifies processing of the radar

²⁴⁰²⁾ Information provided by K. Imaoka of NASDA/EOC and by T. Kozu of CRL

²⁴⁰³⁾ Note: The I/Q mode is a high sample-rate recording mode in which “raw” (without any averaging) I-channel (in-phase) and Q-channel (quadratic phase) components are stored and from which the full Doppler spectrum will be derived

data. In addition, with its Doppler and polarimetric measurement capabilities, CAMPR can be operated on the ground as well, providing the opportunity of continuous rain observations.

P.110 LAC (Large Area Collector)

LAC is a NASA/JSC designed and developed instrument flown on NASA/Ames ER-2 aircraft in support of the JSC Cosmic Dust Program. The original objective was to collect extraterrestrial dust samples from the stratosphere; the goals have been broadened since then to encompass terrestrial and space debris particulates as well.²⁴⁰⁴⁾

Background: JSC began the Cosmic Dust Program in May 1981 with the aim of systematic collection and curation of cosmic dust for scientific investigation. Initial collections were made with instruments mounted underneath a wing using NASA WB-57F aircraft from JSC; the program was extended in 1988 to include Ames U-2 aircraft, and since 1989 ER-2 aircraft. A new generation collection system, namely LAC, was introduced along with the ER-2 aircraft dust collection program support. Catalogs of dust samples are kept at JSC. As of 1995 the program continues to fly both small collectors and LACs.

The dust collectors have surface areas of 300 cm² coated with silicone oil (dimethyl siloxane) and flown on ER-2 aircraft at high altitudes (20 km). The collectors are installed in a specially-constructed wing pylon, which ensures the required level of cleanliness during active sampling periods. LAC instrumentation is exposed in the stratosphere by barometric controls and then retracted into sealed storage containers prior to aircraft descent. In the laboratory at JSC, particles are individually removed from the collectors using glass-needle micromanipulators under a binocular stereo-microscope. All processing and storage of each particle is performed in a Class-100 clean room. Particles are cataloged with descriptions of size, shape, transparency, color, luster, type, etc. All samples collected are available to scientists worldwide.^{2405),2406)}

Sufficient quantities of extraterrestrial materials are collected to allow the chemical and mineralogical compositions of individual particles to be determined. Study of these materials, whose sources may be comets, dust of asteroid collisions or of planetary impacts, and meteorite ablation, provide valuable information about our solar system. Most collected particles have terrestrial origins - they are also available for study from NASA/JSC.

P.111 LARSEN (Airborne Scanning Lidar)

Larsen is a CCRS sensor (developed and built by Optech Inc., CCRS, and the Canadian Hydrographic Service) operational since 1985 for the survey of coastal areas. Larsen measures water depths up to 40 m in clear coastal water with an accuracy of 0.3 m. The system has a swath width of 270 m from an altitude of 500 m and generates a uniform sounding grid pattern, with the soundings spaced about 30 m apart and a position accuracy of about 15 m.

Operating principle: The system uses an optical radar (lidar) technique to measure water depth from an aircraft. A short pulse of infrared radiation and a short pulse of green radiation are simultaneously emitted from the laser toward the water surface. The infrared pulse is scattered from the water surface, while the green pulse penetrates the surface and is scattered from the bottom. Both scattered pulses are detected by a receiver in the aircraft, the elapsed time between the pulses is used to measure the water depth.

Larsen consists of the following major subsystems: transmitter, receiver, electronics, guidance system for positioning, a video camera/video disk system to provide along-track imagery, and a data logger for digital data storage.

The lidar uses a frequency-doubled Nd:YAG laser, operating simultaneously at 1064 and at 532 nm. The average repetition rate is 20 Hz. The laser output beam is directed towards the water by a scanning mirror which with the laser firing control allows a specific and uniform grid pattern to be generated on the water. The location of each laser sounding is determined using aircraft position, altitude and attitude information. Aircraft position is provided by a microwave ranging system, using ground-based transponders of known location, and by GPS. Aircraft height above water is measured by an infrared laser altimeter, and attitude data by an inertial reference system mounted on the sensor.

P.112 LASAL (Large Aperture Scanning Airborne Lidar)

LASAL²⁴⁰⁷⁾ is a NASA/GSFC instrument (PI: S. Palm) flown on P-3 aircraft and operational since 1991. The system is capable of scanning 45° left and right of nadir and also along-track from 45° ahead of nadir to 10° behind nadir (scanning occurs at rates of up to 100°/s). The two-axis scanning feature of LASAL enables a 3-D rendering of the atmospheric aerosol structure below the aircraft.

Measurement technique	Incoherent backscatter
Parameters or constituents measured	Aerosols, clouds
Measurement range	6 km to ground
Vertical resolution	15 m
Laser type and transmitter wavelength	Nd:YAG, 532 nm and 1064 nm
Pulse repetition frequency	50 Hz
Laser energy/pulse	210 mJ for 532 nm and 550 mJ for 1064 nm frequency
Airborne platform of instrument	P-3 aircraft
Receiver size and configuration	56 cm diameter Cassegrain telescope
Receiver FOV	1 mrad
Receiver bandwidth	1 nm (typical)
Detectors	PMT (Photomultiplier Tube for 532 nm) + APD (for 1064 nm)
Signal processing	Analog

Table 734: Specification of the LASAL instrument

P.113 LASE (Lidar Atmospheric Sensing Experiment)

A NASA-sponsored instrument ²⁴⁰⁸⁾ ²⁴⁰⁹⁾ developed at Langley Research Center (Hampton, VA) with the objective to measure water vapor (profiles and column content) and aerosol in the atmosphere with a fine vertical resolution in the altitude range from 0 to 20 km during daytime and nighttime surveys. LASE is based on the DIAL (Differential Absorption Lidar) technique, and uses a tunable Ti:sapphire laser transmitter. The instrument is regarded as the first step in a NASA effort to develop and demonstrate DIAL technology for future spaceborne experiments.

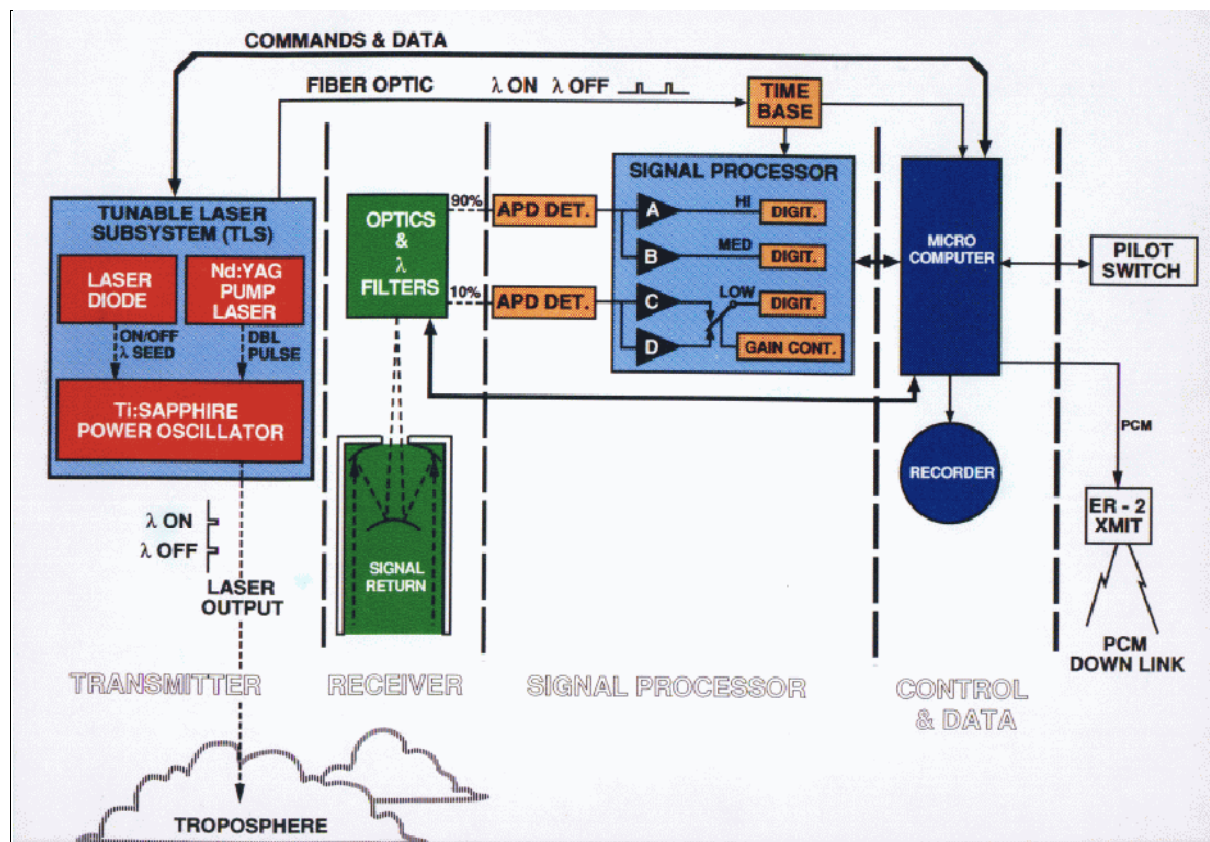

Figure 479: Block diagram of LASE

The tunable laser subsystem (TLS) output laser beam is generated by a Ti:sapphire laser pumped by a doubled Nd:YAG laser (generation of on and offline DIAL wavelengths). The wavelength of the Ti:sapphire laser is tunable from 813 - 818 nm and the spectral output is controlled by injection-seeded narrow band radiation from a semiconductor diode laser. The wavelength of the diode laser is locked to a water vapor line using a frequency modulation technique that uses a water vapor absorption cell. The on and offline laser pulses are

²⁴⁰⁸⁾ W. R. Vaughan, E. V. Browell, "A Lidar Instrument to measure H₂O and Aerosol Profiles from the NASA ER-2 Aircraft," paper presented at the Specialty Meeting on Airborne Radars and Lidars, Meteo-France, Toulouse, July 7-10, 1992

²⁴⁰⁹⁾ <http://asd-www.larc.nasa.gov/lase/ASDlase.html>

transmitted with 400 ns separation (5 Hz pulse repetition rate). LASE can be operated on two different water vapor (H₂O) lines during flight.

The receiver system consists of a 38 cm diameter Dall-Kirkham telescope. The FOV is adjustable remotely by an electronic field stop at the focal point of the telescope. A 300 pm FWHM bandpass filter is used in the aft optics to minimize background noise during day-time missions. To accommodate the in-flight selection of two different pre-selected H₂O absorption lines, the narrow-band filter can be tilted up to 10° for center-band shifts of approximately 2.5 nm (accuracy of tilt mechanism = $\pm 0.1^\circ$). - LASE development started in 1986; the instrument was upgraded during 1992-93 (Ti:sapphire laser, detector signal processor). It has flown on ER-2 aircraft since September 1994. Provision were made in 1999 to fly LASE also on NASA DC-8 and P-3 aircraft. ^{2410) 2411)}

Transmitter: (Ti:sapphire laser)	
Energy	≥ 150 mJ average
Line width	0.25 pm
Pulse repetition rate	5 Hz
Wavelength (tuning range)	813 - 818 nm
Beam divergence	0.60 mrad
Pulse width	50 ns
Receiver:	
Effective area	0.11 m ²
FOV	1.1 mrad
Filter bandwidth ($\Delta\lambda$ FWHM)	0.4 nm (day); 10 nm (night)
Optical transmittance (total)	29% (day); 49% (night)
Detector efficiency	80% APD (Silicon)
Noise equivalent power	2.5×10^{-14} W/ (Hz) ¹² (at 1.6 MHz)
Detectors	2 APD (Avalanche Photo Diodes)
Quantization	12 bit (digitization is phase-locked to lidar pulse)

- Tropics-B (PEM-Tropics-B) (Pacific Exploratory Mission), 1999

P.114 LEAF (Laser Environmental Airborne Fluorosensor)

LEAF²⁴¹²⁾ is a Canadian/US airborne sensor [supported since 1987 by: Canadian Panel on Energy Research, US Minerals Management Service, Fisheries and Oceans Canada, CCRS (Canada Centre for Remote Sensing), American Petroleum Institute, and the US Coast Guard; built by Barringer Research Ltd. of Rexdale, Ontario and BP] for the detection and mapping of oil spills on water, ice and shorelines, and of chlorophyll and other environmental variables in near surface waters. As of 1992 the LEAF system is installed aboard a twin engine Aero Commander aircraft and operated in test programs by Barringer Research Ltd. LEAF uses a XeCl Excimer laser, operating at a wavelength of 308 nm (UV range), measuring fluorescence at 64 colors (channels) between 322 nm and 665 nm.

Table 736: LEAF system specifications

The excitation wavelength of 308 nm seems to be well suited for the stimulation of fluorescence in oils. But laser fluorescence can also be applied to monitor other objects/targets in the field of oceanography and fishery, requiring other (longer) excitation wavelengths.

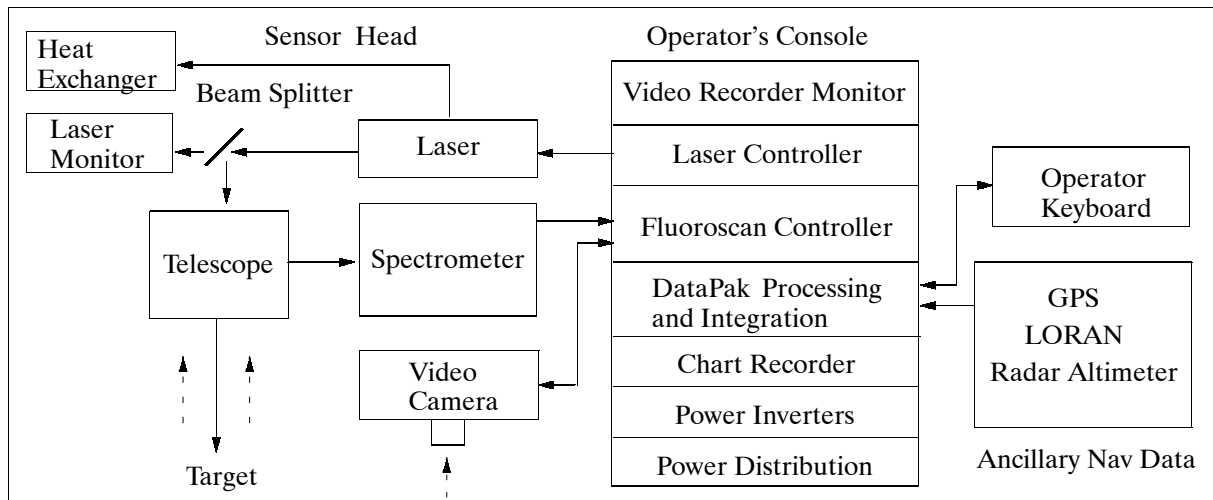

Figure 480: LEAF functional block diagram

P.115 LEANDRE

LEANDRE (Lidar Embarqué Aerosols Nuages Dynamique Rayonnement Environnement; or: Airborne Lidar for Dynamic Radiation Studies of the Environment in Particular of Aerosols and Clouds) is an airborne lidar of CNRS/CNES, France for the study of the lower atmosphere with emphasis on mesoscale boundary layers and free troposphere me-

teorology. Observation of the following atmospheric profile variables: aerosols, water vapor, pressure, temperature, and wind. The instrument can be used in a nadir or zenith pointing direction depending on mission requirements. LEANDRE also serves as a test tool for the ESA ATLID sensor. LEANDRE is flown on a Fokker F27 aircraft.

Lidar instrument	LEANDRE (CNES/CNRS, France), operational since 1990
Measurement technique	Incoherent backscatter
Laser, transmitter wavelength	Nd:YAG: 532 nm, and 1064 nm,
Detection channels	one at wavelength 1064 nm for polarized backscatter two at wavelength 532 nm for depolarized backscatter
Pulse repetition frequency	10 Hz
Laser energy/pulse	150 mJ at 532 nm; 250 mJ at 1064 nm;
Resolution	15 m vertical; 10 m horizontal
Lidar beam pointing configurations	Nadir pointing in two modes: fixed or scanning at $\pm 15^\circ$, or fixed zenith pointing
Telescope	30 cm diameter, Ritchey-Chrétien
A/D converter sampling frequency	10 MHz
Research objectives/applications	Clouds and boundary layer distributions. The depolarized channel (532 nm) is the most suitable for low cloud and PBL objectives.

Table 737: Specifications of the LEANDRE instrument

P.116 LFS (Laser Fluorosensor)

The LFS is an active sensor (of OLS heritage) with the objective to analyze the upper layers of the sea surface (in the nadir direction) from airborne altitudes in the 100 - 300 m range. In particular, the following applications are pursued:

- identification and classification of pollutants on the sea surface
- determination of the film thickness of oil spills (0.1 - 10 μm range) and estimation of the oil volume from a 2-D mapping of the spill
- detection of swimming chemicals and of substances drifting underneath the sea surface
- measurement of gelbstoff concentrations for hydrographic interpretation
- measurement of algae for biological productivity estimations

Operating parameters:		
Size (L x W x H)	1270 x 355 x 958 mm excimer laser; 961 x 460 x 944 mm detector unit	
Weight	317 kg	
Flight altitude	300 m (typical for daylight and for night flights)	
Aircraft ground speed	100-200 knots	
Electrical power	1.0 kVA (in standby), 3.4 kVA (operation, at 110 Hz pulse rate)	
Data interpretation	Real-time	
Lasers:		
Emission wavelength	XeCl excimer 308 nm	Dye (excimer laser pumped dye laser) 382 nm
Pulse energy	150 mJ	20 mJ
Pulse length	20 ns	15 ns
Beam divergence (IFOV)	5 mrad	3 mrad
Repetition rate	200 Hz max, 110 Hz average	20 Hz
Receiver Telescope		
Entrance aperture	Reflective, Schmidt-Cassegrain 20 cm (f/10)	
Scanner		
Full scan angle	Conical type 28° across-flight direction, 35° in-flight direction	
Scan frequency	≤ 20 Hz, selectable	
Swath width	150 m at 300 m flight altitude	
Pixel-to-pixel distance	10 m typical at 300 m flight altitude (200 Hz max laser rep. rate)	

Spectrograph	12 discrete channels, modular
Wavelengths (nm)	344 Raman scatter, $\lambda_{\text{las}} = 308 \text{ nm}$ 330/365/380 Raman baseline, oil and gelbstoff fluorescence 440 Raman scatter, $\lambda_{\text{las}} = 382 \text{ nm}$ 410/470 Raman baseline, oil and gelbstoff fluorescence 500/550/600/650 oil and gelbstoff fluorescence 685 chlorophyll fluorescence
Wavelength selection	Dichroic splitters, interference and blocking filters
Optical bandwidth	10 nm typical
Detectors	Head-on PMT, range gated
A/D conversion	12 channel gated integrator, 11 bit
Computers	All VME-bus, 68020 processor, 16 MHz
Sensor control	Selection of lasers & detectors, control of cycle, film thickness estimation
Classification	Identification of substances
Image processing	Central operator console; images of LFS ground pixel distribution, evaluation of multisensor imagery, data storage on streamer or optical disk

Table 738: Overview of LFS parameters

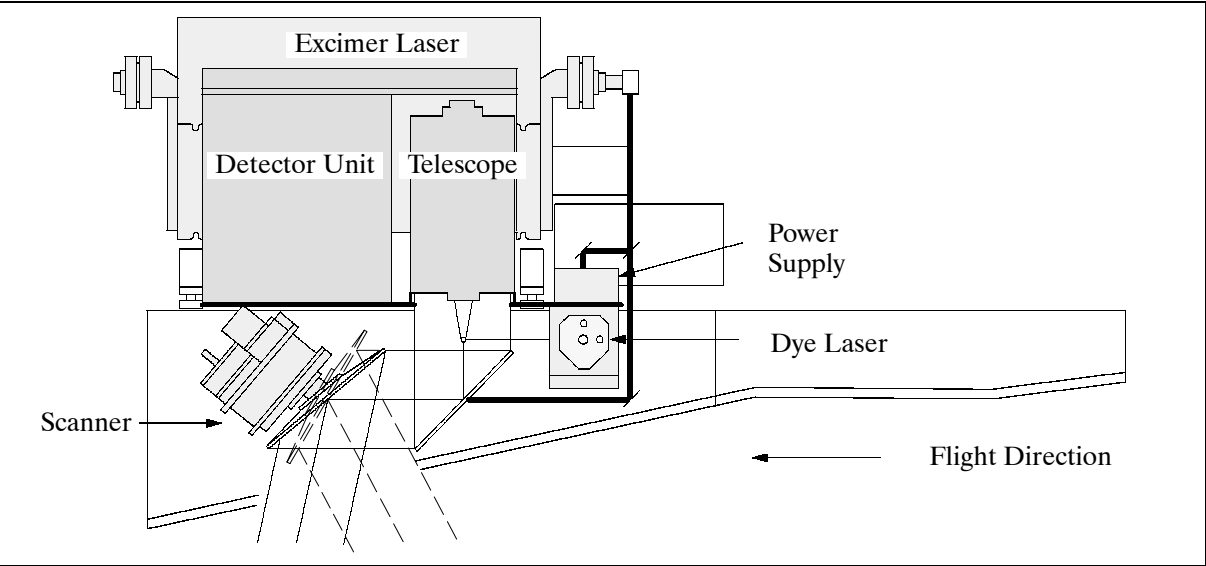

Figure 481: Schematic of the Laser Fluorosensor LFS

LFS was financed by the German Ministry of Research and Technology (BMFT); it was developed by the University of Oldenburg jointly with Krupp MaK, Kiel. The instrument is used for maritime surveillance by the German Ministry of Transportation (BMV), Bonn, as payload on the DO-228 surveillance aircraft of the Naval Air Wing 3 in Nordholz, Germany.

The LFS imaging instrument consists of a high power pulse laser and a telescope receiver and spectrograph for the detection of laser-induced fluorescence and scattering. The laser wavelength is chosen in the UV or blue/green portion of the spectrum where a penetration depth of a few meters into the water can be achieved. At these wavelengths, fluorescence of suspended and dissolved organic matter of natural origin can be detected, also chlorophyll contained in algae, and gelbstoff. In addition to gelbstoff and chlorophyll fluorescence, Raman scattering of water molecules is observed. ^{2413) 2414) 2415)}

As of 1994 a commercial version of LFS is being built by Optimare GmbH of Wilhelmshaven, Germany under a new sensor designation: IALFS²⁴¹⁶⁾ (Imaging Airborne Laser Fluorosensor System). The first system was ordered by the German Ministry of Transportation (BMV) and is being operated by the German Navy (Marinefliegergeschwader 3).

P.117 Leica RC30 (Aerial Camera System)

The Leica RC30 Aerial Camera System is the newest system in the long series of Wild aerial survey cameras of Leica AG, Heerbrugg, Switzerland (formerly named Wild Heerbrugg AG).

Camera Mount	Navigation Computer	Lens Cones
PAV30 gyro-stabilized mount	ACU30 with internal GPS	15/4 UAG-S Wide angle: 90°, f/4 AWAR: 123 Lp/mm
Stabilization range in: Pitch and roll: $\pm 5^\circ$ Drift: $\pm 30^\circ$	Internal silicon disk Up to 8 RS232 interfaces 2 monitors (pilot/navigator)	30/4 NAT-S Normal angle: 55°, f/4 AWAR: 107 Lp/mm
Typical residual angular motion: $< 0.3^\circ/\text{s}$	Leica 9212 GPS, L1, 12 channels DGPS, RTCM	8.8/4 SAGA-F Super wide angle: 120°, f/4
Typical residual deviation from vertical: $< 0.2^\circ$	Navigation accuracy: $< 100\text{ m}$ DGPS accuracy: $< 5\text{ m}$	Film cassettes: single lightweight daylight cassettes

Table 739: Some RC-30 camera parameter options

Background: The mechanical Wild RC camera series started in 1935 with the RC5, followed by the RC5a, RC7, RC8, and RC9, of which over one thousand cameras were sold worldwide. The new electronically controlled series started in 1968 with the Wild RC10 (several hundred were sold). The Wild RC10A was the first microprocessor-controlled aerial camera which was sold in the period 1981- 1986; the Wild RC20, which introduced Forward Motion Compensation (FMC), was sold between 1987 and 1992. Of these two models several hundred cameras were sold. The current model, Leica RC30, was introduced in 1993 together with two new high-resolution lens cones and a serial connection to external computer and sensor systems. A further enhancement is the PAV30 gyro-stabilized camera mount introduced in 1995. ²⁴¹⁷⁾

The RC30 camera system provides such features as:

- FMC (Forward Motion Compensation), the FMC counteracts forward image motion in a range from 1 mm/s to 64 mm/s.
- PAV30 with AMC (Angular Motion Compensation) is a camera mount with built-in gyros and sensors (Table 739). It also functions as a sensor of aircraft attitude angles which are recorded in ASCOT.
- S-Type lens cones with AWAR resolutions of 107 Lp/mm (30/4 NAT-S) and 123 Lp/mm (154 UAG-S). The continuously adjustable shutter speeds go from 1/100 s to 1/1000 s; the aperture is continuously adjustable between f/4 and f/22.
- PEM (Automatic real-time Exposure Control). The PEM sensor is optimized for aerial photography and covers the full range of film types (B/W, B/W-infrared, color-negative, and -positive, false-color-infrared).
- EDI (External Data Interface), standard interface between the camera and the ASCOT, as well as the link to other external devices like GPS receivers, aircraft navigation systems, or mission computers.
- Complete array of interchangeable filters for all exposure conditions, absorption of unwanted spectral ranges, optimizing light distribution in the image plane, correcting color balance of film emulsion.
- ASCOT (Aerial Survey Control Tool), a hardware and software system with an integrated 12-channel Leica GPS receiver to enable reliable survey flight navigation. The following additional functions are provided:
 - Interactive survey flight planning (pre-flight or in-flight)
 - Guidance for the pilot and the operator/navigator on the flight line and during turns, as well as autosearch for the nearest route
 - Automatic exposure release at predefined locations (pinpoint photography)

²⁴¹⁷⁾Information provided by P. Fricker of Leica AG, Heerbrugg, Switzerland

- Automatic in-flight data annotation on imagery (freely programmable)
- Interface to camera mount PAV30 for drift signals provided by external gyros or other sensors and recording residual angles of the gyro-stabilized mount
- Logging of GPS raw data and camera data for post-processing, mission evaluation and reporting
- Output to kinematic GPS post-processing software SKI-AERO
- SKI-AERO (Kinematic GPS post-processing software) to determine camera projection centers and to transfer data to aerotriangulation packages such as PATB/GPS-AERO, HATS, ALBANY or BLUH.

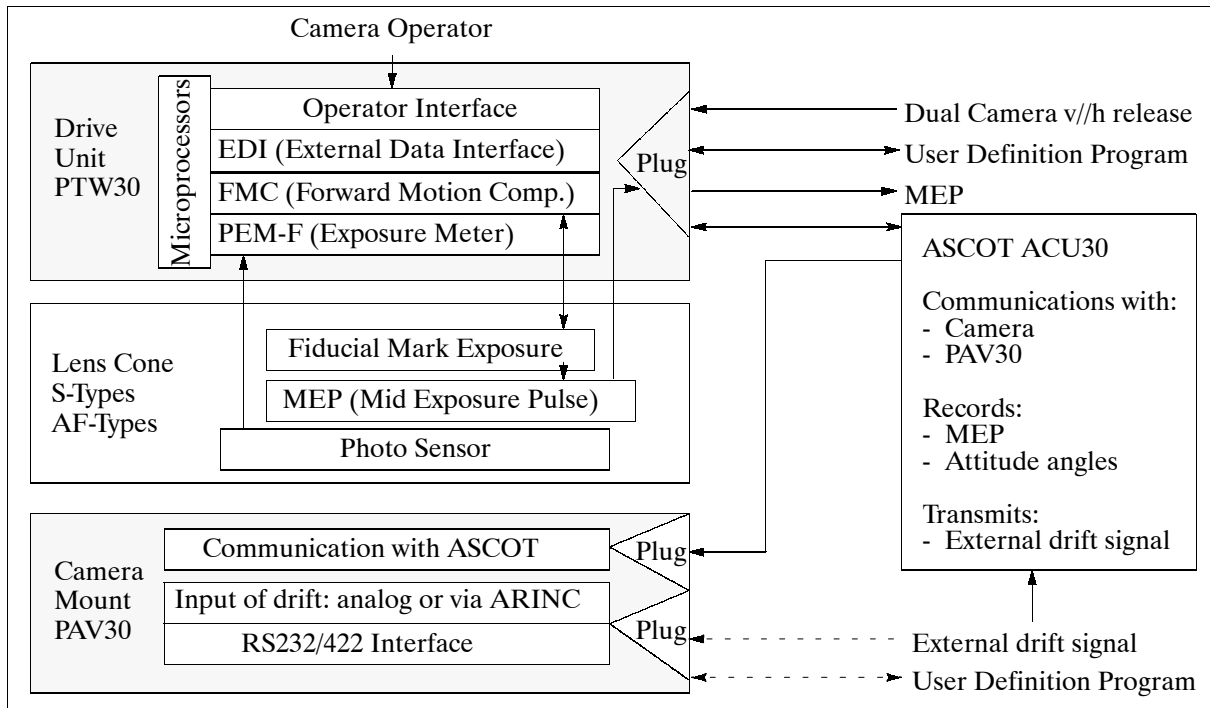

Figure 482: RC-30: Microprocessor control, external connections and communication

P.118 LIP (Lightning Instrument Package)

LIP is a MSFC sensor complement used to investigate relationships between lightning and storm electrification along with a number of underlying and interrelated phenomena - including structure, dynamics, and evolution of thunderstorms and thunderstorm systems, precipitation distribution and amounts, atmospheric chemistry processes, the global electric circuit, and ionospheric/magnetospheric coupling. In these investigations, emphasis is placed on developing algorithms that employ lightning data (and coordinating access to that data) that are observed by optical satellite sensors and that will be observed by future lightning detection satellite sensors such as OTD (Optical Transient Detector), LIS on TRMM (U.183) and the Optical System on FORTE (U.52).²⁴¹⁸

LIP has a heritage that goes back to 1980 and includes sensors to measure the optical and electrical waveforms associated with lightning and lightning spectra in the VIS and NIR ranges. There are upgraded LIP versions as of 1990 that are being flown on ER-2 and DC-8 aircraft in various campaigns (like TOGA/COARE in 1993, CAPE in 1992, StORM-FEST in 1992) along with a number of other sensors (e.g. infrared and microwave sensors) for the acquisition and analysis of multiparameter datasets. The LIP instrumentation can detect total storm lightning and differentiate between intra-cloud and cloud-to-ground dis-

²⁴¹⁸Information provided by R. J. Blakeslee of NASA/MSFC

charges. LIP is considered a technical input provider for satellite sensor development as well as a ground truth data collector for satellite instruments.

The program's objective is also to 'quantify' lightning relationships such as: occurrence and location of embedded convection, the strengths of updrafts and downdrafts, thermodynamic and electrical energy budgets, precipitation amounts and distribution, storm type, dimensions, life cycle, lightning rates, distribution, characteristics (i.e. number of strokes per flash, ratio of intra-cloud to cloud-to-ground lightning, discharge energy, etc.).

ER-2 LIP Instrumentation (since 1986)

LIP consists of two electric field mills, a conductivity probe, and a data system. One of the mills is installed on the upper Q-bay hatch cover, the second is mounted on the aft AMPR faring or on the lower E-bay hatch cover. The conductivity probe is integrated on the right-hand superpod nose cone.

The electric field mills measure the vertical component of the electric field (E_z) over a dynamic range exceeding three orders of magnitude (i.e. there are three gain channels x 1, x 46, and x 2116) for the measurement of fair weather electric fields, large storm systems (e.g. 10-20 kV/m), and the electric charge on the aircraft.

The conductivity probe provides a measure of the air conductivity at the aircraft altitude. Conductivity contributions due to positive and negative ions are measured simultaneously.

All data are recorded on board. The data products are: a) electric field components and aircraft self-charge (continuous record throughout the flight), resolution = 10 Hz; b) air conductivity (continuous record throughout the flight), resolution = 10 Hz.

DC-8 LIP Instrumentation

LIP consists of four electric field mills, a lightning location detector (i.e. a 3M stormscope), and a data system. The field mills measure the electric field vector components over a dynamic range from $E \leq 1$ V/m to over 106 V/m. Abrupt electric field changes are used to identify lightning discharges (flash type and characteristics, storm lightning activity, etc.). The 3M stormscope is a lightning magnetic direction finder that detects lightning atmospherics, obtains a bearing on the discharge, and estimates its distance (detection capability up to a radius of 200 nautical miles).

Absolute calibration of the field mills on the aircraft requires the addition of a "stinger" to the plane. This is a device that allows the aircraft to be charged to a high known voltage in order to more accurately determine the field mill response to electric fields, the geometric enhancement of the aircraft, and the aircraft charge.

P119 LVIS (Laser Vegetation Imaging Sensor)

LVIS is a scanning laser altimeter instrument designed and developed at NASA/GSFC. It is a prototype instrument with the objective to test and validate measurement concepts from aircraft platforms; it serves as the basis for the preparation of the VCL (Vegetation Canopy Lidar) mission with regard to instrument design, performance analysis and algorithm development. ^{2419) 2420)}

LVIS is a pulsed laser altimeter based on run-time range measurements. It operates at altitudes up to 10 km and has a potential FOV of 7° within which footprints can be randomly spaced in the cross-track direction. Scanning is performed using galvanometer-driven scan mirrors that control the pointing of the laser as well as of the telescope IFOV. Footprint

²⁴¹⁹⁾ J. B. Blair, D. L. Rabine, M. A. Hofton, "The Laser Vegetation Imaging Sensor : a medium-altitude, digitization-only, airborne laser altimeter for mapping vegetation and topography," ISPRS Journal of Photogrammetry & Remote Sensing, Vol. 54, 1999, pp. 115-122

²⁴²⁰⁾ <http://jbb.gsfc.nasa.gov/lvis/>

sizes of 1-80 m are possible (dependent on altitude and the focal length of the diverging lens of the output path). The optical system features a telescope with an aperture of 20 cm (5-power telescope with a 25 mm exit pupil, f/2 Petzval ²⁴²¹) objective with 400 mm focal length directing light through a 50 mm focal length f/1.8 eyepiece, which produces a 25 mm collimated beam). A scan mirror directs the beam through a 10 nm bandpass filter and onto a 25 mm molded aspherical condenser lens which focuses onto the 0.8 mm Si:APD detector. The transmitter is a water-cooled, solid-state, diode-pumped, Nd:YAG oscillator-only laser. - A real-time ground-finding algorithm searches a 2 km window that is automatically centered on a valid ground location from a previous shot. The search routine returns the location of the first signal detected searching from the back of the window; thus, ground returns are found before cloud returns eliminating the need for range gating. - The real-time data system performs such functions as waveform collection from the digitizer and instrument performance evaluation; it also controls scan mirror positioning and provides interfaces to GPS and INS (Inertial Navigation System). An LVIS data record contains the transmit waveform, receive-pulse waveform, range between waveforms, noise statistics, GPS time tag, INS attitude, and scan angle.

Parameter	Value	Parameter	Value
Telescope aperture	20 cm diameter	Laser output energy	5 mJ
Telescope TFOV	110 mrad	Laser pulse width	10 ns (FWHM)
Detector FOV	8 mrad	Laser spatial energy pattern	TEM00 (single mode)
Detector bandwidth	90 MHz	PRF	100 - 500 Hz
Bandpass filter bandwidth	10 nm	Laser output wavelength	1064 nm
Digitizer sampling rate	500 Msamples/s	Data rate (at 300 Hz PRF)	150 kByte/s
Digitizer bits	8 (7 effective)	Swath width	900 m (at 8 km alt)
Footprint diameter	1-80 m	Max operating altitude	> 10 km

Table 740: System characteristics of the LVIS instrument

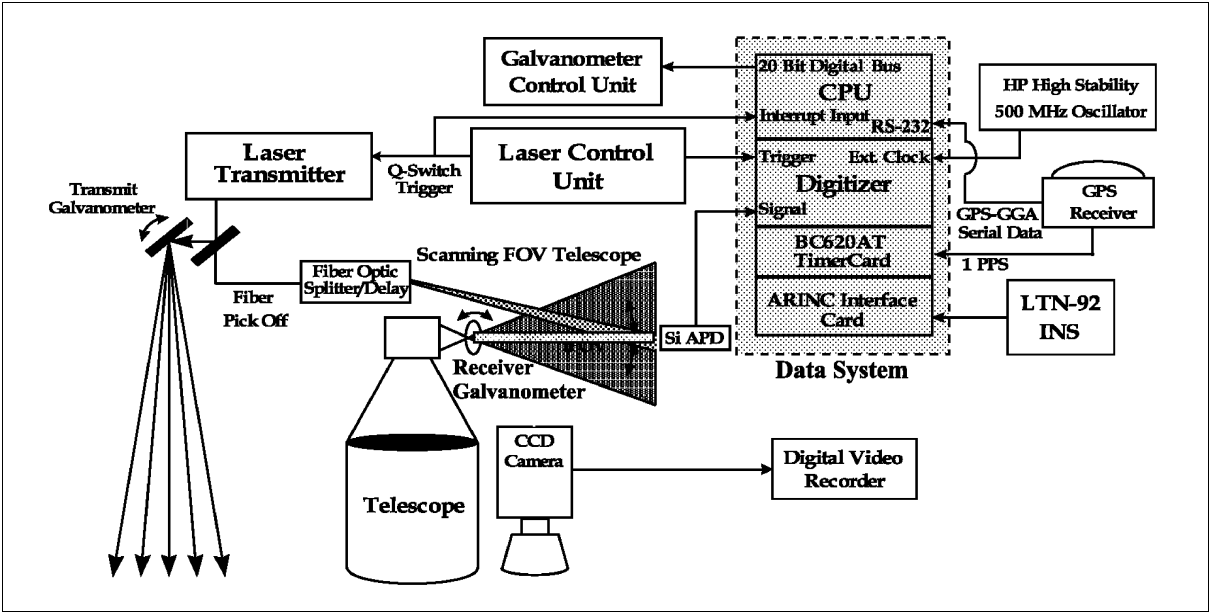

Figure 483: Block diagram of the LVIS instrument

The number of footprints and their across-track spacing is completely adjustable (controlled by the footprint diameter and the laser PRF). Forty footprints of 25 m diameter are

²⁴²¹) Note: The Petzval lens is a high speed, narrow FOV lens composed of two achromatic lenses positioned about an aperture stop. The lens is named after the Austrian mathematician/physicist Joseph Petzval (1807 - 1891) who provided the optical principles in 1840.. F. Voigtländer used the Petzval objective in 1840 to construct his first portrait lens.

needed for a contiguous swath coverage of 1 km. There can also be overlapping of footprints by doubling the PRF.

The LVIS instrument started its first test flight in October 1997. It is flown on two aircraft (T-39 Sabre-Liner and the C-130 Hercules) based at GSFC's WFF (Wallops Flight Facility). It has demonstrated its ability to determine surface topography (including sub-canopy) as well as vegetation height and structure. In March 1998, LVIS mapped the sub-canopy topography, the vegetation height and structure for 500 km² of dense tropical forest in Costa Rica.

P.120 MACAWS (Multi-Center Airborne Coherent Atmospheric Wind Sensor)

MACAWS is a scanning pulsed coherent Doppler lidar instrument designed and developed by NASA/MSFC (PI: J. Rothermel), NOAA/ETL, and NASA/JPL.^{2422) 2423)} First test and integration flights were conducted on the NASA/ARC DC-8 aircraft in the fall of 1995. The objectives of MACAWS are to provide a research tool for dynamic studies of the atmosphere, such as wind measurements of fine-scale phenomena, to provide ground truth for NSCAT (underflights of ADEOS), and to address concepts for prospective spaceborne lidars. MACAWS is also intended to participate in the CAMEX-III campaign program.

Measurement technique	Coherent backscatter
Parameters or constituents measured	Wind velocity and aerosol backscatter distribution (volume)
Measurement range	Up to 30 km (depends on meteorological conditions)
Range resolution (also referred to as: line-of-sight resolution)	300 m nominal (150 - 1200 m range), can be varied by altering the pulse duration
Vertical resolution	Varies with slant range
Radial velocity accuracy	< 0.5 m/s (radial velocities can be measured up to $\pm 30^\circ$)
Measurement times (typically)	8 hr flights (maximum)
Laser type and transmitter wavelength	CO ₂ laser, 9-11 μ m
Pulse repetition frequency	20 Hz (1-30 Hz range)
Laser energy/pulse	0.8 J (0.6 - 1.0 J range)
Airborne platform of instrument	DC-8
Receiver size and configuration	30 cm off-axis paraboloid
Receiver FOV	64°
Receiver bandwidth	± 75 m/s for 10.6 μ m wavelength
Detectors used	HgCdTe cryo-cooled
A/D converter	SAM-70 two channel, 14 MHz, 12 bit (complex video)
Research objectives/applications	Tropospheric and lower stratospheric dynamics, wind and aerosol 3-D structure, clouds, aerosol backscatter, satellite validation

Table 741: Specification of the MACAWS instrument

MACAWS consists of the following basic subsystems: a frequency-stable TEA (transverse-excited atmospheric-pressure) CO₂ laser transmitter producing 0.6-1.0 J in the spectral range of 9-11 μ m (nominally 10.6 μ m and 0.8 J) at PRF of 1-30 Hz (nominally 20 Hz); a coherent receiver employing a cryogenically-cooled HgCdTe IR detector; an off-axis parabolic telescope (0.3 m in diameter, shared by the transmitter and receiver in a monostatic configuration); a ruggedized optical table assembly to ensure stable operation; a scanner using two counter-rotating germanium wedges to refract the transmitted beam in the desired direction; a dedicated INS (Inertial Navigation System) to provide independent aircraft at-

2422) J. Rothermel, "The Multi-Center Airborne Coherent Atmospheric Wind Sensor (MACAWS)," The Earth Observer, Vol. 7, No. 4, July/August 1995, pp. 59-62

2423) <http://wwwghcc.msfc.nasa.gov/macaws.html>

titude and speed data (to compute real-time ground-relative wind velocities); data processing, display and storage devices; and an OCS (Operations Control System) to coordinate all subsystems.

During operation, the pulsed beam is transmitted through the scanner, which may be programmed to direct the beam anywhere within a 64° solid angle. The backscattered signals are detected by the instrument receiver, which processes the Doppler-shifted signal to measure radial wind velocity as a function of range. Wind velocity is then computed with respect to the Earth coordinates using the radial velocities, scanner settings and the INS measurements as input. On-board OCS processing permits the calculation of wind fields and horizontal wind profiles, depending on the scan pattern.

MACAWS has the capability to measure in real-time the 2-D wind field over a broad area. It employs a side scanning (or co-planar) technique, first demonstrated in 1981 the the MSFC airborne Doppler lidar system. In MACAWS, the lidar beam is directed through the forward left side of the aircraft. By alternately directing the beam about 20° forward and aft of the normal relative to the aircraft motion vector, 2-D wind velocities may be obtained at intersecting points within a scan plane. Scanner pointing is rapidly updated using the aircraft attitude information from INS to ensure that all the beams line up within a scan plane. Three-dimensional (3-D) coverage is achieved over a limited atmospheric volume by generating several scan planes (up to five). The OCS and scanner have the flexibility to control the number of scan planes and their angular spacing, depending on the measurement objective.

P.121 MAMS (Multispectral Atmospheric Mapping Sensor)

A NASA-sponsored instrument. MAMS is a modified Daedalus scanner flown aboard an ER-2 aircraft at ARC. Objective: study of weather-related phenomena including storm system structure, cloud-top temperatures, and upper atmosphere water vapor. The scanner retains eight silicon-detector channels in the VNIR region as provided on the Daedalus Thematic Mapper Simulator, with the addition of four channels in the SWIR and TIR regions relating to specific water vapor features.

Channel No.	Wavelength of Channel (μm)
1	LSBs for bands 9-12
2	0.45 - 0.52
3	0.52 - 0.60
4	0.57 - 0.67
5	0.60 - 0.73
6	0.65 - 0.83
7	0.72 - 0.99
8	0.83 - 1.05
9	3.55 - 3.93 low range
10	3.55 - 3.93 high range
11	10.3 - 12.1
12	12.5 - 12.8
Geometric Parameters	
FOV	86°
IFOV	5 mrad
Ground resolution	99 m (at 20 km altitude)
Swath width	37 km (at 20 km altitude)
Pixels/scan line	716
Scan rate	6.25 scans/s
Ground speed	200 m/s
Quantization	8-bit for bands 2-8, 10 bit for bands 9-12

Table 742: Spectral coverage and geometric parameters of the MAMS instrument ²⁴²⁴⁾

MAMS is one of several spectrometer arrays at ARC that mount on a standard Daedalus AADS1268 scanner system [along with TMS (NS001), AOCI, and MAS]. ARC has two

²⁴²⁴⁾ Note: the 3.55-3.93 μm channels can be operated at 6.20 - 6.90 μm as well. The LSBs refer to the Least Significant Bits, which give 10-bit resolution to channels 9-12 on an otherwise 8-bit system

basic scanner systems; the spectrometer sections are interchangeable. MAMS has been flown many times since 1985, as of 1993 the system is more and more being replaced by MAS.²⁴²⁵⁾

Note: MAMS data are not archived at the EROS Data Center since MAMS is an experimental system with low spatial resolution (there is little terrestrial application for the data as all scenes will be predominantly cloud-covered).

P.122 MARA (Multimode Airborne Radar Altimeter)

MARA²⁴²⁶⁾ is a beam-limited 36 GHz radar altimeter prototype designed, built and operated by NASA/GSFC. The system was developed in 1988 to support spaceborne multibeam altimetry investigations and to provide high-precision airborne measurements for ocean, land and ice topographies.^{2427), 2428)} Two distinct sensor configurations are available: the first is a fixed, multibeam altimeter mode; the second mode uses a Scanning Radar Altimeter (SRA), which rapidly scans a single beam across-track to achieve a 64 pixel raster-type scan. Both systems utilize large-aperture (dielectric lens) antennas to generate a small surface footprint which provides higher spatial resolution in comparison to a pulse-limited altimeter. For this reason a beam-limited altimeter is better suited for surfaces where topography varies. MARA has been operated on several aircraft since 1990, among them NASA and NOAA P-3s and a Fokker F-27. The maximum unpressurized operating altitude is 3 km.

Transmitter		Receiver(s)	
Center frequency	36 GHz (Ka-band)	Noise figure	6 dB DSB
Peak power	1.7 kW	IF frequency	600 MHz
PRF (Multibeam)	200 Hz maximum	Bandwidth	220 MHz
PRF (SRA)	10 cross-track scan/s 64 pulses/scan	Detector	Square law
Maximum duty cycle	0.01	Dynamic range	80 dB
Multibeam Mode Antenna		SRA Mode Antenna	
Lens aperture	85 cm diameter	Lens aperture	45.7 cm diameter
3 dB beamwidth	0.62° one-way	3 dB beamwidth	1.4° one-way
Gain	47 dB	Gain	41 dB
Feed configuration	5 separate feeds, pointing angles adjustable to any point within 15° from vertical	Feed configuration	Single horn feed, scanning pattern generated using reflector
		Scan swath	±22° from vertical, cross-track (64 separate angles)

Table 743: MARA system characteristics

Multibeam Mode: The nominal multibeam geometry consists of five separate beams, one pointed at nadir and the others pointed 12° off-vertical with azimuth directions 90° apart and centered on the along and cross-track axes. The surface footprint is 2.9 m for a 400 m altitude (slightly wider off-nadir). The high-resolution footprint and 6 ns transmit pulse translate to nominal rms deviations on MARA surface elevation measurements of ±6 cm at nadir and ±15 cm off-nadir (12° pointing angle). The multiple beam capability is exploited to provide surface slope information and study schemes for improved satellite altimeter range tracking over rough surfaces. A key feature of the system is the ability to digitize and store each return waveform. Return waveform characteristics are used to improve range-

²⁴²⁶⁾ Information provided by D. Vandemark of NASA/GSFC

²⁴²⁷⁾ C. L. Parsons, E. J. Walsh, "Off-nadir radar altimetry," IEEE Transactions on Geoscience and Remote Sensing, Vol. 27, 1989, pp. 215-224

²⁴²⁸⁾ C. L. Parsons, et al., "Topographic Mapping Using a Multibeam Radar Altimeter," IEEE Transactions on Geoscience and Remote Sensing, Vol. 32, No. 6, November 1994, pp. 1170-1178

to-surface tracking and to derive geophysical information related to surface and/or volume backscatter from the target. This mode was used on a recent ice sheet mapping mission over Greenland (1991). The data is being used to study continental ice sheet penetration at microwave frequencies.

Multibeam mode applications: topographic measurements, mm-wave surface/volume backscatter studies.

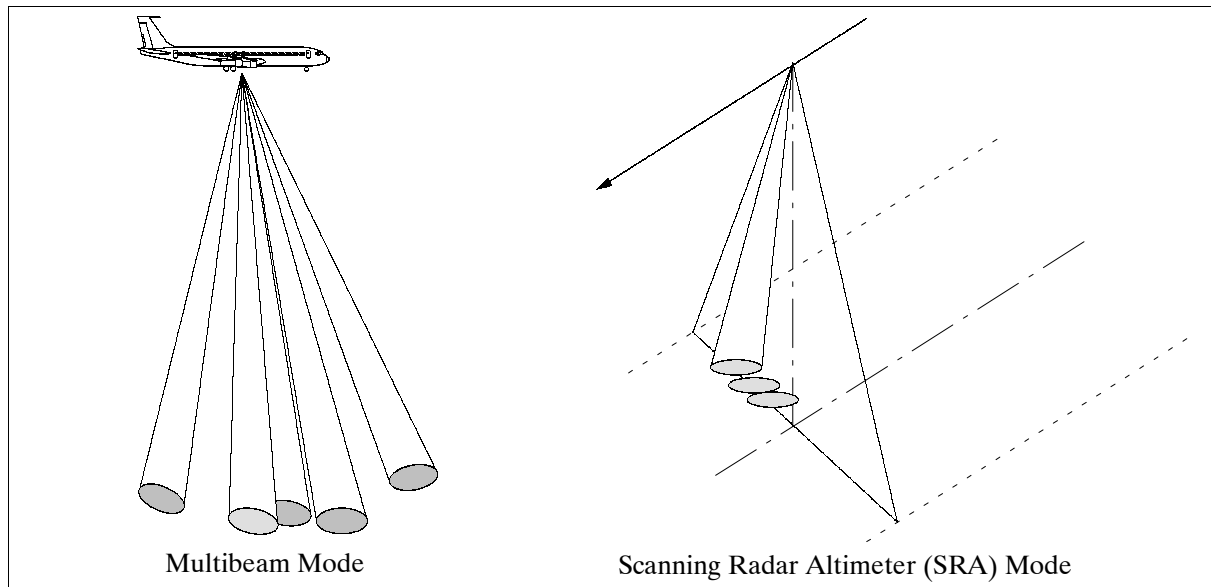

Figure 484: MARA observation configurations

Scanning Radar Altimeter Mode (SRA):

The SRA is a successor to the now-retired SCR (Surface Contour Radar), which was flown in numerous ocean remote sensing experiments.²⁴²⁹ SRA participated in the following campaigns: TOGA/COARE (1993), SWADE (1991), and Grand Banks ERS-1 SAR Wave Experiment (1991). It scans a pencil beam (1° two-way) perpendicular to the aircraft ground track and measures the range at 64 points evenly spaced across a swath whose width is 0.8 times the aircraft height. SRA corrects for the off-nadir geometry and generates a false-color-coded elevation map of the sea surface elevation below the aircraft in real-time. Post-flight data processing routinely produces ocean directional wave height-variance spectra that have shown the SRA's ability to produce high-quality topographic maps for terrain in remote regions.

SRA mode applications: topographic mapping, ocean directional wave spectra measurements, terrain and ocean backscatter studies.

The MARA transmitter subsystem consists of two main elements, frequency generation components in X-band and pulse-forming and amplification components at Ka-band. A crystal oscillator drives two phase-locked oscillators, one at 9.0 GHz and one at 8.85 GHz. The 9.0 GHz signal is multiplied up to 36 GHz, the transmitter frequency. The 8.85 GHz signal is multiplied up to 35.4 GHz to provide local oscillator (LO) for the receiver mixers.

P.123 MARSS (Microwave Airborne Radiometer Scanning System)

The MARSS passive radiometer operates at 89 and 157 GHz, close to the window channels of AMSU-B, which will fly on the NOAA POES satellite series K, L, and M. MARSS is a joint development of the Remote Sensing Instrumentation branch of UKMO, Farnbo-

²⁴²⁹E. J. Walsh, "Surface contour radar directional wave spectra measurements during LEWEX," Directional Ocean Wave Spectra, R. Beal (ed.), Johns Hopkins University Press, 1991, pp. 86-90

rough UK, and of LMD, Palaiseau, France and has been flown on the UKMO C-130 Hercules since 1990. The purpose of the instrument is to validate radiative transfer models at AMSU-B frequencies, specifically through clear air, liquid water and ice clouds, and precipitation, and to verify surface emissivity models, notably for ice and wind-roughened sea. The MARSS instrument has been flown in the SAAMEX, MASTEX, FATE, RENE, AS-TEX, TOGA/COARE, EUCREX and MACSI airborne campaigns.^{2430), 2431)}

The instrument comprises an external pod, mounted on an adapted window on the port side of the aircraft, and can view both upwards and downwards using a scanning mirror which detects radiation through a quasi-optic telescope into a receiver built by Marconi Space Systems. The polarization of radiation which may be detected is determined by the scan angle of the mirror and by aircraft attitude (measured by INS). The 157 GHz channel also has a polarization rotator which allows one of two orthogonal polarizations to be viewed.

Parameter	89 GHz	157 GHz
Radiometer type	total power	
Wavelength	3.3 mm	1.9 mm
IF bandwidth	1.3 - 3.8 GHz double side bands	
Temperature resolution	0.4 K	0.9 K
Integration time	80 ms	
Polarization	single polarization, function of scan angle	
Calibration system	internal calibration targets: one at ambient, one at 60°C	
Instrument mounting location	adapted port side window of C-130	
Beamwidth (FOV) @ 3 dB	10°	
Footprint at 1 km altitude (3dB)	175 m at nadir	
Antenna type	plane mirror with quasi-optic feed-through to 2 feedhorns	
Scan direction	along-track	
Scan mirror positions	±40° in 10° steps, up and down, 2 calibration views	
Scan period	3 s	

Table 744: Parameters of the MARSS instrument

P.124 MASP (Multiangle Aerosol Spectrometer Probe)

MASP²⁴³²⁾ is an in-situ instrument developed by NCAR (PI: D. Baumgardner) with NASA funding, measuring the size and distribution of aerosol particles from about 0.3 to 10 µm in diameter and the index of refraction for selected sizes.²⁴³³⁾ Size is determined by measuring the light intensity scattered by individual particles as they transit a laser beam. Light scattered from particles into a hemisphere from nominally 30-50° forward and 130-150° backwards is reflected by a mangin mirror through a condensing lens to the detectors. A comparison of the signals from the open aperture detector and the masked aperture detector is used to accept only those particles passing through the center of the laser beam. The index of refraction of individual particles can be estimated from the ratio of forward to backscatter signals. A calibration diode laser is pulsed periodically during flight to ensure proper operation of the electronics. The shrouded inlet minimizes angle of attack effects and maintains isokinetic flow through the sensing volume so that volatilization of particles is eliminated.

Figure 485: Schematic illustration of the optical component layout of MASP

MAASP was flown in the ASHORE/MAESA campaign (on ER-2) in 1994 and on the AES Convair-580 (Shuttle underflights) for LITE-1 data verification on STS-64 in September 1994. MASP is scheduled to fly also in the POLARIS, TOTE/VOTE, ACE-1, and CHORUS campaigns. The instrument offers the following design features:

- Isokinetic sampling
- Individual particle classification
- Forward/backscatter ratios
- In-flight validation
- 100 MHz response time

At the end of 1995 a second upgraded MASP instrument is being built at NCAR for the Institute of Atmospheric Physics at the University of Mainz, Germany (S. Borrmann). This instrument is scheduled to fly on a number of aircraft.

P.125 MASTER (MODIS/ASTER Airborne Simulator)

MASTER is a 50-channel imaging spectrometer developed by the NASA Ames Research Center in conjunction with the Jet Propulsion Laboratory. The MASTER instrument was developed to support the calibration and validation activities of MODIS (Moderate Resolution Imaging Spectroradiometer) and ASTER (Advanced Spaceborne Thermal Emission and Reflectance Radiometer) Science Teams. MODIS and ASTER are spaceborne instruments operating on Terra (launch Dec. 18, 1999).^{2434) 2435)}

The MASTER instrument consists of three major components: the scanning spectrometer, the digitizer, and the storage system. The scanning unit was built by Sensys Technology (formerly Daedalus Enterprises) and the digitizer was a collaborative effort between Berkeley

Table 746: Summary of the MASTER instrument characteristics

The MASTER instrument is similar to MAS (MODIS Airborne Simulator) developed by the MODIS project. However, it has 2 key differences: a) MASTER supports a variety of scan speeds allowing it to acquire contiguous imagery from multiple altitudes with differing pixel sizes (Table 746), and b) the channel positions are configured to more closely to match those of ASTER and MODIS. MASTER utilizes four detector arrays to acquire data in the spectral range from 0.4 to 13 μm with band widths ranging 0.04 to 0.5 μm .

The MASTER optical system is composed of a spectrometer mounted on a scanning fore-optic unit. Both the spectrometer and fore-optics portions are mated to an optical base plate. The fore-optics consist of a full-face rotating scan mirror, canted 45° to the flight direction, directing light into an afocal Gregorian telescope with a 15.2 cm paraboloid main mirror. A folding mirror then directs the energy through a field stop aperture, and onto a 2.5 cm paraboloid Pfund assembly, which forms a collimated beam with a 2.5 mrad equivalent field of view. This is then directed by a deviating mirror into the spectrometer unit through a hole in the base plate. The spectrometer is divided into four output sections or ports, each with its own detector array and associated optics. The input energy is wavelength-separated by a chain of dichroic beam splitters, and directed into each of the four output ports of the spectrometer [visible-near infrared (VNIR), shortwave infrared (SWIR), mid infrared (MIR) and thermal infrared (TIR)]. A diffraction grating is mounted at each output port, which spectrally disperses the energy through a lens and onto a linear detector array. The

bandpass of each individual channel is determined by the geometry of the detector array and its location with respect to the grating. Three of the four detector arrays (two InSb and one HgCdTe) are cryogenically cooled with liquid nitrogen; the silicon array for the VNIR channels is temperature-stabilized with a thermal-electric cooler. The HgCdTe array used with the TIR channels also has a cooled linear-variable filter mounted over it to reduce background noise. This grating-based design maximizes optical efficiency, while remaining radiometrically flat to within one percent across the total field of view, and is not spectrally dependant on viewing angle.

Table 747: Spectral characteristics of the MASTER channels

The analog electrical signals from each detector are passed through a series of low-noise preamplifiers on the scan head, and are then passed to a digitizer via shielded twisted-pair cables. The first-stage preamplifiers on the Port 2 and 3 detector arrays (SWIR and MWIR) are cryogenically cooled within the dewar assemblies, to minimize noise. Specially designed adaptive, 16 bit analog-to-digital (A/D) converters are used in the digitizer that actively tracks the DC level of the signal from the cooled detectors. This level, especially from HgCdTe arrays, typically drifts with time, and has been an historic source of calibration error in IR systems. The use of an actively adjusted, programmable preamplifier on the front end of the A/D converter allows this to be nullified, and the signal digitized very accurately, while preserving a full 16 bit dynamic range. Optical isolation was used, together with other noise reducing techniques, wherever possible in the system design. The digitized video signal is then merged with ancillary engineering and external navigation data, and is then stored on the hard disk.

P.126 MCR (Multispectral Cloud Radiometer)

MCR is a NASA/GSFC seven-channel scanning radiometer, operational since 1976, with the objective to measure cloud properties (optical thickness, infrared reflection of clouds,

cloud top heights, cloud top temperature, etc. The instrument has been flown on various missions and aircraft (among them CV-990, WB-57F, ER-2, etc.) at altitudes between 13 and 20 km.²⁴³⁶⁾

Channel Number	Center Wave-length (μm)	Resolution FWHM (μm)	Remarks, Principal Measurement
1	0.7539	0.0010	Clear air thickness
2	0.7605	0.0013	O ₂ A-band, altimetry, volume scattering coefficient
3	0.7635	0.0012	O ₂ A-band, altimetry, volume scattering coefficient
4	1.367	0.002	H ₂ O vapor, H ₂ O vapor amount
5	1.644	0.089	Clear, cloud phase, cloud/snow discriminator
6	2.164	0.094	Clear, cloud phase, particle size
7	10.84	0.81	Clear, temperature

Table 748: Spectral characteristics of MCR

MCR is a mechanical cross-track scanning radiometer employing 45° rotating mirrors. FOV = $\pm 42^\circ$, IFOV = 7 mrad. Nadir pointing. All channels are sampled simultaneously. The optical system of MCR is of nondispersive, filter-dichroic design (Dall-Kirkham telescope). The thermal channels are internally calibrated with two blackbody sources which are viewed in the upward part of the mirror scan. The visible and NIR channels are calibrated from integrating sphere measurements, made before and after each mission. Calibration accuracies are in the order of 5%.

As of 1993 MCR has been transferred to NCAR/ATD (Boulder, CO). An upgrade of the data system is planned. The sensor will be flown on a WB-57F aircraft.

P.127 MEIS (Multi-detector Electro-optical Imaging Sensor)

MEIS is a commercially available multispectral pushbroom scanner of MacDonald Dettwiler and Associates (MDA) in Richmond, BC, Canada.

MEIS was originally developed by MDA under contract to CCRS. MEIS I prototype development was in 1978, the MEIS II instrument has been in operation since 1983 by CCRS (more than 300 missions with MEIS II as of 1993). The data acquired by MEIS II are characterized by high radiometric sensitivity and high spatial resolution (> 0.5 m). Image data are acquired in narrow spectral bands. The integrated charges from each element of the array are sampled and digitized to produce a line image of the scene below. Aircraft motion provides scanning in the forward direction.^{2437) 2438) 2439)}

In addition to the nadir-mode of operation, the MEIS system is used to acquire continuous fore-aft stereo imagery by the addition of a precision stereo mirror module. In stereo mode, two of the eight channels look fore and aft at angles of $\pm 35^\circ$, while six channels look to nadir. The data may be combined with aircraft navigation and attitude data to provide digital terrain information and standard geometrically corrected products.

Applications: vegetation (crop and forest mapping), environmental monitoring (water quality and bathymetry), geology (exploration and mapping), topographic mapping, etc.

Scanner type	Pushbroom CCD scanner, 8 spectral channels
Spectral response	390 - 1100 nm spectral range
FOV (IFOV)	40° (0.7 mrad)
Detector type	Fairchild CCD 122 silicon, buried channel 1728 element linear array, 13 µm x 13 µm photo-elements
Lens type	Angenieux, type R2, format 35 mm; focal length = 24.61 mm; f/2.2-f/22
Line sample rates	25, 50, 100, 200 Hz (operator selectable to match aircraft velocity)
Gains	1, 2, 4, 8, 16, 32 (operator selectable)
Exposure times	5 ms per line sample rate, by powers of 2 (operator selectable)
Data format	1024 pixels recorded per channel and per scan line, 8 bit digitization, ancillary data recorded (sensor parameters, navigation parameters, etc.)
Signal/data processing	<ul style="list-style-type: none"> • correlated double sampling of CCD signal • real-time dark current subtraction • real-time relative gain correction (i.e. radiometric uniformity correction) • real-time image data resampling (provides pixel registration, geometric corrections for optical distortions, and roll correction) • storage in programmable memory of radiometric and geometric coefficients for ten sets of filters • real-time aircraft roll-correction • data rate: 1.75 Mbit/s per channel
Interfaces	Alice real-time display (quicklook capability). High-density digital tape recorder. Inertial navigation system

Table 749: Technical parameters of the MEIS II sensor

Owners/operators of MEIS instruments: CCRS/Innotech Aviation (Canada) aboard a Falcon-20C aircraft (owned by Innotech Aviation). MEIS II is the principal component of the electro-optical sensor package; the other imaging instruments on the Falcon aircraft are an AADS-1260 multispectral scanner from Daedalus, a 230 mm format mapping camera, and in the future, SFSI (see P.183).

Since 1983 the MEIS instrument has been flown on close to 60 remote sensing missions per year. A data acquisition service is also provided on a commercial basis. The Falcon 20-C aircraft can operate at maximum altitudes of 11 km at maximum speeds of 800 km/h. As of 1995 CCRS leased its MAIS-II instrument to Aquarius of Toronto.

P.128 MERES (Multifrequency Radiometer for Remote Sensing of the Sea Surface)

MERES^{2440),2441)} is an operational airborne multifrequency passive microwave radiometer developed by DLR/IRF (Institute of Radio Frequency Technology, Oberpfaffenhofen) with the prime objective to monitor maritime oil pollution (coastal waters of Germany) aboard a DO228 aircraft. The system consists of two offset rotating parabolic mirrors and two radiometer sets, each of which contains in turn three radiometers at the center frequencies of 18.7, 36.5, and 89 GHz. In addition, another 89 GHz radiometer is used to measure the average radiometric sky temperature (sky radiometer).

The system is continuously calibrated with the use of a “hot load” at ambient temperature and a Peltier-cooled ‘cold load.’ Computer systems control, configure and calibrate the instrument, record the data, and allow on-board data reduction and quicklooks for ‘amount of oil estimations’ on the sea surface. The system was tested and qualified between Nov. 1991 and 1993. It is in operation since the end of 1993.

many. The objective is the simultaneous measurement of atmospheric trace gas families (profiles) using the FTS (Fourier Transform Spectrometer) technique from ground sites, balloon platforms, aircraft, and satellites.

P.129.1 MIPAS-LM (Laboratory Model)

MIPAS-LM is the first MIPAS instrument (uncooled version), it was developed by Kayser-Threde of Munich, the Meteorological Institute of the University of Munich (MIM), and the IMK during the first half of the 1980s. During 1986-89 MIPAS-LM was further developed as a field instrument at FZK (operational since 1989). It has been used as a ground-based device for measuring column amounts of trace gases at various sites, also at polar stations, by detecting the attenuated solar radiation. Participation in the CHEOPS III campaign in 1990 and in EASOE (European Arctic Stratospheric Ozone Experiment). Measurement of the following trace gases: O₃, N₂O, CH₄, CF₂Cl₂, HNO₃, NO₂, ClONO₂, HCl, HF.

P.129.2 MIPAS-B (MIPAS Balloon)

A cooled instrument version of MIPAS on balloon-borne platforms (utilizing the limb-sounding technique), to observe vertical profiles of stratospheric species. The first two balloon campaigns took place in France in 1989 and 1990, two others took place in Kiruna, Sweden, in January and March 1992 (EASOE campaign). Limb emission spectra were measured within the altitude range between 5 and 40 km.

The following atmospheric trace gases were identified in the spectra: CO₂, O₃, H₂O, CH₄, N₂O, CCl₄, CF₂Cl₂, CFCl₃, CHF₂Cl, CF₄, ClONO₂, HNO₃, N₂O₅, C₂H₆, and SF₆. Vertical profiles of O₃, CH₄, N₂O, H₂O, CCl₄, CF₂Cl₂, CFCl₃, CHF₂Cl, CF₄, ClONO₂, HNO₃, and N₂O₅ have been derived.^{2447),2448)}

Overall mass of payload	390 kg
Scantime per interferogram	4.6 s
Angle of rotation of pendulum	5.0°
Optical path difference	13.2 cm
Unapodized spectral resolution	0.038 cm ⁻¹
Resolving power at 10 μm	approx. 25000
Reference wavelength (He-Ne)	632.8 nm
Beamsplitter	KCl with Sb ₂ S ₃ -Coating
Number of optical bandpasses	2
Channel 1	770 - 952 cm ⁻¹ (10.3 - 13 μm)
Channel 2	1184 - 1382 cm ⁻¹ (7.25 - 8.45 μm)
Detector type	2 x Si:Ga, 2 x 2 mm
Detector NEP (Noise Equivalent Power)	
Channel 1	4 x 10 ⁻¹³ W/(Hz) ^{1/2}
Channel 2	3 x 10 ⁻¹³ W/(Hz) ^{1/2}
FOV	15 arc minutes
Flight NESR (Noise Equivalent Spectral Radiance)	
Channel 1	2 x 10 ⁻⁸ W cm ⁻² sr ⁻¹ /cm ⁻¹
Channel 2	8 x 10 ⁻⁹ W cm ⁻² sr ⁻¹ /cm ⁻¹

2448) T. von Clarmann, et al., "Determination of the stratospheric organic chlorine budget in the spring arctic vortex from MIPAS-B limb emission spectra and air sampling experiments," Journal of Geophysical Research, Vol. 100, D7, July 20, 1995, pp. 13979-13997

Background: MIPAS-B was built at IMK (Karlsruhe) in cooperation with MIM (Munich) during 1986-89 (pointing system from DLR Oberpfaffenhofen, electronics package from Sensorlab GmbH of Munich). MIPAS-B experienced a crash landing and destruction in March 1992 in the EASOE campaign. A follow-up instrument (MIPAS-B2) has been built at IMK.

P.129.3 MIPAS-B2

The new redesigned instrument was built and integrated between September 1992 and the end of 1994.^{2449) 2450)} MIPAS-B2 was upgraded in several respects compared to its predecessor; it has a broadened spectral coverage to allow also NO₂ and NO species to be measured as well as reservoir species (HNO₃, N₂O₅, ClONO₂) and source gases (CH₄, N₂O, H₂O, CFC11, CFC12, CFC22, CCl₄, CF₄, C₂H₆, SF₆). The altitude resolution is 2-3 km. Secondly the pointing control capability and the attitude measurement of the instrument has been improved considerably. First balloon flights with MIPAS-B2 were carried out successfully on February 11 and March 21, 1995 within the framework of the SESAME campaign.

The MIPAS-B2 instrument consists of five primary modules, 1) the gondola, 2) the LOS (Line-of-Sight) stabilization system, 3) the cryogenic spectrometer, 4) the on-board electronics and telemetry/telecommand subsystem, and 5) the ground control equipment. The gondola has dimensions of 2 m x 1.8 m x 2 m with a mass of 530 kg. The LOS system is based on a miniaturized INS with embedded GPS receiver which provides the attitude and heading reference for the instrument frame with a data rate of 64 Hz (LOS accuracy of 1.5 arcmin, 3 σ). A CCD star camera provides an absolute reference frame for the LOS system.

The MIPAS-B2 spectrometer consists of a three-mirror off-axis telescope, a double-pendulum interferometer (a modified Michelson interferometer), and a four-channel infrared detector system (liquid helium cooled). The spectrometer assembly is embedded in an isolation box and cryogenically cooled to 200 K with solid CO₂. The telescope has two tasks: to adapt the incoming radiation to the interferometer for maximum throughput, and to suppress straylight, originating from the Earth. The double-pendulum interferometer provides two-sided interferograms with a maximal optical path difference of ± 15 cm, resulting in an apodized spectral resolution of 0.033 cm⁻¹. The four-channel detector system with Si:As BIB detectors allows the simultaneous measurement of the most important absorption bands of ozone-relevant molecules between 5.2-13.3 μ m. A full scan of the interferometer takes about 10 seconds. The analog data is sampled with the full clock rate of 47 kHz. After data conversion (16 bit quantization) each channel is numerically filtered, annotated with other information and transmitted to the ground (on-board data reduction) at a data rate of 250 kbit/s. An uplink connection of 1.2 kbit/s provides instrument commandability.

Spectral coverage [cm^{-1}]	NESR [$\text{W}/(\text{cm}^2 \text{ sr cm}^{-1})$]
Channel 1: 763 - 981 (10.2-13.2 μm)	2×10^{-8}
Channel 2: 1136 - 1351 (7.4-8.8 μm)	1×10^{-8}
Channel 3: 1576 - 1671 (6.0-6.36 μm)	6×10^{-9}
Channel 4: 1832 - 1904 (5.25-5.48 μm)	6×10^{-8}
Operating temperature	200 K
Entrance aperture (vertical diameter)	115 mm
FOV (vertical in the limb direction)	17 arcmin
Etendue	$2 \times 10^{-3} \text{ sr cm}^2$
Maximum optical path difference	15 cm
Unapodized spectral resolution	0.035 cm^{-1}
Detector type	Si:As-BIB (mounted in liquid He dewar)
Nominal scan speed	3 cm/s
Sampling frequency	47.4 kHz
Signal frequencies	2.3 - 5.7 kHz
Telemetry/command data rates	250 kbit/s downlink; 1.2 kbit/s uplink

Table 752: MIPAS-B2 instrument characteristics

P.129.4 MIPAS-FT (Flugzeug Transall)

MIPAS-FT^{2451), 2452)} is a cooled airborne instrument developed by Sensorlab and FZK/IMK in 1990-1. It is flown on C-160 Transall (German military) aircraft; started operation during the winter of 1991/92 in the EASOE campaign. Flight altitude: 6-8 km. There are about 15-20 flights per winter, mostly in the arctic region. Simultaneous measurements of: O_3 , HNO_3 , ClONO_2 , NO_2 , H_2O , CH_4 , N_2O , CF_2Cl_3 , CF_2CCl_2 , CHF_2Cl , and CCl_4 . MIPAS-FT is flown within the frame of the German ozone program along with other remote sensors (DOAS, OLEX) as well as with in-situ instruments (Aerosol Experiment and TRI-TIUM).²⁴⁵³⁾

Parameter	Value	Parameter	Value
Optical path difference	$\pm 13 \text{ cm}$	LOS stabilization	Online by roll angle data
Unapodized spec. resol.	0.038 cm^{-1}	LOS accuracy	0.1°
Scan time/interferogram	5.2 s	Blackbody, emissivity	Peltier cooled, > 0.97
Etendue	$2.7 \times 10^{-3} \text{ cm}^2 \text{ sr}$	Blackbody temperature	200 - 300 K
FOV	0.78°	Blackbody stability	$< 0.1 \text{ K}$
Aperture	45 mm	Entrance IR window	ZnSe, AR-coated
Optical efficiency	0.1	IR window reflectance	$< 3\%$
Beamsplitter	KCl, Ge-coating	Optics temperature	200 K
Detector, temperature	Si:Ga $2 \times 2 \text{ mm}^2$, 4 K	Cooling agent	Dry Ice
Bandpass channel 1	$760\text{-}1000 \text{ cm}^{-1}$	Instrument mass	520 kg
Bandpass channel 2	$1150\text{-}1315 \text{ cm}^{-1}$	Power	1.2 kW
Signal frequencies	3.8 - 6.6 kHz	Data rate	38 kbit/s

Table 753: MIPAS-FT instrument parameters

MIPAS-FT participated in SESAME (Second European Stratospheric Arctic and Midlatitude Experiment) in the winters 1993/94 and 1994/95 (total of 6-8 missions with about 200 flight hours). Data of MIPAS-FT are archived in the NILU (Norwegian Institute for Air Research) database at Lillestrom, Norway. They are available to the program experimenters prior to general use.

P.130 MIR (Millimeter-Wave Imaging Radiometer)

MIR²⁴⁵⁴, ²⁴⁵⁵) is a newly developed cross-track imager (passive radiometer) owned and operated by NASA/GSFC (built jointly by GSFC and Georgia Institute of Technology and first flown successfully in May 1992 on an ER-2 aircraft). The system measures radiation at the following frequencies: 89, 150, 183.3 ± 1 , 183.3 ± 3 , 183.3 ± 7 , and 220 GHz. Three additional channels at 325 ± 1 , 325 ± 3 , and 325 ± 8 GHz (near another strong water vapor line at 325 GHz) were installed in 1994. The beam width of MIR is 3.5° for all frequencies, the scan range is $\pm 45^\circ$. The system has a temperature sensitivity of 1 K or less and a calibration accuracy of ± 1 K in the brightness temperature range of 250-300 K. Below 100 K brightness temperature, the calibration accuracy is in the order of ± 2 K. The sensor is flown on NASA ER-2 aircraft at altitudes of 20 km. MIR became operational in May 1992; it took part in the TOGA/COARE mission in early 1993. MIR measures water vapor profiles, clouds and precipitation.

P.131 MIRACO₂LAS (Mid-IR Airborne CO₂ Laser Spectrometer)

A rapidly-tuned CO₂ laser is used as an active sensing device in the spectral range of 9.2 - 11.1 μm . The profiling instrument was developed and built by the CSIRO Division of Exploration and Mining, Sydney, NSW, Australia. The objective is to assess the capability of the mid-infrared region for mineral and geological exploration (spectral reflectance measurements). The research instrument is operated on a Fokker (F-27) aircraft by CSIRO (initial test flights in October 1989).

The CO₂ laser system is continuously excited by a 3 m long glow discharge into a Z-folded resonator, rapidly tuned by a rotating octagonal mirror and a diffraction grating. The laser tunes through approximately 90 - 100 discrete wavelengths, which are produced in bursts of 5-10 μs pulses, with peak output powers of about 100 W and spaced about 5-10 μs apart. The 1.6 ms bursts are repeated at 40 Hz, leading to an average power of about 1 W. The laser beam is used to illuminate a 2 m diameter footprint on the ground from an altitude of 500 m.

²⁴⁵⁴) Information provided by J. R. Wang of GSFC

²⁴⁵⁵) J. R. Wang, P. Racette, "Profiling of Atmospheric Water Vapor with MIR and SSM/T-2 Measurements," Proceedings IGARSS '95, Volume II, pp. 1398-1400

The intensity of the signal scattered upwards by the ground is sampled by a 0.3 m aperture (f/0.83) Cassegrain telescope feeding a 1 mm square HgCdTe detector. The laser system is designed to produce a contiguous line profile of ground reflectance spectra at an aircraft ground-speed of 80 m/s. A small fraction of the laser beam is sampled by a beamsplitter and attenuated by a stack of diffractive mesh attenuators before being sampled by a reference detector for calibration. ^{2456), 2457)}

Figure 488: Schematic illustration of the MIRACO₂LAS instrument

The system acquires ground-truth data using a monochromatic linear-CCD pushbroom imager looking down the path of the laser beam (nadir measurement), which simultaneously records one line for each laser burst. This provides a detailed link between ground information and the position of the laser footprint, with a cross-track FOV of about 30°, which corresponds to 270 m at an operating altitude of 500 m. In order to link the laser data with the larger-scale terrain, a wide-angle video color camera feeding a video color recorder (VCR) is used to provide an overview of the landscape. The laser and CCD data are recorded onto 60 MB streaming tapes, which store about 30 minutes of flight data. The complete MIRACO₂LAS assembly measures about 1 m x 1 m x 2.4 m; its mass is 400 kg. Four racks with an additional mass of 300 kg accommodate power supplies, vacuum and water recirculation pumps, real-time display and the data acquisition system.

P.132 MIRAS (Microwave Imaging Radiometer with Aperture Synthesis)

MIRAS is an ESA microwave imaging radiometer with two-dimensional aperture synthesis that has been developed by a consortium of European companies, institutes and universities [Matra Marconi Space (MMS) of Toulouse, France is the prime contractor; Daimler Aerospace (MBB), Ottobrunn, Germany; ORS GmbH, Vienna, Austria; CERFACS, LAT, and CESBIO (Toulouse, France); TUD of Lyngby, Denmark; UPC Barcelona, Spain]. The MIRAS airborne sensor is a breadboard L-band instrument with the objective to study and to assess the feasibility and performance capabilities of future spaceborne radiometers for the measurement of soil moisture and ocean salinity. The MIRAS instrument can be mounted on top of the rear ramp of a C-130 aircraft, permitting the antenna to be positioned for ground viewing at an elevation angle of 45°. The first flight campaign of MIRAS is planned for the end of 1995.

MIRAS is a passive instrument measuring the brightness temperature distribution of the Earth's surface within its field of view. The design is based on a 2-D aperture synthesis. An

²⁴⁵⁶⁾L. B. Whitbourn, P. Hausknecht, et al., "Airborne CO₂ Laser Remote Sensing System," Proceedings of the 1st International Airborne Remote Sensing Conference and Exhibition, September 12-15, 1994, Strasbourg, France, Volume II, pp. 94-103

²⁴⁵⁷⁾L. B. Whitbourn, "100 Wavelength Rapid-Tuned CO₂ Laser System Applied to Airborne Remote Sensing of Minerals," Proceedings of the International Conference on Lasers 91, San Diego, CA, 1991, pp. 340-347

interferometric Fourier synthesis is applied to derive images from a number of antenna elements operating in the microwave region - the MIRAS concept is very similar to that of ESTAR. The breadboard instrument consists of 11 radiating elements operating on a single polarization, but having dual polarization capabilities. The radiators are arranged in a Y-shape antenna configuration providing star-type coverage in the plane of spatial frequencies used for the aperture synthesis process (note: ‘radiator’ refers to each interferometric antenna element). Every radiator comes in parallel with an L-band receiver which amplifies and transposes the incoming signals to baseband. The local oscillators of the receivers are phase-locked on a common reference to provide coherent operation (measurement of amplitude and phase, instrument delays \ll correlation times). In addition, a dedicated receiver is used for the measurement of the total scene brightness temperature. Each receiver provides two outputs, the in-phase and quadrature signals, to a correlator unit, which performs the analog-to-digital conversion, the 1-bit correlations of all possible signal pairs and the total power measurement of the scene. ^{2458), 2459) 2460)}

Parameter	Value	Parameter	Value
Frequency (L-band)	1.40 -1.427 GHz	FOV (Field of View)	$\pm 30^\circ$ about boresight
Wavelength	λ about 22cm		
Angular resolution	15°	Incidence angle	45° at boresight
Polarization	V-H switched	Radiometric accuracy	3 K
Integration time	2.6 s (at height = 1 km)	Radiometric sensitivity	0.6 K (at swath edge)

Table 754: Performance parameters of the airborne MIRAS instrument

The antenna is pointed into the backward direction of the flight path. The received signal is sampled at 50 Hz (double the bandwidth of 27 MHz minus 2 MHz guard spacing). The spatial resolution is obtained by interferometry (an interferometer can distinguish between directions around nominal boresight with a resolution given by the distance between the furthest pair of antenna elements). Every antenna element sees the same IFOV(=FOV), corresponding to the antenna reception pattern (0.89 wavelength diameter). The 3 dB beamwidth is about 60° . The resulting image has 5 pixels in the across-track and 4 rows in the along-track direction. There are three types of integration times in MIRAS: the correlation time is 300 ms (time used to perform interferometry), the pixel integration time is 2.6 s (time needed to traverse a pixel due to receiver motion), and the image integration time is 5.2 s (pixel time times the number of looks; there are two looks per polarization). The antenna elements have two perpendicular polarizations, each one is measured during 300 ms then a switch is made to the other one. The radius of the antenna arms is about 70 cm. The data rate of MIRAS is about 10 kbit/s.

For internal calibration, both correlated and uncorrelated noise signals are injected into the receiving chains of all receivers. External instrument calibration (in data processing) employs image data of known reference targets as well as phase restoration techniques.

A spaceborne version of MIRAS is in the study phase with the same basic design concept as that of the airborne version (with regard to frequencies, polarization, antenna shape, etc.), but featuring a total of 134 L-band radiator/receiver elements, an optical harness for signal distribution and a correlator unit with about 18000 1-bit digital correlators. Spatial resolution=20-60 km (22 pixels across-track, 15 rows along-track); incidence angle= $45\text{--}55^\circ$; integration time=1s; number of looks per polarization=7; swath width=880 km; revisit time < 3days; radiometric accuracy < 3K; radiometric resolution < 1K; data rate < 300 kbit/s; total antenna mass=120 kg; total instrument mass=230kg; antenna radius=8.3 m.

P.133 MIROR (Michelson Interferometer with Rotating Retroreflector)

MIROR²⁴⁶¹) is an FTIR spectrometer designed and built at the Institute of Optoelectronics of DLR in Oberpfaffenhofen. The instrument is part of an 'air traffic and environment project' funded by BMFT, the German Ministry of Research and Technology. The objective is to perform in-flight measurements of jet engine exhaust gases. Of special interest are the concentrations and emission indices of NO, NO₂, CO, and SO₂ species at aircraft cruise altitudes. The results of these measurements are intended to be used in atmospheric radiation and propagation models. First test flights with MIROR on board the DLR research aircraft ATTAS (VFW 614) were in December 1994 and June 1995.

The MIROR design is based on the results of computer simulations (optical and radiometric parameters) and differs somewhat from a classical Michelson interferometer design (see Table 756). The MIROR interferometer features a rotating retroreflector (a corner cube mirror) which reflects the incoming beam of radiation. The beams enter the reflector under an angle of incidence (α) which is different from zero with respect to the aperture plane. The angle of incidence (α) and the eccentricity of the retroreflector (e) provide the optical path difference between the two interferometer arms. The radiation leaving the corner cube mirror is reflected and passes the device a second time, thus doubling the optical path difference. - The continuous rotation of the balanced beam reflector allows for fast acquisition of interferograms. Idle times between consecutive measurements are very short, as no change in direction of the mirror is needed. The maximum measurement rate is determined by the acquisition electronics.

In the measurement setup the MIROR instrument is positioned in the cabin of the research aircraft (VFW 614). The foreoptics telescope looks into the jet exhaust through an IR-transmitting germanium window; the remotely-sensed gases are detected and analyzed by MIROR. - Three blackbodies (temperature-controlled references) are taken along with the MIROR instrument for in-flight radiometric calibration.

Table 755: Opto-mechanical and operational parameters of MIROR

Figure 490: Schematic MIROR interferometer illustration

Additionally, aircraft and flight parameters (i.e., altitude, speed, fuel flow, exit gas temperature, air temperature, etc.) are recorded during the flight campaigns. From these data and the calculated gas concentrations the emission indices can be determined.

Results of the first campaigns demonstrate the performance of the instrument. The species CO₂, H₂O, NO, and CO were detected and evaluated quantitatively. Additionally, the temperature of the jet was determined with an uncertainty of only a few degrees K.

Operating the MIROR FTS instrument on board the VFW 614 aircraft is considered only the first step of a measurement demonstration. Further projects are planned to install the FTS in a more relevant commercial aircraft environment, such as in an Airbus 340.

Function/Feature	Classical Michelson Design	MIROR Design

Table 756: Comparison of interferometer features

P.134 MISI (Modular Imaging Spectrometer Instrument)

MISI is a hyperspectral imager of the Rochester Institute of Technology (RIT of Rochester, NY). The objective is to develop a configurable state-of-the-art research tool/platform with high spatial resolutions and good radiometric fidelity for the following operational applications: ²⁴⁶²⁾ ²⁴⁶³⁾

- airborne laboratory for Earth observation research
- underflight system for high-altitude aircraft and spaceborne sensor performance evaluation
- versatile data collection platform for acquiring imagery to be used for algorithm development and evaluation of reconnaissance and environmental applications
- survey instrument for demonstration and proof-of-concept studies of image analysis methods in areas such as energy conservation, water quality assessment, and hazardous waste site management. ²⁴⁶⁴⁾

MISI is an airborne line scanner with 70 channels in VNIR and 5 LWIR channels. MISI features a line scanner design collecting 2 lines per scan for high resolution channels and one line per scan for the remaining channels (the high-resolution channels are: VNIR-1, MW-1, and LW). The 6-inch (15 cm) clear aperture mirror spins at up to 82 revolutions per second and folds the image onto a second fold mirror which reflects the image into the Dall-Kirkham (Cassegrain-type) telescope. The converging image is split onto four slightly off-axis ($< 2^\circ$) focal planes by a four-sided pyramid mirror. The on-axis rays pass through a hole in the center of the pyramid mirror and are used to sample the VNIR region. - The modular nature of the focal planes allows instrument upgrades (addition of new focal planes or modification of an existing one). The scanner's total field of view (FOV) = $\pm 45^\circ$ with calibration standards viewed every rotation.

The instrument will be flown on a twin-engine aircraft with camera holes of 44 cm diameter. Flight altitudes will range from 0.3 to 3 km.

²⁴⁶³⁾ J. R. Schott, X. Feng, T. W. Gallagher, "Modular Imaging Spectrometer Instrument," presented at the 4th Annual 1994 IEEE Mohawk Valley Section Dual-Use Technologies and Applications Conference, Rome, NY, May 23, 1994

²⁴⁶⁴⁾ No. of Detectors (column 7 in Table 757): When the number of detectors is 1 or 2, it refers to the number of lines collected per rotation of the scan mirror. The 38 detectors refer to the number of elements in each of the linear array spectrometers. However, only 30 of the 38 elements are actually distinct spectral channels. The extra 8 channels are used for cross-calibration between the two array spectrometers, i.e. there is significant spectral overlap.

P.135 MITE (Megapixel Imaging Technology Camera System)

An electro-optical imaging camera of Eastman Kodak Company, Rochester, NY. MITE offers an all-digital design based on interline CCD detector technology with features like: electronic shuttering, continuous video or single-frame imagery, and microlens overlay on

the sensor for an increased fill factor. All key components are commercial, off-the-shelf products such as camera heads, focal planes, intensifiers, electronically tunable bandpass filters, etc. MITE is commercially available for applications such as reconnaissance and mapping from a variety of airborne platforms. A panchromatic and multispectral version of the MITE system is provided. The multispectral version is tunable between 0.4-0.7 μm and 0.7-1.1 μm . MITE is available in spring 1996.²⁴⁶⁵⁾

Spectral region	400 - 950 nm
Video frame rate (sampling frequency)	15 or 30 frames per second
Quantization	10 bit
CCD detector array size	1024 x 1024 (detector size: 9 μm x 9 μm)
Shutter speeds	130 μs to 0.033 ms (electronic control)
Focal length (f)	f = 28 mm to 1000 mm (variable)
FOV	0.3 rad (for f=28 mm)
IFOV	32 mrad (for f=28 mm)
Instrument mass	45 kg
Data rate	40 MHz at 30 frames/s
Data recording	Hard disk array
Typical flight altitudes (AGL) for camera	1-3 km

Table 758: Parameters of the MITE system

P.136 MkIV (Mark-IV Interferometer)

MkIV²⁴⁶⁶⁾ is a NASA-sponsored FTIR (Fourier Transform Infrared) spectrometer developed and built by JPL for remotely monitoring the composition of the atmosphere. It makes observations from ground-based, airborne and balloon platforms using the solar absorption technique. The instrument derives from the ATMOS sensor, which flew on Shuttle missions in 1985, 1991, and 1992. The main improvement incorporated into the MkIV is the use of two detectors in parallel to cover the entire 600 - 5500 cm^{-1} region simultaneously. Over 30 different atmospheric gases can be measured including: H_2O , CO_2 , O_3 , N_2O , CO , CH_4 , N_2 , O_2 , NH_3 , NO , NO_2 , HNO_3 , HNO_4 , N_2O_5 , ClNO_3 , HOCl , HCl , HF , SF_6 , COF_2 , CF_4 , CH_3Cl , CHF_2Cl , CFCl_3 , CF_2Cl_2 , CCl_4 , OCS , SO_2 , HCN , C_2H_2 , C_2H_6 , and many isotopic variants.

The main components of the MkIV are: an active 2-axis suntracker which feeds direct solar radiation to the beamsplitter; a double-passed Michelson interferometer employing cube-corner retro-reflectors (one moving and one stationary); a leadscrew and drive motor for translating the moving retro-reflector, InSb and HgCdTe detectors, preamplifiers, filters and analogue-to-digital converters (ADCs); a single-frequency He:Ne laser and detection system to trigger the sampling of the infrared signals chains; and a computer to record the digital data and Fourier transform it.

P.137 MMS (Meteorological Measurement System)

MMS²⁴⁶⁷) is a NASA/ARC-developed instrument for ER-2 aircraft. The objective is to collect in-situ meteorological data at high altitudes with high resolutions and accuracies. MMS has been operational since 1986 and has been modified in 1992-93.

The instrument consists of the following major components:

- An air motion sensing system to measure the velocity of the air with respect to the aircraft.
- A high-resolution inertial navigation system to measure the velocity of the aircraft with respect to the Earth.
- A data acquisition system to sample, process and record the measured quantities.

The instrumentation for the air motion system is located in the ER-2 nose and lower fuselage, the inertial navigation system and data acquisition systems are located in the aircraft equipment bay. MMS took part (or will take part) in the following campaigns:

- STEP (Stratosphere Troposphere Exchange Project), 1987
- AAOE (Airborne Antarctic Ozone Experiment), 1987
- AASE (Airborne Arctic Stratospheric Expedition), 1989
- AASE-II (Airborne Arctic Stratospheric Expedition), 1991-92
- SPADE (Stratospheric Photochemistry, Aerosol, and Dynamics Experiment), 1992-93
- MAESA (Measurement for Assessing the Effects of Stratospheric Aircraft), 1994
- ASHOE (Airborne Southern Hemisphere Ozone Experiment), 1994

Performance: MMS provides in-situ measurements of pressure (p), temperature (T), potential temperature (Θ), wind vector (u,v,w), position (altitude, longitude, latitude), pitch (θ), roll (φ), heading (ψ), angle of attack (α), angle of sideslip (β), true airspeed, aircraft eastward velocity (\dot{x}), northward velocity (\dot{y}), vertical acceleration (\dot{z}), and time (t) at a sample rate of 5 times per second. MMS data products are presented in the form of either 1-Hz or 5 Hz time series. The accuracies of the primary products are:

²⁴⁶⁷) Information provided by K. R. Chan of NASA/ARC, Moffett Field, CA

Typical value at 65000 ft		Accuracy
Pressure	60 mb	± 0.3 mb or 0.5%
Temperature	180 K	± 0.3 K or 0.2%
Horizontal wind	25 m/s	± 1 m/s or 4.0%
Vertical wind	< 1 m/s	Resolution: 0.1 m/s

Table 761: Accuracies of primary MMS data products

P.138 MMW-SAR (Millimeter Wave SAR)

The MMW-SAR [also known as the ADTS (Advanced Detection Technology Sensor) radar] is an ARPA-funded instrument, specified at the MIT Lincoln Laboratory (MIT/LL). The original radar system was designed and built by Loral Defense Systems (Phoenix, AZ) and delivered to MIT/LL in 1988. The system has been maintained by MIT/LL since 1988, and new upgraded subsystems have been incorporated. The sensor is flown at altitudes from 150 m to 5200 m AGL, depending on the mode and depression angle selected for the mission. Typically, SAR data is collected at depression angles of 20° and 45° , at altitudes of 2600 m and 5200 m, respectively. Some selected data sets are available to researchers upon written approval of ARPA.²⁴⁶⁸⁾

Frequency	33.56 GHz (Ka-band), 9.6 GHz (X-band), 15.6 GHz (Ku-band)
RF bandwidth	600 MHz
Waveform	Linear FM (deramp on receive)
Transmit polarization	V then H, or L then R
Receive polarization	V and H, or L and R
Transmitter power	84 W peak (Ka-band), 1.7 kW peak (X-band, Ku-band)
Receiver noise figure	6.8 dB
Gimbal order	Azimuth roll-elevation-scan
Antenna beamwidth	1.4° (Ka-band), 4° (X-band, Ku-band)
Antenna peak sidelobe	-27 dB
Polarization isolation	30 dB
Platform	Grumman Gulfstream G-1 aircraft
Recording media	28-channel high-density tape, digital disk
Operational modes	SAR stripmap, SAR spotlight, RAR track, RAR search, calibration
Spatial resolution	0.3 m in range and in cross-range (SAR mode) 0.3 m in range direction (RAR mode)

Table 762: MMW-SAR system parameters

The system consists of an airborne radar that operates at 33.56 GHz (Ka-band), plus a ground processing and archiving system at Lincoln Laboratory. This radar system supports the following objectives: a) investigate the detection and classification of stationary targets using ultra-high resolution data provided by the fully polarimetric SAR mode and Real Aperture Radar (RAR) mode capability, and, b) advance the understanding of millimeter-wave imaging technology. The MMW-SAR is regarded a research tool and is designed to collect large data sets of distributed clutter, target signatures, and targets in clutter.

MMW-SAR has four operational modes:

- 1) SAR stripmap mode: In SAR stripmap mode the antenna is pointed to either side, perpendicular to the aircraft velocity vector. This mode is used to collect long strips of data at a given depression angle. The strips have a cross-range extent of about 400 m. Strip lengths can be chosen from lengths of 5 to 30 km. The stripmap mode is used to collect large amounts of clutter data needed to support the statistical analysis that forms the basis of accurate clutter modeling.

²⁴⁶⁸⁾J. C. Henry, T. J. Murphy, K. M. Carusone, "The Lincoln Laboratory Millimeter-Wave Synthetic Aperture Radar (SAR) and Imaging System," Proceedings of SPIE, Vol. 1630 Synthetic Aperture Radar, 1992, pp. 35-52

- 2) SAR spotlight mode: In the spotlight mode the antenna is aimed at a fixed reference point in a specific target area. The area imaged in this mode is 400 m (range) x 200 m (cross-range). The spotlight mode is used to collect data on specific targets, either in the clear or in clutter, from all aspect angles. The aircraft has the capability of flying either 1) a 4-sided box pattern around the target area to provide up to $\pm 45^\circ$ squint over the target scene, or, 2) an 18-sided polygon pattern to provide up to $\pm 10^\circ$ squint over the target area.
- 3) RAR mode: The RAR modes utilize a real-beam radar mode. The cross-range resolution is a function of the antenna beamwidth and the radar slant range to the target. There are two RAR modes which correspond to the SAR modes. The RAR search mode scans over a strip while the RAR track mode tracks a spot. The RAR modes use the innermost axis of the antenna gimbal to scan the antenna over a wide azimuthal swath. The RAR modes emulate the searching and tracking of a radar seeker.
- 4) Calibration mode: Prior to each data collection pass, the radar is configured in a calibration mode. In this mode a replica of the transmitted waveform, very carefully controlled in amplitude and phase, is injected into the radar frontend ahead of the low-noise amplifiers. This calibration pulse is processed through the system in the same manner as a normal radar pulse. The purpose of the calibration mode is to verify that the receiver gain and phase do not change during mission operations. If any changes are detected by processing the calibration pulses, then these changes can be compensated by appropriate modification to the calibration values used for each pass.

Polarimetric properties. The MMW-SAR instrument is fully polarimetric. The measurement of the complete polarization scattering matrix for each pixel is achieved by transmitting, on alternating pulses, two orthogonal senses of polarization (e.g. horizontal and vertical). There are two orthogonal receive channels, which operate simultaneously following each transmitted pulse. One pair of transmitted pulses generates all four components of the scattering matrix (HH, HV, VH, VV).

The MMW-SAR consists of the following systems: Aircraft Position Location System, Antenna Motion Compensation System, Gimbal Control System, Data Recording System, and Control Computer System.

- Aircraft Location System: INS, Ground-based beacon location system, real-time DGPS receiver, and barometric altimeter. Aircraft position requirement of ≤ 15 m.
- Antenna Motion Compensation System: The short-term (high-frequency) motion of the antenna is measured by an IMU (Inertial Measurement Unit). This data is used as input to compensate the pulse-to-pulse phase of the radar to maintain coherence during the synthetic aperture integration time.
- Gimbal Control System: This consists of a four-axis (azimuth, roll, elevation, and scan) gimbal that points the antenna in the desired direction.
- Receiver and Data Recording System: The received signals (H and V) are amplified by GaAs Low Noise Amplifiers. The preprocessor includes: the A/D converters, the PRF buffer, the cross-plane filter, the bus multiplexer, and the high-density tape interface. The tape recording system consists of an Ampex 28-channel HDT recorder.
- Control Computer System: VAX 4300 computer plus peripherals.

Lincoln Laboratory maintains an 'image formation and data analysis facility.' The Image Formation Processor (IFP) consists of an AMPEX HBR 3000 high density tape playback unit, a Numerix 432 processor, a very large disk-storage unit, a high-speed Visi-net data bus and a control computer.

As of the end of 1995 the radar is being modified to operate as either an X-band or Ku-band system using a wide-band TWTA (Travelling Wave Tube Amplifier) covering the 8-18 GHz band (the modified system will be ready for operation in mid-1996). As part of this upgrade,

a new waveform generator and RF front-end will be installed, which will give the system a finer range resolution capability. The enhanced system capabilities do not allow simultaneous observations in all bands.

P.139 MOBY (Marine Optical Buoy)

MOBY²⁴⁶⁹⁾ is an important ocean-based remote sensing station, funded by NASA and NOAA, and deployed off the coast of Lanai, Hawaii, in February 1994 (Chief scientist: D. Clark of NOAA/NESDIS; most of the buoys H/W and acquisition S/W was engineered and integrated by San Jose State University, San Jose, CA). The buoy was installed in support of the Earth Observing System (EOS); its primary objective is to make in-situ measurements of ‘ocean color,’ the VIS and NIR-range radiation that enters and emanates from the ocean surface. It is the variations of the VIS-reflected radiation that is referred to as ‘ocean color’ (see Glossary), from which other quantities can be derived, such as the abundance of microscopic marine plants, also referred to as phytoplankton. The coordinates of MOBY’s permanent deployment site are: 20° 49.0” N latitude, 157° 11.5” W longitude.

Figure 492: Schematic illustration of the MOBY station

In its role of measuring ocean color, MOBY provides a time-series database for bio-optical algorithm development. The buoy acquires data about 3-5 times per day, providing oceanographers with daily fluctuations in biomass concentrations. The second objective of MOBY is to serve as a calibration reference station for a number of satellite sensors, such as SeaWiFS (on SeaStar), SeaWiFS-II, MODIS, MERIS (EOS instruments), and OCTS on ADEOS. MOBY also has the potential to support other calibration applications, for instance, in the field of atmospheric sciences (atmospheric corrections, radiation budget applications, etc.).

²⁴⁶⁹⁾D. Herring, “MODIS/SeaWiFS Team Deploys Marine Optical Buoy, Continues Marine Optical Characterization Experiment,” *The Earth Observer*, NASA, Vol. 6, No. 1, January/February 1994, pp. 17-22

MOBY consists of six major components, a dual spectrograph, a fiber optic multiplexer, the top-end buoy with solar panels and controlling software, a data relay and acquisition system with a link via GOES, fiber optic radiance and irradiance collectors, and a dichroic water mirror for the dual spectrograph. - The MOBY sensors were calibrated prior to deployment, in addition there is an internal calibration system.

The optical system uses two spectrographs with a dichroic ('water') mirror to measure the radiometric properties with high spectral resolution and stray light rejection. The "water" mirror is designed to transmit the red (630-900 nm) and reflect the blue (380-600 nm) portions of the spectrum (transition from reflectance to transmittance is between 590 - 650 nm). The total spectral range is from 380 - 900 nm with spectral bandwidths of 2-4 nm. This allows for high-accuracy and high-precision radiometric measurements.

The buoy has a total length of 12 m (in the vertical plane), the top 2 m are above the waterline. The buoy's constructional elements are mounted on a fiberglass mast of 11 m in length. The instrument bay is located at the very bottom of the mast. Three booms or 'arms' 2 m in length are mounted horizontally to the mast at depths of 2, 5, and 9 m respectively, supporting instrumentation. The fiber optic radiance and irradiance collectors have been placed at the ends of the arms as well as on top of the buoy (above the surface) to collect light coming into the ocean, and then the light reflected back out of the ocean.

P.140 MSS-5000 (Maritime Surveillance System)

MSS-5000 ²⁴⁷⁰⁾ ²⁴⁷¹⁾ is a commercially available integrated airborne system of SSC, Sweden, consisting of several instruments, with the objective to offer a cost-effective set of tools for the surveillance of sea traffic, pollution monitoring, fishery protection, and border patrol. The system is composed of the following sensors and support systems:

- SLAR (Side Looking Airborne Radar)
- IR/UV (Infrared/Ultraviolet Line Scanner) IR/UV is licensed from Daedalus (see AADS1221 description under P.63.2)
- MWR (Scanning Microwave Radiometer)
- Camera (Photographic Camera System)
- Video (Video Camera System)
- THERMO (Thermal Radiometer)
- MP (Maritime Central Processor)
- Image Link (X-band transmitter/receiver for air-ground communication and vice versa)
- DET (Data Evaluation Terminal, ground-based)

Oper. since	Aircraft Type	Country	Organization	Application	MSS Sensor Complement/Equipment

Table 763: Overview of operational airborne MSS systems

P.140.1 SLAR (Side-Looking Airborne Radar)

The SLAR (Ericsson model) is used for high resolution surveillance of large areas of sea surface. The swath width is 80 km (40 km to each side of the aircraft or 80 km to one side, as selected by the operator). The vertically polarized antenna gives an enhanced sea clutter response, which brings out oil films on the sea surface with high contrast.

The system solution also gives SLAR outstanding performance in small target detection, making it an efficient instrument for fishery surveillance and for search-and-rescue missions. SLAR features a real-time display with several display modes and a number of selectable image enhancement capabilities; in addition it provides automatic target positioning supported by TV screen displays.

Frequency	9.4 GHz (X-band)
Transceiver transmitted peak power	10 kW
Pulse length	0.5 μ s (0.125 μ s option)
Pulse repetition rate	1.2 kHz simultaneously on both sides
IFOV	9 mrad horizontal (along track), 650 mrad vertical (across track)
Antennas	Horizontal beam width Vertical beam width Gain Polarization
	0.5° $\geq 37^\circ$ 31 dBi Vertical
SLAR mass (including 2 antennas)	90 kg

Table 764: System parameters of SLAR

P.140.2 IR/UV (Infrared/Ultraviolet System)

The instrument is described under P.63.2. It is capable of observing minute temperature differences on the water surface and is ideal for mapping oil spills and other types of pollution. Instrument mass = 30 kg.

P.140.3 MWR (Scanning Microwave Radiometer)

MWR is used for detailed mapping of an oil spill; it measures the oil film thickness and provides an estimate of the total oil volume on the surface. The oil film thickness image is real-time color-coded; the data is presented together with the corresponding data from IR/UV.

MWR has four antennas mounted on a rotating platform. This concept has been chosen to provide continuous scanning capability. An important advantage of this concept is that the

incidence angle and the polarization angle are both kept constant during a sweep, reducing to a minimum the influence from other variables.

MWR frequency:	35 GHz
Angle of incidence:	25° (constant)
Polarization:	Horizontal
Swath width	150 m, 300 m, 600 m
Ground resolution:	7 m, 15 m, 30 m
MWR mass	32 kg

P.140.4 Camera (Photographic Camera System)

The camera is a modified Nikon professional hand held camera for standard 35 mm film. The camera system includes a navigation system interface, which provides the film frames, as well as all other sensor data, with real-time information from the aircraft navigation system, such as date, time, latitude, longitude, and heading. Other information such as connector number, mission ID, frame number, etc. can also be added.

Camera type	35 mm single-lens reflex
Picture format	24 mm x 36 mm (standard 35 mm film)
Lens mount	Nikon bayonet mount
Shutter speed	1/8000 s to 30 s
Stutter release	Electromagnetic
Annotation imprint	Special modification for exposure of annotation on each frame
Camera mass	6 kg (including I/F unit), = 2 kg for operator handling

P.140.5 Video (Video Camera System)

Video allows close-up documentation of activities on the sea surface beneath the aircraft. The video signal is complemented with annotation information from the computer. The information is added to each image frame (in the same fashion as for the camera) prior to VHS recording.

Imager	2/3" integrated color mosaic filter signal chip CCD (556 x 581 pixels)
Resolution	≥ 460 lines horizontal
Min. illumination	7 lux
SNR	≥ 46 dB
Shutter speed	Strobe effect shutter available for in-flight operation; 1/2000 s
Format	VHS/S-VHS
Annotation data	Video signal integrated with annotation data + navigation data
Video mass	6 kg (including I/F unit), = 2 kg for operator handling

P.140.6 THERMO (Thermal Radiometer)

THERMO is used to measure the temperature of the water surface below the aircraft. One measurement per second is registered and stored on disk. Each measurement is tagged with annotation data. THERMO parameters: spectral band=8-14 μm , FOV=2°, accuracy=0.5°C, sensitivity=0.1°C.

P.141 MSS (Multispectral Scanner)

MSS is an airborne optomechanical line scanner instrument, developed by ISRO, with the objective to gain experience with all facets of sensor building as well as the collection, processing, and interpretation of multispectral surface data. The instrument (MSS Mark-I)

was initially developed as a five-channel scanner and flight-tested on a Dakota aircraft in 1977. Further improved versions of MSS followed: Mark-II has six channels, Mark-III has seven channels. The MSS design features an all reflective Cassegrain telescope. The instrument consists of the following elements: line scanner, collecting optics, dispersion system, detectors, electronics unit (video processor, signal conditioner, recording system), and calibration system. A single field stop is used for all spectral bands (except thermal) which enables all VNIR channels to view the same resolution element. This provides an inherent band-to-band registration without any further alignment measures. The thermal channel is aligned with the other channels by proper thermal detector alignment.²⁴⁷⁴⁾

Spectral bands (selectable bandwidth with optical filters)	Four bands in the range of 0.45 – 0.90 mm One band in the range of 8 – 14 mm Two bands in the range 1.0 – 3.0 mm
Telescope aperture, f/number	100 mm, 2.8
Scan mirror	Plain mirror elliptical in shape
Dispersion	Beam splitters and filters
Detectors	Photomultiplier tubes in the region 0.45 – 0.90 mm Liquid nitrogen cooled MCT in the region 8 – 14 mm Liquid nitrogen cooled InSb in the region 1.0 – 3.0 mm
Scan rate	300 to 900 rpm (selectable by thumbwheel switch, min step of 6 rpm)
FOV	±20° (for CCT recording on HDT) ±39° (for recording on HDDT)
IFOV	2.5 mrad
System sensitivity NEDT	0.5 K at 300 K
System sensitivity NEDR	0.5% for 0.45–0.90 mm region; 1% for 1.0 – 3.0 mm region
Calibration reference	Wideband tungsten halogen lamp for VNIR channels Two temperature controlled black bodies
Data recording	1) 9-track CCTs 2) Black body temperature and other housekeeping data 3) Provision to record coded messages

Table 563: Specification of the MSS Mark-III instrument

P.142 MTP (Microwave Temperature Profiler)

MTP²⁴⁷⁵⁾ is an airborne passive microwave radiometer designed and built by NASA/JPL. The radiometer measures brightness temperature versus elevation angle and converts this information by statistical retrieval coefficients to profiles of air temperature versus altitude above and below the aircraft. Several MTPs have been flown on four different NASA aircraft during the past 15 years.

An MPT was first flown on a NASA CV-990 aircraft in 1978 and provided tropopause altitude information during the Clear Air Turbulence Flight Test Program. An improved MTP was flown for several years on the C-141 Kuiper Airborne Observatory (NASA/ARC) and produced data revealing that tropopause shapes having inversion layers are twice as likely to produce turbulence than other tropopause shapes.

A smaller MTP was built for NASA's ER-2 aircraft for the Stratospheric/Tropospheric Exchange Project, a series of flights based in Darwin, Australia in 1986 for the study of exchange processes that account for the dehydration of the lower stratosphere. The same MTP was used during the 1987 Airborne Antarctic Ozone Experiment (AAOE), the 1989 Airborne Arctic Stratospheric Expedition (AASE), and the 1991/1992 Airborne Arctic Stratospheric Expedition II (AASE II). Each of these missions studied processes producing stratospheric ozone depletion. An MTP was built for NASA's DC-8 aircraft for use in the AASE II campaign.

²⁴⁷⁴⁾G. Joseph, "IRS-1A Camera – Its Evolution and Realization, Natural Resources Management – a new perspective, book of NNRMS, edited by R. L. Karale, 1992

²⁴⁷⁵⁾Courtesy of B. L. Gary, NASA/JPL

The MTP/DC-8 instrument profiles temperature every 14 seconds, providing an accuracy exceeding radiosonde and satellite analysis of the temperature field throughout the altitude region 7 and 17 km. RMS accuracy, as measured against nearby radiosondes, is better than 1 K over a 7 km region, and better than 2 K over a 12 km region. Performance is unaffected by cirrus clouds or polar stratospheric clouds (PSCs).

The MTP/DC-8 and MTP/ER-2 instruments are total power radiometers that employ a horn antenna with a 7.5° half-power, full-width beam pattern and scan from -60° to $+60^\circ$ in 10 elevation angle steps. The MTP/DC-8 operates at 55.51, 56.66 and 58.79 GHz, and completes a scan every 14 seconds. The MTP/ER-2 instrument operates at 56.67 and 58.80 GHz. The MTP/ER-2 records data on a removable memory card. The electronics weigh 10 kg, and the fairing and other hardware weigh another 5 kg. A lighter MTP is planned to fly on the unmanned aircraft series Perseus (see Table 781).

P.143 MTS (Millimeter-Wave Temperature Sounder)

The NASA-sponsored ²⁴⁷⁶⁾ ²⁴⁷⁷⁾ MIT (Massachusetts Institute of Technology) MTS instrument is an improved version of a fixed-beam 118 GHz temperature sounder built in 1976 and operated aboard NASA's Convair 990 aircraft in 1977 and 1978. - MTS (operational since 1985) is capable of ground-based zenith-viewing at remote sites or of nadir-viewing operation aboard NASA/ARC's ER-2 aircraft. Since 1991 it has also been capable of zenith-scanning operation. Objective: passive observations for temperature sounding and precipitation parameter estimation.

MTS collected data in 33 ER-2 flights in 1986 during the GALE (Genesis of Atlantic Lows Experiment) and COHMEX (Cooperative Huntsville Meteorological Experiment) campaigns, yielding high spatial resolution microwave images of atmospheric O₂ brightness temperatures over clear air, stratiform precipitation, and convective precipitation. MTS has further observed clear air, precipitation, hurricanes, and zenith opacity during 8 CaPE flights in 1991, 22 STORM-FEST flights in 1992, 3 TOGA/COARE flights in 1993, and 8 CAMEX (Convection and Atmospheric Moisture Experiment) flights in 1993.

MTS is a dual-band microwave radiometer system used to measure atmospheric temperature as well as other phenomena affecting transmission in the microwave absorption bands of molecular oxygen. The instrument consists of a scanhead housing, two radiometers and a video camera. Supporting equipment includes detectors, integrators, power supplies, temperature controllers, a video recorder, and a microcomputer. One radiometer is a 53.65 GHz fixed-beam single-channel sensor; the other instrument is a 118 GHz cross-track scanning spectrometer. Since 1993 the 53-GHz system has been able to tune rapidly between 52.8 - 55.5 GHz under digital control. Both radiometers employ symmetric Dicke switching to minimize drift-induced errors in the measured antenna temperature.

A rotating mirror allows for a planar scan of the antenna beam over a $\pm 47^\circ$ FOV. The MTS scanning spectrometer yields about 0.5 K brightness temperature resolution per spot for the probing channels. The corresponding horizontal spatial resolution is 1.6 - 2.3 km for features at 8 km altitude and 2.6 - 3.7 km at the Earth's surface (flight altitude of ER-2 aircraft at 19.5 km, flight speed of 200 m/s). Hot and ambient temperature calibration loads with about 1% reflectivity are viewed once during each scan.

The single-channel fixed beam radiometer senses oxygen emissions near 53.65 GHz. The nadir-viewing 53 GHz antenna has a beamwidth of 7.5° . The 53 GHz radiometer is calibrated by connecting the input port to hot and ambient waveguide terminations via a mechanical waveguide switch. The CCD camera was expanded to a 107° FOV in 1993.

²⁴⁷⁷⁾ Update information provided by D. H. Staelin, MIT

Data products: Data have been used to produce images of temperature and precipitation structure, to infer precipitation cell top altitudes, to detect atmospheric waves, and to determine atmospheric microwave transmittances.

MTS Channel	Sideband Frequencies (GHz)	Sideband Bandwidth (MHz)
0	53.65 ±0.8 (pre CAMEX)	160
1	118.75 ±0.66	170
2	118.75 ±0.84	210
3	118.75 ±1.04	240
4	118.75 ±1.26	220
5	118.75 ±1.47	240
6	118.75 ±1.67	220
7	118.75 ±1.90	270
8	118.75 ±0.50 (post GALE)	125 (post GALE)

Table 765: MTS channel specifications

P.144 MUSIC (Multi-Spectral Infrared Camera)

The MUSIC airborne hyperspectral instrument was developed and built at the Lockheed Palo Alto Research Laboratory, CA. The current version has been operational since 1989 (earlier versions since 1977) and flew on NASA research aircraft at altitudes up to 20 km; a ground-based configuration of the instrument has recently been developed. Applications: chemical vapor sensing, plume diagnostics, spectral signatures.²⁴⁷⁸⁾

MUSIC collects infrared image data simultaneously in the MWIR and TIR spectra. The sensor consists of two parallel optical telescopes, each with its own set of optical filters and detector arrays. Si:In detectors in MWIR and Si:Ga detectors are employed in TIR region. Each detector array is a 45 x 90 pixel matrix for a total of 4050 detectors in each array. All detectors collect data in parallel at up to 80 frames/s. The optical system provides a pixel angular spacing of 0.5 mrad, yielding a total of 22.5 x 45 mrad (1.3° x 2.6°). An indexing filter in each telescope allows for selection of any of seven bandpass filters. Since emphasis in the MUSIC flight program has been on multispectral data, typical modes of operation call for rapid interchange of filters, under computer control, to obtain near simultaneous data in several spectral bands.

The sensor is a cryogenic instrument, with all elements of the optical train behind the entrance window operating at the temperature of liquid nitrogen (78K). The detector arrays are cooled with liquid helium. Because of this cooling, the internal background is very low and the detectors operate close to the BLIP limit as defined by the external signal through the cooled spectral filters. Single frame sensitivity is about 1 μW/cm²/sr/m⁻⁶, varying slightly with the specific band.

In addition to the seven spectral bandpass filters in each telescope, a circular variable filter (CVF) is installed which provides a continuously variable narrow bandpass ($\lambda/\Delta\lambda \sim 100$) which can be tuned continuously by rotating the filter to cover the full spectral range in each telescope. Either the CVF or the discrete filter wheel can be used (pre-programmable control).

In flight, data is recorded in digital PCM format on wideband data tape for post flight analysis. For use in a special mountain top data collection exercise, an alternate gimbal pointing system and an alternate data recording system (direct high-speed disk recording) were developed. The system offers quicklook capability.

²⁴⁷⁸⁾Information provided by W. P. Rudolf of Lockheed

Spectral Parameters		
Spectral range	2500 - 7000 nm	6000 - 14500 nm
Instantaneous range (single CVF position)	350 nm	600 nm
Bandwidth	25-70 nm	60 - 1400 nm
Channels	90	90
Spatial Parameters		
IFOV	0.5 mrad	
FOV	1.3° (across-track) x 2.6° (along-track)	
Pixel/line	45	
Swath	68 m @ 3 km; 450 m @ 20 km altitude	
Electronic Parameters

Table 766: Characteristics of the MUSIC spectrometer

P.145 NAILS (NCAR Airborne Infrared Lidar System)

NAILS²⁴⁷⁹⁾ ²⁴⁸⁰⁾ ²⁴⁸¹⁾ is a heterodyne Doppler lidar instrument of NCAR in Boulder, CO, for use in atmospheric science research (upgrade of instrument in 1993). NAILS was sponsored by NSF to support the university research community. NAILS measures range-resolved backscatter from atmospheric aerosol using a transmitted wavelength of 10.6 μm . The instrument has been used with direct (not heterodyne) detection for measuring profiles of infrared backscatter and for monitoring the structure of marine stratocumulus in the FIRE-I and ASTEX campaigns. NAILS is being upgraded (1995) to include the capability of measuring the atmospheric velocity component along the lidar line-of-sight by means of the Doppler shift of the radiation scattered by the atmospheric aerosol.

Applications: When Doppler upgrades are completed, NAILS can determine the horizontal wind field in quasi-stationary situations by flying a box pattern while pointing horizontally. This is useful for convergence beneath convective clouds and can be used to study entrainment into the side of cumulus clouds. When pointing vertically, the measured vertical velocity can be combined with lidar measurements of constituent concentration to infer vertical fluxes by an eddy-correlation method. Remote measurements of profiles of vertical velocity contribute as well to studies of entrainment in stratus clouds. When used with appropriate conical scanning (not yet added to the system), profiles of the horizontal wind are available to determine the transport of pollutants. In combination with other lidars operating at shorter wavelengths, backscatter measurements from NAILS provide data on aerosol particle size. The middle infrared operating wavelength also provides strong aerosol-to-molecular contrast to define the top of the mixed surface layer.

The lidar system has been flown on the NCAR Electra aircraft and consists of an optical package of approximately 200 kg, electronics rack of approximately 150 kg, and auxiliary equipment (turning mirror, gas supplies, etc.) of about 50 kg. Data are recorded as raw time series of digitized signal return on 8 mm digital tape. The system provides real-time display capability (range-time plot) of the velocity component and backscatter intensity. The raw time series data can be processed (on the ground) to provide any desired type of analysis.

Operating parameters:

operating range (nominal)	0.6 to 10 km
range resolution	± 50 m

²⁴⁷⁹⁾ Information provided by R. Schwiesow of NCAR

²⁴⁸¹⁾ R. L. Schwiesow, M. P. Spowart, "The NCAR Airborne Infrared Lidar System: Status and Applications," Journal of Atmospheric and Oceanic Technology, Volume 12, 1995

velocity accuracy	± 0.5 m/s
pulse repetition frequency	up to 64 Hz

The system uses a pulsed CO₂ TEA (Transverse Excitation Atmospheric pressure) laser as a transmitter, and a continuous-wave CO₂ laser as a local oscillator for heterodyne detection and to seed the TEA laser for single-frequency output. In addition to allowing Doppler measurements, heterodyne operation makes NAILS more sensitive for backscatter profile measurements than it would be with direct detection, due to the reduction of background noise.

P.146 NAPP (National Aerial Photography Program)

A USGS (US Geological Survey) program established in 1987 with the objective to acquire and archive photographic coverage of the conterminous United States at a scale of 1:40,000, using either color infrared (CIR) or black-and-white (B&W) film. The imagery is acquired on a five-year cycle, resulting in a large database that is accessible through the EROS Data Center (EDC) in Sioux Falls, SD, and the Aerial Photography Field Office (AFPO) in Salt Lake City, Utah.

Oversight and policies of NAPP are provided (and partially funded) by a steering committee that includes representatives of the major federal US agencies such as: SCS (Soil Conservation Service), ASCS (Agricultural Stabilization and Conservation Service), USFS (US Forest Service), BLM (Bureau of Land Management), and TVA (Tennessee Valley Authority). Observers (nonvoting members) are: NOAA, EPA (Environmental Protection Agency), and USFWS (US Fish and Wildlife Service).^{2482) 2483) 2484)}

Parameter	English Units	Metric Units
Focal length (f)	6 inch	152.4 mm
Format	9 inch x 9 inch	23 cm x 23 cm
Flight altitude	20,000 ft	6,096 m
Coverage/frame	30,000 ft	9,200 m
Exposure spacing	11,390 ft	3,470 m
B/H ratio	0.57	0.57
Image scale	1:40,000	1:40,000
Film resolution	686 lines/inch	27 lines/mm
Ground resolution	3.3 - 4.9 ft	1.0 - 1.5 m

Table 767: Some NAPP specification parameters

Within NAPP, USGS uses the services of a number of commercial contractors for the data collection task. A set of technical rules was specified by USGS with regard to the sensing instrumentation standards and operational procedures. The cameras within the program are of the types Zeiss RMK and LMK and Wild RC30, providing exposures either in B&W or on CIR (Color Infrared) film at a nominal scale of 1:40,000. Location and attitude data is provided by GPS, IMU, and other aircraft instrumentation. All flights are conducted at an altitude of 20,000 feet (~ 6 km) above mean terrain. The flight lines are in the north-south direction providing full stereoscopic coverage with $\sim 60\%$ forward overlap and $\geq 27\%$ sidelap. Alternate exposure stations are centered on quarter sections of standard 7.5' (minute) quadrangles, referred to as 'quarter-quad.' A minimum sun angle of 30° in flat land is specified, the preferred flying season is generally 'leaf-off.' The B&W photography is pan-

chromatic (0.47-0.73 μm) while the CIR imagery is multispectral with the following bands: 0.5-0.6 μm (green), 0.6-0.7 μm (red), and 0.73-0.88 μm (NIR).

NAPP photography is designed for a wide range of applications such as environmental surveys, agriculture and forestry, land use, geology, water resources, and cartography.

P.147 NASAR-1 (NASDA Airborne SAR-1)

NASAR-1 is a polarimetric L-band SAR instrument designed and developed by NASDA/EORC of Tokyo. Objective: study of L-band radar signature dependency of various target types using a high-resolution and high SNR radar sensor. The instrument is scheduled to be completed in March 1996 and will be installed and flown on a Gulfstream II aircraft along with the CRL-SAR instrument starting with regular observations in fall 1996. NASAR-1 may be operated individually or synchronously with CRL-SAR. An accurate GPS navigation system on the aircraft will permit repeat-pass interferometry with NASAR-1.²⁴⁸⁵⁾

Frequency	1271.490 MHz (L-band)
Wavelength	23.6 cm
Transmitter bandwidth	50 MHz
Polarization	HH, VV, VH, HV (polarimetric)
Pulse width	10 μs
Swath width	16 km at 12 km AGL (Above Ground Level)
Antenna size, type	1.7 m x 0.6 m, planar patch type antenna
Antenna beamwidth	Elevation Azimuth
	$38^{\circ} \pm 4^{\circ}$ $9.8^{\circ} \pm 1^{\circ}$
Ground resolution	Range Azimuth
	3, 5, 10, or 20 m 3 m (3 looks)
Sidelobe level	-20 dB in elevation, -25 dB in azimuth
Transmitter power	> 3 kW
Noise equivalent NRCS	-30 dB (SNR=10 dB)
Signal to ambiguity ratio	> 30 dB
Noise figure	< 1.5 dB
Calibration accuracy	< 0.6 dB
PRF (Pulse Repetition Frequency)	< 1 kHz (variable)
Quantization	8 bit
Data rate	256 Mbit/s
Data recorder	D-1 cassette signal recorder

Table 768: Performance parameters of the NASAR-1 instrument

P.148 NASIC (NASA Aircraft - Satellite Instrument Calibrator)

NASIC is a NASA/GSFC spectroradiometer flown on ER-2 aircraft for the calibration of satellite sensors in the spectral range from 400 to 1040 nm. The instrument is of NOAA heritage and was acquired by GSFC in 1988. The primary objective is to provide input for quantitative calibration estimates by long-term operational sensors with insufficient calibration knowledge due to one or more of the following factors:

- imprecise knowledge of prelaunch calibration parameters
- absence of adequate on-board calibration capabilities
- occurrence of significant in-flight calibration changes over extended periods.

The goal is to compile accurate, long-term records of environmental parameters for use in climate and global studies. The system has been in operation since 1980 and has been up-

²⁴⁸⁵⁾Information provided by M. Shimada of NASDA/EORC

graded several times. Satellite sensors that were calibrated with NASIC include (some only once): AVHRR channels 1 and 2 on NOAA-9, -10, and -11; Landsat-5 TM bands 1-4; GOES-6 and -7 VAS (visible bands), and Nimbus-7 CZCS.²⁴⁸⁶⁾

Telescope focal length	125 mm
Aperture	f/4.8
Grating	600 groove/mm, blazed at 500 nm
Spectral range	400 - 1040 nm
IFOV=FOV	105 - 160 mrad (footprint of 2 - 3 km)
Number of spectral pixels/scan	184
Detector	CCD (silicon) actively temperature controlled
Quantization	12 bit
Platform	ER-2 aircraft with INS, GPS

Table 769: Specification of the NASIC instrument

The calibration method with NASIC underflights requires accurate prediction of the satellite-target viewing geometry, which is necessary to enable the aircraft spectroradiometer to be co-aligned with the satellite viewing vector during the satellite overpass. Small corrections must be applied to account for the effects of the atmospheric path between the aircraft and the satellite, and to account for the difference between the footprints of the two instruments on the target. These corrections, and knowledge of the spectral response function of a given channel of the satellite sensor (radiometer), allow the calculation of equivalent sets of radiance values (from the aircraft measurements) and count values (from the satellite measurements) that correspond to the altitude of the satellite radiometer and the field-of-view of the aircraft spectrometer.

A typical data collection period for underflights of a polar-orbiting satellite is in the order of 3 minutes. Data are collected on the same target area in parallel by the satellite sensor and by NASIC. The method assumes that the two datasets correspond to identical states of scene structure and illumination. The footprint of NASIC is chosen to be much larger than the footprint of the satellite sensor to allow for footprint corrections.

The NASIC instrument ²⁴⁸⁷⁾ is a spectroradiometer of Ebert design with zero-dispersion, a double monochromator and a CCD silicon detector unit. The spectral scan takes approximately 5 seconds and covers 184 positions (25 ms per position or sample) equally spaced in wavelength from 400 - 1040 nm. The NASIC footprint on the ground is a single pixel (there is no spatial scan mechanism); its movement along the ground is controlled by the aircraft motion along the flight path. The spectral resolution is approximately 3.5 nm.

The spectral range of NASIC is configured for each particular application. The measurement of AVHRR sensor channels 1 and 2 may serve as an example: A blocking filter on the front of the detector prevents energy at wavelengths below 380 nm from entering the system. Spectral scans are performed sequentially in pairs, one scan in each pair having a second blocking filter in place to absorb energy at wavelengths below 700 nm, thereby giving a valid radiance spectrum in the range from 700 - 1040 nm; the other scan has the second blocking filter removed, providing a valid radiance spectrum from 400 - 760 nm.

NASIC is gimbal-mounted in the aircraft to allow its optical axis to be directed to a range of angles to the right (i.e. to starboard) and below the aircraft axis. These motions are controlled by an on-board PC through azimuth and elevation drive motors with a positioning accuracy of $\approx 1^\circ$.

²⁴⁸⁶⁾P. Abel, B. Guenther, "Calibration Results for NOAA-11 AVHRR Channels 1 and 2 from Congruent Path Aircraft Observations," Journal of Atmospheric and Oceanic Technology, Volume 10, Aug. 1993, pp. 493-508

²⁴⁸⁷⁾Note: "Zero dispersion double monochromator": two monochromators in series, arranged with aligned spectral scanning functions and with zero spectral dispersion at the final exit slit. This arrangement significantly reduces stray light effects relative to the performance of a single monochromator.

The instrument has been calibrated in the laboratory at GSFC on an irregular schedule usually before and after most flights.

In post-flight processing and analysis, radiances observed by the satellite sensor are modelled from the measured NASIC radiance spectra by convolution integration of the radiance spectra with the sensor's spectral response profiles.

Figure 493: Arrangement of viewing geometries for NASIC calibration

P.149 NAST (NPOESS Aircraft Sounder Testbed)

NAST was developed for the Integrated Programs Office (IPO) as part of a risk reduction effort for future instruments proposed to fly on the future NPOESS satellites. In turn, the program provides the scientific community with valuable measurements of the atmosphere and the Earth's surface from a high altitude platform. In addition to the stand-alone scientific value of these instruments, NAST is used to simulate possible satellite-based measurements useful in experimental validation of different instrument-system specifications and data processing techniques for future advanced atmospheric remote sensors. The primary objectives of NAST are to satisfy the engineering and scientific needs in a cost effective manner while moving the advanced sounder technology forward with a goal to help improve the operational weather forecasts. ²⁴⁸⁸) Specific objectives of the NAST program are to:

- Define optimal spectral characteristics of IR and MW sounders for NPOESS
- Define spatial resolution and scan geometry characteristics of NPOESS sounders required to optimize soundings in the presence of clouds
- Validate parameter retrieval algorithms and expected retrieval accuracies for different climatic zones, meteorological and surface conditions, and cloud situations
- Demonstrate the utility of NPOESS specified sounding system for observing significant atmospheric processes (e.g., storm genesis and evolution, jet-stream position and intensity, sea-breeze phenomena, fog formation and dissipation, clear air turbulence, precipitation and cloudiness, etc.)
- Demonstrate the utility of NAST sounding products in regional mesoscale NWP (Numerical Weather Prediction) models to validate expected improvements in NWP using high vertical resolution satellite sounding data

²⁴⁸⁸) <http://cimss.ssec.wisc.edu/nast/>

- Investigate the utility of NAST data for the retrieval of other NPOESS EDR's (e.g., sea and land surface temperature and emissivity, geometrical and optical properties of clouds, soil moisture, ice content, greenhouse and pollutant gas concentration and profiles, etc.). ²⁴⁸⁹⁾

P.149.1 NAST-I (NPOESS Aircraft Sounder Testbed - Interferometer)

NAST-I is a high resolution Michelson FTS interferometer, developed/built at MIT/LL (Massachusetts Institute of Technology/Lincoln Laboratory) using a BOMEM dynamically aligned interferometer and a University of Wisconsin on-board blackbody calibration system. ²⁴⁹⁰⁾ NAST-I optics, spatial scan system, and electronics were built by MIT/LL; the entire unit was also assembled at MIT/LL. ²⁴⁹¹⁾ NAST-I is of HIS (High-resolution Interferometer Sounder) heritage, a non-scanning instrument, developed at the University of Wisconsin. The NAST-I instrument is maintained by NASA/LaRC.

NAST-I is flown on the NASA/ARC ER-2 aircraft since 1998 in several field campaigns (Wallops-98, CAMEX-3, WINTeX, etc.) to provide experimental observations needed to finalize specifications and to test proposed designs for future spaceborne instruments, specifically the CrIs (Cross-track Infrared Sounder) on NPOESS. The primary science objective of NAST-I is to provide upwelling radiance measurements for the retrieval of geophysical parameters, to support analysis of observed Earth scenes: a) detailed characterization of atmospheric thermal and moisture structure; b) radiative trace gas detection and transport (e.g. O₃, CO, CH₄, N₂O, and CO₂), c) biomass burning studies focusing on atmospheric radiative impact, radiative temperatures of fires, and scene type classification; d) to support pre-launch and post-launch instrument calibration/validation for the EOS and NPOESS programs (e.g. CrIS and ATMS of NPOESS, CERES, MODIS, MOPITT, AIRS and TES of EOS); etc.

Parameter	Value	Comment

Table 770: Overview of NAST-I instrument parameters

The NAST-I instrument is a rapid-scan Michelson interferometer that generates double-sided, bi-directional interferograms. With a ± 2.0 cm optical path difference (OPD), high

²⁴⁸⁹⁾ <http://danspc.larc.nasa.gov/NAST-data/NAST-basic/index.html>

²⁴⁹⁰⁾ Information provided by A. M. Larar and W. L. Smith of NASA/LaRC

²⁴⁹¹⁾ W. Smith, A. Larar, D. Zhou, C. Sisko, J. Li, B. Huang, H. Howell, H. Revercomb, D. Cousins, M. Gazarik, D. Money, S. Mango, "NAST-I: Results from Revolutionary Aircraft Sounding Spectrometer," Proceedings of SPIE, Vol. 3756-28, 1999

spectral resolution (0.25 cm^{-1}) data are collected over the spectral range of 3.7-16.1 μm . NAST-I employs a step-and-stare scanning technique to obtain a cross-track coverage of $\pm 48^\circ$ (FOV) with a total of 13 scene views, each spaced by 7.45° . Two calibration targets (a BB at 30°C and one at ambient temperature) are viewed during each complete scan period in 12.2 seconds. At a flight altitude of 20 km (AGL) the nadir surface resolution (of 7.45° IFOV) translates to a nominal spatial resolution of 2.6 km, the swath width (of $\pm 48^\circ$ FOV) is 45 km. The unapodized spectral resolution of NAST-I is 0.25 cm^{-1} . The three spectral ranges are called:

- SWIR (Short Wave Infrared) in the wavenumber range of: $2083 - 2702\text{ cm}^{-1}$ (corresponding to: $4.8 - 3.7\text{ }\mu\text{m}$)
- MWIR (Mid Wave Infrared) in the wavenumber range of: $1282 - 2083\text{ cm}^{-1}$ (corresponding to: $7.8 - 4.8\text{ }\mu\text{m}$)
- LWIR (Long Wave Infrared) in the wavenumber range of: $621 - 1282\text{ cm}^{-1}$ (corresponding to: $16.1 - 7.8\text{ }\mu\text{m}$), the range is also referred to as TIR (Thermal Infrared).

The optical subsystem consists of three elements: the fore-optics, the Michelson interferometer, and the aft-optics. The input beam of 0.71 cm diameter is converted to a collimated beam of 3.8 cm diameter in the fore-optics. The interferometer produces the interferometrically modulated beams. The beamsplitters of the aft-optics then separate this energy into the three IR bands that are detected by the detector assembly. Dynamic alignment of the interferometer optics is maintained using a metrology helium-neon laser beam which is injected coaxially into the main IR beam.

P.149.2 NAST-M (NPOESS Aircraft Sounder Testbed - Microwave Sounder)

NAST-M is the new MTS (Microwave Temperature Sounder) of MIT, a complete upgrade of the MTS instrument which has been flown by MIT on NASA ER-2 aircraft since 1988. The new MTS, when flown as the microwave component of the NPOESS Aircraft Sounding Testbed (NAST), is designated as NAST-M. The NAST-M instrument is maintained by MIT.

The NAST-M instrument package consists of two total-power radiometers. The first one is a 54 GHz radiometer, a single-sideband system with eight channels between 50.3 and 56.02 GHz. The second one is a 118 GHz radiometer, a double-sideband system with nine channels in the oxygen-line range from $118.75 \pm 0.120\text{ GHz}$ to $118.75 \pm 3.5\text{ GHz}$. Both radiometers measure a single polarization, with the electric field oriented along-track at nadir.²⁴⁹²⁾

Each radiometer consists of the following elements: Antenna (a shared reflector), LNA (no LNA for the 118 GHz system), IF amplifiers, LO (Local Oscillator), power divider, filters, detectors, video amplifiers, and A/D converter. Both systems utilize superheterodyne receivers. The LO frequencies are 46 GHz and 118.75 GHz, respectively. Both LO's are temperature-controlled to prevent gain drift.

NAST-M scanning sub-assembly: Both radiometers have scalar feedhorns with 7.5° 3 dB (FWHM) beamwidths and a shared reflector scan pattern. The reflector is stepped through a full rotation in about 5.5 seconds. A scan consists of 19 spots (footprints) in the cross-track direction ($\pm 65^\circ$) providing a swath width of 120 km, and three calibration spots (a heated internal blackbody, an ambient internal blackbody, and a zenith view through the top of the instrument for a cosmic background). The nadir footprint (spot) diameter is 2.6 km at a flight altitude of 20 km. The nominal integration time for all spots (including calibration) is 100 ms. The instrument data rate is less than 2 kByte/s

A wide-angle high-resolution video camera, part of the instrument package, provides continuous imagery of clouds and surface conditions. The video output is digitized (24 bit

				9	±120	100	1.17

Table 771: Definition of channel passbands of NAST-M

The NAST-M instrument was initially flown in the campaigns CAMEX-3 (Convection and Moisture Experiment) in Florida in the summer 1998 (including 20 overpasses of hurricanes Bonnie and Earl), and in WINTeX (Winter Experiment) in Wisconsin in March/April 1999 (comparison with AMSU instrument data flown on NOAA-15).²⁴⁹³⁾

P.150 NCARNOX (NCAR NO_x Chemiluminescent Sensor)

An instrument package of NCAR/ACD employing the chemiluminescent detection technique to measure NO, NO₂, NO_y and O₃. Each instrument consists of a reaction vessel (of a conically shaped volume of 17 cm³) in which the chemiluminescent reaction takes place. A photomultiplier (PMT) detector is coupled to the reaction vessel through a red cutoff filter (wavelengths > 600 nm, the onset of the NO-O₃ chemiluminescence is transmitted) and a Pyrex thermopane window about 1 cm thick. - The instrument package (mass = 610 kg) has been operational since 1988 and was flown on the NCAR Sabreliner (ELCHEM program) and on the NASA DC-8 in the AASE-II campaign; a further campaign application is TOTE/VOTE.²⁴⁹⁴⁾,²⁴⁹⁵⁾

Principle of operation: NO, NO₂, and NO_y are detected simultaneously using three identical chemiluminescence detectors for NO. Ambient NO₂ is photolysed to NO (efficiency 50%) and total odd nitrogen (NO_y) is converted to NO using the gold catalyzed CO reduction technique. The instrument detection limits for NO, NO₂, and NO_y depend somewhat on altitude, but are better than 5 pptv for 1-minute averages of NO and NO₂ and better than 30 pptv for 2-second averages of NO_y. Ozone (O₃) is detected using a much smaller reaction volume and pure NO as the reagent gas. The instrument sensitivity is 2000 cps (counts per second)/ppbv yielding very high SNR for normal atmospheric levels of ozone. All four instruments are operated at constant pressure, temperature and flow, yielding a constant sensitivity independent of altitude. - The instrument package was upgraded as of 1995. The inlet now has three channels, two being used for NO_y (forward- and rear-facing) measurements and operated at 150°C (forward-facing inlet for particulate NO_y). The third inlet channel is aft-facing for the measurement of NO, NO₂, and O₃.

P.152 NEC-SAR (NEC Corporation SAR)

NEC-SAR is a prototype model of a small, lightweight, high-resolution SAR from NEC Corporation of Tokyo, Japan.²⁴⁹⁷⁾ The objective is to obtain high-resolution contour maps at a scale of 1:25,000. The test flight program of the original instrument started in July 1992; test flights for the interferometric SAR began in July 1993 (3-5 m rms height accuracies are obtained).

Figure 494: Radar imaging modes of the NEC-SAR prototype instrument

Parameter	Value
RF center frequency	9.53 GHz (X-band)
Wavelength	3.1 cm
Expanded pulse length	4 μ s
Digital chirp signal bandwidth	50 MHz
Polarization	HH

²⁴⁹⁶⁾Information provided by P. Spyers-Duran of NCAR

²⁴⁹⁷⁾Information provided by H. Shinohara of NEC Corporation

Parameter	Value
Antenna size	340 mm x 100 mm
Baseline distance for interferometric mode	600 mm
Antenna gain	21.0 dBi
Antenna 3 dB beam width, azimuth	7.5°
Antenna 3 dB beam width, elevation	26.0°
Transmit peak power	3000 W
Transmit average power	12 W
Noise figure	≤ 10 dB
Receiver dynamic range with AGC/STC	≥ 30 dB
Nominal pulse repetition frequency (PRF)	≤ 1200 Hz
Nominal PRF for interferometric mode	600 Hz
Quantization (bit/sample, I or Q), narrow swath mode	6
Quantization (bit/sample, I or Q), wide swath mode	3
Sampling rate	63.5 MHz
Echo buffer memory capacity (I or Q)	2176 words
Nominal data rate onto high density tape	32 Mbit/s
Maximum recording time per tape (1/2 inch video)	22 minutes
Spatial resolution, range x azimuth	4.5 m x 4.5 m
Number of statistically independent looks	≤ 6
Accuracy of calibration	≤ 1 dB
Aircraft platform	Cessna 208
Ground speed	280 km/h
Observation altitude (nominal)	3000 m
Incidence angle, (near range, center range, far range)	42°, 55°, 68°
Incidence angle, (near range, center range, far range)	62°, 75°, 88°
Narrow mode swath width (nominal altitude of 3 km)	5 km
Wide mode swath width (nominal altitude of 3 km)	10 km

Table 772: Specification of the NEC-SAR prototype model

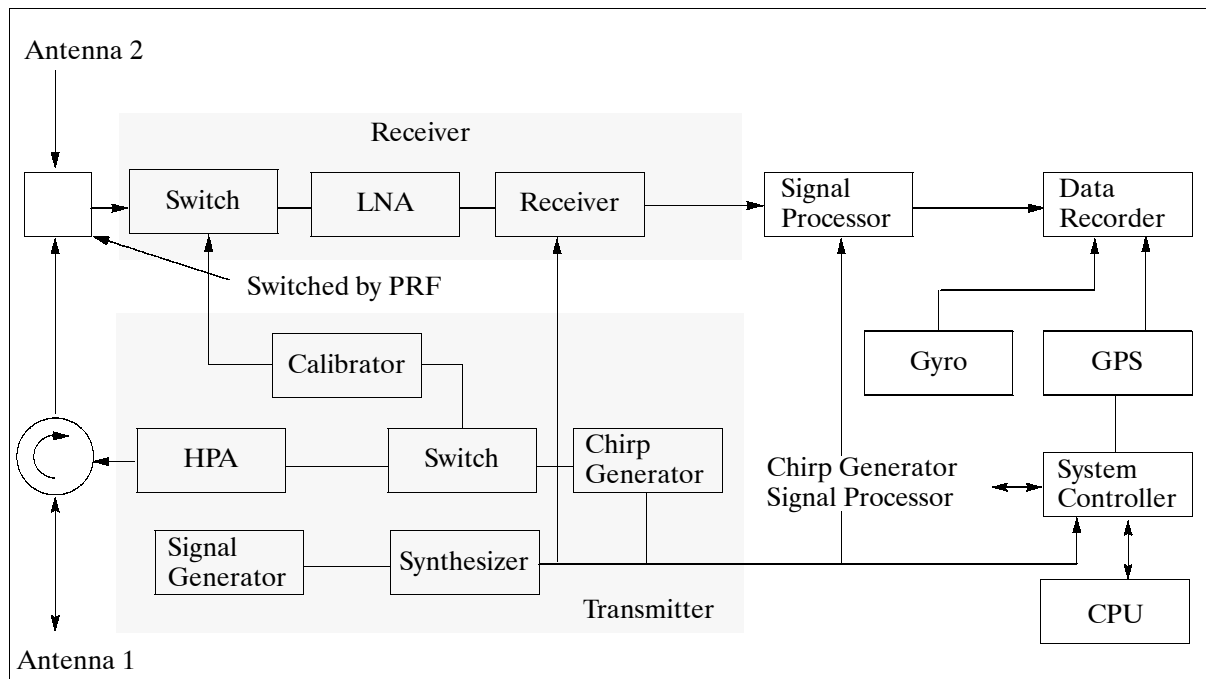

Figure 495: NEC-SAR block diagram (interferometric SAR mode)

NEC developed the instrument from its internal R&D funds. After prototype capability testing NEC will eventually offer the SAR instrument commercially for such applications as topographic mapping, volcano surveillance, search and rescue operations at sea, reconnaissance, etc.

P.153 NOAA/AOC Airborne Program

The NOAA/AOC (Aircraft Operations Center) at MacDill AFB (near Tampa) Florida, created in 1983, is charged with managing NOAA aircraft, personnel, and facilities in support of NOAA aircraft programs. Prior to 1983, AOC was known as the 'Office of Aircraft Operations' (OAO). AOC is involved in the following airborne programs:

Parameter/Measurement	Instrument Manufacturer and Model
Pressure measurement: Static pressure (fuselage and wingtip) Dynamic pressure (fuselage #1 and #2, wingtip) Flow angle pressure (fuselage, AB, Bp, DAP, DBP) Radome flow angle system (AP, BP, dynamic, impact)	Rosemount 1281AF Rosemount 1281AF, 1221F1AF Rosemount 1221F2VL, 1221F2AF Rosemount 1221F1VL, 1221F1AF, 1201F2

Table 773: Overview of some standard instrumentation on NOAA/AOC P-3 aircraft

Heavy Aircraft Program: WP-3D Orion also referred to simply as “P-3’s” (two aircraft from Lockheed, N42RF and N43RF). The aircraft were built in 1975 and 1976 (four engine turboprop). They support a wide variety of national and international meteorological and oceanographic experiments (hurricane research and reconnaissance, etc.).

The on-board instrumentation varies with the research objectives. The following sensors/systems are referred to as “Standard P-3 Instrumentation.”²⁴⁹⁸) Numerous other instruments are also flown depending on the requirements of a given project.

- C-band lower fuselage radar
- X-band Doppler radar (tail)
- Expendable bathythermograph
- Sea surface temperature radiometer
- SFMR (Stepped Frequency Microwave Radiometer)
- Dropwind sonde profiling
- Cloud physics system, cloud particle probes

²⁴⁹⁸) NOAA brochure and further information provided by J. D. DuGranrut of NOAA/AOC at Mc Dill AFB

- Aerosol sampling system
- Pyranometers, pyrgeometers
- Radiation sensors
- Navigation systems: Inertial, GPS, Loran C
- Meteorological instruments (for measuring static and dynamic pressures, horizontal and vertical winds, ambient/dewpoint temperature, atmospheric electrification, etc.).
- ASDL (Aircraft/Satellite Data Link)

Light Aircraft Program: Seven smaller aircraft, a mix of jet, turboprop and piston-powered single and twin engine aircraft.

- Citation II, Cessna - N52RF and Citation I
Instrumentation: Wild RC10 & RC20 aerial cameras, GPS for photographic positioning. The aircraft are primarily used for aerial photography (nautical charting and airport obstruction programs). The side-by-side camera layout allows simultaneous exposures with different types of film.
- Gulfstream Turbo Commander AC690A (N53RF)
Instrumentation: Wild RC8 or RC10 aerial camera, gamma ray spectrometer (used for airborne snow survey).
- Twin Otter, DeHavilland DHC-6, two aircraft (N48RF)
Instrumentation: observation bubble ports, nose mount for video camera, aerial camera hatch. The aircraft is used in low-level low-speed surveys (marine mammal and sea turtle counts, enforcement of fishery regulations, etc.).
- Aero Commander AC-500S (Shrikes), two aircraft (N47RF and N51RF)
Instrumentation: Wild RC8 aerial camera, gamma ray spectrophotometer (N51RF). The sensors aboard N51RF measure the background level of natural gamma radiation in the summer, and snow cover in the winter. The difference allows NWS (National Weather Service, USA) hydrologists to determine water content for flood predictions.
- Lake Seawolf, (2 aircraft)
The Seawolf aircraft are used for aerial marine surveys.

Helicopter Program: Three helicopters

- Bell 212, two helicopters (N60RF and N61RF)
Instrumentation: GNS 500, Loran, Omega, GPS. The Bell 212s are based in Anchorage, Alaska. They are used to locate polar bears, tow sensors, establish geodetic bench marks, monitor/assess oil spill damage and provide logistical support for environmental studies.
- McDonnell-Douglas MD-500A (N59RF)
Instrumentation: Loran. The MD-500 spends about 4 months each year aboard the NOAA ship "David Starr Jordan" flying porpoise surveys in the eastern tropical Pacific.

P.153.1 NOAA WP-3D Doppler Radar System

NOAA/AOC²⁴⁹⁹,²⁵⁰⁰,²⁵⁰¹) flies three radar systems installed on two WP-3D Orion aircraft (since about 1985) to support a large meteorological and oceanographic research user community. Each Orion aircraft offers a three instrument weather detection radar installation with the following configuration:

- 1) **NTR** (Nose-mounted Doppler Turbulence-detection Radar)
NTR is a commercial system manufactured by Rockwell/Collins (commercial name: WXR700C; it is used in many commercial aircraft). In the WP-3D installation (since 1983) the NTR is a pilot's radar; the data is not currently recorded. NTR provides a 180° scan of a 5.5 cm wavelength C-band radar.

²⁴⁹⁹) D. P. Jorgensen, P. H. Hildebrand, Ch. L. Frush, "Feasibility Test of an Airborne Pulse-Doppler Meteorological Radar," *Journal of Climate and Applied Meteorology*, Volume 22, 1983, pp. 744-757

²⁵⁰⁰) J. R. Parrish, "New NOAA OAO WP-3D Doppler Radar System," internal paper of NOAA/OAO, Miami, FL

²⁵⁰¹) D. P. Jorgensen, "Mesoscale and convective-scale characteristics of mature hurricanes. Part I: General Observations by research aircraft," *Journal of Atmospheric Sciences*, Vol. 41, 1984, pp. 1268-1285

- 2) **LFR** (Lower Fuselage Radar)
LFR is an AOC-modified version of the original equipment made by Videotronics. It is a horizontally-scanning radar instrument measuring reflectivity parameters (note: the term ‘reflectivity’ means actually ‘water content’), the scan is 360° , the sensor is a 5.5 cm wavelength C-band radar (built by Videotronics, Sigmet).
- 3) **TDR** (Tail-mounted Doppler Radar)
TDR is an X-band radar with a Doppler receiver and pulse pair processor. It evolved from an engineering prototype system (first flown in 1979 to test the feasibility of making Doppler radar measurements) to its current state (1994) as part of an integrated radar data processing, display and recording system. The TDR instrument is a vertically-scanning X-band (3 cm wavelength) Doppler radar measuring reflectivity parameters and wind velocity profiles. It was built by Sigmet and Videotronics, and modified by AOC; the tail receiver was made by AOC.

Note: the term ‘reflectivity’ is used here to describe ‘water content’ and depends on the Z/R relationship. The parameter Z is the amount of radar energy reflected from the target (rain and water drops), usually measured in dBm. The variable R is the rainfall rate. Depending on the size distribution of the hydrometeors (scatterers) in the cloud, the relationship between the reflected energy (Z) and the rainfall rate (R) changes. Therefore, different Z/R relationships are used for different classes of clouds (maritime versus overland, tropical versus mid-latitude, etc.).

Parameter	Nose Radar NTR	Lower Fuselage Radar LFR	Tail Doppler Radar TDR
Transmitter frequency	5.445 GHz \pm 6.6 MHz	5.370 GHz \pm 6.7 MHz	9.315 GHz \pm 11.6 MHz
Frequency band	C-band	C-band	X-band
Transmitter wavelength	5.51 cm	5.59 cm	3.22 cm
Transmitter pulse	3.0 μ s	6.0 μ s	0.5 μ s
PRF	400 pps	200 pps	1600 pps
Peak transmitter power	70 kW (min)	70 kW (min)	60 kW (min)
Receiver dynamic range	80 dB	80 dB	80 dB
Antenna polarization		linear horizontal	linear vertical
Gain, main beam	34 dB	37.5 dB	40 dB
Gain, sidelobe	23 dB down	23 dB down	23 dB down
Horizontal beam width	3.6°	1.1°	1.35°
Vertical beam width	3.6°	4.1°	1.90°
Sweep rotation rate	4 rpm	4 rpm	variable up to 10 rpm
Pulses averaged per radial sample			32
Antenna stabilization Fore/Aft tilt range	$\pm 20^\circ$ (pitch and roll)	$\pm 10^\circ$ (pitch and roll)	$\pm 25^\circ$ (pitch and roll)
Nyquist interval: Radial velocity Maximum range	185 km	371 km	12.89 m/s 93 km
Range resolution (half pulse length)			75 m

Table 774: Characteristics of the NOAA WP-3D Orion radars

The LFR and TDR instrument data are digitally recorded on front-loading 9-track tape drives (a 1994 upgrade permits recording the data on 4 mm DATs). The new on-board data system (since 1988) features real-time control and data display capabilities (color graphics, menu selection of instrument status and control options, split-screen display of instrument data, playback feature of recorded data, etc.). The on-board data processing capabilities permits some 2-D Doppler motion analysis. All three radars are operated simultaneously.

P.153.2 Scan Strategies of TDR

NOAA/AOC (Aircraft Operation Center) at MacDill AFB (near Tampa, Florida) has been flying a vertically-scanning airborne Doppler radar on its two P-3 research aircraft since 1985. Objective: study of severe convective storms, mesoscale convective systems, subtropical rainbands, and hurricanes, etc..²⁵⁰²⁾

Figure 496: Horizontal beam pattern projections from the P-3 Tail radar

The scan strategy for past studies have either used two or three quasi-orthogonal flight legs (an 'L'- or 'U'-shaped flight pattern) or a single P-3 leg combined with a volume scan from a ground-based Doppler radar to derive mesoscale wind fields over regions as large as 80 km by 80 km (see Figure 496). The P-3 radars are (in these flight pattern conventions) vertically scanning radars (RHI = Range-Height Indicator) in a plane normal to the aircraft's ground track.

A new scanning technique, named FAST (Fore/Aft Scanning Technique) has been tested for the TDR instrument to collect 'pseudo-dual-Doppler' data from a straight-line flight path in about half the time of an "L"-shaped flight pattern. FAST consists of collecting two beams of data, one pointing $\sim 25^\circ$ forward from the plane normal to the flight path, and one beam pointing aft of about 25° . - The FAST procedure consists of alternatively scanning the

²⁵⁰²⁾D. P. Jorgensen, T. Matejka, J. D. DuGranrut, "Multi-Beam Techniques for Deriving Wind Fields from Airborne Doppler Radars," submitted to the Journal of Meteorology and Atmospheric Physics, Spring 1994, Special Issue on Remote Sensing - Information provided by J. D. DuGranrut of NOAA/AOC at MacDill AFB, FL

P-3's tail radar antenna forward and then aft of the normal to the aircraft's heading. If two radars and two antennas mounted back to back are used (as for ELDORA, see chapter P.76), then the fore/aft scans can be done simultaneously. The AFAST (alternative FAST) procedure consists of first scanning the antenna forward as the aircraft approaches the region of interest, then slewing the antenna to scan toward the rear as the aircraft passes the region. For the TOGA/COARE campaign the full FAST scanning capability was used on both P-3 aircraft as the standard antenna scan mode of the TDRs.

Either the FAST scan can be used, or the antenna may be stabilized to scan normal to the aircraft track. The antenna used for FAST is a dual-beam antenna (built by LCTAR/CRPE and similar to the one used by NCAR on ELDORA). A waveguide switch permits the selection of either the forward-looking beam or the aft-looking beam.

The effective horizontal data spacing of dual-Doppler derived winds from the FAST or AFAST method is directly proportional to the rotation rate of the antenna and the aircraft's ground speed. Nominal P-3 ground speed is from ~ 110 m/s near sea level to about 150 m/s at 6 km altitude. The basic control mechanism for horizontal data spacing is a variation in the rotation rate of the radar antenna and in the scan width. For the complete 360° vertical rotation mode, the effective horizontal data spacing for a straight line flight is:

$$\Delta d = 2 V_{gs} \Delta t$$

Where Δd is the horizontal spacing in meters, Δt is the time (in seconds) for a complete rotation, and V_{gs} is the aircraft ground speed. With a maximum rotation rate of 10 rpm and a nominal speed of 120 m/s, the horizontal spacing of scans is 1400 m.

Figure 497: Schematic illustration of the fore-aft scan technique (FAST)

Doppler radar data preprocessing. Prior to the construction of wind fields the airborne Doppler radial velocity data must be corrected for radial velocity biases introduced by the aircraft's motion; the aircraft attitude effects must be removed from the measured angles (i.e. coordinate transformation from the aircraft-based to the Earth-relative system). The radial velocity data must be unfolded prior to data interpolation onto Cartesian grids.

P.153.3 ASDL (NOAA Aircraft Satellite Data Link)

An ASDL system was installed on the two P-3 aircraft of NOAA/AOC with the objective to transmit directly and automatically key meteorological and navigational parameters to

NWS/NHC forecasters via GOES/DCS (see F.4.1 for GOES/DCS description) satellites and the NOAA/NESDIS ground segment.²⁵⁰³) In the overall system configuration the ASDL functions like a DCP (Data Collection Platform) in the ground system, capable of transmitting data at a rate of 100 bit/s to the GOES/DCS platform.

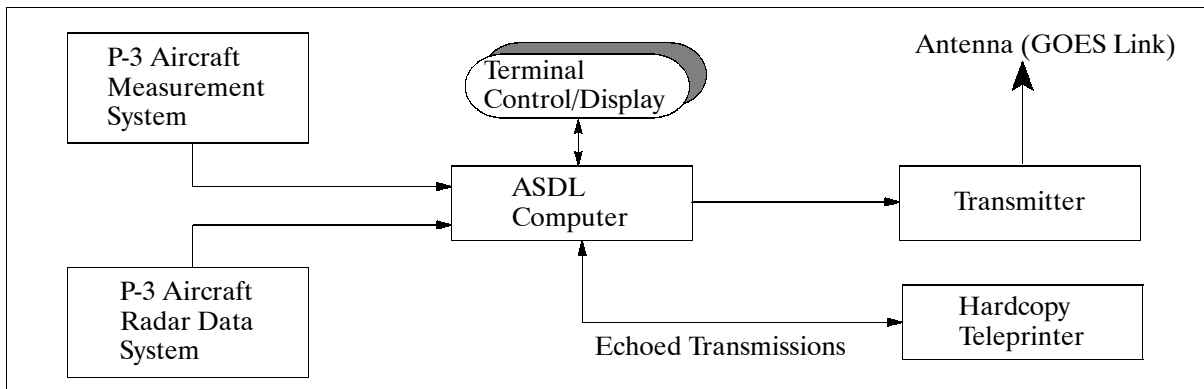

Figure 498: Schematic diagram of the ASDL system aboard the NOAA P-3 aircraft

Background: The ASDL system evolved as a direct result of the NHC (National Hurricane Center) requirement for near-real-time availability of flight level data from tropical cyclones. The initial ASDL system was designed and installed on a P-3 aircraft in 1977; the first successful operational test was during hurricane Anita in September 1977. Since then ASDL has been used in dozens of reconnaissance flights into hurricanes and tropical cyclones in the Atlantic and Pacific Oceans.

ASDL offers a number of message products to give forecasters better first-hand meteorological information. During the years of operational support there have been a number of system updates.

P.153.4 ODW (Omega Dropwind Sonde)

The P-3 aircraft are equipped with a dropwind sonde system using Omega radio signals to track the sonde on its way to the ground or the ocean, measuring wind speeds at regularly spaced levels. This information, along with the pressure, temperature, and relative humidity information transmitted back by the sonde, is coded and incorporated in the ODW message text. One message per sonde is normally sent through the ASDL system.

Note: the ODW system is scheduled to be phased out in about 1996. It will be replaced by the next generation VAPS (Vertical Air Profiling System), which uses GPS to measure wind profiles. VAPS is in the development phase as of 1994.

P.153.5 NOAA P-3 Infrared Radiometers

Three infrared radiometers in one package are 'standard P-3 instruments' (Barnes Model PRT-5 with AOC control units).

- Measurement of sea surface temperature. IR-radiometer: spectral region = 9.5 - 11.5 μm ; measurement range = -20°C to 75°C ; resolution = 0.003°C ; accuracy = 0.5°C ; response time = 40 ms.
- Observation of CO_2 absorption temperature. IR-radiometer: spectral region = 14-16 μm ; measurement range = -42 to 30°C ; resolution = 0.002°C ; accuracy = 1.0°C ; response time = 1.5 s.
- Monitoring of upward-looking temperature. IR-radiometer: spectral region = selectable.

²⁵⁰³) J. D. Parrish, E. R. Darby, J. D. DuGranrut, A. S. Goldstein, "The NOAA Aircraft Satellite Data Link (ASDL)," NOAA Technical Memorandum OAO 3, NOAA internal paper, May 1984

P.153.6 AXBT (Air Expendable Bathythermograph)

An SSQ-36 AXBT system is carried on P-3 aircraft for the measurement of vertical ocean temperature profiles (to depths of 300 m and more). The expendable instrument is ejected from the aircraft. After landing in the water, AXBT deploys a radio antenna and a probe that sinks through the ocean layers. Measured water temperatures at all depths are radioed back to the aircraft and recorded; they can also be transmitted via ASDL, if required. The AXBT instrument is a standard US Navy bathythermograph used to measure ocean water temperature profiles.

P.154 NOAL (NOAA Ozone Airborne Lidar)

Background: NOAL is the new name of the former UV-DIAL instrument as of mid-1994. The UV-DIAL²⁵⁰⁴ sensor is a cooperative development of US-EPA (US Environmental Protection Agency), 'Environmental Monitoring Systems Laboratory' (EMSL), Las Vegas, with the University of Nevada's 'Desert Research Institute,' and the Harry Reid Center for Environmental Studies. The PI (R. Alvarez) and the instrument transferred in 1994 from US-EPA to NOAA/ERL/ETL in Boulder, CO.

Applications: research tool for the measurement of concentrations of ozone and other trace gases and pollutants in the atmosphere, determination of air quality, etc.

DIAL is a multi-wavelength lidar concept that uses the wavelength-dependent absorption of atmospheric constituents to measure their range-resolved concentration. Measurements of absorption of laser beams are obtained at "on-wavelengths" (for which the gaseous constituent is strongly absorbing) and "off-wavelengths" (for which the gaseous constituent is not strongly absorbing) to provide solutions to the lidar equation in ratio form in terms of these wavelengths.

The NOAL instrument is based on a KrF (krypton fluoride) excimer laser which generates 700 mJ, 20 ns pulses at 248 nm at a maximum pulse repetition rate of 20 Hz. The laser beam is split up - 1/3 of the power being focused into a hydrogen (H₂) Raman cell, and 2/3 into a deuterium (D₂) Raman cell. These Raman cells produce transmitted laser beams at frequencies shifted from the KrF fundamental by integral multiples of the vibrational frequency of hydrogen and deuterium.

The receiver section consists of a downlooking telescope for collection of the backscattered light and a spectrograph/detector system for detection of the individual laser lines. The telescope is a classical Newtonian design with a 0.5 m diameter, f/2.5 primary mirror, arranged in noncoaxial configuration with the laser transmitter. The telescope images the received light into the entrance slit of a custom Czerny-Turner spectrograph, which in turn images each of five different wavelengths [276.9 nm (S₁ of H₂), 291.6 nm (S₂ of D₂), 312.9 nm (S₂ of H₂), 319.4 nm (S₃ of D₂), and 359.4 nm (S₃ of H₂)] onto a separate photomultiplier tube (PMT). The PMTs are mounted directly in the focal plane of the spectrograph and are gated for the appropriate measurement range. The signals are digitized by 12 bit A/D converters with a maximum spatial resolution of 15 m. The data of the NOAL are stored on magnetic tape and simultaneously displayed on a monitor in real-time to allow for operational control of the system. In addition, information of the viewing scene for NOAL is provided by a downward-looking video camera.

Test campaign in southeastern Michigan:²⁵⁰⁵ The system was flown in a mid-sized aircraft (DeHavilland C-7 Caribou) for initial airborne testing in the Great Lakes area in May 1992. During these test flights several two-dimensional ozone distributions were acquired. The

²⁵⁰⁴)H. Moosmüller, R. J. Alvarez, R. M. Jorgensen, C. M. Edmonds, D. H. Bundy, D. Diebel, M. P. Bistrow, J. L. McElroy, "An Airborne Lidar System for Tropospheric Ozone Measurement," presented at the 86th Annual Meeting of AWMA, Denver, CO, June 13-18, 1993

laser was operated at a repetition rate of 20 Hz; data from 300 consecutive shots were averaged for each vertical ozone profile (horizontal resolution of 1.17 km at an average flight speed of 280 km/h). The vertical resolution of about 150 m is determined by a sampling interval of 30 m and smoothing over five data points. Ozone concentrations have been calculated from 90 m above ground to 150 m below the aircraft flight altitude.

Figure 499: Optical setup of the NOAL system

Results: Range-resolved data on gaseous concentrations and on relative density (in terms of lidar backscatter) of aerosol distributions can be obtained in the lowest two to three kilometers of the atmosphere in cells beneath the aircraft in the vertical plane along the flight path (sounding profile). Cell resolution is a joint function of laser firing rate, data digitization, data averaging and smoothing rate, and horizontal aircraft speed.

P.155 NPL Instruments

NPL (National Physical Laboratory, Teddington) in the United Kingdom has operated two ground-based remote sensing mid-infrared spectrometers since 1991 for the detection of stratospheric trace gases. Both instruments have been deployed in various international field campaigns, including ESMOS (European Stratospheric Monitoring Stations) of NDSC (Network for the Detection of Stratospheric Change), EASOE (European Arctic Stratospheric Ozone Experiment), and SESAME (Second European Stratospheric Arctic and Midlatitude Experiment).²⁵⁰⁵

P.155.1 FTS (Fourier Transform Spectrometer)

FTS is a Bruker IFS 120M instrument which is used to detect the stratospheric gases HCl, HF, HNO₃, N₂O, CH₄ and ClONO₂ from solar absorption spectra in the 3 - 13 μm region. It

²⁵⁰⁵J. L. McElroy, et al., "Airborne UV-DIAL Measurements of Ozone Distributions in Southeastern Michigan," presented at 86th Annual Meeting of AWMA, Denver, CO, June 13-18, 1993

²⁵⁰⁶Information provided by N. A. Martin of NPL

has a maximum unapodized spectral resolution of 0.002 cm^{-1} (defined as $1/2 L$, where L is the maximum optical path difference).

The IFS 120M features a permanently aligned Michelson interferometer with the source beam striking the beamsplitter at a 30° angle of incidence. The two-detector design enables simultaneous collection from two data channels (the InSb and HgCdTe detectors are nitrogen cooled).

In mid 1994 NPL adapted the FTS for deployment on an airborne platform (BAe Jetstream), operated by Cranfield University. A fast-response solar tracker was also developed and interfaced to the FTS specifically for this purpose. The Jetstream aircraft has a ceiling altitude of 7 km and an endurance of 3.5 hours, giving a total range of approximately 1300 km. Preliminary flights were able to record spectra of stratospheric HCl. During the SESAME campaign the FTS was located on the ground at Aberdeen where the ClO radical was detected for the first time.

P.155.2 TDLHS (Tunable Diode Laser Heterodyne Spectrometer)

The TDLHS is an NPL-developed instrument capable of detecting stratospheric ClONO_2 , HNO_3 , and O_3 . The instrument measures total column amounts in a manner similar to the FTS. Solar radiation is collected and combined with the output of a mid-infrared tunable diode laser (the local oscillator, LO) on a ZnSe beamsplitter. Both beams are then focused onto a fast (310 MHz) HgCdTe photomixer. The solar absorption spectrum is obtained from the heterodyne difference frequency, which is in the radio frequency region.

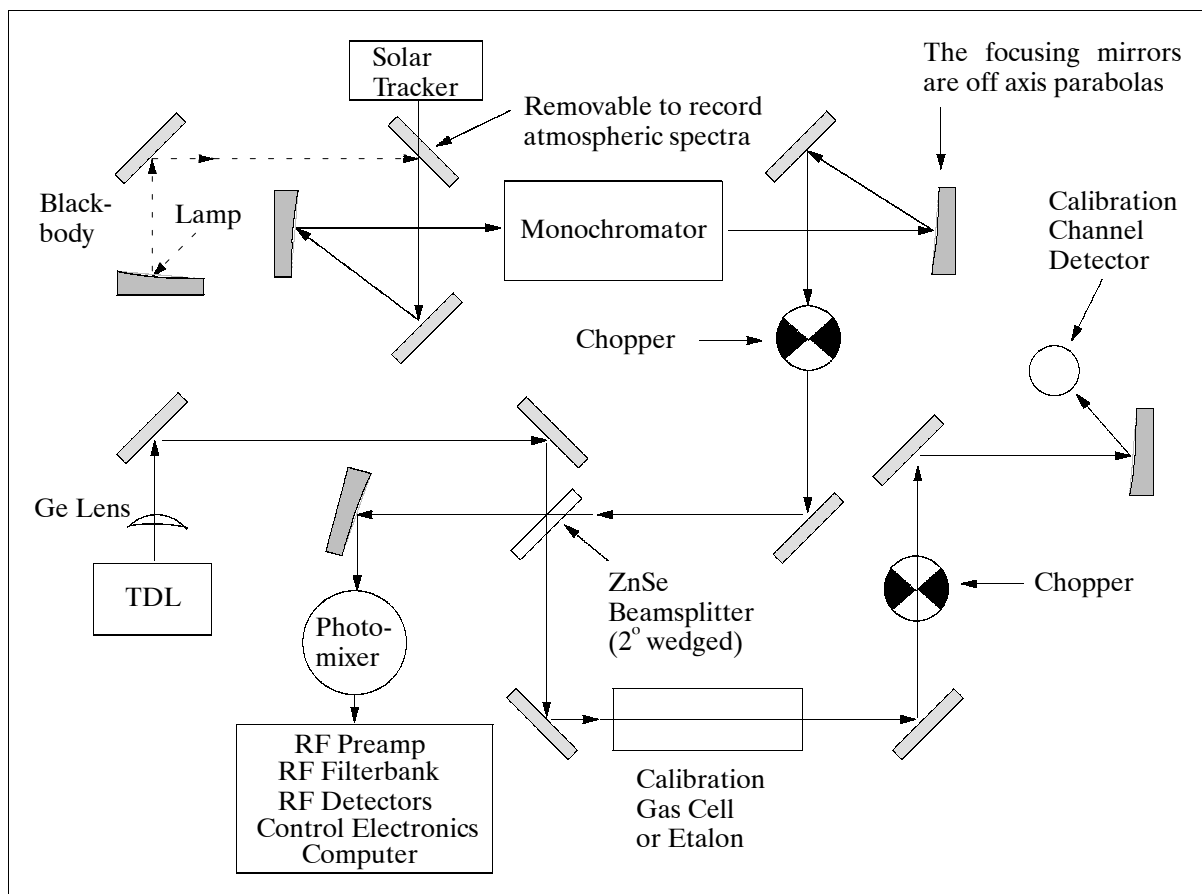

Figure 500: Schematic diagram of the Tunable Diode Laser Heterodyne Spectrometer

The high resolution of the TDLHS is governed by the narrow bandwidth of the RF filter, which is sufficiently narrow to enable some altitude-resolved information to be obtained.

For convenience there is a bank of four RF filters (5-56 MHz, 2-20 MHz, 0.95-10 MHz) which enables spectra to be simultaneously recorded at four different double side band resolutions (0.0037 cm^{-1} , 0.0013 cm^{-1} , 0.0007 cm^{-1} , and 0.0003 cm^{-1}).

The local oscillators are continuously tunable and are available throughout the 3-30 μm region.

So far, measurements have been focused at long wavelengths for ClONO_2 (780 cm^{-1}) and HNO_3 (868 cm^{-1}) where the sensitivity of the FTS begins to fall off and the heterodyne efficiency increases.

Data collection is based on tuning the LO wavelength over the atmospheric absorption feature of interest. At present, this requires about seven minutes with an integration time constant of 0.5 s. Upgrades are planned for the future.

P.156 NS001 (Thematic Mapper Simulator)

The NS001 multispectral scanner is a NASA-developed Thematic Mapper Simulator (TMS) flown on board the C-130B aircraft based at Ames Research Center, Moffett Field CA. This scanner contains the seven Landsat 4 and 5 TM bands plus a band from 1.131 - 1.35 μm .

The NS001 is flown at low and medium altitudes. The format of the flight data consists of 838 8-bit words per frame (data for one wavelength band throughout a scan line). Of these, 699 are the video information and the remainder ancillary information (Greenwich time, scan line number, calibration lamp voltage and current, blackbody temperatures, etc.).

Band No.	Wavelength of Band (μm)
1	0.458 - 0.519
2	0.529 - 0.603
3	0.633 - 0.697
4	0.767 - 0.910
5	1.13 - 1.35
6	1.57 - 1.71
7	2.10 - 2.38
8	10.9 - 12.3
Geometric Parameters	
FOV	100°
IFOV	2.5 mrad
Ground resolution	7.6 m (at 3000 m altitude)
Swath width	7.26 km (at 3000 m altitude)
Pixels/scan line	699
Scan rate	10-100 scans/s

Table 775: Spectral coverage and geometric parameters of the NS001 instrument

P.157 NUSCAT (Airborne Ku-band Scatterometer)

NUSCAT²⁵⁰⁷⁾ was developed by NASA/JPL for airborne experiments to improve geometrical model functions relating ocean backscatter to wind vectors, to serve as a test bed scatterometry technology demonstration, and to provide surface truth measurements for spaceborne scatterometers. NUSCAT was flown on the Ames C-130B aircraft and operated by JPL to record ocean backscatter data during SWADE (Surface Wave Dynamics Experiment) in February - March 1991. The experiment was conducted off the coast of Maryland and Virginia where several buoys are anchored. About 30 hours of data were taken in a

²⁵⁰⁷⁾Information received from S. Nghiem and S. Durden of JPL

total of 10 flights over a wide variety of oceanic conditions, including wind speed as low as 2 m/s to more than 12 m/s and significant wave height from below 1 m to well above 5 m.

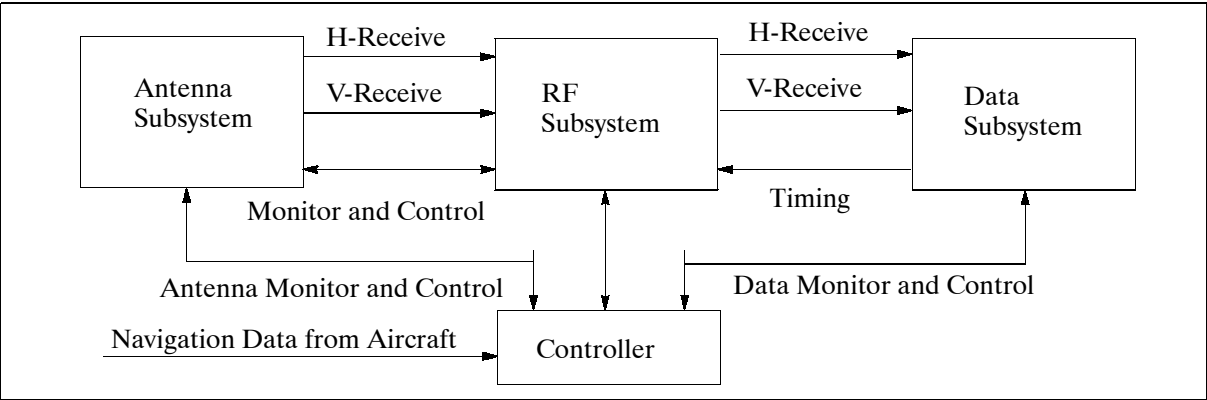

Figure 501: NUSCAT system block diagram

The NUSCAT system is composed of an antenna subsystem, an RF subsystem, a data subsystem, and a controller. The antenna is a parabolic disk with a peak gain of 32 dB and a beam width of approximately 3°. The antenna is placed inside a radome on the tail of the C-130B aircraft, and is mounted on a gimbal which is used to rotate the antenna in complete azimuthal scans at selected incidence angles. The antenna subsystem is connected through a rotary joint to the RF subsystem. When the system is transmitting either H or V polarization, two receiver subsystems are used to collect simultaneously co- and cross-polarization returns. The radar echoes from each pulse are amplified, down-converted to I/Q samples and digitally square-law detected. The returns from multiple echoes are integrated over 0.5 seconds and then recorded on computer-compatible tapes.

The internal system calibration is performed by injecting a transmit signal into the receiver through a calibration loop. The relative calibration accuracy involves the uncertainty in measurements of transmit power, receiver gain, position in antenna angles and altitude, sampling circuit, electromagnetic wavelength, rotary joint loss, radome loss, and attenuators, and is estimated to be ± 0.23 dB. The measured power accuracy depends on the number of independent samples and the signal-to-noise ratio. The operating frequency is dithered over 100 MHz to generate additional independent samples (N), which effectively reduces the communication noise $K_{pc} \propto N^{-1/2}$. The absolute accuracy is subjected to several sources of errors under laboratory test, such as attenuation, calibration loop loss, antenna gain, beamwidth, and various losses from VSWR (Voltage Standing Wave Ratio), waveguides, and rotary joints. The antenna gain is determined by the three-horn measurement method at the JPL Antenna Range.

To evaluate the system stability and absolute calibration, data are collected over the ocean surface at 10° incidence where the backscatter is insensitive to surface roughness conditions. In experimental flights, the NUSCAT antenna scans in azimuth in 10° steps. During a 4-second period for each step, NUSCAT collects data and moves to the next step. The data are recorded as functions of incident angles up to 60° in 10° steps, azimuthal angles in complete azimuthal circles, and horizontal and vertical polarizations.

Operational frequency	13.9 to 13.995 GHz
Polarization	HH, VV, HV, VH
Incidence angle	0 to 70° (60 to 70° by using the aircraft roll)
Incidence angle slew rate	10°/s
Azimuth angle	0 to 360°
Azimuth angle slew rate	10°/s
Operational altitude	0.5 km to 15 km
Pulse repetition frequency	1.5 to 10 kHz
Pulse length	2 to 65 μ s
Frequency diversity	pulse-pulse independence (1 MHz steps available in 100 MHz bandwidth)

σ_0 sampling rate	2/second for quick-look
System dynamic range	observe winds from 2 - 50 m/s
Data collection	quick-look system, baseband digital recording
Calibration	transmit signal injection; 0.23 dB relative; 1.1 dB absolute
Transmit power	+ 51 dBm
Noise floor	-110 dBm
Frequency	13.95 GHz
Frequency diversity	up to 32 with 100 MHz bandwidth
Sampling rate	2/s
Data collection	8 bit A/D converters
Instantaneous dynamic range	30 dB
Antenna gain	32.0 dB
Antenna beamwidth	$\sim 3.1^\circ$
Timing	> > 4 sets
Bandwidth	4, 2, 1 and 0.2 MHz
Polarization	direct and cross-simultaneously
Gimbal RF path	rotary joints

P.158 OLS (Oceanographic Lidar System)

OLS is an airborne instrument for fluorosensor detection of maritime oil spills. It was developed by the University of Oldenburg and utilized as an experimental sensor in 1983-86 by the University of Oldenburg.

Lasers:	Excimer	Dye (excimer laser pumped dye laser)
Emission wavelength	308 nm	450/533 nm
Pulse length	12 ns	6 ns
Peak power	10 MW	1 MW
Repetition rate	≤ 10 Hz	≤ 10 Hz
Receiver Telescope	f/10, Schmidt-Cassegrain (0.4 m diameter)	
Spectrograph	8 discrete channels, modular	
Wavelength detection	344,366, 380, 450, 500, 533, 650,,685 nm	
Wavelength selection	dichroic splitters, interference and blocking filters	
Detectors	PMT, EMI 9821/9818	
Digitizer	Biomation 6500, 500 MHz, 11 bit	
Computer	LSI 11/23 with floppy disk, hard disk and magtape	
Total mass	500 kg	
Resolution (Footprint)	2.5 m at 245 m flight altitude	

Table 777: Overview of the OLS parameters

Application: synoptic mapping of hydrographic conditions in extended coastal regions.

OLS is a nonimaging sensor with excitation and detection wavelengths appropriate for the investigation of naturally occurring sea water compounds. The instrument is installed on a DO-228 aircraft and has been flown in many campaigns. ²⁵⁰⁸⁾ ²⁵⁰⁹⁾ ²⁵¹⁰⁾

P.159 OVID (Optical Visible and Near-Infrared Detector)

OVID is an imaging spectrometer with dispersion grating and CCD technology which is owned by MPIfM Hamburg and the Free University of Berlin. The instrument has been op-

P.160 PBMR (Pushbroom Microwave Radiometer)

PBMR is a multibeam L-band (1.413 GHz) radiometer providing simultaneous cross-track radiometric measurements. ²⁵¹²⁾ The system is owned and developed by NASA's Langley Research Center (Hampton, VA) and operated by WFF of GSFC. Objectives: to provide an engineering prototype to investigate such pushbroom technologies as microwave integrated circuit receivers, digital signal processing within the radiometer, and local oscillator distribution. The instrument is considered as a research tool providing, in addition, some practical applications for soil moisture research.

Center frequency	1.413 GHz
RF bandwidth	25 MHz
Sensitivity	1.0 K
Calibration accuracy	2.0 K
Antenna	4 beam
Scan angles	$\pm 8^\circ$ and $\pm 24^\circ$ from nadir
Beam crossover	3 dB
Sidelobe levels	-13 dB

Table 779: PBMR system parameters

PBMR became operational in 1983 and has been flown in NASA C-130 or P-3 aircraft at low altitudes (< 1500 m), providing low-resolution images with a swath width of about 1.2 times

²⁵¹¹⁾Information provided by T. Kriebel of DLR

²⁵¹²⁾Information provided by J. R. Wang of GSFC and by T. Schmugge of USDA Hydrology Lab

the flight altitude. The instrument is mainly used for remote measurements of soil moisture and ocean salinity; it took part in the HAPEX campaigns in 1986 and 1992 as well as in the FIFE program in 1987-89.

The radiometer is a Dicke Switching Noise Injection System. This technique provides a very stable radiometer by greatly reducing the effect of receiver noise and gain functions. The antenna system utilizes a Butler matrix feed to produce the required simultaneous beams at discrete cross-track angles. The system produces four beams, pointing at the cross-track direction of $\pm 8^\circ$ and $\pm 24^\circ$ from nadir; the beam width is about 16° .

P.161 PERSEUS (Unmanned High-Altitude Research Aircraft)

A commercially-developed high-technology aircraft program for high-altitude atmospheric research (NASA-supported since 1991 through a cooperative agreement). The Perseus platform carries lightweight monitoring instruments - the objective is to offer adequate means for sampling the chemistry and dynamics of the upper troposphere and stratosphere, in particular in the polar regions. The idea is the provision of a low-cost platform (in equipment as well as in operation compared with space flight) to satisfy a multitude of requirements from the research community.

‘Perseus’ represents a family of remotely-controlled drones, designed and developed by ‘Aurora Flight Sciences Corporation,’ Manassas, VA. The family consists of the following models: ²⁵¹³⁾ ²⁵¹⁴⁾ ²⁵¹⁵⁾ ²⁵¹⁶⁾

- Perseus-POC (Proof-of-Concept). This is a one-of-a-kind technology demonstrator. First flight of POC on November 8, 1991.
- Perseus-A. Designed primarily for stratospheric research. Perseus-A uses a unique closed-cycle engine powered by liquid oxygen and gasoline to achieve altitudes of 25 - 30 km with payloads of 50 - 100 kg.
- Perseus-B. Designed for upper troposphere and lower stratosphere research. Perseus-B combines the airframe and flight control system from Perseus-A with a two-stage turbocharged engine. It is an aircraft intended for long-range and long-endurance flights.
- Theseus. An extension of the Perseus program. Twin-engine aircraft with a fault-detecting, reconfigurable control system.

The remotely-controlled aircraft requires a ground station during its flight missions. Such a ground station consists of work stations for the aircraft pilot, an avionics engineer, a flight engineer, and the science payload operators.

The pilot has three video screens for basic flight information (altitude, speed, heading, etc.). A navigation monitor traces the aircraft’s location along its pre-programmed flight path on a map. The avionics engineer monitors both airborne and ground station computers, the integrity of RF links, and the system configuration. The flight engineer monitors engine performance and other aircraft systems.

As of early 1996 the aircraft in the program are in various phases of flight testing and up-grading of prototype versions to meet their performance envelopes.

Table 780: Performance requirements of the Perseus aircraft family

A ground station consists of a (mobile) container equipped with computers for all operations, a GPS receiver, and multichannel narrow-band UHF (430-450 MHz band) radios for ground-air communications in both directions.

Airborne flight control relies on a central computer which supports communication, navigation, operation of the autopilots and control of the propulsion system. Sensors continuously monitor the aircraft state and pass the information to the pilot on the ground as well as to the airborne autopilot and navigation systems. Roll and pitch is sensed by a vertical gyro; a three-axis magnetometer reports heading; angular rates are sensed by rate transducers; while angle of attack and sideslip are measured with vanes. Airspeed and barometric altitude are also measured by pressure transducers. Position data is determined by GPS.

The fully-digital autopilot can operate in several independent modes designed to improve flight safety. Perseus can be flown in ‘autonav’ mode. This is a computer flight with GPS input to follow waypoints along a preplanned flight path. In case of a loss of uplink command, autonav will automatically return the aircraft to a designated recovery area.

Applications: large-area surveys with long-endurance and long-range flights. Hurricane studies from above the storm; etc.

P.162 PHARUS (PHased ARray Universal SAR)

PHARUS is a polarimetric C-band airborne SAR, a Dutch project carried out by TNO Physics and Electronics Laboratory (TNO-FEL) in The Hague, together with NLR (National Aerospace Laboratory) in Amsterdam, and the Delft University of Technology (DUT). The program is sponsored in part by the Ministry of Defense and the Netherlands Research Sensing Board.

Radar type	Coherent pulse radar
RF frequency	5.25 GHz (C-band)
PRF	2-5 kHz nominal, dependent on the ground speed
Waveform type	linear FM (chirp)
Pulse length	12.8 μ s before and 32 ns pulse compression
Pulse compression ratio	400
Pulse bandwidth	45 MHz nominal (expandable to 100 MHz)
Generation technique	I/Q memory read-out
DAC frequency	87.5 MHz, 8 bit
Total memory capacity	4096 bytes
Total peak transmit power	960 W (maximum, 560 W with antenna in a tapered mode)
Module peak transmit power	20 W
Number of modules	8 (transmit and receive)
Range	3-14 km
Antenna	8 elements antenna with 4 patches each uniform, no tapering
Polarization	vertical
Azimuth beamwidth	9°
Azimuth presumming factor	1 - 64 (depending on imaging mode)
Azimuth scan angle	-12° to +12° (1° step)
Elevation beamwidth	24°
Elevation pointing angle	fixed
Mechanical elevation angle	20, 30, and 40° (depression angle)
Resolution	4.8 m in range, 1 m single look in azimuth
Sampling frequency in range	87.5 MHz (A/D conversion) 4096 x 8 bit
Data storage rate	8.2 Mbit/s
Airplane	Swaeringen Metro (NLR's laboratory aircraft)
Altitude	3 - 6 km
Speed	100 m/s
Position and motion registration	IRS, ARA

Table 782: Parameters of the SAR testbed PHARS

The objective is the operation of a full polarimetric C-band SAR (wavelength = 5.66 cm) on an aircraft for Earth surface imaging. The PHARUS system was test-flown from September to December 1995 (the program started in 1988). A national campaign is planned for 1996; applications include: defense, agriculture, forestry, tidal waters, bottom topography, cartography. The PHARUS system has an active phased-array patch antenna (image mode flexibility, selection of resolution). Antenna pointing on board the aircraft is maintained through the phased array, rather than by mechanical stabilization.

A polarimetric radar is capable of measuring the complex scattering matrix of every resolution cell. In comparison with traditional radar systems which usually measure only a single fixed polarization, more information on the target surface is gathered by a polarimetric SAR. The information contained in the scattering matrix enables synthesis of every possible transmit and receive polarization by signal processing. Since the brightness of targets in a radar image depends on polarization, the contrast can be optimized, and targets may be classified or even identified. ^{2517) 2518) 2519)}

The operating frequency of PHARUS is 5.3 GHz, the same as used by AMI on ERS-1 (the azimuth resolution of PHARUS will be approximately 1 m). This allows data comparison and additional aircraft data collection in projects demanding high temporal coverage of test sites.

Mode	Resolution (m)	No. of Looks	Altitude (km)	Noise equiv. γ (dB)	Swath (km)	Range (km)	Incidence range (°)
1 polarization	4	3	6.0	-30	11.2	16	31-68
1 polarization	8	8	6.0	-30	14.6	20	31-73
1 polarization	16	20	6.0	-30	20.0	26	41-77
4 polarization	4	4	4.5	-40	4.4	8	26-56

4 polarization	16	20	6.0	-40	7.9	13	31-62
2 polarization (ASAR)	24	4	14.0	-25	9.8	20	18-46

Table 783: Basic PHARUS modes

PHARS - Testbed/Prototype Phase of PHARUS

Radar type	Coherent pulse radar
RF frequency	5.3 GHz (C-band)
PRF	4000 Hz nominal, dependent on the ground speed
Waveform type	linear FM (chirp)
Pulse length	12.8 μ s or 25.6 μ s before pulse compression
Bandwidth	40 MHz nominal, 100 MHz maximal
Total peak transmit power	475 W
Range	26 km
Antenna	48 elements antenna with two rows of 24 patches
Polarization	transmit: H or V; receive: H and V
Azimuth beamwidth	2.3°
Azimuth presumming factor	depends on the operating mode
Azimuth scan angle	-20° to + 20° (0.5° step)
Elevation beamwidth	24°
Elevation pointing angle	fixed
Elevation scan angle	+15 to - 15° with respect to the pointing angle, 0.5° step
Resolution	3.75 m in range
Sampling frequency in range	100 MHz (A/D conversion) 16384 x 8 bit
Data storage rate	100 Mbit/s
Airplane	Cessna Citation II
Altitude	14 km max
Speed	150 m/s
Position and motion registration	IRS, ARA, GPS

Table 784: Nominal PHARUS specifications

The objective of the PHARS testbed is to develop the technology for the PHARUS design. The first test flight of PHARS was performed on November 8, 1990. The PHARS instrument records a swath width of 7 km up to a range of 13 km. The azimuth resolution is in the order of 6 m with five independent looks, or 1.2 m for single look. The aircraft motion is

successfully compensated with off-line processing, using trajectory measurements from motion sensors both inside the aircraft and in the radar pod. The PHARS testbed results were introduced into the PHARUS design.²⁵²⁰⁾

PHARS participated in the NORCSEX '91 campaign (ERS-1 calibration/validation) off the coast of Norway, the 'WEU Benefit Assessment Study on Satellite Simulation' in 1993, and also during the flooding in the Netherlands in February 1995.

P.163 PI-SAR (Polarimetric and Interferometric - SAR)

PI-SAR is an airborne X-band and L-band instrument developed as a joint project by CRL (Communications Research Laboratory, a division of the Ministry of Posts and Telecommunications of Japan) and NASDA in the time frame 1993-1996. PI-SAR is installed on a Gulfstream-II aircraft. The overall objectives are to provide high-resolution polarimetric and topographic (interferometric) imagery along with all data processing capabilities for a variety of applications.

The instrument was initially referred to as CRL-SAR. First flight tests were conducted in the summer 1996. Both radars observe the same region simultaneously by sharing the source signal from a stable oscillator. There is also a support mode for independent observations for each SAR. At four looks the horizontal resolution is 1.5 m in X-band and 3 m in L-band. The X-band system features a cross-track interferometric capability, achieving ground height accuracies of 2 m after data processing.^{2521) 2522) 2523)}

Frequency	X-band (9.5547 GHz)	L-band (1.2712 GHz)
Instrument mass	707.6 kg (includes INS)	422.2 kg
Slant range resolution	1.5 m / 3 m	3 m / 5 m / 10 m / 20 m
Azimuth resolution (4-look processing)	1.5 m / 3 m	3 m / 6 m
Noise equivalent NRCS	< -40 dB for HH	< -30 dB for HH
Polarimetry Polarimetric phase accuracy	HH, HV, VV, VH; < 5°	HH, HV, VV, VH; < 5°
Interferometry: base line phase accuracy height accuracy	2.30 m < 5° < 2 m (rms)	
Radiometric accuracy	< 0.5 dB	< 0.5 dB
Incidence angle of antenna	Variable between 10-75°	Fixed, 20-60°
Antenna size	106.5 cm (length) x 20 cm	155 cm x 65 cm
Antenna gain	> 26.5 dB	> 18 dB
Beam width in azimuth, range	2.3°, 40°	9.8°, 38°
Sidelobe elevation, azimuth	< -20 dB, < -25 dB	< -17 dB, < -25 dB
Cross-polarization isolation	< -33 dB	< -25 dB
Transmitter peak power	6.3 kW	3.0 kW
Pulse length	10 µs	10 µs
PRF (Pulse Repetition Frequency)	< 3 kHz	< 1 kHz
Transmitter bandwidth	100 MHz	50 MHz
Transmitting/receiving electronics	All digital	All digital
Data sampling rate	120 MHz / 60 MHz	61.725/30.863 MHz
Data quantization	8 bit for both I and Q	8 bit for both I and Q
Data rate	512 Mbit/s	256 Mbit/s

Frequency	X-band (9.5547 GHz)	L-band (1.2712 GHz)
Ground swath width, flight altitude	>15 km, at 12 km AGL (Above Ground Level) for polarimetric or interferometric support modes	
Swath for parallel polarimetric and interferometric mode of observation	About 4 km	

Table 785: Performance parameters of PI-SAR

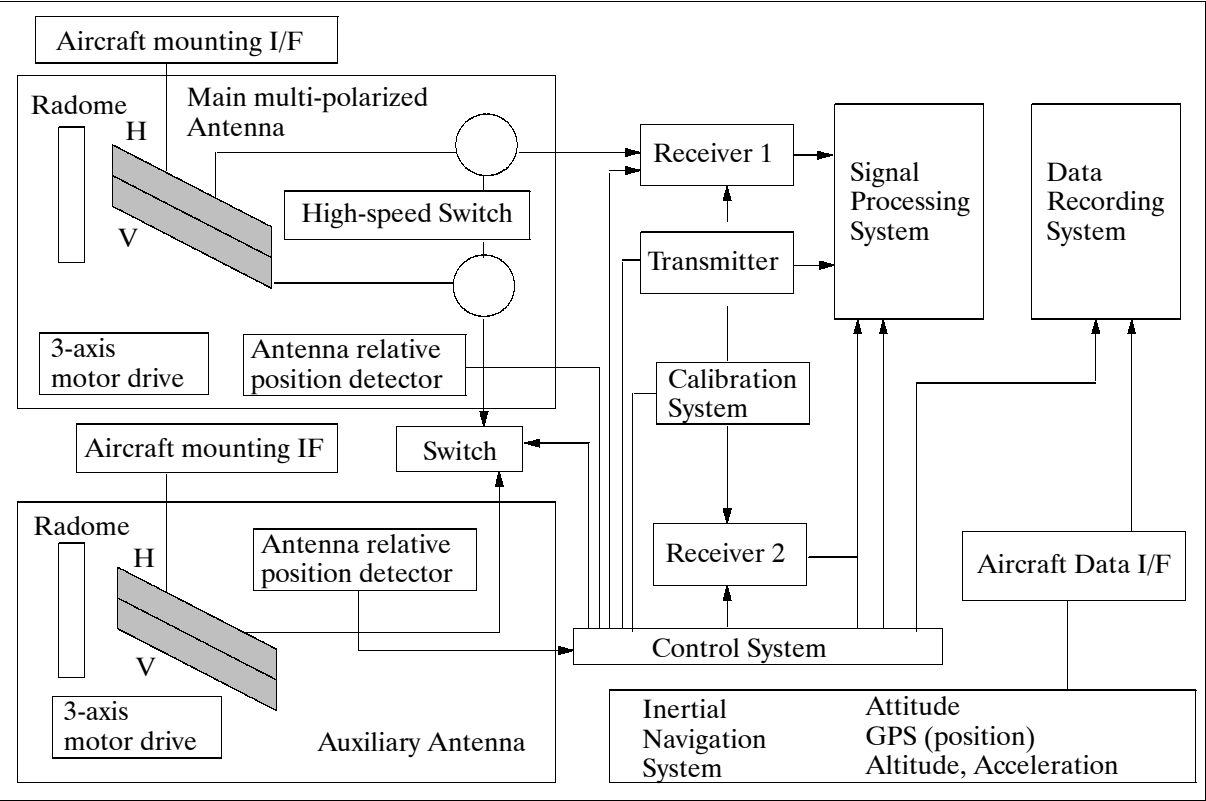

Figure 502: Block diagram of the PI-SAR

PI-SAR consists of the antenna assembly (slotted waveguide phased array with an aperture length of 0.93 m), a transmitter, two receivers, a data recording subsystem, control subsystem, a data processing system, aircraft data input interface, and a calibration system. Each antenna is installed in a radome. The X-band antennas can be pointed in the roll direction to get a more favorable look angle, and in the yaw direction ($\pm 6.5^\circ$), to compensate for drift. There are three slotted waveguide planar arrays in X-band (two V-polarized and one H-polarized antenna) installed in two radomes. For the L-band SAR, a microstrip planar array antenna is fixed under the aircraft. The polarimetric data are collected by transmitting pulses from the H- or V-polarized antenna alternatively and by receiving the echo from the ground target by both, the H- and V-antennas. Interferometric data are taken by transmitting from the left V-antenna and receiving by both, the left and right radome antennas. For the simultaneous polarimetric and interferometric support mode, a measurement cycle consists of three transmissions. - A dedicated ground processing facility provides all functions for data processing and analysis.

P.164 PMS (Particle Measuring Systems Inc.) Instruments

Commercially available meteorological instrument package of PMS of Boulder, CO, USA. PMS has developed a complete line of aircraft-mountable instruments which allows real-time “in-situ” sizing of atmospheric particles (particle spectroscopy). The two-dimensional (2-D) probes provide image analysis, as well as size spectra. The 1-D probes provide only size spectra (see Table 786 for overview).

All of the probes use a helium/neon laser as illumination source with light-scattering techniques used for sizing small particles down to 0.1 µm in diameter. Optical array imaging techniques are used for sizing large particles up to 12,400 µm in diameter. ²⁵²⁴⁾

	Instrument Model Number	Sizing Range Diameter (µm)	No. of Size Channels	Resolution (µm)	
Light – Scattering Probes	PCASP-100X	0.10 - 3.00	15 plus oversize	0.02 - 0.50	One-Dimensional Probes
	FSSP-300	0.3 - 20	31	0.05 - 1.00	
	FSSP-100 (Option A)	(R3) 0.5 - 8.0	15	0.5	
		(R2) 1.0 - 16	15	1.0

			150 - 9300 max	150 max	

Table 786: Overview of PMS aircraft-mountable probes

Each optical array probe (OAP) uses a linear array of silicon photo-diodes as a sensor that is illuminated by a laser beam forming optics and mirrors. The beam is directed out from the probe enclosure through one hollow extension with a mirror at its tip, which reflects the beam across the sampling region of the probe to the tip of the other extension. This other extension also has a mirror which reflects the beam back into the enclosure and onto the array sensor.

According to PMS information (6/1993) over 350 instruments configured for aircraft operation have been sold worldwide. The FSSP-100 was delivered over 150 times; more than 160 OAPs are in operation (of these, about 70 instruments are 1-D versions, 60 are 2-D versions, and the remainder are Grey Probes).

Sensors/Instruments:

PCASP-100X (Passive Cavity Aerosol Spectrometer Probe)

This instrument measures the aerosol spectrum. It selects 0.10 - 3.0 µm diameter particle sizing; resolution = 0.025-0.375 µm (progressively weighted). Owner/operator: NCAR Boulder, CO (mounted in Electra).

²⁵²⁴⁾Several brochures were provided by PMS Inc. of Boulder, CO

FSSP-100 (Forward Scattering Spectrometer Probe)

FSSP-100²⁵²⁵) is an airborne instrument for particle size measurements with the following general fields of application: cloud physics, pre-cloud and haze measurements, general air pollution monitoring, stack plumes, cooling tower plumes, wind blown dusts, fuel plumes, traffic pollution assessment, etc.

The FSSP instrument is an optical system using a laser beam in a high order multimode 5 mW He-Ne tube. The beam is focused to approximately 200 μm diameter using condensing optics with a 60 mm effective focal length. Particles passing through the laser beam in the sampling aperture scatter energy into the optics.

The FSSP has four overlapping size ranges with each size range divided into 15 linear size intervals providing up to 60 size channels in the 0.5 - 47 μm range. FSSP interfaces with a PMS data acquisition system.

- Option A: 0.50 - 47 μm diameter particle sizing
- Option B: 1.0 - 95 μm diameter particle sizing
- Size resolution: One channel, 0.5 μm typical in most sensitive range
- Sampling: Sample area: 0.3 mm^2 , volume sampling rate: 30 cm^3s^{-1} @ 100 ms^{-1}
- Environment: $\pm 40^\circ\text{C}$; altitude: 0 - 12 km; humidity: 0 - 100% RH;
- Probe size: 101.6 cm length, 18 cm diameter
- System mass: 18.2 kg

Owners/operators of FSSP-100 instruments: DLR, Institute of Atmospheric Physics, Oberpfaffenhofen (mounted in Falcon); NCAR Boulder, CO (mounted in Electra), etc.

OAP-230X (Optical Array Cloud Droplet Probe)

The instrument selects 10 - 200 μm per array element. there are 30 size channels. Note: the instruments designated with a n X suffix are designed for the 'cloud droplet configuration,' with only 61 mm between probe tips.

Owners/operators of instruments: DLR, Institute of Atmospheric Physics, Oberpfaffenhofen (mounted in Falcon); and others.

OAP-200Y (Optical Array Precipitation Probe)

The instrument selects 300 μm per array element; there are 15 size channels. The precipitation configuration is designated with a Y suffix; it measures larger particles and comes with a 261 mm distance between probe tips.

OAP-2D-GA2 (Greyscale Cloud Droplet Probe)

The instrument selects 10 - 100 μm per array element. The grey scale 2-D probes employ a 64-element array technology with two data bits stored for each element, resulting in 128 bits per image size. The grey probes provide important depth-of-field information that is not available from standard 2-D probes (four shadow levels for each element).

OAP-2D-GB2 (Greyscale Precipitation Probe)

The instrument selects 50 - 150 μm per array element; 62 size channels.

P.165 PMS (Portable Multichannel Spectrometer)

PMS is a commercially available instrument (since 1993) that was developed and built by Spectral Signatures Ltd. of Dublin, Ireland [it is of PIMS (Portable Imaging Spectrometer) heritage developed by the Physics Department of the University College Dublin]. The

²⁵²⁵) "Forward Scattering Spectrometer Probe, Model FSSP-100," brochure of PMS, Boulder, CO, USA

instrument features the simultaneous recording of multiple spectra in the range from 0.4 - 0.86 μm (VIS/NIR) by using customized frontend fiber optics (up to 12 separate input ports). As of fall 1994 there are six instruments in operation (JRC of Ispra, Italy; GKSS, Geesthacht, Germany; Environmental Protection Agency of Ireland; University College Dublin; Teagasc Agricultural Development Agency, Ireland; Analytical Services Ltd, Dublin Ireland).²⁵²⁶⁾

Applications: vegetation monitoring; water quality and optical property assessment of marine and inland waters; dye tracing in marine environments; spectrophotometry, etc.

The instrument employs the following integrated functions/features:

- Fiber optic input technology - the basic system provides 12 input ports providing the capability of viewing 12 different targets simultaneously.
- A CCD detector array
- Frame grabbing technology
- Video storage of all acquired data (8 mm video cassettes, over 3.5 GB of data storage capacity). All image data are annotated with GPS position data, which is provided by one of the tape's audio channels.
- The instrument is compact and portable; it is provided with batteries for autonomous operation (no aircraft power is needed) and can be flown on practically any platform.

Spectral range	0.4 to 0.86 μm
Spectral resolution	5 nm (with 100 μm slit); 8 nm (with input fiber only)
Frame integration time	40 ms
Frame readout time	25 Hz
CCD array	Hitachi Denshi KP-M1 Interline Transfer CCD: 512 x 512 pixels
Diffraction grating mirror	American Holographic f/2.3 "Flat Field" grating with a diameter of 91 mm, 100 grooves/mm
SNR	17:1 per frame at 632.8 nm for a 5% reflecting surface irradiance of 1.2 $\text{W/m}^2 \text{sr}^{-2}$ at 8 nm bandwidth
FOV	1-20° (depends on the optics used), it is 10° with basic frontend optics
IFOV	~ 6 mrad (with 10° FOV)
Instrument power	10 Watt at 6 Volt
Battery capacity	sufficient for 3 hours of on-board operation
Instrument mass	17 kg total (this includes instrument plus batteries)

Table 787: Instrument parameters of PMS

The incoming radiation from a fiber port is reflected from a plane mirror onto a diffraction grating mirror, separating the radiation into a linear spectrum which is projected onto the CCD array. Each spectrum on the array is 512 pixels by 12 pixels in size. The digital data is obtained by a frame grabbing technique which takes the analog signal and then sums for a number of frames (40 ms is the minimum integration time for one video frame) and across the width of the spectrum of 12 (instrument) pixels. This operation is carried out simultaneously on each of the 12 spectra. The resulting output signal is a digital string (an ASCII string of dimension 1 x 512). Each spectrum is oversampled and represented by 512 data points, i.e. sampled at 1 nm intervals. However, the resolving power - the ability to distinguish between sharp peaks - is approximately 4-5 nm. - The PMS is usually employed as a reflectance measurement instrument. This is particularly appropriate when one or two of the 12 fibers is used to monitor the downwelling radiation. Calibration in the field is done with respect to a reference white standard.

At instrument resolution level the effective quantization and/or dynamic range is > 12 bits. This is made up of the 8-bit A/D converter in the frame grabber and the CCD pixel summing

²⁵²⁶⁾Information provided by S. Green and E. O'Mongain of Spectral Signatures Ltd. of Dublin, Ireland

[pixel summing in the spatial dimension (< 12 pixel equivalent) and 4 pixel summing in the spectral dimension, i.e. < 48 pixel summing].

The instrument's use in mapping is to provide a 'hyper-spectral dimension' to multispectral imaging. The spectra gathered by PMS can be registered with a multispectral image to provide spectra associated with the different regions identified on the image. For example: PMS can be flown along with a Daedalus ATM instrument on the same aircraft - to give a hyper-spectral dimension to the resulting image. - The setup is indeed a very low-cost solution and with far less data than the standard hyper-spectral image cube.

Figure 503: Schematic diagram of PMS optics

P.166 POLDER (Airborne Instrument)

POLDER (Polarization and Directionality of the Earth's Reflectances) is an airborne sensor of CNES/LOA of France (passive optical imaging radiometer). Objectives: validation of the spaceborne system concept of POLDER to be flown on ADEOS (see D.1); preparation and validation of operational algorithms for the spaceborne version; measurement of the polarization and directionality of reflectances from natural surfaces and from the atmosphere.

POLDER makes sequential measurements at several wavelengths as well as at several polarizations. Each target area is measured at different wavelengths, polarizations, and view angles as the aircraft travels forward.

POLDER has been flown on a CNES balloon in 1989 and on the French research aircraft ARAT since 1990. Nominal flight altitudes are between 4 and 6 km. POLDER participated in campaigns over land surfaces in France, Germany, USA, UK, and Niger (HAPEX-SAH-EL), over the ocean (MEDIMAR), in the Antarctic (RACER), and in cloud campaigns ASTEX and EUCREX.²⁵²⁷⁾

The airborne POLDER instrument design is very similar to that of the spaceborne version, consisting of three principal components: a CCD matrix detector, a rotating wheel carrying

²⁵²⁷⁾Information provided by F. M. Bréon, Centre D'Etude de Saclay, Gif sur Yvette, France

the polarizers and filters, and a wide FOV telecentric optics system. The main differences on the instrument itself are:

- The CCD matrix is 384 x 288 pixels in size on the airborne version, allowing a FOV of $\pm 51^\circ$ (along-track) x $\pm 43^\circ$ (across-track) - the spaceborne version has a CCD matrix of 274 x 242 effective elements.
- The filter wheel contains 10 filter slots (16 on the spaceborne version).
- The polarization filters are selected for each flight to suit the particular measurement objectives.

The spectral range of the instrument: 400 - 950 nm (same as spaceborne version); the spectral parameters are defined in Table 1166. POLDER is calibrated in the lab with an integrating sphere.

Figure 504: Optical design concept of the POLDER instrument

POLDER observation principles: Owing to its two-dimensional characteristics, the CCD sensor matrix can observe any target within the instrument's swath under different viewing directions, allowing an estimation of the target's bidirectional reflectance properties. The 10 channel sequence (10 filter slots) is repeated every 10 seconds, which corresponds to four rotations of the filter wheel. During this 10 second observation interval, a given point on the Earth's surface remains within the instrument FOV; its bidirectional reflectance can be inferred. The data rate for a 10 second scene corresponds to: $384 \times 288 \times 10 \times 2 \text{ bytes} / 10 \text{ seconds} = 1 \text{ MByte/s}$. Note: the airborne pixels are not binned one by two; rather, the electronics encode each pixel value over two bytes. - As the aircraft passes over a target, radiance measurements are performed for each spectral band. These measurements provide a sampling of the target's BRDF (Bidirectional Reflectance and Distribution Function) and BPDF (Bidirectional Polarization Distribution Function).²⁵²⁸⁾

Measurement channels: 15 channels (three channels for each polarized band, one channel for each unpolarized band). The ground spatial resolution is a linear function of altitude; at 5 km flight altitude the resolution is 35 m. The swath width is approximately twice the altitude dimension (with a cross-track FOV of $\pm 43^\circ$).

P.167 PORTOS

PORTOS²⁵²⁹) is a French (CNES) passive microwave radiometer made by Matra Marconi Space. PORTOS has five dual-polarized frequencies of 5, 10.7 23.8, 36.5, and 90 GHz. PORTOS became operational on the ground in 1991, in the airborne version in 1992. It is flown on the French ARAT (Fokker 27) aircraft at altitudes ranging from 300 m to 5000 m. PORTOS is a single-beam profiler (IFOV=FOV=11°). Since PORTOS is a profiler (i.e. measuring in the vertical plane), ‘mapping’ is performed by flying a series of parallel flight paths, separated by the length of a footprint (3 dB). The instrument resolution is linked to its mid-power beam of 11°. The incidence angle is variable from 0 to 50° in the along-track direction and from nadir toward the back of the plane.

The PORTOS range of frequencies corresponds to those of MIMR (Multifrequency Imaging Microwave Radiometer) to be flown on METOP-1. Hence, PORTOS serves as a research tool for MIMR modeling with regard to instrument technology as well as with respect to algorithm development. PORTOS observation data allow the retrieval of the following parameters: soil moisture, biomass of vegetation, qualification of vegetation cover, seasonal vegetation cycles, surface roughness, atmospheric integrated water content, and surface-equivalent temperature.

PORTOS has been flown on a number of missions (including HAPEX-Sahel) together with POLDER, and also with other airborne instruments such as PBMR, ASAS, NS001, TIMS on their respective aircraft platforms for reasons of observation data comparison and synergism. PORTOS measurements in conjunction with spaceborne missions were: DMSP (SSM/I), ERS-1 (ATSR/M, AMI, AMI-SCAT), NOAA (AVHRR), SPOT (HRV), Landsat (TM), etc.

Frequency (GHz)	Polarization	Beamwidth at 3 dB	Radiometric Resolution	Bandwidth (MHz)	Efficiency at -20 dB
4.9 - 5	H, V	< 16°	1 K	100	70%
10.6 - 10.7	H, V	13°	0.9 K	100	96%
23.6 - 24	H, V	10°	1.2 K	400	97%
36.3 - 36.7	H, V	11°	1.1 K	400	97.8%
88.5 - 89.5 90.5 - 91.5	H, V	10.7°	0.6 K	2000	98%

Table 788: Specification of PORTOS observation parameters

Calibration methods employed with PORTOS:

- N₂L and hot target on the ground
- use of water bodies in flight
- reference thermocouples and instrument model during acquisition

P.168 PRIRODA Airborne Instruments

The following PRIRODA/MIR sensors partake as airborne instruments (mostly with reduced functional capability) aboard an Ilyshin-18 aircraft (see chapter D.28 for PRIRODA sensors) in a PRIRODA preparatory program consisting of several campaigns. The program started in 1992. The nominal monitoring altitude is 6 km.

The Ilyshin-18 aircraft offers a range of speed from 330-700 km/h, a maximum altitude of 7 km, a maximum flight time of 6.5 hours, and a payload power source of 30 kW (±27 V). The aircraft position is determined by the navigation system and by GPS.

- **SAR Travers** = Synthetic Aperture Radar (active microwave sensor). Objective: determination of reflection and scattering parameters of surface objects in the microwave region. SAR Travers operates to the left side of the aircraft (in flight direction).

²⁵²⁹) Information provided by Y. H. Kerr of LERTS

- Wavelength /frequency 10 cm / 3 GHz (S-band)
- Impulse frequency 3 kHz
- Length of impulse 0.12 ns
- Antenna size 150 cm x 10 cm
- Angle of incidence range 45-63°
- Swath width 20 km
- Polarization VV
- Spatial resolution 20 m
- **IKAR-D2** = Passive Microwave Radiometer (Delta), conical scanning 3-channel sensor. Objective: radiometric measurements of the Earth's surface. IKAR-D2 uses an antenna system with a rotating reflector for a conical scan with a beam look (scan) angle of 30° from nadir. The survey pattern is semi-cycloidal.
 - Wavelengths: 0.8 cm, 1.35 cm, and 2.25 cm
 - Spatial resolution 140 -370 m (depending on wavelength)
 - Swath width 6 km
- **IKAR-P** = Passive Trace Microwave Radiometers RP-225 and RP600. Antenna beam width of 9°; the look angle of the antenna beam from nadir is 40°; the radiometric resolution of RP-225 = 0.1 K and 0.15 K for RP-600.
 - Wavelengths: 2.25 cm and 6.0 cm
 - Polarization V and H
 - Beam diameter on ground 160 m
- **MKS-M** = Passive Multichannel Trace Radiometer (nadir pointing). The instrument provides 13 spectral bands with a bandwidth of 15-20 nm. The pointing beam width of the telescope is 0.46°, providing a footprint of about 48 m x 48 m at 6 km flight altitude. The sampling rate is 31.25 Hz (this provides an oversampling rate of about 6 at the flight speed of 110-125 m/s).

Spectral Channel	Wavelength (nm)	Sensitivity K ₁ (μW/cm nm sr)	Sensitivity K ₂ (μW/cm nm sr)
1	408.2	1.3392	6.4983
2	443	0.8858	4.2837
3	484.5	0.8986	4.1902
4	519.3	1.1401	5.1806
5	569.6	0.9555	4.3055
6	615.4	0.9070	4.1468
7	649.3	0.9632	4.0503
8	685.5	1.0142	4.7921
9	750	1.1437	5.3971
10	815	1.1715	5.5424
11	870.5	1.8492	8.8984
12	932.8	1.3909	7.4121
13	1026	1.5313	7.4559

Table 789: MKS-M instrument parameters

- **MSU-M** = Multispectral Scanner (electro-mechanical scanner, nadir-pointing).
 - Wavelengths 0.5-0.6 μm, 0.6-0.7 μm, 0.7-0.8 μm, 0.8-1.1 μm
 - FOV 90°
 - IFOV 5.8' (spatial resolution = 18m)
 - Scanning frequency 8 Hz
 - Swath width 13 km
- **RODIS** (see P.177, participated in Oct. 1993 campaign)
- **AFA-41/20** = Aerial Foto Apparatus. The camera has an objective with a focal length of 200 mm.

- Frame format 18 cm x 18 cm
- Spatial resolution 47 lines per mm (at frame center)
- Spatial resolution 10 lines per mm (at frame edge)
- **IRI** = Infrared Imager (IRE scanning instrument). Objective: surveying of oil spills on water surfaces, terrain subsurface fires (hot spots) and pipeline leaks. Spectral range = 8 - 14 μm ; dynamic range = 100 K; swath width = 6 km; spatial resolution = 6-8 m; sensitivity = 0.05 K.

P.169 PSR (Polarimetric Scanning Radiometer)

PSR is a NOAA-sponsored versatile airborne microwave imaging radiometer developed by the Georgia Institute of Technology and NOAA/ETL (Environmental Technology Laboratory at Boulder, CO) for the purpose of obtaining polarimetric microwave emission imagery of the Earth's oceans, land, ice, clouds, and precipitation. The PSR was designed to provide several specific and unique observational capabilities from various aircraft platforms. The original design was based upon several observational objectives: ²⁵³⁰⁾ ²⁵³¹⁾ ²⁵³²⁾

- To provide fully polarimetric (four Stokes' parameters: T_v , T_h , T_U , and T_V) imagery of upwelling thermal emissions at four of the most important microwave sensing frequencies (10.7, 18.7, 37.0, and 89.0 GHz), thus providing measurements from X- to W-band
- To provide the above measurements with absolute accuracy for all four Stokes' parameters of better than 1 K for T_v and T_h , and 0.1 K for T_U and T_V
- To provide radiometric imaging with both fore and aft look capability (rather than single swath observations)
- To provide conical, cross-track, along-track, and spotlight mode scanning capabilities
- To provide imaging resolutions appropriate for high resolution studies of precipitating and non-precipitating clouds, mesoscale ocean surface features, and satellite calibration/validation at Nyquist spatial sampling.

The first PSR instrument consists of a set of polarimetric radiometers housed within a gimbal-mounted scanhead drum. The scanhead drum is rotatable by the gimbal positioner so that the radiometers can view any angle within 70° elevation of nadir at any azimuthal angle (a total of 1.32 sr solid angle), as well as external hot and ambient calibration targets. The configuration thus supports conical, cross-track, along-track, fixed-angle stare, and spotlight scan modes.

Background: The original scanhead (denoted "PSR/D" for its use of digital correlators), developed in 1995-96, consisted of four polarimetric radiometers operating at 10.7, 18.7, 37.0, and 89.0 GHz. In order to efficiently utilize the scanhead faceplate area, the 10.7 and 37.0 GHz radiometers utilize a common dual-band antenna, while the 18.7 and 89.0 GHz receivers each utilize single-band antennas. The precise radiometric bands measured by the PSR are X- (10.6-10.8 GHz), Ku- (18.6-18.8 GHz), Ka- (36-38 GHz), and W-bands (86-92 GHz). These bands were selected to provide sensitivity to clouds, precipitation, and surface features over almost one decade of microwave bandwidth at octave intervals. PSR/D evolved into PSR/A during 1998 by replacement of the digital correlators with analog correlators. This replacement was performed as an experiment to study the two correlator types.

²⁵³¹⁾ <http://www1.etl.noaa.gov/radiom/psr.html>

²⁵³²⁾ J. R. Piepmeier, A. J. Gasiewski, M. Klein, V. Bohm, R.C. Lum, "Ocean Surface Wind Direction Measurement by Scanning Microwave Polarimetric Radiometry," Proceedings of the International Geoscience and Remote Sensing Symposium, Seattle, WA, July 6-10, 1998

PSR/A instrument	Configuration valid from 1997 to present, operating in 10.7, 18.7, 21.5, 37.0 and 89 GHz. Use of digital correlators in 1997 (PSR/D).
Antenna type	All antennas are of the lens/corrugated feedhorn type and are dual orthogonal-linear polarized with grooved rexolite lenses.
Antenna beam widths	8° (for both X- and K-bands), and 2.3° (for both Ka- and W-bands)
Beam efficiencies	95-97% range, all on-axis cross-polarization isolations exceed -27 dB
Receiver types in PSR/D	Dual-channel superheterodyne with a common local oscillator driving each of two identical mixers The 10.7 and 18.7 GHz receivers were single sideband (SSB) and used high electron mobility transistor (HEMT) preamplifiers, while the 37.0 and 89.0 GHz receivers are double sideband (DSB).
Polarimetric detection	T_v , T_h , T_U , and T_V were measured using custom three-level (1.6 bit) digital correlators operating at 1 Gsample/s. Current capability (PSR/A) is for T_v , T_h , T_U and T_V at 10.7 and 18.7 GHz, T_v , T_h , and T_U at 37 and 89 GHz, and T_v , and T_h at 21.5 GHz, all using analog correlation.
Bandwidth frequency	The correlators allowed detection and cross-correlation of 500 MHz wide intermediate frequency bands at the Nyquist sampling rate
IF subband division used	To allow detection of the full IF bandwidths available from the various receivers (up to 2000 MHz)
Instrument processor	An 80486 PC, an 8-channel digital correlator bank and 4 total-power tri-polarimetric radiometers installed inside a 51 cm diameter rotating scan-head drum.
Additional detectors in scanhead	Includes a NSTC CCD color video camera oriented in the direction of the antenna main beams.
Scanning mechanism and instrument calibration	A nadir-viewing 2-axis gimbal mount is used to scan the radiometers in the airstream outside the aircraft. External hot and ambient calibration targets are viewed periodically.
Mechanical characteristics	No use of radome. Torsions are <0.01° for positioning accuracy and to reduce aerodynamics
Total instrument mass	About 500 kg, (the positioner and scanhead are 380 kg, an additional 90-160 kg are used for instrument electronics equipment, depending on aircraft type)
Total instrument power	400 W to 1800 W depending on outside air temperature
PSR/C instrument	Configuration valid from June, 1999
Channel definition (GHz)	5.82-6.15 (v, h), with 10° antenna beamwidth 6.32-6.65 (v, h), with 10° antenna beamwidth 6.75-7.10 (v, h, U, V), with 10° antenna beamwidth 7.15-7.50 (v, h) with 10° antenna beamwidth 10.6-10.8 GHz (v, h, U, V) with 7° beamwidth being implemented for August, 2001 for CAMEX 4 campaign. 9.6-11.5 μ m IR (v+h) with 7° beamwidth
PSR/S configuration. The PSR/S scanhead is implemented for first use in 2001, and permits imaging over a wide range of microwave sounding and imaging bands.	
Channel definition (GHz)	18.6-18.8 (v, h, U, V), with 7° beamwidth 21.4-21.7 (v, h), with 7° beamwidth, H ₂ O 36-38 (v, h, U, V) with 7° beamwidth 52.6-57.5 x 7 (V) with 3.5° beamwidth, O ₂ measurements 86-92 (V,H,U) with 3.5° beamwidth 118.750 x 7 (V) with 3.5° beamwidth, O ₂ measurements 183.310 x 7 (V) with 1.8° beamwidth, H ₂ O measurements 325.153 x 3 (V) with 1.8° beamwidth, H ₂ O measurements 337-343 (V,H,U) with 1.8° beamwidth 380.197 x 5 (V) with 1.8° beamwidth, H ₂ O measurements 424.763 x 5 (V) with 3.5° beamwidth, O ₂ measurements 496-504 (V,H) with 1.8° beamwidth 9.6-11.5 μ m IR (v+h) with 1.8° beamwidth

Table 790: PSR/A, PSR/C and PSR/S instrument parameter definitions

The PSR instrument is flown since 1997 on two NASA aircraft: the DC-8, and Orion P-3B, and is capable of being operated on several others. The instrument has been used in support of the following campaigns: 1) Labrador Sea Deep Convection Experiment (March, 1997), 2) HOWEX (Hurricane Winds Experiment) in Sept.-Oct. 1997, 3) CAMEX-3 (Third Convection And Moisture Experiment) took place from Aug. 6 - Sept. 23, 1998 at Patrick AFB, Florida to study Hurricanes Bonnie, Danielle, Earl and Georges, 4) SGP99 (Southern great

Plains Experiment). SGP99 occurred over Oklahoma in July of 1999 to study soil moisture imaging at C-band, 5) Meltpond 2000 experiment, June-July 2000. Meltpond was flown out of Thule, Greenland to study high-resolution imaging of arctic sea ice. Both SGP99 and Meltpond 2000 were organized in preparation for the NASA Aqua AMSR mission.

PSR/L instrument	Configuration valid for 2002
Channel definition (GHz)	1.400 - 1.406 (v, h), with 10° beamwidth 1.407 - 1.313 (v, h), with 10° beamwidth 1.414 - 1.420 (v, h), with 10° beamwidth 1.421 - 1.427 (v, h), with 10° beamwidth 1.400 - 1.427 (v, h, U) with 7° beamwidth 1.45 scatterometer (VV, HH, VH) with 10° beamwidth RGB video
PSR/E instrument	Configuration planned for 2003/4
Channel definition (GHz)	149-151 (v, h) with 1° beamwidth 183.310 x 4 (v) with 1° beamwidth, H ₂ O 218-222 (v, h) with 1° beamwidth 325.153 x 4 (v) with 1° beamwidth, H ₂ O 460-464 (v, h) with 1° beamwidth 680-686 (v, h) with 1° beamwidth 870-878 (v, h) with 1° beamwidth 9.6 - 11.5 µm IR (v+h) with 7° beamwidth RGB video
PSR/R instrument	Configuration planned for 2003/4
Channel definition (GHz)	35.0 Doppler Radar (VV, HH) with 2° beamwidth 9.6 - 11.5 µm IR (v+h) with 7° beamwidth RGB video

Table 791: Planned instruments of PSR/L, PSR/E and PSR/R

The primary goal of the P-3 Labrador Sea flights was to collect data to verify the utility of passive ocean wind vector sensing in high seas, with secondary goals being to better characterize the thermal emission and backscattering signatures of the wind-driven ocean surface. The PSR was flown under a variety of meteorological conditions in coordinated patterns over both ocean buoys along the eastern U.S. coast and an instrumented research vessel (the RV Knorr) within the Labrador Sea. The flights resulted in the acquisition by the Ocean Winds Imaging (OWI) science team of the first high-tion polarimetric conically-scanned imagery of the ocean in a broad set of microwave bands, and the first combined joint high-resolution passive and active imagery of the ocean surface. The term high-resolution refers here to a factor of ten beyond that available from spaceborne instruments, typically between 300 m to 3 km spot sizes, and Nyquist sampling.

All versions of polarimetric scanning radiometers are a compatible series of scanheads, channels, polarizations, and beamwidth. The following PSR versions (PSR/L, PSR/E, and PSR/R) are in the planning stage with PSR/L funded for design in 2001.

P.170 RACS (Rotating Antenna C-band Scatterometer)

RACS is a superheterodyne Doppler radar/scatterometer airborne instrument that was developed and built by the University of Hamburg (Institut für Meereskunde) to measure ocean surface winds. RACS has been operational since 1987.^{2533), 2534)}

The instrument measures the normalized radar cross-section (NRCS) of the ocean surface in VV polarization as a function of antenna look direction. The surface wind vector is re-

²⁵³³⁾V. Wismann, "Wind Measurements over the Ocean with an Airborne C-band Scatterometer during the ERS-1 Calibration and Validation Campaign," ERS-1 Geophysical Validation, Workshop Proceedings, April 27-30, 1992, ESA wpp-36, pp. 5-9

²⁵³⁴⁾Information provided by V. Wismann of IFARS, Wedel, Germany

trieved from the NRCS values for each antenna revolution by curve fitting the results to an empirical C-band model.

The scatterometer is a superheterodyne Doppler radar operating at 5.32 GHz. It contains two phase-locked oscillators with a difference frequency of 80 MHz and an output power of 30 mW. The transmitted signal of 5.32 GHz is amplified by a solid-state amplifier of normal 2 W output power and then pulsed by pin-diode switches. The duration of the transmitted pulse is 45 μ s, the width of the receiving gate is 5 μ s. The backscattered signal from the ocean surface is amplified by a low noise amplifier and mixed with the 5.24 GHz reference signal of the local oscillator. Then the intermediate frequency (IF) is downconverted to an audio frequency of 50 kHz by applying an oscillator with a center frequency of 80 MHz.

The internal calibration is achieved by coupling a small fraction of the transmitted signal into the receiving channel. This internal calibration includes the RF oscillator and the solid-state amplifier, but not the transmitter switch, the circulator and the antenna in the transmitting channel. In the receiving channel all components are included.

RACS was flown in several campaigns (Toscane 2/Front 1987, TEMPO in 1989) including RENE-90 and -91. As of 1995 there are plans to upgrade RACS to full polarimetric capability.

Instrument type	Superheterodyne Doppler radar
Frequency	5.32 GHz (C-band)
Wavelength	5.7 cm
Antenna (2) Beamwidth: incidence angle = 45° Beamwidth: incidence angle = 30°	Two VV polarized planar microstrip antennas (the beam axis is squinted 30° and 45° off the antenna normal respectively) 6.0° in elevation and 5.6° in azimuth 5.38° in elevation and 3.65° in azimuth The antenna rotates at 1 revolution/minute (scan rate). The antenna beam scans the ocean surface conically at an incidence angle of 45° or 30°, respectively
Instrument Platform	DO-228
Operational altitude for RACS	500 - 5000 m
Nominal ground speed	100 m/s
Mass of microwave rack	15 kg
Mass of antenna	70 kg
Mass of operator rack	45 kg
Power consumption	400 VA @ 28VDC; 300 VA @ 220 VAC

Table 792: RACS instrument parameters

P171 Radius (Microwave Radiometer)

RADIUS²⁵³⁵⁾ is an airborne microwave radiometer owned and operated by NPO Vega of Moscow. The instrument was built by NPO Vega in 1986. RADIUS is utilized in agriculture, land reclamation, forestry, geology, oceanology, hydrometeorology, etc. Some of the measured parameters are:

- Ground surface moisture content. Volume content of free water in the upper soil layer (20 - 100 cm thick)
- Biomass of the above-water part of vegetation (rice, reeds) 3-5 scale values
- Degree of mineralization and chemical pollution of interior water reservoirs with an accuracy of 1-3 g/l (depending on the concentration range).
- Water surface temperature variations in basins with an accuracy of 0.5-1.0°C.
- Depth of underground water level from 0 to 2.3 m (3-5 scale values).
- Thickness and packedness of ice on rivers and seas.

The scanning rate of the instrument can be adjusted for any speed or altitude of the aircraft. The instrument and science data are recorded on magnetic tape, a quicklook capability is provided. The instrument is offered for commercial use.

²⁵³⁵⁾Information provided by Y. Krilov of NPO Vega, Moscow

Frequency	Number and Size of Angle Resolution Cells in Line	Survey Method
15.2 GHz 5.475 GHz 1.425 GHz 0.700 GHz	$15 \times 3.5^\circ = 52.5^\circ$ $5 \times 10^\circ = 50^\circ$ $2 \times 25^\circ = 50^\circ$ $1 \times 53^\circ = 53^\circ$	Scanning Scanning Two commutated spatial beams One spatial beam
The swath width in each band is about equal to the flight altitude		
Fluctuation sensitivity in channels		0.5 - 1.5 K
Power		800 W
DC Voltage		27 V
Total Instrument Mass		320 kg

Table 793: Specification of the RADIUS instrument

P.172 RAMS (Radiation Measurement System)

A NASA-sponsored instrument being flown since 1986 on a number of aircraft, such as: ER-2, DC-8, Electra, NCAR Electra, Sabreliner, NOAA P-3 and others. RAMS is an integrated system of several radiometers. The system provides airborne measurements to support analysis and theoretical calculations of cloud properties and radiation fields. RAMS data are usually compared and validated with satellite radiance measurements. RAMS consists of the following instruments:²⁵³⁶⁾

- **BBHSR** (Broad Bandpass Hemispheric Solar Radiometer) for total flux measurements. One BBHSR instrument is installed on top and one is installed on the bottom of the ER-2 fuselage. BBHSR features an electrically calibrated pyro-electric detector with optical chopping and null-balanced operation. Spectral region from 0.26 to 2.6 μm .
- **BBHIR** (Broad Bandpass Hemispheric Infrared Radiometer). The BBHIR system consists of two radiometers which flip for sequential up and down viewing (FOV: hemispheric nadir and zenith flipping). Because of sequential measurements, IR net fluxes can be found with very high accuracy. Spectral range from 5 to 40 μm .
- **TDDR** (Total Diffuse Direct Radiometer). The system consists of two instruments, one on the top and one on the bottom of the aircraft. TDDR is a multichannel narrow spectral bandpass (5-10 nm) flux radiometer; narrow shadow arms sweep over the radiometer dome of the TDDR in orthogonal directions at regular intervals. This radiometer is used for optical depth determinations and direct/diffuse ratios (a measurement sequence permits the separation of the direct and diffuse components of the intensity field).
- **NFOVR** (Narrow FOV Radiometer). The instrument measures IR irradiance in two spectral channels (5 to 40 μm region) in a 0.006 mrad FOV in the nadir direction. This radiometer uses a liquid nitrogen-cooled blackbody reference and provides upwelling infrared intensities above the clouds (high accuracy measurements of brightness temperature for cold cloud tops).

RAMS has been flown in the following projects/campaigns: STEP, FIRE, CEPEX, AGASP, Kuwait Oil Field Fires Experiment, Pinatubo Airborne Mission, AASE-II, TOGA/COARE, and others.

Radiometer	Measurement	FOV
BBHSR	total flux	hemispheric nadir and zenith
BBHIR	IR flux	hemispheric nadir and zenith flipping
TDDR	7 narrow band VIS/NIR filters	hemispheric with oscillating orthogonal shadow rings
NFOVR	6.7 and 10.3 μm cryogenic BB	nadir viewing 15° FOV

²⁵³⁶⁾“TOGA/COARE Mission Plan,” NASA paper, November 1992, pp. 58-59

P.173 RAMSES (Radar Aéroporté Multi-Spectral d'Etude des Signatures)

RAMSES is an experimental multiband airborne radar of ONERA (French Aerospace Research Establishment, Palaiseau). The system has been operational since 1990 and is currently (1995) flown on board a Transall C160 aircraft from the French Test Center (CEV). It has the capability of analyzing the effect of various instrument parameters such as frequency carrier, polarization or waveform. RAMSES has been flown in many campaigns to provide experimental data required by studies in the field of airborne and spaceborne radars.²⁵³⁷⁾

RAMSES is a high-resolution radar operating in up to two simultaneous frequency bands, the choice is between L-, C-, X-, Ku-, Ka- and W-band. The system design is modular, providing a number of configuration options with regard to flight parameters (altitude, velocity, angle of incidence) and system (frequency, polarization, waveform, interferometry).

The aircraft (Transall C160) is equipped with INS (Inertial Navigation System), radio-altimeter, and GPS receiver. Kalman-filter combining INS and DGPS can be computed to provide accurate aircraft motion compensation. The maximum operating altitude is 4000 m; the nominal ground speed for SAR operation is 75 m/s; the depression angle of the antennas can be varied mechanically within the range of 5° - 60°.

RAMSES is being used for civilian and military applications. Civilian uses include: remote sensing, wind-shear detection, and meteorological applications. Military uses are: air-to-ground guidance, map-matching methods for navigation purposes, battle-field surveillance and reconnaissance. RAMSES is also used as a research tool to investigate system-related problems of system performance and data analysis.

Frequency Band	L	S	C	X	Ku	Ka	W
RF center frequency (GHz)	1.6	3.2	5.3	9.5	14.5	35	95

P.174 RENE

RENE²⁵³⁸) is a FM/CW (Frequency Modulated/ Continuous Wave) side-looking radar scatterometer of CNRS/CETP (France). The instrument name ‘RENE’ does not stand for any acronym; it is simply a proper name. A switch allows the signal to be successively transmitted on two orthogonal polarizations, while the backscattered signal is simultaneously received on each of these polarizations thanks to two separate receiving channels. RENE is installed on a helicopter and has been operational since 1992. Applications: research investigations on radar polarimetry applied to land and vegetation remote sensing.

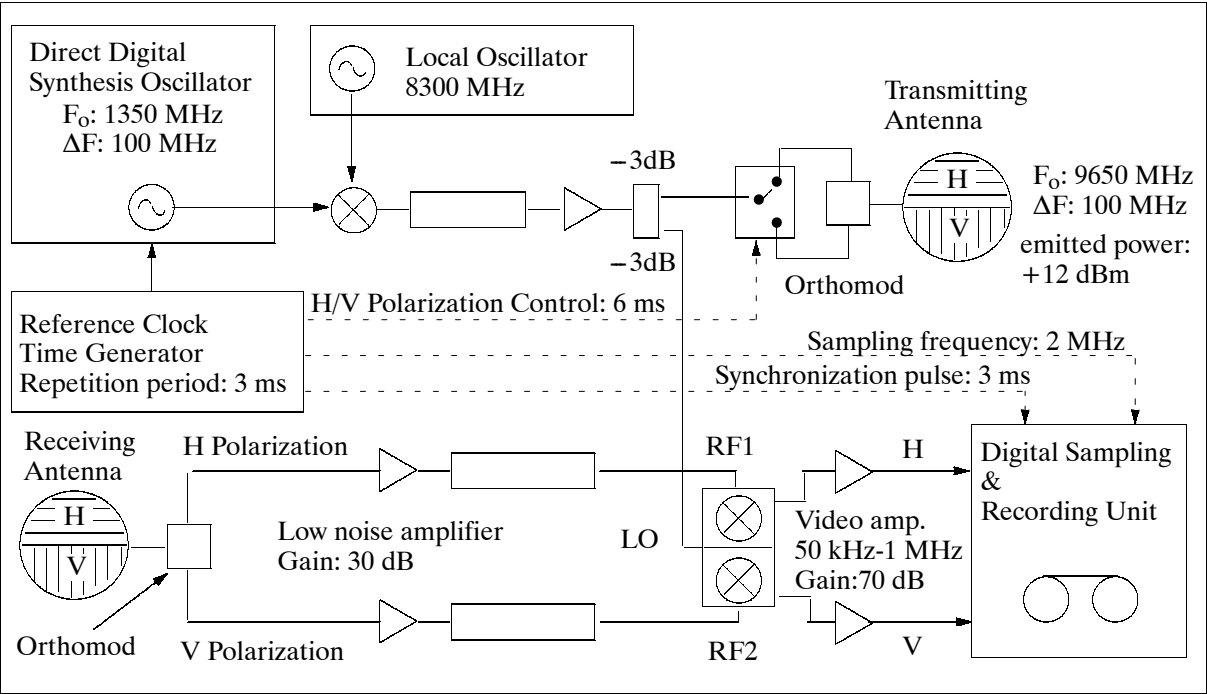

Figure 505: Schematic of X-band FM/CW polarimetric radar scatterometer

RENE features two different antenna designs, a dual polarization corrugated horn as transmitting antenna and a dual parabolic receiving antenna. This design permits polarimetric studies because its cross polarization isolation is larger than 40 dB and the cross-talk term error is less than -36 dB. Its aperture leads to a swath width of 30 meters at a nominal flight altitude of 300 m.

The accuracy requirements of the instrument necessitate a calibration procedure in phase and amplitude using trihedral and dihedral corner reflectors.

Measurement technique	FM/CW radar scatterometer
Operational frequency	9.65 GHz (X-band)
Polarization	HH, VV, VH, HV (fully polarimetric)
Incidence angle	10 - 85°
Transmitted power	16 mW (12 dBm)
Modulation	Sawtooth - period 3 ms
Bandwidth	200 MHz
Transmitting antenna	Corrugated horn
Gain	10,3 dB
Beamwidth (3 dB)	60°

²⁵³⁸)N. Le Loch, D. Vidal-Madjar, J. P. Hardange, “On the calibration of the helicopter-borne polarimetric radar RENE,” paper accepted for IEEE Transactions on Geoscience and Remote Sensing, 1994

Measurement technique	FM/CW radar scatterometer
Receiving antenna (first version)	Parabolic antenna
Gain	32.6 dB
Beamwidth	3° x 3° (3 dB)
Cross-polarization isolation	> 40 dB
Polarimetric cross-talk error (isolation)	< -36 dB
Receiver gain	H = 90.9±0.9 dB (in the frequency interval used) V = 91.2±0.9 dB (in the frequency interval used)
Ancillary data	Clock, antenna rotation angles, flight parameters (pitch, roll, heading, speed, etc.)
Spatial resolution	30 m in cross-track and 1 m in the range direction
Nominal flight altitude	300 m

Table 796: RENE instrument characteristics

P.175 RESSAC (Radar pour l'Etude du Spectre des Surfaces par Analyse Circulaire)

RESSAC is an airborne FM/CW radar ocean wave spectrometer developed and built by CRPE at Issy-les-Moulineaux, France, and supported by CNES and ESA, with the objective to provide geophysical validation for the ERS-1 wave measurements. RESSAC is a rebuilt version of the airborne scatterometer 'ERASME' of CRPE. The instrument is based on the same principle of measurement as ROWS of NASA/GSFC/WFF (see P.178). RESSAC makes use of the FM/CW (Frequency Modulated Continuous Wave) technique and operates at C-band (same frequency as AMI of ERS-1). The instrument can be mounted on two aircraft, either the DO228 (of DLR) or the Merlin-IV of Météo-France. The nominal flight altitude is 6 km. The transmitting and receiving antennas look at an angle of 14° from nadir and perform one rotation per minute around the vertical axis.

Ocean wave characteristics (long ocean waves) are measured by means of a real aperture radar which is looking at angles near the vertical and rotating around a vertical axis. The measurement principle consists in relating the modulation of the backscattering cross-section within the footprint on the ocean surface to the slope of the ocean waves.

Parameter	Value
Measurement technique	FM/CW (real aperture radar)
Mean frequency	5.35 GHz (C-band)
Transmitted power	32 mW (15 dBm) or 3400 mW (35.3 dBm)
Receiver	total gain 93.5 dBV
Modulation	Upward linear frequency modulation duration 5.71 ms (sweep time) bandwidth 68 or 137 MHz (selectable) repetition period 6.5 ms
Antennas	Polarization HH Mean incidence angle 14° Beam width (at 3 dB) ±6.5° in elevation ±1.7° in azimuth Two-way gain ≈ 36 dB Rotation in azimuth 360°/minute Closest sidelobe 20 dB below maximum (at mean frequency) 11° away from beam axis in azimuth
Signal processing	FFT analyzer, 512 points (400 retained) Adjustable analyzed band of 100 kHz width Resolution 250 Hz in frequency 1.56 m in range Number of integrations 4, 8, 16, or 32 Digitized output with a 0.1 dB sensitivity
Ancillary data	Clock, antenna rotation angles Flight parameters (pitch, roll, heading, speed, etc.) from NIS through ARINC output protocol

Table 797: The RESSAC instrument characteristics

RESSAC was flown in the RENE-90 and -91 campaigns off the coast of Norway.²⁵³⁹⁾, 2540) In addition RESSAC has been utilized in two other campaigns: SWADE (Surface Waves Dynamics Experiment) in February-March 1991 off the US East Coast (supported by NASA and ONR), and SEMAPHORE in October-November 1993 in the North Atlantic (Azores region), supported by French research organizations. The objectives for using RESSAC in the last two campaigns were two-fold:

- characterization of the surface (waves, wind) and analysis of the associated physical mechanisms (interactions between wind and surface gravity waves, between waves and current
- study of the relationship between remotely-sensed quantities and surface properties.

P.176 RMK (Reihenmeßkammer - Metric Camera)

RMK²⁵⁴¹⁾ is a commercially available aerial survey camera series of Carl Zeiss, Oberkochen, Germany. Background: The first instrument series with the name of 'RMK' started in 1955, and was followed by the 'RMK A' series until the end of 1989. Over 800 'RMK A' series cameras have been sold worldwide. The current series, 'RMK Top,' has been built since 1990. Each series represents a new generation in camera technology for a wide range of photogrammetric applications. As of 8/1993 the RMK Top series has been sold in the following countries: Germany, United Kingdom, USA, Norway, Italy, France, Thailand, Indonesia, and India.

DLR (Institute of Optoelectronics) operates three aerial survey cameras, type Zeiss RMK A (23 cm edge length image size) aboard a DO 228 aircraft with the primary objectives of forest mapping and aerial photography for topographic maps, etc. Cameras RMK A 8.5/23 and 15/23 have been in operation since 1975, RMK A 30/23 since 1986.

Designation	Camera Type	Lens Type Focal Length	Aperture (f-stops)	Angular field diagonal (later.)	Max. nominal distort.	Principal uses/Comment
RMK A 8.5/23	125° super wide-angle	S-Pleogon A 85 mm	f/4, f/5.6, f/8	125° (107°)	7 µm	Large-area photographic coverage for small-scale mapping
RMK A 15/23	Standard wide-angle	Pleogon A 153 mm	f/4, f/5.6, f/8, f/11	93° (74°)	2 µm	General work, i.e. aero-triangulation topographic and large-scale mapping
RMK A 30/23	Standard normal-angle	Topar A 305 mm	f/5.6, f/8, f/11	56° (41°)	3 µm	Aerial mosaics, orthophoto maps, first-order mapping and base maps for urban areas
RMK A 60/23	Narrow-angle	Telikon A 610 mm	f/6.3, f/9, f/12.5	30° (21°)	50 µm	Special purpose camera: a) high-altitude photography; b) city surveys; c) 1:250 or 1:500 scale flights; d) aerial mosaics
RMK Top 15	Standard wide-angle	Pleogon A3 153 mm	f/4-f/22	93°	± 3 µm	Successor to RMK A 15/23
RMK Top 30	Standard normal-angle	Topar A3 305 mm	f/5.6-f/22	56°	± 3 µm	Successor to RMK A 30/23

Table 798: Specifications of the Zeiss aerial survey camera series RMK

²⁵³⁹⁾D. Hauser, et al., "RESSAC a New Airborne FM/CW Radar Ocean Wave Spectrometer," IEEE Transactions on Geoscience and Remote Sensing, Vol. 30, No. 5, September 1992, pp. 981-995

²⁵⁴⁰⁾D. Hauser, G. Caudal, B. Chapron, "Observation with the RESSAC Airborne Radar During RENE-91," ERS-1 Geophysical Validation, RENE 1991, Workshop Proceedings, April 27-30, 1992, Penhors France, ESA wpp-36, August 1992, pp. 47-53

²⁵⁴¹⁾"Aerial Cameras and Accessories," and "RMK TOP - Survey Camera System for Aerial Photography," Carl Zeiss brochure

The RMK modular system offers convenient interfaces for accessory and new component adaptation (identical for all cameras) such as: a suspension mount, an FK 24/120 film magazine, and an ICC central interval computer. The system provides such features as:

- Automatic leveling control (HCON)
- Drift control (DCON)
- Automatic image sequencing and exposure mechanisms
- FMC (Forward Motion Compensation) up to 30 mm/s of forward motion is compensated without impairing the geometric quality of the camera.

Note: due to the aircraft's motion, the image moves relative to the stationary film while the shutter is open. This forward motion causes object points to be represented as lines instead of points. so that the resolution is reduced. FMC counteracts this problem.

The RMK Top camera is equipped for functional combination with a GPS receiver subsystem. The shutter design allows constant access time for mid-exposure time. The pulse emitted at the mid-point of exposure and, as a result, the instant of exposure, is fed to the GPS with an accuracy of 0.1 ms. The software package T-Flight permits coordinate interpolation of the projection centers in relation to the position measurements, which are available at 1 second intervals. If the GPS also serves as a navigation system, the serial exposures can be triggered by GPS. GPS data can also be exposed onto the film as auxiliary data.²⁵⁴²⁾

For context information: the Metric Camera (German/ESA experiment on Spacelab-1 in Nov. 1983, see chapter J.22 was a slightly modified Zeiss camera of the type RMK A 30/23.

P.177 ROSIS (Reflective Optics System Imaging Spectrometer)

ROSIS²⁵⁴³⁾ is a compact airborne imaging spectrometer developed jointly by DASA/MBB, GKSS and DLR (Institute of Optoelectronics) and based on an original design by MBB for a flight on ESA's EURECA platform. The instrument was modified slightly after some test flights in 1992, and was again available from the summer 1993. After completion of the first development phase, ROSIS belongs to both GKSS (Institute of Physics) and DLR. Both organizations test, maintain and operate the instrument and process the data. After the initial test phase of the modified instrument, it is planned to make the sensor available to a large user community inside and outside of Germany within a suitable environmental utilization program.

Spectral range	430 - 830 nm
Spectral sampling interval	4 nm
FOV, IFOV	$\pm 8^\circ$, 0.56 mrad
Pixel size at 3 km AGL	1.8 m x 1.8 m
Tilt capability along flight direction	$\pm 20^\circ$
Nr of spectral bands, Nr. of pixels	115, 512
Data quantization	14 bits

Table 799: Specification of ROSIS-03

The design driver of ROSIS was its application for the detection of spectrally fine structures in coastal and inland waters. This task determined the selection of the spectral range, bandwidth, number of bands, radiometric resolution and tilt capability for sun glint avoidance. However, ROSIS can be used just as well for monitoring of spectral features above land or within the atmosphere. So far, ROSIS was mainly used for the preparation of the imaging spectrometer MERIS to be flown on ESA's ENVISAT. Since accurate radiometric calibra-

tion of ROSIS-01 and -02 was inadequate, a new instrument, ROSIS-03, was developed and integrated in the time frame 1996-98 by Schneider Systemtechnik.²⁵⁴⁴⁾

P.178 ROWS (Radar Ocean Wave Spectrometer)

ROWS is an active airborne sensor developed and operated by NASA/GSFC with the objective to measure the ocean’s directional gravity-wave spectrum. ROWS has been operational since 1978 and has been installed on several aircraft, the most recent aircraft were WFF’s T-39 and P-3.

Parameter	Value
Frequency	13.9 GHz
Pulse type	Linear FM, 100 MHz bandwidth, 1.2 μs chirp
Pulse length	12.5 ns compressed
Peak power	2 kW
Pulse Repetition Frequency (PRF)	100 Hz
Dynamic range	70 dB
Detection	Noncoherent, square law
Antennas	a) 10 x 4° (elevation x azimuth) printed circuit array, vertical polarization, 16° boresight, 6 rpm rotation rate b) vertically-pointing 29° pyramidal horn
Data system	PC-based with full waveform capture using a 100 or 500 MHz digitization rate

Table 800: ROWS instrument characteristics

Figure 506: Illustration of ROWS dual-mode measurements

ROWS is a high-resolution radar with two distinct continuously-operating modes, namely the spectrometer mode and the pulse-limited altimeter mode.

- The spectrometer mode data are generated with a near-nadir-pointing, pencil-beam antenna which rotates in azimuth. The data are used to derive two-dimensional ocean wave spectral estimates and directional radar backscatter information.

²⁵⁴⁴⁾F. Lanzl, A. Müller, “Imaging spectroscopy: strategic activities at the DLR Institute of Optoelectronics,” Proceedings of SPIE, Vol. 3753, Denver, CO, July 19-21, 1999, pp. 24-34

- The pulse-limited altimeter mode radar returns are derived using a vertically-pointed horn antenna. Ocean significant wave height and surface wind speed are inferred from the altimeter return.^{2545),2546)}

Applications: measurements of the directional ocean gravity-wave spectrum, ocean wave height, and surface wind speed/stress. Recent field measurements with ROWS participation are:

- High Resolution Remote Sensing Program in 1993
- Surface Wave Dynamics Experiment (SWADE) in 1991
- Grand Banks ERS-1 SAR Wave-Mode Validation Experiment in 1991
- Labrador Extreme Wave Experiment (LEWEX) in 1987

P.179 R-SLAR (RRL-SLAR)

The X-band instrument was sponsored by JEA (Japan Environmental Agency) and developed at Radio Research Laboratory (RRL, CRL is the new name as of 1987) of Tokyo, Japan. Objectives: quantitative measurements of normalized radar cross-sections (NRCS) of backscattered radiation from sea surfaces, generation of 2-D images. The instrument has been flown for oil slick observations, wind vector estimations, etc. since 1986 on a Merlin-IV A aircraft (Fairchild Swearingen).^{2547), 2548)}

The slotted waveguide array antenna provides a pencil beam pattern of 0.57° beamwidth in azimuth and a cosecant-squared pattern of 40° beamwidth in elevation. The antenna depression angle may be changed manually only on the ground. A high power coaxial magnetron generates 70 kW peak power with $0.2 \mu\text{s}$ pulse width and a PRF of 1 kHz. The low noise figure ($\approx 3\text{dB}$) of the receiver results in a minimum detectable received level of -103 dBm with a bandwidth of 7.4 MHz. The swath width is 20 km with a geometrical resolution of about 40-80m in azimuth and about 35 m in the range direction. Flight altitudes are between 2 - 4 km with incidence angles of 60° .

Parameter	Value	Parameter	Value
Antenna		Data processor	
Type	Waveguide slot array	Sampling interval	$0.1 \mu\text{s}$
Beam pattern	Gauss (Az), Cosec^2 (El.)	Sampling length	$180 \mu\text{s}$
Beam width	0.57° (Az.), 40° (El.)	No. pulse integration	64 / 128 / 256 / 512
Polarization	VV	Sampling start range	0.6 / 2.4 / 4.8 / 9.6 km
Peak gain	33.8 dB	Recording	Digital magnetic tape
Aperture size	38 cm x 4.5 cm		
Transmitter		Receiver	
Frequency	9.53 GHz (X-band)	Bandwidth	7.4 MHz
Transmit tube	Coaxial magnetron	Noise figure	3.2 dB
Peak power	70 kW	Dynamic range	80 dB
Pulse width	$0.18 \mu\text{s}$	Swath width	$\sim 20 \text{ km}$
PRF	1000 Hz	Resolution (H=Alt in km; θ =incidence angle)	$Az = 10H/\cos\theta \text{ (m)}$ $\text{Range} = 27/\sin\theta \text{ (m)}$
Total instrument mass	$\sim 300 \text{ kg}$	Power	$\sim 1 \text{ kW}$

vide qualitative and quantitative information on backscattered radiation in the troposphere and lower stratosphere, and to provide a capability to map the atmospheric parameters/constituents in 3-D for better visualization. Real-time qualitative backscatter data from SABL are required in identifying target volumes of the air to be sampled.

The basic design of the lidar is that of a compact coaxial lidar system. The instrument mount in the modified fuel tank does not permit any heating or pressurizing of the pod. This implies large temperature changes of the instrument during flight. The temperature effects are minimized by the use of a transmitter/receiver of SABL from a common optical platform. The beam overlap between the transmitter/receiver is computer-controlled using micro-positioners to steer the laser beam as necessary. Other temperature-sensitive components of SABL are temperature stabilized. ²⁵⁴⁹⁾

The transmitter/receiver design permits the configuration of the receiver to be easily changed depending on the observation requirements. The basic configuration allows two wavelength measurements. The optimum range of measurements can be adjusted with FOV and overlap adjustments, depending on whether measurements are to be made close to the aircraft or at distances up to 10 km.

SABL is controlled by two computers. The pod computer controls all instrument functions (the lasers collect and digitizes the return signals, controls the output beam steering mirror, monitors all environmental functions, etc.). The second computer within the C-130 interfaces to the pod computer, records all data and provides quicklooks and operator control.

Lidar measurement technique	incoherent backscatter
Transmitter parameters: Laser type and transmitter wavelengths Laser energy/pulse Pulse length Polarization Pulse rate Divergence Beam size	Nd:YAG; 1064 nm and 532 nm 75 mJ, 50 mJ (125 mJ total) 15 ns linear (1000:1) 60 Hz 1 to 4 mrad 0.63 cm
Receiver Parameters Telescope size and configuration Telescope speed Background filter bandwidth Background filter transmission	35 cm diameter, Cassegrain telescope f/2.5 to f/4.0 0.0002 μm for 1064 nm; 0.0001 μm for 532 nm > 30% for 1064 nm; > 30% for 532 nm
Detectors	PMT for 1064 nm; APD for 532 nm
FOV	1 - 6 mrad
Digitizer	12 bit, sample rate \geq 20 MHz
Data rate	200 - 400 kByte/s
Measurement range	0 - 10 km
Range resolution	7.5 m
Airborne platform of instrument	C-130, SABL will be mounted in a modified fuel tank that is flown outboard of the aircraft engine
Research objectives/applications	3-D aerosol and boundary layer structures, identification of target volumes, etc.

P.181 SASAR (South African SAR)

SASAR is a modular SAR instrument in development/integration by the University of Cape Town, South Africa. The objective is to provide a surveying capability for geological and en-

²⁵⁴⁹⁾B. Morley, et al. "NCAR's Scanning Aerosol Backscatter Lidar (SABL): Design, Specifications, and Implementation Plan," Proceedings of the 1st International Airborne Remote Sensing Conference and Exhibition, September 12-15, 1994, Strasbourg, France, Volume II, pp. 83 - 93

vironmental applications. Future extensions with C- and L-band are in the planning. The C-band is chosen for general imaging and moisture detection, while the VHF-band of SASAR offers a surface/foilage penetrating capability, a feature that will be used for subsurface water location surveys in arid regions.

The long-term system concept is reflected in Table 803. For the prototype VHF system, a short, monochrome pulse of 175 ns will be used. The pulse compression implementation will be done later by using a stepped-frequency system, i.e., 64 monochrome pulses of 5 μ s stepping over the bandwidth to achieve the needed resolution.²⁵⁵⁰⁾

Parameter	C-band (future extension)	VHF-band
Center frequency, wavelength	5.3 GHz, 6 cm	141 MHz, 212 cm
Sensor calibration repeatability	1.5 dB (radiometric)	1.0 dB
Slant range resolution	6 m	25 m
Peak power	2 kW	600 W
Pulse modulation	linear FM	stepped frequency linear FM
Pulse Length	5 μs	5 μs
Radar PRF (nominal)	1250 Hz	1250 Hz
Antenna Size Type Polarization	1.2 x 0.4 m dual polar patch array interspersed with VHF monopole array HH, VV, HV, VH	3 x 1.5 m dual polar array of inclined monopoles on a ground plane HH, VV, HV, VH
Swath Characteristics		
Swath width	28 km	42 km
Number of pixels	4096	4096
Start of swath from track	10 km	10 km
Incidence angle (near)	45°	45°
Incidence angle (far)	74°	78°
Nominal operating altitude	10 km (Boeing 707 platform of South African Air Force)	
Image Parameters		
Image size	2048 x 2048 pixels	
Image dynamic range	8 bit	
Image azimuth sidelobe level	-42 dB	
Range pixel size (slant)	6 m	10 m
Azimuth pixel size	10 m	
Peak range sidelobe	-30 dB	
Speckle resolution	1-6 looks	
Motion compensation	yes	
Image storage media	Exabyte cartridge	
Data recording rates	500 kByte/s (for each of the 4 channels)	
Maximum recording time	2.5 hr	
Annotation data	GPS, IMU	

Table 803: Specification of the SASAR instrument

The VHF antenna is dual polar (VV, HH) array, providing combinations of polarization, one at a time. All antennas will be mounted on a removeable “cheek” which is fitted just aft of the cockpit on the starboard side of the aircraft. All frequency bands of SASAR look into a common footprint and are operated simultaneously. The polarimetric measurement sequence is as follows:

- VHF-band VV transmit, followed within microseconds by a C-band HH transmit
- Receive VHF-band VV and VH, as well as C-band HH and HV
- Then transmit of VHF-band HH and C-band VV
- Receive of VHF-band HH and HV, as well as C-band VV and VH

²⁵⁵⁰⁾ M. R. Inggs, “A South African Multispectral Polarimetric Airborne SAR System,” Proceedings of the 1st International Airborne Remote Sensing Conference and Exhibition, Strasbourg, France, September 12-15, 1994, Volume II, pp. 1 - 12

The sensor prototype system is due to fly in June 1996 and will be fitted with only a single-frequency (VHF-band) receive and recording system. Also, no antenna switch will be fitted, so that only a fixed polarization combination can be recorded for each pass. The real-time processor uses a DEC Alpha workstation implementing a low resolution quasi-focussed algorithm. Each of the four T/R (Transmit/Receive) radar systems is connected to an individual high-data-rate recorder.

P.182 SB-RAS Airborne Instruments

The instruments listed below were built and are operated by SB-RAS (Institute of Atmospheric Optics (of the Russian Academy of Sciences), Tomsk, Russia.

P.182.1 MAKREL-2 Lidar

Makrel-2 is a lidar instrument of the Institute of Atmospheric Optics (PI: V. S. Shamanaev) in Tomsk, Russia. It was designed and built in the mid-eighties for the investigation of atmospheric aerosols, of clouds, of upper and lower water surfaces/layers.²⁵⁵¹⁾ When sounding clouds it is capable of measuring their distance, their optical depth, and their phase state. In studies of industrial emissions, Makrel-2 determines the aerosol optical scattering coefficient as a function of the aerosol mass concentration and the asphericity of the particles. When sounding water layers, the lidar measures the extinction coefficient (turbidity); it identifies the presence of optical anomalies in the water column (hydrosol and plankton); it measures the height of wind-driven waves (≥ 0.4 m) and laser-induced luminescence.

Two instruments of Makrel-2 have been flown starting in 1986 on board two Ilushin-18 DORR aircraft for the purpose of fish school detection in Murmansk and Vladivostok. The typical flight altitude for sea sounding operations is 200 m, corresponding to the altitude of low boundary clouds in the Russian North and Far East.

Measurement technique	Elastic scattering, fluorescence
Parameters or constituents measured	Scattering coefficient, linear polarization
Measurement range	2 km in atmosphere, 30 m in marine environment
Vertical resolution	1.5 m
Measurement times	Day and night
Laser type and wavelength	Nd:YAG, 532 nm
Pulse repetition	Up to 20 Hz
Laser energy/pulse	30 mJ
Airborne platform	Aircraft: Ilushin, Antonov-30, helicopter: MI-8
Receiver size and configuration	15 cm (type?)
Receiver FOV	2 - 20 mrad
Receiver bandwidth	1.5 nm
Detectors	PMT FEU-144 type
A/D converter	10 ns, 7-bit, 3 channels
Research objective/applications	Observation of marine waters and the atmosphere above the water, detection of fish schools and of sea pollutants

Table 804: Specification of the Makrel-2 Lidar instrument

The Ilushin aircraft has a ceiling altitude of 8.5 km and a flight endurance capability of 12 hours. Other instruments flown besides the Makrel-2 instrument on the Ilushin are:

- IR radiometer for the measurement of SST (Sea Surface Temperature) and ocean color

²⁵⁵¹⁾Information provided by V. S. Shamanaev of the Institute of Atmospheric Optics, SB-RAS, Tomsk, Russia

- Video camera
- Sensors for the measurement of temperature and humidity on board the aircraft

A third copy of the Makrel-2 lidar was installed on board a MI-8 helicopter and used as a fluorosensor by the oil patrol ecological services of Tyumen, Siberia.

A fourth Makrel-2 lidar has been flown by SB RAS in a series of airborne experiments, which are conducted aboard an Antonov-30 aircraft since 1989.²⁵⁵²⁾ As of 6/1994 plans call for the Makrel-2-4 operations in Western Siberia and at Lake Baikal.

As of 1994 there is an agreement between SB-RAS and NOAA (Environmental Technology Laboratory in Boulder, CO) to provide NOAA with a modified Makrel-2 lidar instrument.

The Antonov-30 aircraft has a maximum take-off mass of 24 t, a flight speed range of 250-450 km/h, a maximum range of 2400 km, flight endurance = 5.5 h, flight altitudes between 100-8100 m, electrical power = 12 kVA for instrument support. The scientific instrument suite consists of the following sensors:

- Gas analysis complex and aerosol complex: Collection of air samples by gas analyzers, photoelectric counters and nephelometer (thermo-optical and hygro-optical), solar spectrometer to determine the total content of gas pollutant in the atmospheric column, added in 1990, and an HPM-4 gas chromatograph. Measurement of meteorological parameters (air temperature, humidity, pressure, etc.) and of trace gases, aerosols (measurement of number density, particle size distribution, mass concentration, scattering coefficient, etc.), ozone concentration, CO₂ concentration.
- Makrel-2 lidar (added in 1990)
- Svetozar lidar (added in 1990)
- M2M lidar (added in 1990)
- Spectrophotometer (VIS and near-UV spectral ranges). Measurement of the upwelling radiation from the atmosphere and from the ground. Spectrometer specifications: lens diameter = 0.2 m, focal length = 0.4 m, FOV = 0.4°, rate of angular scanning = 0-20°/s, range of scanning in the elevation angle = 0-90°; spectral bands (half-bandwidth of the filter): 0.400 (0.008), 0.487 (0.006), 0.551 (0.008), 0.630 (0.008), 0.670 (0.008), 1.060 (0.015), 1.221 (0.016), 1.620 (0.020) μm.
- Radiometer (measurement in the 8-15 μm spectral range, TIR). Specification: lens diameter = 28 mm, focal length = 56 mm, FOV = 1°; rate of angular scanning = 0-20°/s; angle of scanning = 0-90°; range of measurable radiant temperatures = 250-320 K; temperature threshold sensitivity = 0.2 K; time constant = 1s; spectral band centers (half-band width of the filter): 8.1 (0.22), 9.1 (0.24), 10.2 (0.24), 12.1 (0.48), 14.8 (0.56) μm.
- IV-03 Thermal Imager. Monitoring of thermal pollutants (added in 1990).

P.182.2 Svetozar-3 Lidar

Svetozar-3 is a lidar instrument of the Institute of Atmospheric Optics (PI: V. S. Shamaev) in Tomsk, Russia, with the objective of aerosol sounding in the atmosphere. It was designed and built in 1980. In the period of 1982-85 it served as a sea sounding instrument on board the Ilushin-14 and -18 aircraft. A coaxial video camera was used along with the Svetozar-3 lidar. In 1994 Svetozar-3 was upgraded with a more energetic laser and with a modern data processing system.

²⁵⁵²⁾ V. E. Zuev, B. D. Belan, D. M. Kabanov, et al. "The 'Optik-E' AN-30 Aircraft Laboratory for Ecological Investigations," *Atmospheric and Oceanic Optics*, Vol. 5, No. 10, October 1992, pp. 658-663

The Svetozar-3 instrument was preceded by Svetozar-1 in 1975 (wavelengths of 690 and 1060 nm, energy pulse = 5 mW, pulse length = 30 ns). The Svetozar-2 lidar was a simpler model.²⁵⁵³⁾ Both lidars (Svetozar-1 and -2) were equipped with an oscilloscope recording system. They are not in use anymore.²⁵⁵⁴⁾

Measurement technique	Elastic scattering, elliptic polarization
Parameters or constituents measured	Stokes vector, multiple scattering
Measurement range	2 km in atmosphere, 200 m in clouds
Vertical resolution	3.75 m
Measurement times	Day and night
Laser type and wavelength	Nd:YAG, 532 nm and 1064 nm
Pulse repetition	Up to 10 Hz
Laser energy/pulse	10 mJ
Airborne platform	Aircraft (what type? what altitudes?)
Receiver size and configuration	10 cm diameter 3 telescopes
Receiver FOV	1 - 32 mrad
Receiver bandwidth	2 nm
Detectors	PMT FEU-84 type, FEU-83 type
A/D converter	25 ns, 6-bit, 4 channels
Research objective/applications	Observation of clouds and dense aerosol pollutions

Table 805: Specification of the Svetozar-3 lidar instrument

P.182.3 M2M (Makrel-2 Modified)

M2M is a lidar instrument of the Institute of Atmospheric Optics (PI: V. S. Shamanaev) in Tomsk, Russia with the objective to measure meteorological parameters in the atmosphere. Two instruments of M2M are installed on the Antonov-30 aircraft.²⁵⁵⁵⁾

Measurement technique	elastic scattering, ring-shaped FOV
Parameters or constituents measured	scattering coefficient
Measurement range	2 km in atmosphere, 200 m in clouds
Vertical resolution	3.75 m
Measurement times	day and night
Laser type and wavelength	Nd:YAG, 532 nm
Pulse repetition	up to 20 Hz
Laser energy/pulse	100 mJ
Receiver size and configuration	20 cm diameter
Receiver FOV	10 - 70 mrad
Receiver bandwidth	1.5 nm
Detectors	PMT FEU-84 type
A/D converter	20 ns, 7-bit
Research objective/applications	Upper boundary of cloudiness and dense atmospheric pollutions

Table 806: Specification of the M2M Lidar instrument

P.183 SFSI (SWIR Full Spectrographic Imager)

The SFSI instrument is a development by CCRS of Ottawa, Canada (in cooperation with the National Research Council of Canada) with the focus on the SWIR (Short Wave In-

²⁵⁵³⁾ V. S. Shamanaev, K. D. Shelevoy, M. V. Trukhanenko, "Meteorological Airborne Laser Radar," Aspects of Remote Sensing of the Atmosphere, Tomsk, 1975

²⁵⁵⁴⁾ "Meteorologisches Laser Ortungsgerät Svetojar," Feingerätetechnik, DDR, 1977, Vol. 26, No. 10, p. 467

²⁵⁵⁵⁾ A. I. Abramochkin, I. E. Penner, V. S. Shamanaev, "A Lidar for Subsatellite Investigations of Clouds," Atmospheric and Oceanic Optics, Vol. 4, No. 3, March 1991, pp. 264-265

frared) region of the electromagnetic spectrum. First test flights with SFSI were carried out in October 1994.

SFSI covers a wavelength range from 1.2 μm to 2.4 μm in 115 contiguous 10.4 nm wide spectral bands. A 2-D detector array technology is used, providing a full image cube consisting of 496 pixels by 580 lines. The special feature of this sensor is its ability to achieve a spatial ground resolution down to 0.2 m using the pitch-scan technique (originally proposed for HIRIS). 2556) 2557) 2558)

SFSI employs a Loral-Fairchild CAM6003 camera, which has a 488 x 512 PtSi Schottky barrier CCD array. The control electronics, data processing, and data recording system have been developed to store 'image cubes' (see Figure 361) consisting of 580 lines by 496 pixels by 115 spectral bands by 8 bits in RAM (they are subsequently downloaded onto MO disk). The slowest operation in the chain, namely the MO disk recording rates, limits operation to the acquisition of discrete image cubes in the flight path. A future upgrade to a high data rate tape recorder (helical scan type) will permit continuous image acquisition and recording at full 12-bit digitizer resolution at a data rate of 75 Mbit/s.

Within a pilot project flown in Nevada in June 1995 over desert terrain, the SNR was measured under operational conditions with a solar zenith angle of 27° . The SNR peaked at 120:1 in the 1.2 - 1.32 μm window, and at 80:1 in the 1.50 - 1.79 μm and 2.0 - 2.4 μm regions.

Detector	
Orientation in focal plane	V = spectral dimension; H = spatial dimension
Number of elements	V = 488 (244 after on-chip summing), H = 512
Center spacing	V = 25 μm (50 μm after on-chip summing), H=31.5 μm
Cell area A	$7.88 \times 10^{-6} \text{ cm}^2$
Fill factor	0.367
Full well capacity	$5 \times 10^5 \text{ el}$
Array size	V = 12.2 mm, H = 16.1 mm
CCD transfer mode	Interline
Quantization (digitization)	12 bit
Optics	
Effective focal length	95 mm
Pixel angular IFOV	0.4 mrad
Total FOV	9.4°
Pitch-scan range	$\pm 50^\circ$ (maximum)
Focal ratio	f/1.8
Mean linear dispersion	$9.6 \mu\text{m nm}^{-1}$
Effective band width	10.4 nm
Data Recording (Burst mode)	
Image frame size (pixels, lines)	496 pixels x 3072 - 580 lines
Number of spectral bands	21 - 115 (selectable)
CCD frame rate / image line rate	50 Hz
Selectively recorded dynamic range	8 bit
Data rate into VRAM	25.0 Mbit/s
Buffer size (VRAM)	32 MByte
Data rate onto MO (magneto-optical) disk	335 kByte/s

Table 807: SFSI system parameter specification

P.184 SHOALS (Scanning Hydrographic Operational Airborne Lidar Survey)

SHOALS is a joint program of the US Army Corps of Engineers (USACE), Vicksburg, MS and the Canada Department of Science, Industry, and Technology. Objective: Survey of wa-

2558) Information provided by K. Staenz of CCRS

ter depths in navigation channels as well as general bathymetry in harbors and coastal waters. The lidar system was designed and built by Optech Inc. of Toronto, Canada. SHOALS field tests were completed in March 1994; the instrument is of LARSEN heritage. The SHOALS program, including survey operations and research and development, is based at the Joint Airborne Lidar Technical Center of Expertise in Mobile, AL. ²⁵⁵⁹⁾ ²⁵⁶⁰⁾ ²⁵⁶¹⁾ ²⁵⁶²⁾

USACE conducts an extensive annual hydrographic survey program in support of planning, design, construction, and maintenance of federal projects. SHOALS is an airborne survey instrument designed to augment the USACE fleet of conventional survey vessels. It is capable of surveying about 8 km² per hour with soundings every 4 m under normal operating conditions. The scan pattern and the survey speed can be modified to obtain higher sounding densities. The swath width corresponds to 1/2 of the aircraft altitude (= 1/2 radian). Typically, SHOALS operates at altitudes of 200 m and a speed of 60 m/s giving a survey swath of 110 m and a horizontal spot density of 4 m.

The water depth is measured by a pulse of infrared radiation (1064 nm) and a pulse of green radiation (532 nm). Both pulses are emitted simultaneously. The infrared pulse is scattered from the water surface while the green pulse penetrates the water and is scattered from the bottom surface. The time difference between the surface return and the bottom return signals corresponds to the water depth. ²⁵⁶³⁾ ²⁵⁶⁴⁾

Lidar instrument	SHOALS (operational since 1994)
Measurement technique	Incoherent backscatter
Parameters or constituents measured	Water surface and bottom depths
Laser type and transmitter wavelength	Nd:YAG: 1064 nm (infrared) and frequency doubled to 532 nm (blue-green)
Pulse repetition frequency	400 Hz
Pulse width	6 - 7 ns
Laser energy/pulse	5 mJ for blue-green and 15 mJ for infrared
Nominal scan rate	3 Hz (variable)
Swath width (FOV)	0.5 rad (28.6°)
Receiver size and configuration	20 cm diameter, Cassegrain telescope
Receiver FOV	0.05 radian
Receiver bandwidth	10 nm for 1064 nm frequency, 3 nm for 532 nm frequency
Detectors used	1 PMT and 4 APD (Avalanche Photodiode Detectors)
Instrument mass	500 kg
Airborne platform of instrument	Bell 212 helicopter (ground speed up to 100 knots)
Survey altitudes	200 m (variable)
Maximum depth measurements	60 m (max)
Vertical position accuracy	± 15 cm
Horizontal accuracy DGPS, RTK	± 3 m, ± 1 m
Sounding density	4 m grid (variable)

Table 808: Specification and performance of the SHOALS instrument

SHOALS was modified in 1996 to include topographic capabilities. The blue-green frequency (532 nm) is used to measure topographic elevations. SHOALS features three airborne subsystems: Transceiver (TRS), Aircraft Positioning and Auxiliary Sensors (APASS),

and Acquisition, Control and Display (ACDS), in addition there is a ground-based data processing system.

- TRS consists of a laser, scanner and receiver. TRS transmits laser pulses in a defined scan pattern and receives backscattered energy from these pulses to produce depth soundings. The scanner (developed by SAAB Instruments) scans the laser in a 180° arc across the forward flight direction. Sounding spacing in both directions (along-track and across-track) is selectable (the scanner uses feedback from APASS to compensate for pitch and roll). The nominal scan rate is 3 Hz. The scan width (swath) may be adjusted from 5% to 70% of the aircraft altitude.
The receiver includes a telescope (Cassegrain design, 20 cm aperture, FOV = 0.05 radians and secondary optics). The detection system is composed of five detectors (1 PMT, 4 APD). Laser backscatter energy from the surface and bottom is detected by five receiver channels, three are water surface channels (IR, Raman, and green wavelengths) and two bottom channels (both green wavelengths). The return signals are digitized into 1 ns bins as the backscattered energy is being sensed. Four channels of the return signals are digitized and time-tagged; the fifth channel is used to discriminate between water surface and land surface.
- APASS serves to collect GPS data (geographic positioning), to provide an inertial reference frame (aircraft attitude), and to generate a video image of the area being scanned. Since 1966 the SHOALS positioning comes mostly from DGPS, providing position accuracies of ± 3 m in the horizontal and ± 0.15 m in the vertical direction. In RTK (Real-Time Kinematic) mode operation, the horizontal position accuracy improves to ± 1 m.
- ACDS serves as an operator interface to monitor and to control all system functions, including raw data recording. The system offers data preprocessing and display of the water depth in real time (200 soundings/s).

P.185 SILVACAM (Real-time False Color CCD Video Camera)

SILVACAM is a commercially available instrument of Karelsilva Oy of Finland for environmental monitoring (operational since 1992). SILVACAM produces in real-time Color Infra-Red (CIR) video images. The spectral ranges for SILVACAM are green (490-580 nm), red (580-680 nm), and NIR (760-900 nm). The 'false color' technique converts the invisible NIR spectral band into a false (red) color, indicating the state of vegetation health (healthy vegetation has a strong reflection in NIR). Applications of SILVACAM are in forestry, agriculture, geology, surveying.

Parameter	Description
Image pickup device	1/2 inch interline CCD array (3 spectral bands: green, red, NIR)
Effective number of pixels	683 (horizontal) x 582 (vertical) in PAL standard, or 670 (horizontal) x 492 (vertical) in NSTC standard
Electronic shutter speeds	1/60 (normal), 1/250, 1/500, 1/1000 (switchable)
Color system	PAL (r-Y, B-Y method encoder), MII, VHS, S-VHS, RGB
Synchronization	Internal (built-in SPG), or external (composite video or black burst signal)
Lens mount	1/2" bayonet
Sensitivity	f/4, 2.000 lux (+18 dB)
SNR (standard)	55 dB typical (contour correction off, gamma 1, bandwidth 5 MHz, Matrix off, chroma off)
Horizontal resolution	500 TV lines
Video signal output	
26 pin connector	Composite video signal (VBS) 1 Vp-p, and separate Y/C signals (compatible with S-VHS) or component signal (Y/R-Y/B-Y for MII or R/G/B 0.7 V-p 75 Ohm)
7 pin connector	Separate Y/C signals (in Y/C 433 mode only) compatible with super VHS
Test output terminal	Composite video signal (VBS) 1 Vp-p (any one of IR, R or G signals can be selected using the internal select switch)

Parameter	Description
System parameters	
Voltage	12 V DC (10.5 - 15 V)
Current	< 1.5 A
Mass of SILVACAM	2.7 kg
Camera mount configurations	a) Normal down-looking (FOV = 60°) b) Forward-looking c) Across-track scanning

Table 809: Technical parameters of the SILVACAM Video Camera

The camera is also provided with a GPS receiver for geo-referencing of the video data (the GPS signal along with UTC is superimposed on the video signal). The video data may be stored on different storage media (S-VHS video cassette recorder is normal, MII, etc.). The video data can be integrated in digital or analog format with other data using GIS techniques. ²⁵⁶⁵⁾ ²⁵⁶⁶⁾ ²⁵⁶⁷⁾

Data: Ampex FR 3030 high-density digital recorder for data playback, and a quicklook facility (Honeywell 1856 A Visicorder with a 1226 film processor) are available.

P.186 SLAR (Side-Looking Airborne Radar, NLR)

SLAR²⁵⁶⁸⁾ is used as a research tool to survey and to monitor land and sea surfaces. The Dutch digital SLAR is a joint development of the Physics and Electronics Laboratory (TNO) of Delft University of Technology, and NLR. The instrument is installed in the NLR Metro II laboratory aircraft.

In order to enable multitemporal registration of data, a set of algorithms has been installed on an NLR computer to geometrically correct acquired SLAR data for variations in aircraft attitude and motion through simultaneously recorded inertial reference parameters. Furthermore, radiometric corrections for system parameters are performed to calculate radar backscatter coefficients.

Parameter	Specification
Frequency	9.4 GHz (X-band), HH-polarized
Transceiver	transmitted power pulse length pulse repetition frequency
	25 kW 50 ns 200 Hz
Dynamic range (special amplifier)	80 dB
Digitalization	video bandwidth (after filter) sampling frequency samples per line bits per sample
	dc - 10 MHz 50 MHz (20 ns) 4096 8
Pixel size (final)	7.5 x 7.5 m / 15 x 15 m
Range	max 12 km
Resolution	range (across track) azimuth (along track) radiometric
	7.5 m 10 mrad (two-way) 0.3 dB
Flight altitude	100 - 6000 m
Ground speed	90 m/s

Table 810: SLAR specification

P.187 SMIFTS (Spatially Modulated Imaging FTS)

SMIFTS²⁵⁶⁹⁾ is a cryogenically cooled, spatially modulated imaging Fourier transform interferometer-spectrometer for spectral measurements in the 1 - 5 μm range. The instrument was designed and built at the Department of Geology and Geophysics of the University of Hawaii, Honolulu - sponsored by the Office of Naval Research (ONR) and by DARPA. First successful helicopter test flights with a prototype SMIFTS took place in the summer of 1993 over lava fields of the Kilauea volcano on the island of Hawaii. - The new technology provided by SMIFTS invites a more detailed discussion of some imaging issues and of comparisons with other concepts.

Spectral Parameters		Spatial Parameters	
Spectral range	1.0 - 5.2 μm	IFOV	0.66 mrad
Spectral bandwidth	40 - 100 wavelengths	FOV	9.7°
No. of bands	35 - 90	Pixels/line	256
Electronic Parameters		Swath width	330 m, 2000 m
Quantization	12 bit		
SNR	1000 - 2000	Platform	Helicopter
Data rate	8 Mbit/s	Altitude (nominal)	2000 m
Detector array (InSb)	256 x 256 pixels		

Table 811: Specification of some SMIFTS parameters

The SMIFTS technology encompasses a combination of characteristics that are not available from other spectral measurement technologies (see Table 812). These are as follows:

- Broad, detector-limited wavelength range
- Wide field-of-view (FOV); spectral characteristics are independent of the size or geometry of the input aperture at the focal plane of the input optics.
- Simultaneous measurement of all spectral channels
- Compact instrument design
- Moderate spectral resolution ($\lambda/\Delta\lambda = 100$ to 1000)
- One dimension of imaging
- No moving instrument parts

The SMIFTS instrument contains three major optical subsystems: a Sagnac interferometer, which produces the spatially modulated interferogram; a Fourier transform lens, which frees the spectral properties from dependence on aperture geometry and allows the wide FOV; and a cylindrical lens, which reimages one axis of the input aperture onto the detector array providing the one dimension of imaging.

The Sagnac interferometer is known as a triangle path or common-path interferometer, because the two beams emerging from the beamsplitter, one in reflectance and one in transmission, follow the same path in opposite directions. These two beams, observed beyond the interferometer, form two images of an input source. For an interferometer with perfect symmetry, the two images of the sources are coincident and no interference effects are observed, i.e., there exists perfect constructive interference. If either mirror M_1 or M_2 is displaced, then the two beams traverse different paths, and the two images of the source are displaced orthogonally to the line-of-sight in opposite directions. As these two images are of the same source, they are mutually coherent and interference occurs. The detector array is used to sample the resulting interference pattern.

The spectrum is recovered from the interferogram via inverse Fourier transform of the interferograms of such sources. The proven Fourier transform spectroscopy, utilizing a Michelson interferometer, serves as a basis to obtain the sampled interference pattern from

²⁵⁶⁹⁾ P. G. Lucey, T. Williams, K Horton, K. Hinck, C. Budney, "SMIFTS: A Cryogenically Cooled, Spatially Modulated Imaging Fourier Transform Spectrometer for Remote Sensing Applications," SPIE Proceedings, Volume 1937, April 14-15, 1993, Orlando, FL

the input source. All of the principles which apply to Michelson interferometers also apply to the spatially-modulated interferometer, as described here; no derivation of the spectrum from the interferogram is required.

System Technology	Resolution $\lambda/\Delta\lambda$	Wavelength range	Mov-ing Parts	Simultaneous ac-quisition of all spectral channels	Throughput	Remarks
SMIFTS	$10^2 - 10^3$	Broad (detector-limited)	no	yes	very high	slit & FOV independent
Grating	$10^2 - 10^5$	Narrow (optics-limited)	no	yes	low	narrow slit required
Prism	$10^2 - 10^3$	Narrow (optics-limited)	no	yes	low	
Michelson Interferometer	$10 - 10^5$	Broad (detector-limited)	yes	no	very high	sequential acquisition
Filter (electronically tunable)	10^2	Narrow (optics-limited)	no	no	very high	sequential acquisition
Filter (mechanical)	$10 - 10^3$	Broad (detector-limited)	yes	no	very high	sequential acquisition
Filter (mask)	10^2	Narrow (optics-limited)	no	yes	very high	
Filter (mask)	10^2	Broad (detector-limited)	no	no	very high	sequential acquisition

Table 812: Overview of some hyperspectral sensor technology characteristics

Figure 507: Concept of a spatially modulated imaging interferometer FTS

Light from a foreoptics system is focussed on the aperture. The Sagnac interferometer divides the input image into two images separated laterally with respect to the optic axis. These images are coherent and so produce an interference pattern. The Fourier transform lens removes dependence of the interference pattern on the detector array from any dependence on the position or shape of the input aperture which defines the IFOV. The cylindrical lens re-images the input aperture onto the detector along the dimension normal to the page which causes each row of the detector element to contain the spectrum (after transformation) of the corresponding point on the input slit. Unlike a dispersive spectrometer, the slit can be arbitrary in width without affecting the resolution of the spectrum or the wavelength calibration.

SMIFTS is a cryogenically cooled instrument utilizing a 256 x 256 element InSb detector array covering the spectral region from 1 to 5 μm . The sensor is usually operated in one of two modes, collecting approximately 90 channels from 1-5 μm with 100 wavenumber resolution, or approximately 35 channels from 3 - 5.3 μm with 40 wavenumber resolution. The cross-track IFOV of the sensor is 0.5 mrad and has a swath width of 256 pixels. The along-track IFOV is variable in order to maximize the SNR for specific applications. Spectral resolution is independent of aperture geometry.

Some definitions in the context of SMIFTS:

Broad wavelength range. - SMIFTS relies upon the Fourier transformation of the interference pattern produced by two mutually coherent source pairs to obtain the spectrum of the source. The range of the spectrum is limited principally by the spectral response of the detector array employed, with second order effects due to transmission and reflection characteristics of the optics. A SMIFTS spectrometer can, with a single detector, cover the entire sensitivity range of that detector. Grating spectrometers covering a range of several μm suffer significant losses due to methods required to overcome the phenomenon of overlapping orders (e.g. multiply blazed gratings), or require multiple detector arrays or spectrometers.

Wide FOV. - The spectral characteristics of SMIFTS are independent of the size or geometry of the input aperture at the focal plane of the input optics. As an interferometer, the instrument is not constrained by the resolution-luminosity product. Hence, continuous monitoring of large FOVs are possible while preserving spectral resolution and range. A grating spectrometer requires a narrow input slit to preserve spectral resolution, so that large FOVs cannot be continuously monitored, but must be scanned. The input aperture of the SMIFTS can be varied arbitrarily if desired, for example to preserve spatial resolution at a variety of ranges or to increase SNRs at the expense of spatial resolution.

Simultaneous measurement of all spectral channels. - This characteristic is shared by imaging spectrometers based on diffraction gratings or prisms. The importance of this characteristic is that it ensures that each spectral measurement and each spectral channel has observed the target over the same time interval. Spectrometers based upon Michelson interferometers or tunable filters or wedge filters observe targets sequentially. If the object/target varies over the time scale of the data acquisition, intrinsically or due to tracking errors, then sequential spectrometers suffer from the effect of 'jitter noise.' Simultaneous acquisition ensures that the entire spectrum is a true time average of the target over the integration period.

Moderate spectral resolution. - The resolution of interferometer spectrometers is proportional to the number of samples taken of the interferogram. SMIFTS uses a CCD detector array to sample the interferogram. Hence, the spectral resolution is a function of the number of detector elements along the interferogram axis of the array. By measuring a single-sided interferogram, the spectral resolution in inverse centimeters ($\Delta\sigma$) can be defined as : $\Delta\sigma = \sigma_c / (0.8 \times N)$, where σ_c is the high frequency cutoff, and N is the number of pixels along the interferogram axis of the array. The '0.8' reflects that a small portion of the interferogram must also be measured on both sides of the centerburst to preserve phase information. Modern IR arrays range in size from roughly 100 to 1000 pixels on the largest axis, so that the spectral resolution attainable by a SMIFTS in terms of $R = \sigma/\Delta\sigma$ is also roughly 100 to 1000. CCDs in the VIS range are available in much larger sizes, so resolutions in the order of 2000 - 4000 is possible in the range of silicon CCDs.

One dimension imaging. - On the 2-D detector array utilized by a SMIFTS, one axis contains the spectral information, the other axis contains the spatial information along one axis of the source. If a slit aperture is used with the SMIFTS, then the information present on the array is directly analogous to that collected by a grating imaging spectrometer. Each row of the array contains the spectrum of the corresponding point along the slit aperture. Unlike the grating spectrometer, the slit of the SMIFTS can be made arbitrarily wide, so that the area from which a row derives the spectrum can be roughly square, or extremely elongated,

depending on application needs. In wide field applications, each row of the detector array contains the spectrum of a long narrow rectangle, with a width corresponding to the width of the detector element as mapped on the focal plane, and arbitrary length. One spatial axis is then retained even for wide field monitoring.

P.188 SOFIA (Stratospheric Observatory for Infrared Astronomy)

SOFIA is a cooperative NASA and DLR astronomy observatory on an airborne platform, a modified and refurbished Boeing 747-SP aircraft. The overall objective is to provide a long-term (20 years) high-resolution observation capability in the infrared spectrum. The airborne solution with flight altitudes of 12-14 km was selected since most of the incoming radiation in FIR (Far Infrared) is being absorbed in particular by the water vapor of the Earth's lower atmosphere (troposphere). At SOFIA's flying altitudes, the telescope is above 85% of the Earth's atmosphere and more than 99% of the atmospheric water vapor, thus providing an excellent observation capability for infrared radiation. Many objects in space emit most of their energy at infrared wavelengths. Infrared radiation characterizes a multitude of rich and varied physical processes. It is expected that SOFIA will be a major factor in the development of observational techniques and of new instrumentations. Some of the scientific topics, addressed by the SOFIA users include the following fields:

- Interstellar cloud physics and star formation in our galaxy
- Proto-planetary disks and planet formation in nearby star systems
- Origin and evolution of biogenic atoms, molecules, and solids
- Composition and structure of planetary atmospheres and rings, and comets
- Star formation, dynamics, and chemical content of other galaxies
- The dynamic activity in the center of the Milky Way
- Ultra-Luminous IR Galaxies (ULIRGs) as a key component of the early universe.

SOFIA is part of NASA's Origins Mission. Under an international agreement between the United States and the German governments (MOU signed in Dec. 1996), the SOFIA telescope is being supplied by the German Aerospace Center (DLR). The SOFIA telescope is being developed and built for DLR by a consortium with MAN Technologie AG as prime contractor, and by Kayser Threde GmbH of Munich, Germany. DLR is supplying additional operation support in return for a portion of SOFIA's valuable observing time. For NASA, the SOFIA program is being developed and operated by a team of industry experts led by USRA (Universities Space Research Association). SOFIA will be based at NASA's Ames Research Center at Moffett Federal Airfield, California, and is expected to begin flying in late 2002.

P.188.1 Payload/Instrument Complement

The SOFIA telescope structure is a so-called dumbbell design with the optics at one end of the dumbbell and the science instruments on the other end, in between the aircraft bulkhead, which separates the telescope cavity from the cabin. The following are some basic operational objectives: ²⁵⁷⁰⁾ ²⁵⁷¹⁾

- Continuous access to the science instruments during flight
- Research/observation hours per year: 960
- Time per flight at cruising altitudes: > 6 hours
- Unvignetted field of view: ± 4 arcmin (elevation range: 20° - 60°)
- Effective telescope aperture: 2.5 m

²⁵⁷⁰⁾A. Krabbe, "The SOFIA Telescope," Proceedings of the Symposium on Telescopes and Instrumentation 2000, Munich, Germany, March 2000

²⁵⁷¹⁾H. J. Kärcher, E. Sust, H. Bittner, "The Selection of the Telescope Concept for SOFIA," in SOFIA, Astronomy and Technology in the 21st Century, Editors: R. Titz, H-P. Röser, Wissenschaft und Technik Verlag, Berlin, pp. 17-20

- Telescope optical image quality, 80% image diameter: 1.5 arcsec
- Telescope pointing stability: 0.2 arcsec rms

The optical telescope design employs the classical Cassegrain configuration with a Nasmyth focus. The parabolic primary mirror is a monolithic 2.705 m diameter Zerodur (a glass/ceramic material) mirror, lightweighted to 900 kg by a special arch shape and by hexagonal holes bored from the backside. The mirror employs a rigid CFRP structure connecting the mirror to the telescope trusswork structure and the Nasmyth tube. The hyperbolic secondary mirror is attached to a drive system providing focusing and optical alignment as well as a wide range of chopping capabilities, programmable by either a user-supplied analog or TTL curve, or by the telescope control electronics. A flat tertiary mirror reflects the beam into the infrared Nasmyth focus, 300 mm behind the instrument flange. If the tertiary mirror is replaced by a dichroic mirror, the transmitted optical radiation is reflected by a second tertiary mirror, at a distance of 289.2 mm behind the dichroic mirror, and sent to the visible Nasmyth focus where it feeds into the FPI (Focal Plane Imager) guiding camera system for the support of tracking functions. In addition, two on-axis imaging and guiding cameras are available: WFI (Wide Field Imager) and FFI (Fine Field Imager), see Table 814.

The SOFIA tracking imaging package consists of three instruments: WFI, FFI, and FPI. In addition, there is TRC (Tracker Control Processor) to provide tracking control for the acquisition and tracking functions. All imagers have separate image control units for image digitizing and instrument control.

Overall telescope mass + instruments	ca. 20,000 kg
Optical layout of PM telescope	Cassegrain telescope with Nasmyth focus, permanent access to science instrument from cabin
Structural layout	CFRP structure in dumbbell shape with trusswork metering tube
Rotation isolation system	Hydrostatic bearing with 2 ring segments, 1.2 m diameter, 10-30 bars pressure
Vibration isolation system	12 springs/dampers around the hydrostatic bearing in longitudinal and tangential directions
Nominal system f-ratio	19.6
Primary mirror (PM)	Diameter of 2.705 m, effective aperture 2.5 m, lightweighted Zerodur structure (Schott) on 18-point whiffle-tree support, PM ratio f/1.28, aluminum coated, focal length = 3200 mm, mirror mass about 900 kg, mirror center hole = 420 mm,
Secondary mirror (SM)	Consisting of C/SiC material, aperture stop = 352 mm diameter, aluminum coated, focal length = 4770.65 mm
SM functions	Provision of focus, alignment, chopping (2-axis in arbitrary directions, offset, three point, stationary)
Tertiary mirror (TM)	Consisting of 2 flat exchangeable mirrors, dichroic (gold coated) and non-dichroic (aluminum coated)
System focal ratio	f/9.6
Spectral range covered	0.3 to 1,600 μm (VIS, IR, FIR, MW), prime wavelength range: 15-300 μm . SOFIA's wavelength range covers nearly four decades of the electromagnetic spectrum, from the visible, throughout the infrared and submillimeter range to the microwave region.
Unvignetted field of view (FOV)	8 arcmin (for chop amplitudes up to 10 arcmin)
Ranges of telescope motion	Elevation 15-70 degrees (20-60 degrees unvignetted), cross-elevation and LOS $\pm 3.0^\circ$
Diffraction-limited wavelength	$> 15 \mu\text{m}$ (i.e., resolution = $(\lambda/10 \mu\text{m})$ arcsec for $\lambda > 15 \mu\text{m}$)
Image quality of telescope optics	at 0.6 μm wavelength = 1.5 arcsec on-axis (80% encircled energy)
Image pointing stability	0.2 arcsec rms when using on-axis focal plane tracking 0.8 arcsec rms when using on-axis fine-field tracking
Image pointing accuracy	0.5 arcsec when using on-axis focal plane tracking 3 arcsec when using on-axis fine field tracking

Table 813: Some key telescope characteristics

Figure 508: Optical system of the SOFIA telescope

The **WFI** (Wide Field Imager) and **FFI** (Fine Field Imager) instruments are mounted on the telescope structure in the cavity and boresighted to the main telescope. They observe the star field through their own optics. The third camera, the **FPI** (Focal Plane Imager), uses the visible path of the main telescope. Each imager consists of a camera head and a separate camera controller for source data quantization, data handling and housekeeping functions. The detector assembly uses a 1024 x 1024 back-illuminated CCD array (SiTe) with 14 μm pixel size (full frame type with mechanical shutter).²⁵⁷²⁾

P.188.2 Complement of German Science Instruments

GREAT (German Receiver for Astronomy at Terahertz Frequencies), PI: R. Güsten of MPIfR (Max-Planck Institut für Radioastronomie), Bonn. Other participants of the consortium are: University of Cologne, DLR/Berlin, and MPAe (Katlenburg-Lindau). GREAT is a high-resolution dual-channel heterodyne spectrometer providing observations in up to three frequency windows with the following objectives: ²⁵⁷³⁾ ²⁵⁷⁴⁾

- Low-frequency band with a frequency range of 1.4 - 1.9 THz (or 158-187 μm) covers the important atomic fine-structure line of ionized carbon (University of Cologne)
- Mid-frequency band in the frequency range of 2.4 - 2.7 THz (or 110-125 μm). The studies are centered on the cosmologically relevant 1-0 transition of deuterated molecular hydrogen (HD) at 2.6 THz and the rotational ground state transition of OH ($^2\text{II}_{3/2}$), (MPIfR)
- High-frequency band operates at a frequency of about 4.7 THz (63 μm). Study of the transition of atomic oxygen (DLR/Berlin).

The receivers employ sensitive superconducting mixer elements, SIS tunnel junctions or hot electron bolometers. The intermediate frequency band of a few GHz width is linked to an array of acousto-optical spectrometers (AOS), provided by the University of Cologne.

FIFILS (Field-Imaging Far-Infrared Line Spectrometer), PI: A. Poglitsch of MPE Garching. Cooperation with the Astrophysical Institute of the University of Jena. The objectives are to provide a unique tool for astronomical 3-D spectral imaging (2-D spatially and 1-D spectrally) of line emissions in the far-infrared. This new feature enables to instantaneously cover a velocity range of about 1500 km/s around selected FIR spectral lines, for each of the 25 spatial pixels. Observing in the far-infrared permits FIFILS to make significant contributions to a number of astrophysical problems. The scientific goals and topics include: ²⁵⁷⁵⁾ ²⁵⁷⁶⁾ ²⁵⁷⁷⁾

- Triggered star formation and the interstellar medium in merging/interacting galaxies
- The relationship between active galactic nuclei and starburst galaxies
- Local and extragalactic star formation
- The evolution of ultraluminous infrared galaxies (ULIRGs)
- The morphology of heating and cooling in galaxies
- The interstellar medium in low-metallicity environments (such as dwarf galaxies).

The instrument features two separate medium resolution (R of about 1700) liquid helium cooled grating spectrometers with common fore-optics feeding two large Ge:Ga detector arrays (16 x 25 pixels each). The two long-slit Littrow-mount grating spectrometers provide simultaneous observation of an object in two spectral lines in the wavelength ranges of 42-110 μm , and 110-210 μm , respectively, in 1st and 2nd order. Multiplexing takes place both spectrally and spatially. An image slicer is employed to redistribute 5 x 5 pixel spatial FOV (diffraction-limited in each wave band) along the 1 x 25 pixel entrance slits of the spectrometers. Anamorphic collimator mirrors keep the spectrometer compact in the cross-dispersion direction (to fit through the passenger door). The spectrally dispersed images of the slits are anamorphically projected onto the detector arrays, to independently match spectral and spatial resolution to detector size.

The optical slicer is the key to the integral field concept of the optical system. By using three specially-designed mirrors in sets of five, the 2-D image is sliced into 5 rows, followed by an optical rearrangement of the 5 rows into a single 1-D row of 25 pixels, representing in effect a traditional long slit. Afterwards, a Littrow-mount grating is utilized to disperse the light. Hence, the total data cube is obtained in the data reduction process.

²⁵⁷⁷⁾ <http://fifils.mpe-garching.mpg.de/>

Instrument internal blackbody calibrators are used for calibration and flat-fielding. The signal levels are comparable to the thermal background of the telescope. An image rotator compensates for field rotation during long exposures. Estimated system NEP (Noise Equivalent Power) of the spectrometer is about $2 \times 10^{-15} \text{ W}/(\text{Hz}/\text{pixel})^{0.5}$, including atmospheric and telescope transmission losses.

Parameter	Channel 1	Channel 2
Spectral range	42-110 μm (or 2.7 - 7.1 THz)	110-210 μm (or 1.4 - 2.7 THz)
Detector type (photoconductor)	Ge:Ga (Gallium-doped Germanium)	Stressed Ge:Ga
Spatial pixels	5 x 5	5 x 5
Spectral pixels	16	16
Pixel size	6 arcsec	12 arcsec
FOV (Field of View)	30 arcsec x 30 arcsec	60 arcsec x 60 arcsec
Velocity resolution	150-300 km/s	150-300 km/s
Instantaneous velocity (spectral) coverage	1500-3000 km/s	1500-3000 km/s
Line sensitivity (5 sigma in 1 hr)		
50 μm	$5.5 \times 10^{-17} \text{ W m}^{-2}$	-
100 μm	$3.5 \times 10^{-17} \text{ W m}^{-2}$	-
150 μm	-	$2.2 \times 10^{-17} \text{ W m}^{-2}$
200 μm	-	$1.4 \times 10^{-17} \text{ W m}^{-2}$

P.188.3 Complement of US Science Instruments

The U.S. instruments are funded through the USRA instrument development program for SOFIA, as part of the NASA development and operations contract. FLITECAM is funded by USRA out of the observatory development program.

HOPI (High-speed Occultation Photometer and Imager), PI: E. W. Dunham and J. L. Elliot of the Lowell Observatory, Flagstaff, AZ. The objective is to use HOPI for observing stellar occultations. HOPI is a special-purpose science instrument designed to provide simultaneous high-speed time-resolved imaging photometry at two optical wavelengths. HOPI and FLITECAM are mounted in parallel onto the SOFIA telescope to acquire simultaneously data at two optical wavelengths and one NIR wavelength.

Spectral range	0.30 - 1.1 μm
Spectral resolution	Defined by filters, as narrow as 0.003 μm , with ≥ 6 position motorized filter wheels on both channels.
Number of channels	2 with 1, 2, or 3 subframes per channel
Time and 3-D position accuracy	1 μs and 30 m via GPS
Maximum frame rate	20 ms for 3 80 x 80 pixel subframes per CCD 10 ms for 1 80 x 80 pixel subframes per CCD
Maximum time resolution	0.5 ms (in binned strip-scanning mode)
Read noise	≤ 6 electrons max; ≤ 3 electrons for slow read
FOV on SOFIA	5.6 arcmin x 5.6 arcmin, 8 arcmin diagonal
Optical system	- 80% enclosed light in 2 pixel box - Distortion well characterized for chopper testing - Shack-Hartmann capability in one channel, ≥ 20 spots across pupil with x-y adjustment of the lenslet array
Detector arrays	Silicon CCDs; EEV CCD47-20 frame transfer thinned, back-side illuminated, high speed, low noise, frame transfer devices with a 1 k x 1 k format and 13 μm pixels. One is anti-reflection coated for use at UV and blue wavelengths while the other is optimized for visual and red wavelengths.
CCD quantum efficiency	88% peak, $\geq 40\%$ from 0.35 μm to 0.85 μm

Table 816: Parameters of the HOPI instrument

EXES (Echelon-Cross-Echelle Spectrograph), PI: J. Lacy, University of Texas at Austin. The objective is the study of molecular gas in quiescent clouds and in proto-stellar disks. The instrument contains an echelon grating cross-dispersed by an echelle grating. ²⁵⁷⁸⁾

The EXES optics consist of three sections: focal reducing fore-optics, the echelon chamber, and the cross-dispersion/long-slit grating chamber. The fore-optics image the telescope secondary onto a cold pupil and reimage the telescope focal plane with 2:1 de-magnification through a filter wheel onto a slit wheel. The echelon chamber contains the high resolution echelon grating and its collimator/camera mirror. The grating chamber contains an echelle and a first-order grating, their collimator/camera mirror, focal reduction lenses, and the detector array. Four different operating modes can be used:

- High-resolution cross-dispersed mode: (resolution is about 100,000 wavelengths) all three chambers are used, with the echelle grating serving as the cross-disperser for the echelon
- Mid-resolution long-slit mode (resolution of about 10,000), the echelon chamber is bypassed, and the echelle serves as the primary disperser
- Low-resolution long-slit mode (resolution is about 2,000), a low-order grating mounted on the back of the echelle is used as the disperser
- In acquisition-camera mode, the low-order grating is turned face-on to act as a low efficiency (about 10%) mirror.

The echelon is essentially a 1 m long, 10 cm wide, R10 diffraction grating, with 7 mm groove spacing diamond-machined in a single piece of aluminum.

CASIMIR (Caltech Submillimeter Interstellar Medium Investigations Receiver), PI: J. Zmuidzinas of Caltech, Pasadena, CA. ²⁵⁷⁹⁾ ²⁵⁸⁰⁾ The objective is to study a wide range of astrophysical problems ranging from the evolution of galaxies to the birth and death of stars. The instrument is a submillimeter and FIR range (500-2000 GHz) heterodyne receiver with a very high spectral resolution ($v/\Delta v > 10^6$) capable of velocity-resolved observations of galactic objects. CASIMIR has also a very high sensitivity due to advances in superconducting detector technology by using SIS (Superconductor-Insulator-Superconductor) and HEB (Hot Electron Bolometer) mixers.

Species	Transition	Frequency (GHz)	E _{lower} (K)	Atmospheric Transition (1 mm H ₂ O) (SOFIA)

Table 817: Selected Submillimeter lines of CASIMIR

The optics of CASIMIR are contained in a sealed (non-cryogenic) box on which two helium cryostats are mounted. Each cryostat contains two receiver bands (each band covers about

²⁵⁷⁸⁾ <http://nene.as.utexas.edu/exes/>

²⁵⁷⁹⁾ http://www.sofia.usra.edu/observatory/instruments/first_light/abs_zmuidz.html

²⁵⁸⁰⁾ http://www.sofia.usra.edu/observatory/instruments/first_light/tables.html

150 GHz); up to 4 bands are available on any given flight. SIS mixers using Nb:Ti:N superconductors are used up to 1200 GHz; HEB mixers are used for higher frequencies. The receiver noise temperatures are below 0.3 K/GHz for the SIS bands and 0.7 K/GHz for the HEB bands. The local oscillators are solid-state continuously tunable multiplier sources driven by either Gunn oscillators or HEMT (High Electron Mobility Transistor) power amplifiers. A mirror, mounted on a rotary stage inside the optics box, selects which cryostat receives the telescope beam. The back-end spectrometers (4 GHz bandwidth) are mounted on the SOFIA telescope.

SAFIRE (Submillimeter And Far InfraRed Experiment), PI: S. H. Moseley, NASA/GSFC. The prime objective is to explore the physical conditions and astrophysical processes in a variety of astrophysical environments using a large number of lines in the 145 - 655 μm wavelength regime from key molecular, ionic, and atomic species as well as gas and dust continuum emission. SAFIRE can determine the energy balance and physical conditions in many important phases of the interstellar and circumstellar environment by imaging these regions in lines arising from molecular, atomic and ionized components, along with the dust emission.

The instrument is a versatile imaging Fabry-Perot spectrograph, covering the spectral range of 145-655 μm , with a spectral resolving power ranging over 1,000 - 10,000. The initial configuration of the instrument (Phase I) has only a single spectrometer with a 32 x 32 TES (Transition Edge Sensor) bolometer array. The 1 mm square pixels correspond to 10.6 arcsec in size, smaller than the resolution limit of the SOFIA telescope over the entire instrument spectral band. The TES array uses a SQUID based cryogenic multiplexing amplifier, allowing observations of very low flux sources, limited only by the sky and telescope background. - Later augmentations will upgrade the instrument with a second 32 x 32 array, behind a lower resolution Fabry-Perot (resolving power of 100) spectrometer. A slit and grating is also being used in this beam to provide non-imaging spectroscopy. ²⁵⁸¹⁾ ²⁵⁸²⁾

Spatial resolution	1.2 λ/D or about $(\lambda/10 \mu\text{m})$ arcsec pixels; e.g., 10 arcsec at 100 μm
Field orientation	Selected with cryogenic K-mirror
Wavelength/mode change	about 1 minute
Spectroscopic modes	
Spectral range	17-210 μm
Slit size	about 2.5 armin long with a selectable width between 2 and 35 arcsec
Three 2-D detector arrays (spatial x spectral)	17-40 μm ; 128 x 86 Si:Sb BIB array with 1.3 arcsec pixels 40-120 μm ; 24 x 16 Ge:Sb photoconductor array with 7 arcsec pixels 120-210 μm ; 12 x 8 stressed Ge:Ga photoconductors with 14 arcsec pixels
High resolution mode	Spectral resolution: $\lambda/\Delta\lambda = 1.2 \times 10^6 \mu\text{m}/\lambda$ Free spectral range: $\Delta\nu = 200\text{-}300 \text{ km/s}$
Low-resolution mode	Spectral resolution: $\lambda/\Delta\lambda = 10^4 \mu\text{m}/\lambda$ Free spectral range: $\Delta\lambda=0.1\lambda$
Imaging Mode	
Spectral bands 92)	18 μm , 25 μm
Spectral resolution	$\lambda/\Delta\lambda = 5$
FOV (Field of View)	2.5 arcmin x 2.5 arcmin (no slit); 1 arcmin x 2.5 arcmin (with a slit)
Detector array type/format	128 x 128 Si:As BIB with 1.3 arcsec pixels

Table 818: Specification of the AIRES instrument

AIRES (Airborne InfraRed Echelle Spectrometer), PI: E. Erickson of NASA/ARC. AIRES is a high-resolution, FIR, long-slit grating spectrometer designed for studies of a broad range of phenomena occurring in the interstellar medium. These include accretion and outflow in protostars and young stellar objects, and the morphology, excitation, and dy-

²⁵⁸¹⁾ <http://pioneer.gsfc.nasa.gov/public/safire/>

²⁵⁸²⁾ http://www.sofia.usra.edu/observatory/instruments/first_light/safire_flyer.pdf

namics of neutral and ionized gas at the Galactic center. AIRES measures in particular spectroscopically interstellar gas at FIR wavelengths with simultaneous imaging along a 2.5 arcmin strip in the cross-dispersion direction. The large echelle grating disperses light to achieve high spectral resolution. The entire optical system is cooled to 4 K with liquid helium.²⁵⁸³⁾

FORCAST (Faint Object infraRed CAmera for the SOFIA Telescope), PI: T. Herter, Cornell University, Ithaca, NY. The objectives include multicolor imaging of the galactic center, Vega-like dust clouds, and star formation in our galaxy, normal spiral galaxies and active galaxies. FORCAST is a wide-field mid/far-infrared camera featuring two channels with selectable filters for continuum imaging in the 4-8 μm 16-25 μm and/or 25-40 μm regions. Simultaneous imaging can be performed in two channels. Individually selectable filters define the band center and bandwidth for each channel. The detector arrays, of size 256 x 256, employ Si:As and Si:Sb (BIB) technology to provide high-sensitivity wide-field imaging (the spectral resolution $\lambda/\Delta\lambda$ is about 10). FORCAST samples at 0.75 arcsec/pixel providing an IFOV of 3.2 arcmin x 3.2 arcmin. Diffraction-limited imaging is obtained for $\lambda > 15 \mu\text{m}$. Large objects can be easily imaged and for small objects, chopping can be performed on the array to increase the duty-cycle (sensitivity).²⁵⁸⁴⁾

FLITECAM (First Light Infrared Test Experiment Camera), PI: J. Horn of UCLA. FLITECAM is a multi-purpose NIR/SWIR camera, with the objective to:

- Test the SOFIA telescope assembly imaging quality
- Provide seeing-limited imagery from 1-3 μm and diffraction-limited imagery from 3-5.5 μm to cover science applications
- Conduct various science projects with moderate-resolution spectroscopy from 1-5.5 μm
- Operate in parallel with HOPI
- Produce first-class imagery for public outreach.^{2585) 2586) 2587)}

Detector	ALADDIN (InSb) with 1024 x 1024 pixels						
Readout speed	<100 μs for the smallest subframe (32x16 pixels) or about 15 readouts/s for the full frame						
Plate scale	Low resolution: 0.47 arcsec x 0.47 arcsec per pixel High resolution: 0.12 arcsec x 0.12 arcsec per pixel						
FOV (Field of View)	Low resolution: 8 arcmin diameter High resolution: 2 arcmin diameter						
Spectral range	1.0 - 5.5 μm for imaging; L-band for pupil viewing						
Spectral resolution	Between 1000 - 2000 with a 2 arcsec slit						
Camera throughput	About 0.4 in imaging mode; >0.38 in pupil viewing mode

²⁵⁸⁷⁾<http://flitecam.astro.ucla.edu>

the science community for general scientific use as a facility instrument. FLITECAM provides wide-field imaging, narrow-band imaging, and moderate resolution spectroscopy. The opto-mechanical design of the instrument consists of an aperture mechanism, a collimator, three fold mirrors and a double filter wheel. Another fold mirror redirects the optical beam through the f/5 optics onto the detector array. The SOFIA f/19.6 telescope produces an 8 arcmin circular FOV of 114 mm in diameter. This FOV is re-imaged onto the detector with a plate scale of 0.47 arcsec per pixel, a pixel size of 27 μm , and an f/5 camera.

HAWC (High-resolution Airborne Wide-bandwidth Camera), PI: D. A. Harper, University of Chicago. The instrument is being designed and constructed by GSFC, RIT (Rochester Institute of Technology), USRA, and the University of Chicago. The objective is to provide a sensitive, versatile, and reliable far-infrared (FIR) imaging capability for the astronomical community. HAWC is a broadband, FIR camera designed to cover the spectral range of 40-300 μm at the highest angular resolution possible with SOFIA. The instrument utilizes a 12 x 32 pixel array of bolometer detectors constructed using the silicon pop-up detector (SPUD) technology developed at GSFC. The array is cooled by an adiabatic demagnetization refrigerator and operated at a temperature of 0.2 K. ²⁵⁸⁸⁾

Note: The term NEFD stands for Noise-Equivalent Flux Density. The term “Jy” refers to “Jansky,” the unit of radio-wave emission strength, in honor of Karl G. Jansky (1905-1950) an American engineer whose discovery of radio waves (1931) from an extraterrestrial source inaugurated the development of radio astronomy. Jansky published his findings in 1932 while working at Bell Telephone Laboratories in Murray Hill, NJ.

The Jy is a unit of radiative flux density (or radio-wave emission strength) which is commonly used in radio and infrared astronomy. $\text{Jy} = 10^{-26} \text{ W}/(\text{m}^2 \text{ Hz})$. The units of $\text{Jy} (\text{Hz})^{-1/2}$ then refer to the noise power. Another subtlety which is sometimes confusing is that this choice of units for the noise refers the noise to an integration time of 1/2 second. Astronomers also commonly refer the noise to “a one second integration time”. ²⁵⁸⁹⁾

Parameter	Band 1	Band 2	Band 3
Center wavelength	6.0 μm	110 μm	200 μm
Bandwidth	0.5 $\Delta\lambda/\lambda$	0.5 $\Delta\lambda/\lambda$	0.5 $\Delta\lambda/\lambda$
Pixel size (2 pixels per Airy disk FWHM)	2.8 arcsec	5.1 arcsec	9.3 arcsec
FOV (Field of View)	34 x 90 arcsec	61 x 163 arcsec	112 x 298 arcsec
NEFD (extended source, background limit, Airy disk FWHM)	0.35 Jy x $(\text{Hz})^{-1/2}$	0.45 Jy x $(\text{Hz})^{-1/2}$	0.28 Jy x $(\text{Hz})^{-1/2}$
NEFD (point source, background limit, Airy disk FWHM)	0.70 Jy x $(\text{Hz})^{-1/2}$	0.90 Jy x $(\text{Hz})^{-1/2}$	0.56 Jy x $(\text{Hz})^{-1/2}$
NEFD (point source, background limit, Airy disk FWHM)	8.2 m Jy (1 hour)	10.6 m Jy (1 hour)	6.8 m Jy (1 hour)

Table 820: Parameters of the HAWC instrument

P.189 Spectra-View

Spectra-View® is an airborne, multispectral digital remote sensing system manufactured by Airborne Data Systems, Inc., Wabasso, MN, USA. The first instrument was built in 1992. The Spectra-View system integrates imaging with DGPS (Differential GPS) and precision IMU (Inertial Measurement Unit) services to provide georeferenced digital images in a spectral range from visual to thermal infrared. The instrument is modular and configurable, it can support up to eight bands of spectral data at spatial resolutions of 0.25 - 2.0 m at aircraft speeds up to 400 km/h (above 400 km/h at 1 m resolution or larger). With an instrument

²⁵⁸⁸⁾http://www.sofia.usra.edu/observatory/instruments/first_light/HAWC_Flyer.pdf

²⁵⁸⁹⁾Information provided by D. A. Harper of the University of Chicago.

mass of 31 kg and a power consumption of 300 W, Spectra-View can be installed on virtually any aircraft. A vast spectrum of applications can be supported with the imagery obtained.

Each pixel in an image contains data from each spectral band, producing radiometrically corrected, full-resolution data with removable and selectable filters. It allows customers to select specific bandwidths and centers on each detector for acquisition of precise spectral data. ²⁵⁹⁰⁾

A software package comes along with Spectra-View taking care of all controls of a completely integrated system incorporating imagery, location and aircraft. All information stored on a removable data drive, is brought directly into a ground-based PC for processing into geo-referenced, band-registered imagery. Data formats available include: BSQ (Band Sequential) raster file, GeoTIFF, and band registered sequential raster files. These files can be imported directly into existing GIS software.

Spectral bands	4 to 8 bands of MS (Multispectral) data may be configured
Spectral range	0.4 - 8.0 μm (coverage of VNIR, SWIR, MWIR)
Optical system	Most systems are provided with multiheaded camera systems Standard lenses are: 12.5 mm f stop 1.4 for the 1 k x 1 k units and 20 mm f stop 2 for the 2 k x 2 k systems A zooming band is added on request for scene identification
Detectors (area arrays, 4 are shown, support of 3 to 8 arrays is possible)	1 k x 1 k MS, 2 k x 2 k MS, 4 k x 4 k MS, and 4 k x 7 k Pan
Cooling	Sterling cycle cooling of detectors
Geo accuracy of imagery	± 2 m on the fly
Laptop functions available	Shutter speed setting, view of histograms, view of scenes, guidance information, etc.
Source data storage	On removable hard disks (swappable in flight)
Instrument mass, power, size	31 kg, 300 W, 38 cm x 42 cm x 61 cm

Table 821: Instrument parameters of Spectra-View

Most systems provided by the system integrator are 4-band instruments in the visible range of the spectrum (0.4-1.0 μm) which do not require detector cooling. A Sterling cooling system is provided for observations in the infrared region. The system integrator provides also a limited amount of data acquisition for demonstration purposes to his customers.

P.190 SRI Lidar Systems

SRI (Stanford Research Institute) International of Menlo Park, CA has supported atmospheric research with lidar instruments since 1963. The first instrument built and operated in 1963 was a ruby lidar with the name of MK-I for the measurement of aerosols and clouds in the lower atmospheric boundary layer (ground-based instrument). Instrument versions up to Mk-IX in 1972 followed. The first SRI airborne lidar experiment was in 1967 and used the Mk-V system.

P.190.1 ALPHA-1, -2 (Airborne Lidar Plume and Haze Analyzer)

The ALPHA ²⁵⁹¹⁾ ²⁵⁹²⁾ ²⁵⁹³⁾ sensor program consists of two instruments, ALPHA-1 and ALPHA-2, designed and built by SRI International (PI: E. E. Uthe); ALPHA-1 was first flown in 1979 in the Los Angeles Boundary Layer Study ALPHA-2 (of ALPHA-1 heritage)

²⁵⁹⁰⁾<http://www.airbornedatasystems.com/Index.htm>

²⁵⁹¹⁾E. E. Uthe, W. Viezee, B. M. Morley, J. K. S. Ching "Airborne Lidar Tracking of Fluorescent Tracers for Atmospheric Transport and Diffusion Studies," Bulletin of the American Meteorological Society, Vol. 66 No. 10, October 1985, pp. 1255-1262

started operation in 1986 in the NSF-sponsored Antarctic Boundary Layer Study. Both instruments are lightweight aerosol-backscatter lidar systems that may be flown on a variety of airborne platforms (the lidars normally are flown on a Queen Air platform). SRI operates the instruments on a contractual basis. Customers for service flights are: NOAA, USAF, NSF, EPA US Forest Service, NCAR, DoD, or private industry.

Some field experiments with ALPHA-1 participation:

- SEADEx (Shoreline Environment Atmospheric Dispersion Experiment, 1982)
- VENTEx (Venting Experiment, 1985 sponsored by EPA)
- PMV&D (Plume Model Validation and Development)
- CAPTEX (Cross-Appalachian Tracer Experiment, 1983, sponsored by EPA)

ALPHA-2 took part in the following campaigns:²⁵⁹⁴⁾

- AGASP-2 (Arctic Gas and Aerosol Sampling Program-2, in 1986)
- Antarctic Boundary Layer Study (2), C-130 and C-131 aircraft, 1986, sponsored by NSF and NOAA
- Lidar/Radiometric Cirrus Cloud Study, 1988, sponsored by USAF
- Airborne Lidar Target Detection, C-130, 1990
- Kuwait Oil Fire Analysis, Electra, 1991, sponsored by NCAR/NSF

The ALPHA-1 system was constructed as a two-wavelength system for observing distributions of aerosol concentration in the atmosphere. An Nd:YAG laser and frequency doubler generates 532 and 1064 nm wavelength radiation. Two independent receivers and data channels simultaneously observe range-resolved atmospheric backscatter and surface-reflected energy at the transmitted wavelengths.

Measurement technique	elastic scattering, fluorescent scattering
Parameters or constituents measured	aerosols, fluorescent particles
Measurement range	1 - 5 km
Vertical resolution	1.5 to 15 m
Laser type and transmitter wavelength	ALPHA-1: Nd:YAG, Spectra Physics DCR-II, 532 + 1064 nm ALPHA-2: Nd:YAG, Photonics YQL-112D, 532 + 1064 nm
Pulse repetition frequency	10 Hz (typical)
Laser energy/pulse	ALPHA-1: 100 mJ at 1064 nm and 20 mJ at 532 nm (old system) 350 mJ at 1064 nm and 150 mJ at 532 nm (modified system) ALPHA-2: 100 mJ at 1064 nm and 30 mJ at 532 nm
Airborne platform of instrument	C-131 aircraft, Queen Air, or other
Receiver size and configuration	ALPHA-1: 35 cm Schmidt Cassegrain telescope ALPHA-2: 35 cm Dall-Kirkham telescope
Receiver FOV	1 - 2 mrad
Receiver bandwidth	0.5 nm (typical)
Receiver optical filtering	dichroic filter/long-wave pass narrow band filters 1064 nm: 45% maximum transmission, 4.6 nm wide 532 nm: 45% maximum transmission, 0.86 nm wide
Detectors	ALPHA-1: APD's, ALPHA-2: PMT and APD
Signal processing	digital
A/D converter	10 bit, 20 MHz (2), or 8 bit, 100 MHz (2)
Research objectives/applications	aerosol, cloud, diffusion studies, plume observations from forest fires, etc.

Table 822: Specification of the ALPHA-1 and ALPHA-2 instruments

Demonstration of atmospheric transport and dispersion of FDP (Fluorescent Dye Particles) tracers for various meteorological conditions and FDP release scenarios (CAPTEX

2592) E. E. Uthe, B. M. Morley, N. B. Nielsen, "Airborne lidar measurements of smoke plume distribution, vertical transmission, and particle size," Applied Optics, Vol. 27, February 1, 1982, pp. 460-463

2593) E. E. Uthe, "Elastic scattering, fluorescent scattering, and differential absorption airborne lidar observations of atmospheric tracers," Optical Engineering, January 1991, Vol. 30, No. 1, pp. 66-71

2594) B. M. Morley, E. E. Uthe, W. Viezee, "Airborne Lidar Observations during AGASP-2," Journal of Meteorology, Volume 29, March 1990, pp. 268-271

campaign). - For the airborne lidar/FDP experiments, one ALPHA-1 receiver was used to observe aerosol elastic backscattering at 1064 nm, the other receiver was modified for fluorescent light at 600 nm, while rejecting the backscattered light at 1064 and 532 nm. Hence, simultaneous mapping of an FDP cloud that emits at 600 nm, and the atmospheric structure revealed by aerosol gradients, could be achieved with a modified ALPHA-1 system.

The ALPHA-2 lidar is a miniaturized version of the ALPHA-1 model. It can be used to study particle distributions and optical properties (lidar plume-opacity measurement technique for EPA plume enforcement regulations/controls).

P.190.2 RFUV (Raman, Fluorescent and UV-DIAL Lidar)

RFUV is an SRI International sensor flown on a Queen Air platform since 1991.²⁵⁹⁵⁾ Objective: mapping vertical ozone distributions in the lower atmosphere (troposphere, air-quality measurements in urban areas).

Laser Transmitter		Laser Receiver	
Laser type	Questek 2520vβ	Telescope	35 cm Cassegrain
Pulse energy	300 mJ	Detector	EMI 9893B/350Q
Repetition rate	30 Hz	Range rate	4 μs
Pulse length	25 ns	FOV	1 mrad
FOV (divergence)	0.1 x 0.3 mrad	Filter transmission	20%
Raman pulse energy	40 mJ	Filter bandwidth	20 nm
Raman divergence	0.5 mrad		

Table 823: Operational characteristics of the RFUV Lidar

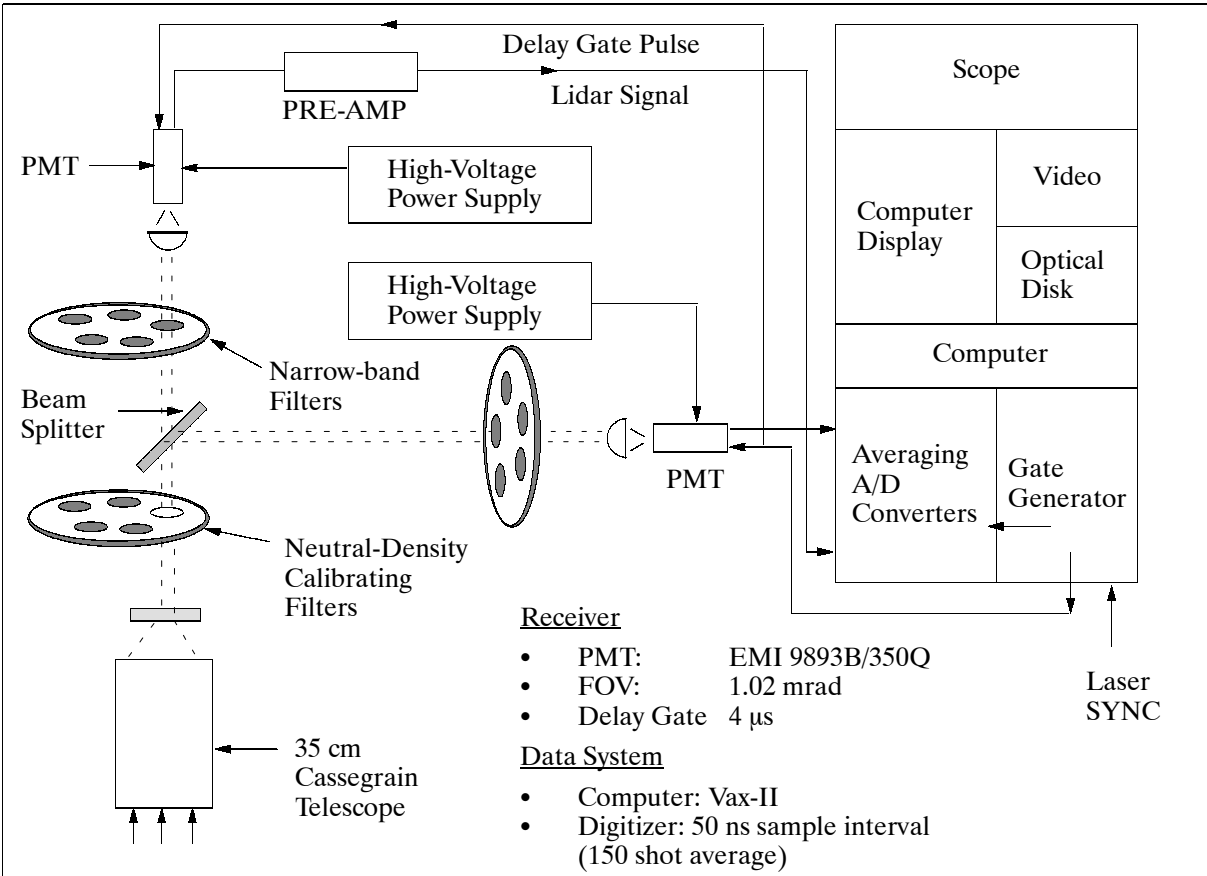

Figure 511: RFUV receiver and data system

²⁵⁹⁵⁾N. B. Nielsen, E. E. Uthe, J. M. Livingston, E. J. Scribner, "Compact Airborne Lidar Mapping of Lower Atmospheric Ozone Distributions," Reprint from the Proceedings of the International Conference on LASERS '91

The instrument (UV-DIAL technique) uses an excimer laser transmitter and a gas-filled Raman cell to generate the DIAL wavelengths required for the ozone measurements. The wavelength pairs are generated by a 248 nm wavelength krypton fluoride (KrF) laser and a Raman cell containing hydrogen or deuterium, or both. The residual 240 nm wavelength energy is blocked from radiation into the atmosphere to aid receiver rejection of elastic backscattered laser energy. The lidar wavelengths are within or near the solar-blind region, which greatly reduces background noise. The first and second Stokes lines of hydrogen - 277 and 313 nm - provide measurements to the longest ranges, and the first and second Stokes lines of deuterium - 268 and 291 nm - are used to gain higher sensitivity to ozone concentrations. A combination of mixed deuterium and hydrogen gas provides wavelengths of 277 and 291 nm.

The RFUV is used in a nadir pointing direction and is normally flown at altitudes of 1500 - 2100 m above ground. The aircraft flight duration is typically three to four hours, adequate for most air-quality data-collection programs. The first application of the RFUV took place in LMOS (Lake Michigan Ozone Study) in 1991.

In 1994 the RFUV lidar was upgraded with a four-channel receiver to improve the dynamic range in the UV-DIAL configuration and to provide multiwavelength observation in the fluorescent configuration. Plans call also for operation of the RFUV in either airborne or van-mounted configurations.

A new miniaturized airborne data system has been constructed (1994) for use with all three lidar systems. In addition, SRI International is installing other lidar-supporting sensors on the Queen Air aircraft including a camera, a FTIR radiometer, and a 8-12 μm radiometer (PRT-5).²⁵⁹⁶⁾

P.191 SSTR (Sea Surface Temperature Radiometer)

SSTR is a NASA/JPL precision infrared multichannel filter wheel radiometer for sea surface temperature measurements. The radiometer is a basic research instrument, designed to improve understanding of the way in which water vapor absorbs outgoing thermal infrared radiation from the sea surface, and to improve techniques to correct for water vapor absorption effects in satellite-based sea surface temperature retrievals. Since 1986, the instrument has been flown on manned blimps, tethered aerostats, and research turbo-prop aircraft. The radiometer was flown most recently in the TOGA/COARE campaign on the NCAR Electra aircraft, and made extensive observations of the sea surface temperature structure in the tropical Pacific Ocean.²⁵⁹⁷⁾

The instrument operates in a nadir pointing position; it has a precision of 0.002 °C at 300 K for an electrical bandwidth of 0.1 Hz.

Electrical Bandwidths	0.1, 1.0, 10.0 Hz
Chopping frequency	100 Hz
Telescope	Cassegrain
Collecting aperture	20 cm
FOV	1 mrad
Optical filters	6 - contiguous between 825 cm^{-1} and 1005 cm^{-1} (9.95 - 12.12 μm)
Detector	HgCdTe (LN_2 - cooled)
SNR	0.006 K (@ 1 Hz, 940 cm^{-1} , 300 K)

P.192 STAR (Sea-Ice and Terrain Assessment Radar)

Star-1 and Star-2 are X-band SAR sensors of Intermap Technologies Inc. of Englewood, CO, formerly (prior to Sept. 1996) of INTERA Information Technologies Ltd., Calgary, Canada.

P.192.1 Star-1 and Star-2

Background: Star-1 was developed by ERIM (Environmental Research Institute of Michigan) and INTERA. ERIM designed and built the instrument, INTERA provided the aircraft, the real-time SAR processor, peripheral equipment, the integration of all instruments, and operates the sensor in the field. The program started in 1982; the sensor became operational for commercial applications at the end of 1983 (some limited amount of research is carried out for INTERA's own in-house activities). The Star imaging SAR system was designed for and first applied to the monitoring of ice conditions in arctic waters. The radar imagery provided essential information for the petroleum drilling operations in that region. This first system has since been modified and another similar one has been built. Since 1993 INTERA owns and operates two airborne radar systems: Star-1 and Star-2. In 1995 the INTERA company was renamed IITC Holdings Ltd of Calgary. The STAR-1 instrument is operational, while the STAR-2 instrument is no longer in service.^{2598) 2599) 2600)}

Applications:

- Terrain mapping (agricultural, forest cover and land use mapping; geologic exploration, cartographic mapping, etc.)
- Off-shore drilling support in ice-covered waters
- Marine transportation support in ice-covered waters
- Data source for sea ice forecast models
- Oceanographic applications (ocean currents and fronts, wave directional spectrum, shallow water anomalies)

Parameter	Star-1 Instrument	Star-2 Instrument
RF center frequency (X-band)	9.375 GHz	9.375 GHz
Transmitted pulse length	30 μ s	30 μ s
PRF (Pulse Repetition Frequency), scaled to ground speed	960 Hz (1200 Hz max)	666 Hz max @ 450 knots (230 m/s)
Range pixel size (4096 pixels)	6 or 12 m	15 or 25 m
Azimuth pixel size	4.2 m	15 or 25 m
Swath width	23 or 46 km	60 or 100 km
Speckle reduction	7 independent looks	> 20 looks
Maximum far range	70 km	
Incidence angle mid-swath	73 or 78°	79 or 82°
Synthetic aperture length (mid-swath)	480 or 640 m	900 or 1200 m
Duty factor (percentage of time in which the radar is transmitting the microwave energy)	4%	2%
Peak transmitted power	2 kW	6 kW
Receiver noise	3 dB	3 dB
Antenna gain	30 dB	32 dB
Scene dynamic range	> 40 dB	> 40 dB
Minimum detectable signal	< -30 dB σ^0 noise equiv. at 70 km max. range	< -30 dB σ^0 noise equiv. at 120 km max. range
Geometric distortion	with GPS < 3 pixels plus terrain height effects	with GPS < 3 pixels plus terrain height effects

Parameter	Star-1 Instrument	Star-2 Instrument
Slant to ground range conversion	selectable on or off	selectable on or off
Peak range side lobe	- 20 dB	- 20 dB
Peak azimuth side lobe	- 25 dB	- 25 dB
Range to near side (typical)	15 to 20 km	20 km
Range to far side (typical)	40 to 70 km	84 to 125 km
Image formation time	real-time (10-20 s delay)	real-time (10-20 s delay)
System calibration repeatability	1.2 dB	1.2 dB
System mass	450 kg	1130 kg (2 radars)
Power requirements	6 kVA (28V)	12 kVA (28V), 2 radars
Bandwidth of recorded signal	ground speed dependent, max. 250 kByte/s	max. 2 x 250 kByte/s
Antenna size	1.2 x 1.5 x 0.6 m	5.5 x 1.5 x 1.0 m
Antenna gimbal requirements	roll, pitch and yaw synchronization from INS	roll, pitch and yaw (ARINC 429 digital data from LTN 90 INS)
Antenna polarization	HH (transmit and receive)	HH (transmit and receive)
Aircraft type	Cessna Conquest	Challenger 600
Observation altitude	8.84 km	10.6 km
Along-track velocity	280 knots (144 m/s)	400 knots (205 m/s)
Note: ARINC 429 is an aircraft data communication bus standard, while LTN 90 is the Litton model number of the Inertial Navigation System (INS) that INTERA uses.		

Table 825: Typical system parameters of the Star-1 and Star-2 SAR instruments

The Star-1 system is mounted on a Cessna Conquest Turbo prop aircraft. It operates in two resolution modes: 6 m pixel mode imaging a 23 km wide swath, and a 12 m pixel mode imaging a 46 km swath. INTERA has used the system to fly surveys in over 20 countries for various applications such as ice monitoring, geological mapping and base mapping for logistical aspects of petroleum and mining programs, classification of vegetation cover and forest management, cartographic mapping, and various environmental applications related to geomorphology and natural resources.

The Star-2 (built in 1986) is mounted on a Challenger jet and also operates in two resolution modes: 15 m pixel mode images a swath 60 km wide, and a 25 m pixel resolution mode for a swath 100 km wide. Star-2 is equipped with a dual-sided radar so that it can image up to two swaths 100 km on either side of the aircraft simultaneously. This aircraft is used as of fall 1993 for ice reconnaissance in arctic waters and along the Canadian eastern seaboard to assist with navigation activities in those regions. The Challenger aircraft with Star-2 is ideally suited for the regional repetitive coverage required for surveillance applications.

INTERA has developed all the processing software for generating radar imagery collected by its SAR systems. In particular, it has made significant advances in radar processing software integrating GPS and other navigational information with radar data to provide accurate geographic control to the imagery, including the capability to generate topographic products with very limited ground control. INTERA also combines radar data with other types of remotely-sensed data, working with the imagery in a GIS environment and deriving interpretative products for numerous applications.

P.192.2 STAR-3i

STAR-3i is an airborne interferometric X-band SAR system of Intermap Technologies Inc. of Englewood, CO, for commercial mapping applications and services. Provision of high-resolution and high-pointing accuracy imagery, generation of DEMs (Digital Elevation Models) and ortho-rectified images - a full suite of services are offered. Note: In 1996, Inter-

map bought Image Mapping Services Division of Intera Information Technologies Corporation. ²⁶⁰¹⁾ ²⁶⁰²⁾ ²⁶⁰³⁾

The STAR-3i is of IFSARE (Interferometric SAR for digital terrain elevation data) design. It was developed by ERIM and JPL under DARPA funding. In 1997, Intermap Technologies bought STAR-3i from ERIM International. ²⁶⁰⁴⁾

The radar interferometer is formed by a spatially-separated dual-antenna design providing the capability to relate the signals from both antennas in such a way that signal phase differences can be detected. The STAR-3i system is divided into sensor and processor segments. The sensor segment consists of a dual-channel SAR, an inertial measurement unit (IMU) and a GPS system located on board the aircraft (LearJet-36). A second ground-based GPS provides DGPS data within a ground range of 200 km from the collection site. The processor segment consists of position/attitude, image formation, and digital terrain elevation processors.

Two antennas (slotted waveguide) are mounted on a rigid structure that controls the antenna baseline separation (about 1 m; effective azimuth beamwidth of 1.45° , elevation beamwidth of about 30°). This rigid baseline assembly is attached to a gimbal that orients the antenna boresight in azimuth normal to the swath to be mapped. The IMU is rigidly attached to the antennas. The antenna/IMU assembly is fastened to the airframe through the azimuth and pitch gimbals and covered with a specially-designed radome. - The motions of IFSARE are measured by GPS and IMU as the instrument moves in its flight path. This information is recorded and later combined in the position/attitude post-processor to precisely reconstruct the actual path of the antenna phase centers.

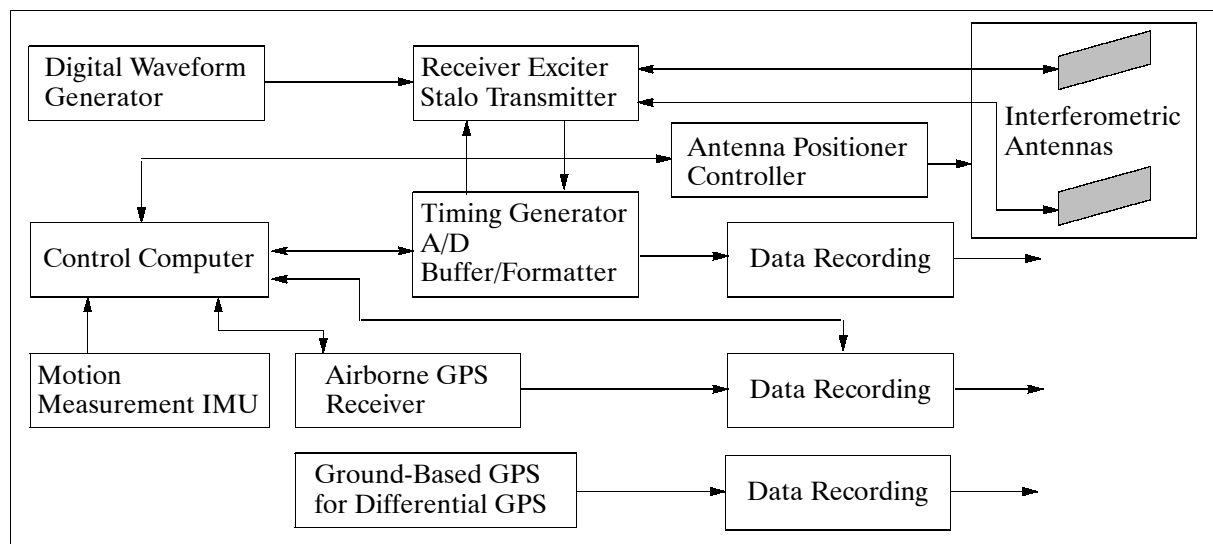

Figure 512: Schematic illustration of STAR-3i sensor segment

The processing segment generates DTE (Digital Terrain Elevation) products from the collected interferometric SAR phase histories, motion and auxiliary data. The position/attitude determination processor combines the highly accurate motion data with airborne and ground-based GPS data to generate all needed information to align the radar signals for proper focusing during the image formation process. A Kalman filtering process produces a

²⁶⁰⁴⁾ Note: Intermap bought ERIM's IFSARE system and renamed it STAR-3i. ERIM has still a test bed IFSARE system on a Convair-580 for research purposes only

full bandwidth motion history which is more accurate than either the high-frequency IMU data or the low-frequency DGPS data alone. These algorithms also determine the location of the radar data with respect to local and global coordinate systems. Full system performance is maintained as long as the ground GPS receiver is within 200 km of the collection site.

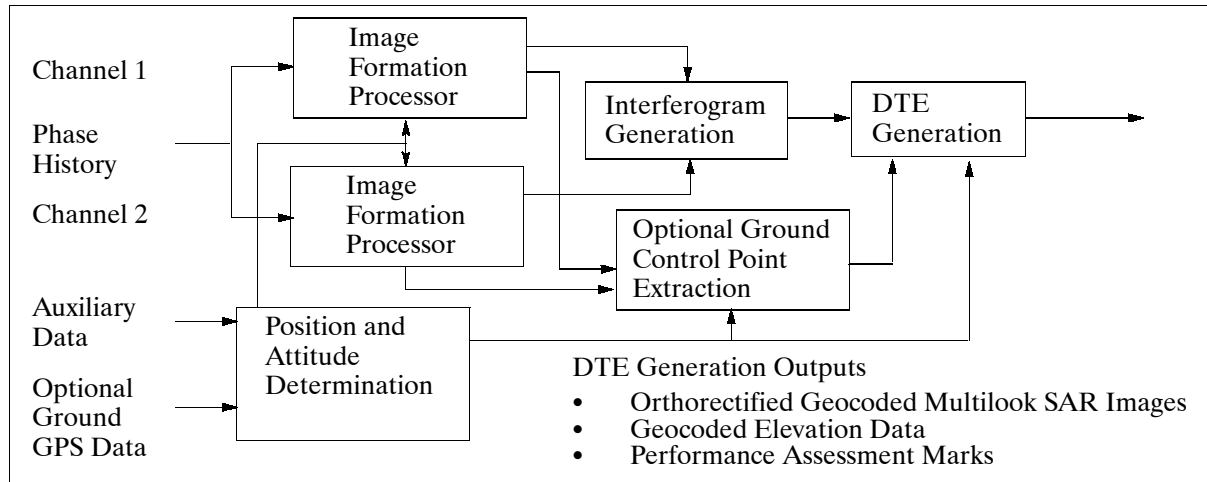

Figure 513: Functional diagram of the STAR-3i ground processing segment

The image formation processor compares the received signal phase histories in two SAR images. Interferograms are then generated from these images by the DTE processor and used with motion data to generate elevation data. Points on the ground are geocoded by geometrically combining the relative range, along-track position and depression angle of the radar antennas with the absolute position and attitude of the aircraft. The output products are both DTE and geolocated, and orthorectified radar imagery at the selected pass spacing. The outputs are provided as a 2-D grid of elevation values or radar imagery samples in the WGS-84 (World Geodetic System - 1984) coordinate system.

Parameter	Normal Swath	Narrow Swath	Wide Swath
Frequency	9.5675 GHz (X-band)		
Polarization	HH

P.193 SUMAS/ASUR/RAL-Sensor (Submillimeter Radiometers)

SUMAS (Submillimeter Atmospheric Sounder) is a passive microwave radiometer designed and developed by the Institute of Environmental Physics at the University of Bremen, Germany. In winter 1991/92 the sensor was flown for the first time on board the DLR Falcon aircraft with the objective to investigate chemical processes in the middle and lower arctic stratosphere. The SUMAS receiver operates in the range of 625 - 650 GHz, permitting the detection of various trace gases such as ClO, HCl, N₂O and O₃. The instrument participated in the EASOE campaign where it was the only sensor to measure ClO.²⁶⁰⁵⁾ In 1992/93 SUMAS carried out validation flights for two spaceborne sensors: MAS on Shuttle and MLS on UARS.²⁶⁰⁶⁾

The original SUMAS frontend was modified in 1993/4 by the introduction of a liquid helium-cooled SIS (Superconductor-Insulator-Superconductor) diode mixer (of SRON, Groningen, NL) which resulted in considerably improved spatial resolutions. The modified SUMAS frontend was renamed **ASUR** (Airborne Submillimeter SIS Radiometer)²⁶⁰⁷⁾ and participated (with the original SUMAS backend) in the SESAME campaigns of 1994/95 (26 flights over northern Sweden and Spitzbergen). - In 1995 the SUMAS backend was upgraded with new spectrometers from ESA/ESTEC, namely: **AOS** (Acousto-Optical Spectrometer) and **CTS** (Chirp-Transform Spectrometer), as defined in Table 828.

All receivers consist of the following components: quasi-optics, hot/cold calibration unit, Martin-Puplett type single-sideband filter and diplexer. The latter injects the multiplied signal (times 6) of a Gunn oscillator into the mixer diode. The intermediate frequency (IF) signal is amplified and further downconverted to match the input frequencies of the spectrometers. The spectra observed under an up-looking angle of 10 - 20° are processed by a retrieval method to obtain vertical concentration profiles between 10 - 50 km with an altitude resolution of 8 - 10 km.

Since 1991 the SUMAS backend has been flown in combination with various frontends, these were:

- SUMAS frontend (old)
- SMS (Submillimeterwave Sensor, an ESTEC breadboard sensor), now at the University of Bern
- ASUR frontend
- THOMAS
- RAL-Sensor [a frontend developed by RAL (Chilton, UK), for measurements in the 500 GHz frequency range. This instrument is also capable of detecting weak BrO lines.]

As of 1995 further frontends are being developed to be flown in combination with the new SUMAS backend. A GOME (ERS-2) validation campaign (Kiruna/Spitzbergen region) with ASUR/SUMAS is planned for February/March 1996.

Sensor	SUMAS frontend (old)	ASUR frontend	RAL Sensor
Mixer	GaAs Schottky (open structure)	Nb tunnel SIS junction (waveguide)	Lead alloy SIS junction (waveguide)
Frequency	625 - 650 GHz	625 - 690 GHz	491 - 503 GHz
1st IF	11.08 GHz	11.08 GHz	3.7 GHz
Sensitivity T _{sys} (SSB)	4000 - 10,000 K	700 - 800 K	800 - 900 K

P.194 Sunphotometer

A NASA-sponsored instrument developed and operated at ARC.²⁶⁰⁸) The multiwavelength airborne tracking sun photometer is used for measuring solar radiation. The measurements provide a record of atmospheric optical depth and transmissivity data and permit the atmospheric correction of remotely-sensed data. The instrument is mounted on the exterior of the aircraft, e.g., DC-8, C-130, C-131, Twin Otter or CV 990. It automatically tracks the sun while simultaneously measuring six wavelengths (channels) of incoming solar radiation.

Each channel consists of a doubly baffled entrance tube, inference filter, photodiode detector, and integral amplifier. The entrance baffles define a detector FOV with a measured half angle of 2.2° . The six filter/detector/preamp sets are mounted in a common heat sink maintained at $45 \pm 1^\circ\text{C}$. Filters are currently (1993) centered at 382, 451, 526, 861, 940, and 1060 nm. Filter full widths at half-maximum (FWHM) are 6 to 15 nm.

Solar tracking is achieved by azimuth and elevation motors driven by error signals derived from a differential-shadowing sun sensor. Data are digitized and recorded every 2 to 10 seconds. The science data set includes the six detector signals, detector temperature, sun tracker azimuth and elevation angles, tracking errors, and time.

There are a number of applications/objectives for the sun photometer:

- Mapping the optical depth spectra of aerosols, jet fuels, forest fires, etc.
- Assessment of the impact of the Pinatubo cloud on atmospheric radiation and climate, mapping the optical depth spectra of the volcanic cloud in the northern and southern hemispheres (May-June 1993 campaign).²⁶⁰⁹, ²⁶¹⁰, ²⁶¹¹)
- Provision of validation measurements for the spaceborne instrument SAGE II (Stratospheric Aerosol and Gas Experiment II) on ERBS (see chapter A.13).

Wavelength (μm)	FWHM (Full width half maximum) Bandwidth (μm)
0.382	0.0122
0.451	0.0062
0.526	0.0091
0.861	0.0130
0.940	0.0127
1.060	0.0152

Table 829: Detector wavelengths and FWHM wavelengths of the Sun Photometer

Optical depth spectra are inverted for the derivation of stratospheric particle size distributions and ratios relating mass, area, extinction, and lidar backscatter.

P.194.1 HIRAASS (High Resolution Airborne Autotracking Sun Spectrometer)

A proposed project to DOE by Ames Research Center. HIRAASS is to be flown on airborne missions (also on Perseus A aircraft), with the objective to measure optical depths and vertical extinction profiles of aerosols, clouds, water vapor, ozone, and nitrogen dioxide. The instrument design draws on the experience of the ARC ‘Sunphotometer.’ The instrument achieves fine spectral resolution (1 to 2 nm) by combining a grating with a linear array detector spanning the spectral range from 350 nm to 1020 nm. An additional photodiode channel extends the spectral range to 1550 nm for better characterization of large aerosol particles.

P.195 THOMAS (THz OH Measurement Airborne Sounder)

THOMAS is a heterodyne instrument designed and developed at DLR/IOE (Oberpfaffenhofen, partial funding by EC) with the objective to observe trace gases, in particular OH, in the stratosphere by thermal emission.^{2612) 2613) 2614)} Other molecules to be measured are: H₂O, O₃, O₂, NO₂, NO, CO, HCl, HOCl. The sensor derives its heritage from another heterodyne system developed by MPI for Radioastronomy, Bonn (H. P. Röser), which was used for astronomical observations. THOMAS made its first measurements of stratospheric OH (at 2514 GHz) in June 1994. The instrument is flown on a Falcon aircraft. THOMAS participated in the SESAME campaign (in February/March 1995)

The instrument is a heterodyne receiver whose local oscillator (LO) is an optically pumped far infrared (FIR) laser. The thermal emission of the trace gases is spatially overlapped with the LO radiation in a diplexer (Martin-Puplett-Interferometer) and then focused on the GaAs Schottky mixer diode (detector) in an open-structure corner cube. The intermediate frequency is amplified, filtered and downconverted a second time to match the center frequency of an acousto-optical spectrometer (AOS). Measurements are taken at a constant up-looking angle between 10-20°.

Mixer	GaAs Schottky diode in an open structure mount
Local oscillator	Optically pumped gas laser at 2522 GHz (118 μm) with 10 mW output power
1st IF	8.46 GHz (for OH)
2nd LO	Synthesizer: 6.55 GHz (for OH)
AOS	2048 channels
center frequency	2.1 GHz
resolution	1 MHz
nominal bandwidth	± 700 MHz
Sensitivity	T _{sys} (DSB) = 18000 K (DSB=Double Sided Band)
Data rate	8 MByte/s
Instrument mass, power	400 kg, ~ 2kW
Initial results	OH concentration profiles between 15-50 km with an altitude resolution of 10-20 km, column densities for mesospheric OH between 50-100 km.

Table 830: Specification parameters of THOMAS

P.196 TOPOSYS (Scanning Laser System)

TOPOSYS is a commercially available laser system designed and built by TopoSys GmbH, Ravensburg, Germany. The instrument is capable of general terrain mapping from an air-

craft; the information is used to generate high-precision digital elevation models (DEMs). TOPOSYS may be employed for a number of survey and planning applications such as: power transmission lines; road, railway and pipeline planning; power line clearance surveys; tree height mapping for forest inventories; shoreline mapping and control; erosion monitoring, etc. TOPOSYS-1 was the prototype instrument introduced in 1994. TOPOSYS-2 is an enhanced version operational since the fall of 1999. The instrument is flown on on light aircraft as well as in helicopters. DGPS position data is obtained with an L1/L2 GPS receiver at a rate of 1 Hz, while LINS (Laser Inertial Navigation System) collects position and attitude data at a rate of 64 Hz. Both data streams are merged for off-line flight-path restitution, obtaining position and attitude data at 64 Hz. ²⁶¹⁵⁾ ²⁶¹⁶⁾

Parameter	Value	Parameter	Value
Laser source	Erbium-Fiber, eye-safe	Receiver	Avalanche photodiode
Transmitter wavelength	1535 nm	Scan rate	630 Hz
Laser energy/pulse	0.25 - 2.5 W	Number of pixels/line	127
PRF	83 kHz	Max. operating altitude	1000 m
IFOV	6.6 mrad	Spatial grid of DEM	2 x 2 m
FOV (1000 m altitude)	250 m ($\pm 7^\circ$)	Range accuracy	<3 cm
Sensor mass	25 kg	Power	28 VDC
Mass of data system	80 kg (19" rack)		

Table 831: Parameters of the TOPOSYS-2 model

TOPOSYS consists of the following components: a lidar line scanning sensor, a precision Laser Inertial Navigation System (LINS - measurement of position and attitude), a data recording system, and a ground-based data processing system. The sensor measures the run-time of laser pulses by scanning in the cross-track direction with an incremental angle of 0.1° . The linsescanner provides a pixel size of about 0.4 m from a survey altitude of 1000 m. This permits the generation of ortho-photos of the survey area. The ground-based module consists of a data processing software package taking into account all data types (sensor data, housekeeping data, and the location/attitude data) and permitting DEM generation and a variety of map projection and data output and formats.

P.197 TRWIS (TRW Imaging Spectrometer)

TRW of Redondo Beach, CA has developed and built a set of commercially available airborne hyperspectral imaging spectrometers, operational since 1990 (TRWIS-A was initially a laboratory model). The instruments provide a real-time measurement display with features for vegetation or mineral identification, or quantification (crop health, biomass algae content, etc.). The three TRWIS-B instruments and one TRWIS-II instrument became operational in 1994. ²⁶¹⁷⁾

TRWIS-II uses a customized IR lens foreoptics system, a SPEX 270M spectrometer and a modified InSb camera. The IR focal plane array hybrid is a FLIR camera type array which uses a direct injection readout. The detector array is cooled with liquid nitrogen. Data are calibrated using a spectrally flat and spatially uniform calibration standards. ²⁶¹⁸⁾

TRWIS-III consists of two grating spectrometers covering the upwelling spectral radiance in VNIR (0.4-1.0 μm) and the SWIR (0.9-2.5 μm) regions. Both spectrometers are co-aligned to have virtually identical fields of view. The refractive elements in the two instru-

First operation	1990	1991	1992	1996

Table 832: Specification parameters of the TRWIS instrument family

The SWIR focal plane uses a 2.45 μm wavelength cutoff Mercury Cadmium Telluride (MCT) detector with an array of 256 x 256 detectors. The instrument offers very good SNR values due to relatively long integration times and low thermal background. The detector array of the SWIR spectrometer is cooled to 115 K using a TRW-developed pulse tube cryo-cooler.

Data: TRWIS-A, TRWIS-B and TRWIS-II data are recorded onto VHS video recorders at 60 frames/s with 8-bit resolution. TRWIS-III provides digital data recording at 12-bit resolution, 60 frames/s, over the 384 x 256 focal plane array at a rate of 70.8 Mbit/s.

P.198 TSCC (Tilt Scan CCD Camera)

TSCC is a high-definition imaging radiometer based on an electro-optical camera of NASA/ARC and GSFC. The camera is nose-mounted in the aircraft with forward or aft tilt up to 53°. Objectives: bidirectional reflectance and polarization studies. The system captures high-resolution digitized images and stores the imagery on magnetic tape. The camera is a commercially available product of Kodak (KAF-1400) with a silicon array imager.

Wavelengths are selected by a rotating filter wheel. There are plans for upgrades (2 k x 2 k camera array and 60° FOV). Wavelength channels can be either polarized or nonpolarized. The instrument flew on ER-2 aircraft for the 1991 and 1992 FIRE projects, for SCAR, and for the 1993 TOGA/COARE cloud studies campaign. The tilting scan rate is programmable in order to track and multiple-image cloud scenes at differing altitudes.

Data collection parameters of TSCC:

Frame rate 24 images every 6 seconds
Tilt angle Forward tilt up to 42°, aft tilt up to 53°
FOV (nominal) 15°, 30°
Data storage Tape cassette
Capacity 5 GByte

Spectral coverage	400 - 950 nm
Filtration	6 position filter wheel (6 spectral filters) polarizing filter
Nominal spectral filters	420, 480, 530, 680, 875, 950 nm (with 10 nm bandwidth)
Lens (interchangeable)	28 mm, 14 mm
Aperture	f/2.8
IFOV	0.2 mrad
Spatial resolution (ground)	4.8 m at aircraft altitude of 20000 m
Frame size	1280 pixels x 1025 pixels (recorded)
Image size (ground)	6.2 km x 4.9 km

Table 834: Characteristics of the TSCC

P.199 TU-134A (Tupolev Flying Laboratory)

The Tu-134A is a converted Russian passenger aircraft (owned and operated by NPO Vega) dedicated to airborne observation campaigns as well as to instrument development of future systems. The aircraft is equipped with a number of sensors to suit the requirements of particular campaigns. The aircraft/laboratory is used on a contractual basis. Some of the instruments are: IMARC (radar), SIR (Scanning Infrared Radiometer), AFA (Aerial Foto Apparatus), and navigation instruments, along with their support equipment.²⁶¹⁹⁾

Applications: geology, oceanology, agriculture, ecology, cartography, etc. . IMARC is also used for research (i.e. testing of other SAR instruments, and for algorithm development).

P.199.1 SIR (Scanning Infrared Radiometer)

Spectral range	7 - 14 μm
Swath width	120°
V/H ratio (V = aircraft velocity; H = height)	0.16 - 1.2 s ⁻¹
Radiometric resolution at 20°C with SNR = 1	0.3 °C
Line frequency	500 Hz
Image scale on film with 80 mm width	1 : M _x = 1 : H/ (33.42 x 10 ⁻³)
Observation heights	200 - 1000 m

Table 835: Specification of some SIR sensor parameters

P.199.2 IMARC (Imaging Multifrequency Airborne Radar Complex)

IMARC is multifrequency polarimetric SAR with the objective of Earth surface sensing. IMARC was developed and built NPO Vega, the instrument went through the following development phases:

²⁶¹⁹⁾Information provided by Y. Krilov of NPO Vega, Moscow

- operational since 1983 with a 1-frequency SAR, (4 cm wavelength)
- operational since 1990 with a 2-frequency SAR, (4 cm and 254 cm)
- operational since 1993 with a 3-frequency SAR, (4 cm, 68 cm and 254 cm)
- available with a 4-frequency SAR in 1994, (4, 23, 68, and 254 cm)

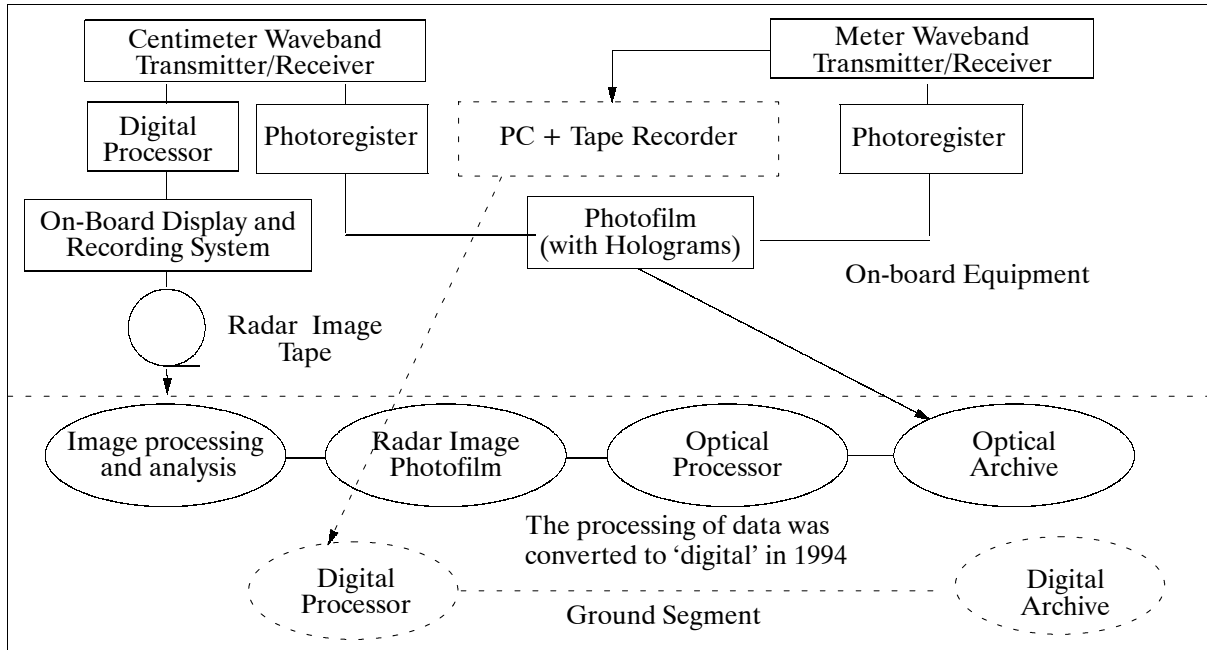

Figure 514: Block diagram of IMARC ²⁶²⁰⁾

Parameter	Waveband			
Waveband (cm)	3.9	23	68	254

Parameter	Waveband
Mass of instrument (kg)	1500
Flight altitude (m)	500 - 3000
Flight speed (km/h)	500 - 600

Table 836: Technical specifications of IMARC

The different frequency bands of IMARC are independent modules and may operate individually or simultaneously, depend on user requirements. During 1993 IMARC on-board data recording has been changed from holographic photofilm recording to an all-digital recording system; in 1994 the ground system was to be changed to an all-digital system (see Figure 514).

P199.3 AFA-41/10 (Aerial Foto Apparatus)

Camera type AFA 41/10
Focal length 100 mm
Film width 180 mm

P200 UMMCI

The UMMCI (University of Michigan Multichannel Chemiluminescence Instrument) sensor of the University of Michigan (Ann Arbor, MI) employs the chemiluminescent detection technique for in-situ measurements of NO, NO₂, NO_y, and O₃. UMMCI is of NCAR-NOX heritage; it has four channels for the simultaneous measurement of trace gases in the atmosphere; all channels use the excited NO₂ product from the NO+O₃ reaction. The first three channels employ a photon counting technique (for the detection of NO, NO₂ and NO_y), while the chemiluminescent detector of the fourth channel uses an electrometer. A photolytic converter upstream of one of the NO detectors converts NO₂, and a catalytic converter (hot Au with CO) upstream of another NO detector converts the NO_y family species to NO.

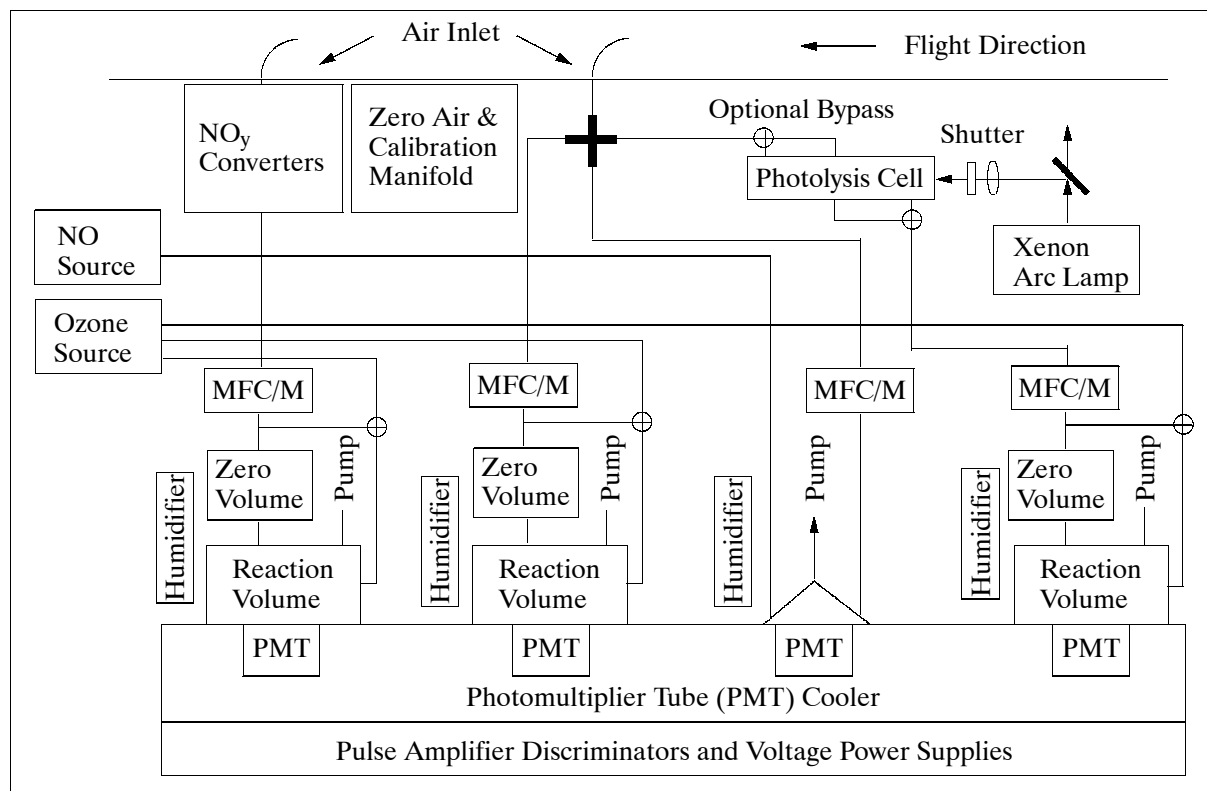

Figure 515: Schematic illustration of UMMCI elements

Major UMMCI elements are: reaction vessel, photolytic converter, ozonizers, MFC/M (Mass Flow Controller/Meter), CO and NO gas containment vessel, calibration system, O₃ calibrator, data acquisition and control system, pumps, and a notebook computer with printer. UMMCI is in its test phase as of mid-1995, it is scheduled to be flown on a NASA/WFF P3-B aircraft in the PEM-Tropics campaign (August - October 1996).²⁶²¹⁾

- Accuracy: $\leq 30\%$ for NO, NO₂, and NO_y; $\leq 10\%$ for O₃
- Detection limits: ≤ 5 pptv for 1-minute averages of NO and NO₂; ≤ 50 pptv for 2-second averages of NO_y; ≤ 1 ppbv for 2-second averages of O₂
- Response time: raw data are normally collected over 1-second intervals and averaged over longer intervals as appropriate
- Instrument mass = 275 kg; power = 5.0 kW (start power = 11.6 kW)

P.201 VIFIS (Variable Interference Filter Imaging Spectrometer)

The latest VIFIS^{2622), 2623)} version is a miniature imaging spectrometer research instrument which utilizes a new spectral image acquisition technique based on three synchronized CCD-imager modules aligned to a common field of view. In this design, two modules are fitted with variable interference filters (VIF), one VIS-range filter and one NIR-range filter, respectively; the third module is a normal videograph unit without the variable filter attachment. Analysis of the design and test results demonstrates that such a hybrid three-CCD instrument has the potential of acquiring both wavelength spectral image data and directional spectral image data, in a single pass. The instrument was built by the Department of Applied Physics and Electronic & Manufacturing of the University of Dundee, UK. Test flights with the three-module hybrid VIFIS instrument started in May 1994 on a Cessna aircraft. Earlier test flights with a single-module prototype instrument started in August 1991.

Applications: VIFIS is a flexible hyperspectral image acquisition instrument for a variety of environmental monitoring tasks such as: mapping of shallow water bottom targets, growth and distribution of phytoplankton, crop discrimination, oil spill detection and mapping, etc.

A VIFIS imager module is simply a modified CCD video imager whose detector array is spectrally filtered by a closely attached linear-variable interference filter. The bandpass wavelength at different regions within such a filter is linearly varied along one axis. The hybrid VIFIS concept requires two imager modules. They are identical except that one module is being fitted with a variable interference filter, while the other module features a normal bandpass filter. This arrangement displays the capability of acquiring both wavelength spectral image data and directional spectral image data.

The 2-D CCD image format of the VIS and NIR imaging modules provides 752 separate pixel columns of data - it could be used to produce 752 contiguous spectral bands. However, for reasons of data handling, only 60 narrow contiguous bands are typically extracted/reconstructed with bandwidths of 10-14 nm in VIS and 14-18 nm in NIR regions. Note: the 30 spectral bands for each region are flexibly defined and extracted from 30 different spectral locations of a VIFIS sensor frame which has 756 spectral columns. Each band is associated with a different center pass. - The processed data product is a hyperspectral image cube.

All VIFIS CCD-imaging modules are full-frame imagers, generating a sequence of instantaneous 2-D images as synchronized snapshots. The resulting images are almost free of geo-

²⁶²¹⁾Information provided by M. A. Carroll, Space Physics Research Laboratory, University of Michigan, Ann Arbor, MI

²⁶²²⁾X. Sun, J. M. Anderson, "An Easily-Deployable Miniature Airborne Imaging Spectrometer," Proceedings of the 1st International Airborne Remote Sensing Conference and Exhibition, Strasbourg, France, September 12-15, 1994, Volume II, pp. 178-189

metric distortion due to this ‘frozen image technique.’ - The video images can of course be displayed on a screen in real-time during data collection.

Imager type of the 2 (variable filter) modules	1/2" interline transfer CCD; Sensor pixel array: 752x582
Video Camera Format Video SNR Shutter speeds	3 channel synchronized data 50 dB 8 steps to 1/10,000 second
Spectral ranges VIS Imaging Module NIR Imaging Module Panchromatic Module	440 - 640 nm (30 bands with bandwidths 10-14 nm) 620 - 890 nm (30 bands with bandwidths 14-18 nm) 400 - 1100 nm
Spectral resolution	< 2.5% of the pass wavelength
Spectral Filter	LVF400-700 & LVF600-1100 (Linear Variable Filter)
Image sampling rate (variable)	25 frames/s
Swath width (FOV) IFOV	variable, typical 31.5° (572 pixels in cross-track direc.) approximately 1 mrad x 1 mrad
Aircraft altitude (above ground)	variable, from 600 m
Digital data format Primary snapshot Spectral sub-windows Track-recovery-image Number of spectral bands	768 x 572 pixel array with a pixel depth of 24 bit variable 572 pixels by variable length (typical 2560), 24 bit pixels variable, typical = 60 contiguous bands
Data rate (RGB analog video rate)	equivalent to 90 GByte/h (data of all three imagers)
Instrument mass	sensor head = 0.8 kg (all imaging modules) Controlling, recording and monitoring units = 5 kg (without battery), using a 12-volt rechargeable battery
Instrument power	12 volt, 660 mA

Table 837: Specification of the hybrid VIFIS instrument

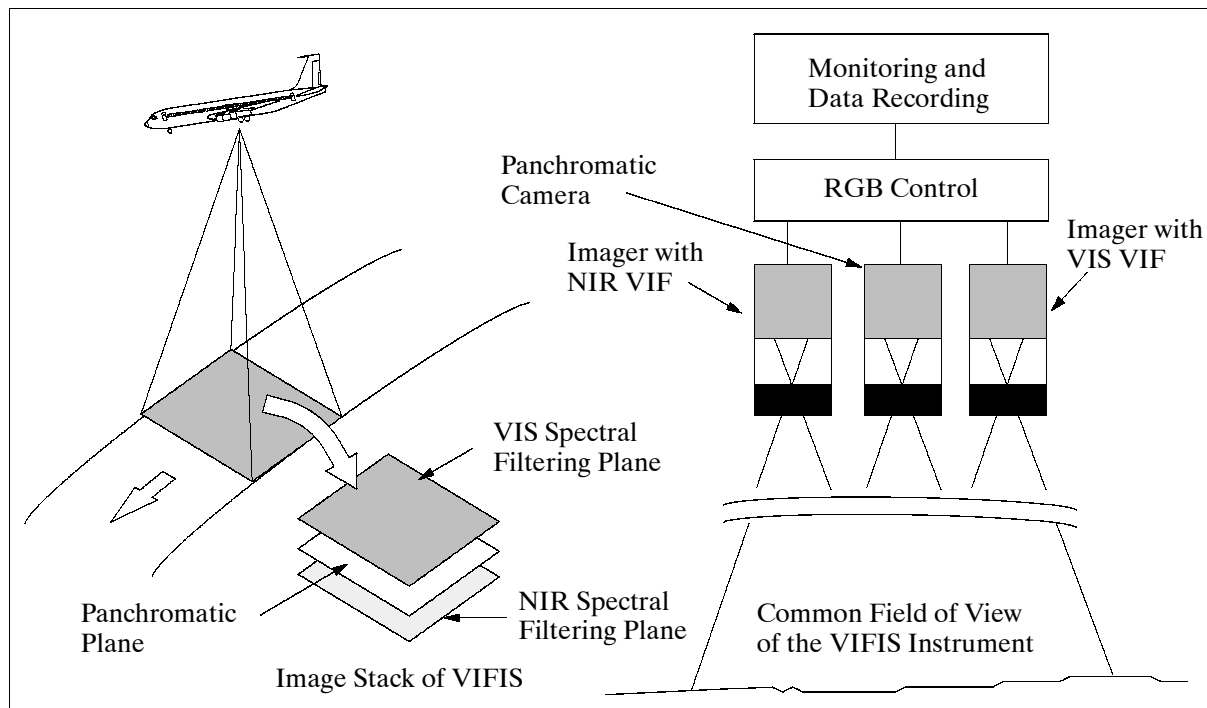

Figure 516: Schematic illustration of the three-imager VIFIS instrument

A third panchromatic video camera (without filtering) is added in parallel to the two-module filter assembly. The combination of the panchromatic data channel with the two spectrally filtered data channels offers an even-better reference (in terms of accurate focus and for spectral ratio measurements) and increased spectral information content. The three simultaneous output channels are combined into the format of the standard RGB video signal; this analog setup provides a means for handling and recording enormous data rates.

Post-flight data analysis offers a wide range of processing options. One data product consists of a set of reconstructed track-recovery images, each of which is monochromatic and mosaicked from many VIFIS primary video segments extracted from a sequence of video frames. Another product is the target-tracking snapshot spectral-subwindow set.

P.202 VIRL (Visible and near Infrared Lidar)

VIRL is a NASA/GSFC²⁶²⁴) airborne lidar instrument with the objective to study the source and characteristics of atmospheric aerosol particles (measurement of aerosol backscatter cross-section at the fundamental and doubled Nd:YAG laser wavelengths of 1.064 μm and 0.532 μm , and in addition, at 2.16 and 1.54 μm). The instrument has been operational since 1989 and is flown on NASA ER-2 and DC-8 aircraft; it participated in the GLOBE (Global Backscatter Experiment) flights in November 1989 and in May-June 1990 (to support laser wind sounder development), as well in the TOGA/COARE campaigns in 1993 (to explore the maintenance of the West-Pacific warm pool).

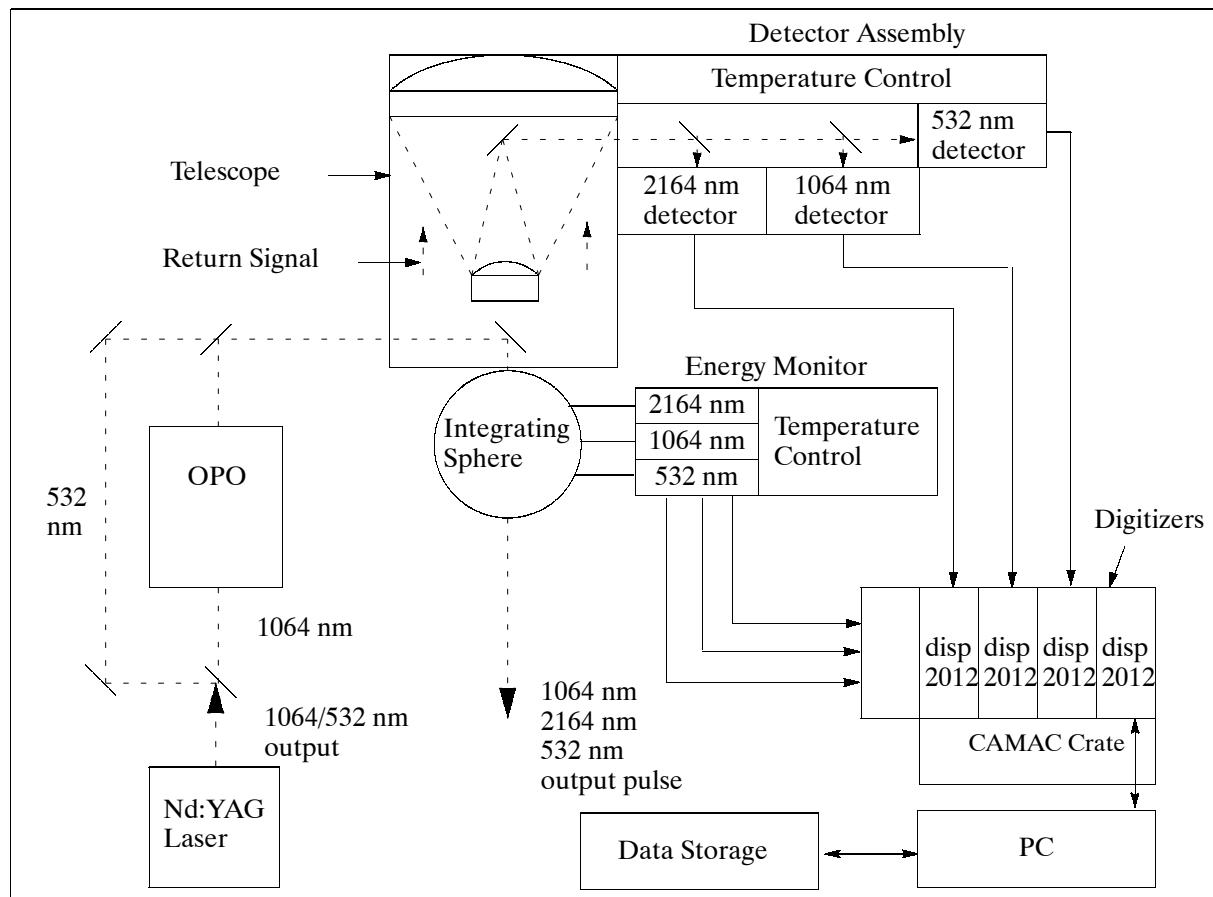

Figure 517: Schematic overview of the VIRL instrument

The instrument permits simultaneous measurements of aerosol and cloud backscatter at multiple wavelengths. The advantage of a 1.5 and 2.1 μm lidar is eye-safe operation and increased sensitivity to aerosol characteristics. The parallel and perpendicular polarized components of the lidar return are stored in separate channels. An Optical Parametric Oscillator (OPO) is used to convert the 1.064 μm output of the Nd:YAG laser to generate a pulse at 2.16 μm . The system employs incoherent signal detection. VIRL has a 12-bit digitizer that resolves data that varies over 4 orders of magnitude. Linear amplifiers are used

²⁶²⁴)J. D. Spinhirne, S. Chudamani, J. F. Cavanaugh, "Visible and Near IR Lidar Backscatter Observations on the GLOBE Pacific Survey Missions," Seventh Symposium on Meteorological Observations and Instrumentation and Special Sessions on Laser Atmospheric Studies, Jan. 14-18, 1991, New Orleans, LA

which allow precise resolution of very small signals. The basic pulse rate of the laser is 50 Hz, but data is recorded as a sum of 10 shots at 5 Hz. The data system acquires also navigation data (DADS) from the DC-8 in real time and appends it to each lidar return data record. Navigation data is processed to account for aircraft banks, rolls and pitches during turns and climbs. Appropriate altitude corrections are made and verified by comparing with the very large lidar return from the ocean surface when the instrument is nadir pointing.

Table 838: VIRL instrument characteristics

An important factor is accurate calibration. The system offers a new calibration technique based on hard target laser measurements.

P.203 VIS (Video Imaging System)

VIS is a NASA-sponsored instrument at ARC.²⁶²⁵⁾ It consists of a video camcorder pointed downward, and a video cassette using super VHS tape. VIS records terrain and atmospheric conditions below the aircraft, such as cloud cover or desert overpasses. The data collected are used to justify or explain anomalous results obtained by other sensors flown in conjunction with VIS.

The VIS instrument became operational in 1992; it is typically flown as a tracking camera for cloud-top mapping missions only, as the spatial resolution is too coarse to be very useful from ER-2 altitudes for terrestrial viewing. The VIS camera has a single objective; one of the listed lenses is installed prior to a flight.

- Hitachi KP-C551 color camera, color system: NTSC

480 hr	4.0 s

- Resolution (S-VHS): 400 lines
- FIGI configuration 24 hour mode, 12 mm lens, 1/2000 @ f/5.6. Note: FIGI refers to the island of Fiji in the South Pacific; the CEPEX (Central Equatorial Pacific Experiment) campaign, an atmospheric water vapor/greenhouse study, was conducted in March/April 1993.

P.204 WAOSS (Wide-Angle Optoelectronic Stereo Scanner)

A DLR instrument existing in two versions: a) as a spaceborne sensor on the ARGUS TV platform of the Russian planetary mission Mars-96 (to be launched in October 1996), and b) as an engineering instrument on a DLR aircraft (DO-228) for Earth observation.

Background: The WAOSS instrument was initially proposed in 1988 by the Institut für Kosmosforschung (IKF), East-Berlin, for the Soviet Mars-94 mission. Objectives: synoptic observation of the Martian surface, photogrammetric evaluation of surface imaging data, generation of digital terrain maps, and derivation of contour lines with a camera, providing an along-track stereo imaging capability. - After German unification in October 1990, the project was inherited by DLR (sponsored by BMFT/DARA).²⁶²⁶⁾

P.204.1 WAOSS (Spaceborne Version)

The Mars-96 project is managed by IKI (Space Research Institute) of Moscow. The ARGUS system consists of three main scientific remote sensing instruments: HRSC (High Resolution Stereo Camera, 0.4 - 0.8 μm , FOV = 10°); OMEGA (a French imaging spectrometer, 0.5 - 5.2 μm), and WAOSS.

The WAOSS system is a compact monoblade device consisting of camera head, electronic modules, and interface boards in one unit. The along-track stereo imaging system is based on 3 CCD-lines (single optics and focal plate), operating in pushbroom mode, and taking images simultaneously in the forward-, nadir- and backward-pointing direction of the orbital ground track. The convergence angle is 25° (angle between forward- and nadir-pointing directions, and angle between nadir and backward-pointing directions).

Note: The Mars-96 satellite launch (November 17, 1996) from Baikonur failed to obtain a Mars orbit.

Parameter	Value	Parameter	Value
Optics	Spitmo - Russar-96	No. of CCD lines	3 (forward, nadir, back.)
Focal length, f	21.7 mm	Spacing of CCD lines	10.1 mm
FOV (across-track)	80°	Elements/CCD line	5184
IFOV (quadratic)	0.323 mrad	Element spacing	7 μm
Mars pericenter height	200 / 300 km	Radiometric resolution	8 bit
Swath width (nadir)	336 / 503 km	Ground resolution, min	65 m / 97 m
Spectral range (nadir, forward, backward)	580 - 770 nm, 470 - 670 nm	R/T data comp. method	DCT-DPCM
Instrument mass	8 kg	Data compression factor	2 - 20
Date rate	500 kbit/s max (with data compression and macro-pixel formation)	Power consumption	18 W

Table 839: WAOSS instrument parameters

P.204.2 WAOSS (Airborne Version)

The qualification model (QM) of the WAOSS (spaceborne version) has been used (in the current version since 1994) for airborne remote sensing with the aim:

²⁶²⁶⁾Information provided by D. Oertel of DLR, Institute of Optoelectronics

- to verify the sensor parameter settings and control
- to obtain data for testing the developed 3-line CCD stereo reconstruction algorithms
- to check hardware and software reliability, including the real-time data compression routines.

The specification of ‘WAOSS airborne’ corresponds to the parameters of Table 839, however with the swath widths and ground resolutions corresponding to the flight altitudes over ground. The output data rate is limited to 0.5 Mbit/s due to the Mars Mission design concept of this sensor.

P.204.3 WAAC (Wide-Angle Airborne Camera)

Parameter	Value	Parameter	Value
Optics	Spitmo - Russar-96	No. of CCD lines	3 (forward, nadir, back.)
Focal length, f	21.7 mm	Spacing of CCD lines	10.1 mm
FOV (across-track)	$\leq 80^\circ$	Elements/CCD line	5184
IFOV (quadratic)	0.323 mrad	Element spacing	7 μm
Flight altitude, nominal	5 km ($v=200$ km/h)	Radiometric resolution	8 bit
Swath width (nadir)	8.4 km	Ground resolution, min	1.6 m x 1.6 m
Spectral range, nadir forward, backward	580 - 770 nm 470 - 670 nm	Data compr. method Data compression factor	DCT-JPEG 2 - 20
Data rate	100 kbit/s - 24 Mbit/s	Instrument size	285 x 190 x 202 (mm)
Instrument mass	4.4 kg	Power consumption	15 W

Table 840: WAAC instrument parameters

DLR developed and manufactured a compact 3-line CCD stereo camera for airborne remote sensing (tests flights started in the 2nd half of 1995). WAAC is a lightweight airborne version of WAOSS. The optical head and the analog electronics of WAAC are identical to WAOSS, while the digital subsystem of WAAC does not include units developed for the deep-space mission. WAAC is therefore not data-rate limited, as is the case for WAOSS.

P.205 WHiRL (Wide-angle High-Resolution Line-imager)

WHiRL is a single-channel prototype CCD imager of CCRS, Ottawa, Canada. The instrument is a research tool with the goal in mind to obtain high-quality digital imagery in remote sensing applications such as forestry and topographic mapping. The sensor offers a wide angular field of view ($\text{FOV} = 70^\circ$ and 6000 pixel swath width) and a high spatial resolution. WHiRL has been flown in test flights in 1991 providing resolutions (pixel sizes) down to 0.25 m (1070 m altitude). At a flight altitude of 12 km the resolution is 2.8 m and the swath width 12.8 km. The goal of the WHiRL program is the eventual development of a multispectral pushbroom imager for economical monitoring applications.²⁶²⁷⁾

Parameter	Description
Scanner type	Pushbroom CCD scanner, 1 spectral channel
Spectral response	595 nm
Bandwidth (FWHM)	20 nm
FOV (IFOV)	70° (o.23 mrad.)
Detector type	Loral Fairchild CCD 191, buried channel 6000-element linear array
Lens type	Custom design f/2.8 retrofocus, focal length = 43 mm
Line sample rates	56.6 to 320 lines/s in steps of $2^{1/2}$
Gains	1 to $4 \times 2^{1/2}$ in steps of $2^{1/2}$
Exposure time	3.125 to 17.678 ms in steps of $2^{1/2}$ - (3.125 ms corresponds to a flight speed of 80 m/s)

²⁶²⁷⁾ R. A. Neville, R. Marois, J. W. Schwarz, S. M. Till, “Wide-angle high-resolution line-imager prototype flight test results,” Applied Optics, Vol. 31, No. 18, 1992, pp. 3463-3472

Parameter	Description
Quantization	12 bit
Data format	12 tracks of HDDT in aircraft transcribed onto CCT in standard (LGSOWG) format post-flight
Signal/data processing	none at present (1993)
Interfaces	Alice real-time display (quicklook capability for subswath) High-density digital tape recorder (time code generator onto HDDT) Inertial navigation system recorded on a separate tape, can be merged with image data post-flight

Table 841: WHiRL sensor characteristics

P.206 WINDRAD (Wind Radiometer)

Windrad²⁶²⁸⁾ is a dual-frequency passive polarimetric microwave radiometer (K-band) designed and built by JPL. The objective is the measurement of ocean surface multipolarization brightness temperature and the deduction of wind direction and speed (by varying the thermal radiation over azimuthal angles relative to the wind by a few degrees Kelvin). Initial proof-of-concept flights (with a single-frequency instrument) on a DC-8 aircraft were conducted in November 1993.

Frequency	19.35 GHz (K-band)
Antenna beamwidth	3.6°
Antenna sidelobes	< -30 dB
Polarization	V, H, 45° (R), -45° (L), phase shifter set to 90°
Dicke switch rate	500 Hz
System noise temperature and background	530 K
Radiometer bandwidth	500 MHz

Table 842: WINDRAD instrument parameters

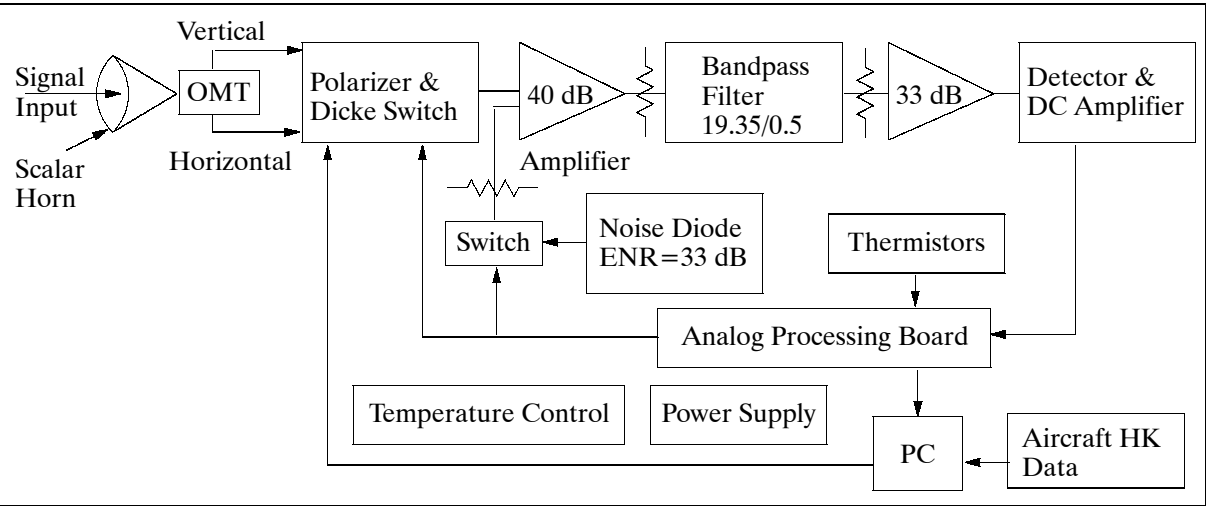

Figure 518: General block diagram of Windrad

WINDRAD is a direct detection Dicke-switch radiometer with noise injection to achieve a better balance between the alternating antenna reference measurements. All microwave components are mounted on a temperature-controlled plate to achieve good gain stability; they are also insulated to prevent external signal interference. The radiation signals enter-

2628) S. H. Yueh, W. J. Wilson, F. K. Li, S. V. Nghiem, W. B. Ricketts, "Polarimetric Measurements of Sea Surface Brightness Temperatures Using an Aircraft K-band Radiometer," IEEE Transactions of Geoscience and Remote Sensing, Vol. 33, No. 1, January 1995, pp. 85-92

ing the antenna are split into horizontal and vertical polarization components (E_h and E_v) by an orthogonal mode transducer (OMT). A microwave waveguide switch network is used to produce the four polarizations using the two linearly polarized orthogonal components as input. In the waveguide switch network, a Magic-Tee is used to take the sum and difference of vertically and horizontally polarized electric fields to produce the $\pm 45^\circ$ linear polarizations with the phase shifter set to the 0° phase position. - At each polarization setting, 22 pairs of antenna and reference load measurements are made, with an integration time of 88 ms and reduced to one brightness temperature sample.

P.207 WIS (Wedge Imaging Spectrometer)

The WIS is a hyperspectral instrument developed by Hughes Santa Barbara Research Center (SBRC) on Corporate Independent R&D (IR&D). Flight demonstrations of the instrument were performed in 1992, sponsored in part by ARPA and other US government agencies.²⁶²⁹⁾

The WIS sensor offers a novel spectral separation technique in which the spectral separation filters are mated to the detector array to achieve two-dimensional sampling of the combined spatial/spectral information passed by the filter. The technique obviates the need for a complex aft-optics assembly. The filter mask technique utilized in WIS compares to the general performance characteristics of the last row in Table 812.

The linear spectral wedge filter is a thin-film optical device that transmits radiation at a center wavelength that depends on the spatial position of illumination on the filter. On one side of the substrate, the device has thin-film depositions that are tapered linearly in thickness along one direction, resulting in a wedge shape. Since the bandpass center wavelength for a thin-film stack depends fundamentally on the stack layer thickness, the center wavelength of the passed radiation varies linearly with position parallel to the tapered edge of the filter stack. In the direction parallel to the untapered edge, the center wavelength is constant. Filter blocking stacks, required to control out-of-band leakage in the wedge filter, are on the opposite side of the substrate. Because the spectral bandwidth of a thin-film stack depends primarily on the structure of the stack (i.e. the relative thickness of the layers and their compositions), it is a constant percentage of the center wavelength ($\Delta\lambda/\lambda$). SBRC has developed designs with bandwidths of 3%, 2%, 1%, and 0.5%.

When an array of detectors is placed behind the wedge filter device, each detector in the “spectral” dimension will receive radiation from the scene at a different center wavelength - the array output is, in essence, the sampled spectrum of the scene. By using an area array of detectors, the detected scene information will vary spatially in one direction and spectrally in the other. Scanning the filter/array assembly along the spectral dimension will then build a spatial image (2-D) in each of the detected spectral bands, thus creating an imaging spectrometer.

The WIS sensor concept does not provide simultaneous spectral sampling of all spatial location within the sensor field of view. Instead, the sensor samples each ground point in all spectral bands over a short period of time (in the order of 1 s) by using the forward motion of the aircraft to “pushbroom” the ground image across the WIS detector array. The data are then registered in postprocessing to superimpose the spectral bands.

In the WIS flight demonstration unit (FDU), each of the 64 spectral bands comprises 128 spatial elements. The corresponding nominal ground coverage and spatial resolution is a function of the principal data collection parameters: altitude, velocity, detector integration time, and optics focal length. In addition, since the desired data collection parameters may require the use of a ground velocity that is too fast for a given aircraft, the WIS data acquisi-

²⁶²⁹⁾Information provided by E. S. Putnam of Hughes SBRC

tion system allows a selected number of data frames to be skipped for every frame that is recorded.

Two new Focal Plane Arrays (FPAs) are under development (end of 1993), one for the VNIR and one for the SWIR region. They will be configured as illustrated in Figure 519 and summarized in Table 843, allowing total deposition to occur on one side of a single substrate, as opposed to the three substrates required for the FDU when a single filter covered the entire array. In addition, the spectral bandpass of each filter can be tailored to requirements relating to the phenomena to be sensed in these spectral regions.

Parameter	Existing VNIR (WIS-FDU)	New VNIR Instrument (WIS-VNIR)		New SWIR Instrument (WIS-SWIR)	
Filter	1	1	2	1	2
Spectral range (μm)	0.40 - 1.03	0.40 - 0.60	0.60 - 1.0	1.0 - 1.80	1.80 - 2.50
Number of bands	64	129	265	81	90
Spectral resolution ($\Delta\lambda/\lambda$, %)	1.8	2.4	0.9	2.1	1.0
Spectral resolution (nm)	7.2 - 18.5	9.6 - 14.4	5.4 - 8.6	20.0 - 37.8	18.0 - 25.0
Detector material and type	Si CCD	Si CCD		InSb	
Detector size (μm)	(128 x 64)	18 (512 x 512)		40 (320 x 210)	
Telescope focal length (mm)	55 and 108	27.4		61.0	
FOV (swath width) (degree)	10 and 15	19.1°		12.0°	
IFOV (mrad)	1.36	0.66		0.66	
Spatial resolution (m) at observation altitude of 1.5 km	0.5 - 5	1		1	
Data quantization (bit)	12	12		12	
Data rate (Mbit/s)	22.5 @ 6 ms dwell	69 @ 10 ms dwell		23 @ 16 ms dwell	

Table 843: Specification of the WIS flight demonstration unit and future models

Figure 519: The WIS-VNIR FPA scheme of the linear spectral wedge concept

Filter 1 of the new WIS models is optimized for sensing vegetation, plant litter, and iron oxide materials; filter 2 for monitoring biological events near the ‘red edge’; filter 3 for discrimination of rocks, soils, and contained water, and filter 4 for direct identification of surface materials based on absorption features. The WIS-VNIR is expected to be ready in early 1995 for demonstration and use, the WIS-SWIR in late 1995.

Image data processing of WIS imagery requires some rectification processing (as with all other image data as well). For instance, for hyperspectral processing it is necessary to insure that the spectra from a point in the image truly corresponds to a single point (finite small region) in the scene. The applied processing involves re-registration of the band images.

The WIS-FDU was flown on a Sabreliner 40 aircraft for proof-of-concept demonstrations. The aircraft was equipped with a GPS receiver and other navigational instruments.

Part Q Survey of Campaigns

Campaigns are generally coordinated efforts by a number of institutions, with long lead times, involving normally a large set of instruments, to study complex problems of a regional and interdisciplinary nature. Examples of such investigations might be: 'the chemistry and radiative fluxes of the upper atmosphere in the polar region,' or 'the energy budget in the planetary boundary layer at the ocean/atmosphere interface.' Depending on the scientific objectives, such a campaign may involve parallel observations from airborne, spaceborne, and ground-based sensors (stationary, ship-based, truck-mounted, tower-mounted, moored and/or floating buoys); there may be supportive services by other existing networks or databases, and there may be international cooperation on many levels - there are simply no limits to diversity with regard to logistics and capabilities, except money. The very portability of instruments, in particular the capabilities of airborne platforms, create the degrees of freedom needed for experimentation to observe the environment.

The frequent mentioning of campaign participation in the description of airborne sensors prompted me to start also a survey of campaigns. There seems to be a need for short descriptions of campaigns in order to put activities into a proper context and to gain a better perspective. This survey demonstrates the breadth of experimentation, the interdisciplinary nature of campaigns, and the amount of work being undertaken on all levels by a worldwide research community.

A general problem encountered in generating this survey is the literature survey itself. The sheer size and duration of many campaigns favors a topical reporting style of certain 'campaign aspects' by many authors. This results in a loss of the overall picture. In addition, the publications of a single campaign (or program) may continue over time periods of years. I concentrated on 'campaign descriptions' (e.g. the scope); some information sources confused this with the reporting of scientific results. Expect for 'special issue' campaign reports in a single journal (which are becoming more frequent), it is very difficult for me to track all the publications on campaigns; this may lead to fractional reporting (with regard to participants, time frames, instruments, objectives, subcampaigns, cooperations, funding agencies, etc.) on my side. Whenever possible, I tried to get reviews by one or more campaign participants or by agencies; however, I was not always successful; sometimes I was dissatisfied with the results (the problem of incompleteness is always there). I certainly appreciate all the tips and hints I received by so many reviewers that lead in turn to other campaigns. For myself, the campaign survey had all the ingredients of a detective story.

Below is an alphabetical list of campaigns covering mostly the decade starting in about 1985 (naturally, there are also some campaigns before 1985, and there are also some overviews of scientific programs); however, in view of the vast number of campaigns, there cannot be any claim of completeness. I have a feeling that my survey is in reality only the tip of the iceberg. The general pattern used for a campaign write-up tries to cover the following items (if available):

- Science objectives
- Time frame
- Geographic area of campaign
- Major participants
- Platforms/instruments
- Parallel observations by ground-based and/or spaceborne instruments

The campaign survey itself forced me to look also at the observation programs (WCRP, GEWEX, etc.) of international organizations like IGBP, WMO and IOC. A short overview of these international programs and their overall structure is given in Appendix Q.2. A good portion of the international programs is in turn reflected in Appendix Q.1.

Q.1 Campaigns

AAOE (Airborne Antarctic Ozone Experiment, 1987)^{2633), 2634), 2635)}

Multiagency campaign [NASA (LaRC, ARC, JPL, GSFC, HQ), NCAR, NOAA, CIRES, Harvard, U. of Denver, U. of Washington, U. of Wyoming, UKMO, CNRM, etc.] conducted over Antarctica during August and September 1987 (winter and early spring) from Punta Arenas, Chile. Objective: testing of chemical and dynamical ozone hole theories in computer models of the stratosphere using aircraft data. The data was primarily collected on-board the NASA ER-2 and DC-8 aircraft which flew into the ozone hole, along with ozonesonde data collected from April through November 1987 at four Antarctic stations: Halley Bay, McMurdo, Palmer Station, and the South Pole (satellite data: SAM II, TOVS, TOMS, SAGE II). The campaign was funded by NASA, NOAA, NSF, universities, and overseas meteorological agencies.

ER-2 collected information on 3-D winds, pressure, temperature, temperature profiles (± 1 km from flight level), chlorine monoxide, bromine monoxide, ozone, nitric oxide, reactive nitrogen, total water, nitrous oxide, whole air sampling, condensation nuclei, aerosol size distribution and composition, and cloud particle images and sizes. - The DC-8 flew at the lower edge of the hole and deployed a combination of remote sounding of the overlaying atmosphere with some in situ sampling. Vertical distributions of ozone and aerosols above the cruising aircraft were mapped. The DC-8 collected ozone and aerosol profiles overhead by lidar, and measured ozone, bromine oxide, OClO, nitrogen dioxide, nitric acid, and hydrogen chloride. In situ methods yielded ozone, total water, and whole air sampling.- The AAOE data are available from the NASA/ARC archive (on CD-ROM).

AASE-I, -II (Airborne Arctic Stratospheric Expedition)

NASA campaigns (with participation by many other institutions in the USA) with the objective to gain a better understanding of the effects of heterogeneous processes on the partitioning of the chlorine and nitrogen chemical families in the lower stratosphere. In particular, the work primarily concerns the effects of those heterogeneous processes associated with sulfate aerosols and modeling of the chemistry of the stratosphere. NASA/AMES ER-2 and DC-8 aircraft were used. Investigations have been undertaken to study the effect of ozone distribution on arctic polar vortices and of the temperatures associated with the formation of Polar Stratospheric Clouds (PSCs).

The AASE-I field campaign²⁶³⁶⁾ took place in 1989, staged from Stavanger, Norway.

The AASE-II field campaign²⁶³⁷⁾ was carried out from October 1991 through March 1992 in Fairbanks, Alaska and Bangor, Maine. The NASA/ARC ER-2 and DC-8 aircraft and balloons were employed to carry a suite of instruments into the lower stratosphere.

ABLE (Atmospheric Boundary Layer Experiment)

The ABLE program is a component of the NASA GTE (Global Tropospheric Experiment), a long-term study of the chemistry of the atmospheric boundary layer. A number of campaigns are part of the GTE program [ABLE 1, ABLE 2A, etc.; also the CITE (Chemical Instrumentation Test and Evaluation) series]. The data of the ABLE program are available at NASA/LaRC.

ABLE 1 (Atlantic Boundary Layer Experiment)^{2638), 2639), 2640)}

A NASA-sponsored campaign conducted off the coast of Barbados in the tropical Atlantic/Caribbean region (12-14° N, 56-59° W) in June (13-30) 1984. The objective was to study the vertical distribution of DMS (dimethylsulphide) in the marine boundary layer (troposphere). Ground-based and airborne (NASA/WFF Electra with UV DIAL sensor and others) samples were collected. Flight tracks were concentrated in the area to the east of Barbados (13° 10' N, 59° 30' W). ABLE-1 flights in the Barbados region observed a massive infusion of Saharan dust. - A secondary objective was the characterization of the boundary layer over the wet tropical forest of Guyana. On June 27, 1984 flights were made with the Electra over the forest at different heights (150 m to 450 m, and 3-5 km).

ABLE 2A (Amazon Boundary Layer Experiment)²⁶⁴¹⁾

ABLE 2A was a NASA/INPE (scientists from LaRC, GSFC, INPE, and US and Brazilian universities) campaign conducted in the Amazon region of Brazil during July and August 1985. The campaign focused on assessing the role of biosphere-atmosphere interactions on the chemistry of the troposphere over tropical forests and wetlands. The dry season was selected in order to provide the best opportunities for characterizing the chemistry of the undisturbed (nonprecipitating) atmospheric boundary layer. Another objective was to compare results with the Shuttle Mission 'MAPS' (Measurement of Air Pollution from Space, see chapter J.11). - The scientific objectives were accomplished through a coordinated measurement program (NASA/WFF Electra aircraft, a tethered balloon, a 45 m meteorological tower, surface trace gas and meteorological sites, and free-flying sondes). - A complementary program of studies, AGE (Amazon Ground Emissions), operated three surface sites during the same time period as ABLE 2A, including a research vessel, R/V Amanai, sampling along the Rio Solomoies and Rio Amazonas, an anchored floating laboratory in Lago Calado, 80 km west of Manaus, and a forest site in Reserva Ducke near Manaus. -The Electra flew a series of 15 missions (nadir-pointing UV DIAL instrument and others to determine 2-D distributions of aerosols, ozone, and clouds). In situ measurements of CO₂, CO, CH₄, nonmethane hydrocarbons NMHC, NO, DMS, aerosol composition and meteorological parameters were conducted during flights.

ABLE 2B (Amazon Boundary Layer Experiment)²⁶⁴²⁾

A follow-up campaign to ABLE 2A, but in the wet season of the Amazon region, conducted during April and May 1987. Same objectives as for ABLE 2A, an enhanced effort was placed on the ABLE 2B studies to determine the role of local-to-mesoscale convective activity on the atmospheric distribution of trace gas and aerosol species. Collaboration of over 100 US and Brazilian scientists sponsored by NASA and INPE. Observations were conducted from the ground (portable automated stations, towers, etc.), from the air (21 flights with Electra aircraft, 3 tethered balloons, rawinsondes), and from spaceborne sensors (GOES imagery). - The complementary AGE program was also conducted.

ABLE 3A (Arctic Boundary Layer Expedition)²⁶⁴³⁾

A NASA-sponsored campaign (scientists from NASA/LaRC and US universities) conducted in the arctic/subarctic regions of North America and Greenland during July and August 1988. The campaign is regarded as the first comprehensive investigation of the sources,

sinks and distribution of trace gas and aerosol chemical species in a northern high-latitude region during summer months. The campaign goals placed emphasis on the role of biosphere-atmosphere interactions in determining the chemical composition of the troposphere and on processes which influence the tropospheric ozone budget. The suite of chemical species measured include the following gases: methane (CH_4), carbon monoxide (CO), carbon dioxide (CO_2), nonmethane hydrocarbons (NMHC), acetic acid (HA), formic acid (HFO), nitric oxide (NO), nitrogen dioxide (NO_2), total 'reactive' nitrogen gas (NO_y), nitric acid (HNO_3), peroxyacetyl nitrate (PAN), peroxypropionyl nitrate (PPN), ozone (O_3), and aerosol chemical composition and distribution.

The scientific objectives of ABLE 3A were accomplished through a coordinated program of chemical and meteorological measurements at surface sites in Alaska and on the NASA/WFF Electra research aircraft. - A complementary program of surface-based biogeochemical studies, termed BREW (Biospheric Research on Emission from Wetlands), was conducted in Bethel, Alaska, during the period of ABLE 3A. - Aircraft missions were conducted from bases in Alaska (Barrow, Bethel, Cold Bay) and Greenland (Thule).

ABLE 3B (Arctic Boundary Layer Expedition)²⁶⁴⁴

ABLE 3B is a second campaign into the northern high latitudes (north central and north-eastern regions of Canada). ABLE 3B involved collaboration with the Canadian Northern Wetlands Study (NOWES) during July-August 1990 with the objectives as for ABLE 3A and continuation of ABLE 3A. The primary focus of the collaborative effort was to assess the importance of the Hudson Bay lowlands as a source of global methane. NOWES established an extensive ground-based, aircraft, and remote sensing program. The NASA/ABLE 3B campaign established a similar coordinated measurement program. Studies involving coordinated ground- and aircraft measurements (NASA/WFF Electra) were centered on Kinosheo Lake in the Hudson Bay lowlands and on forest/wetland sites near Schefferville, Quebec.

ACE-1 (First Aerosol Characterization Experiment)

ACE-1 was planned in collaboration with IGBP/IGAC/MAGE to take place in late 1995 in the vicinity of Cape Grim, Tasmania (participation of New Zealand, Australia, Europe, USA, and Asia. The objective is to study the DMS (Dimethylsulphide) flux and its conversion to aerosols in a region (remote marine atmosphere) where anthropogenic influences are minimal.

ACE-2 (Second Aerosol Characterization Experiment)

ACE-2 within IGBP/IGAC/MAGE is planned for the summer (June-August) of 1997 to take place over the 'polluted' North Atlantic Region.

ACSYS (Arctic Climate System Study)²⁶⁴⁵

A WCRP regional program which started its observational phase in 1994 (10 year program). The goal of ACSYS is to ascertain the role of the Arctic in global climate. ACSYS seeks to develop and coordinate national and international science activities with the following overall objectives:

- To understand the interactions between Arctic Ocean circulation, ice cover and the hydrological cycle
- To initiate long-term climate research and monitoring programs for the arctic region
- To provide a scientific bases for an accurate representation of arctic processes in global climate models.

The major study areas of ACSYS are:

- 1) Arctic Ocean circulation program

²⁶⁴⁴) R. C. Harris, S. C. Wofsy, et al., "The Arctic Boundary Layer Expedition (ABLE 3B): July-August 1990," *Journal of Geophysical Research*, Vol. 99, No. D1, January 20, 1994, pp. 1635-1643

²⁶⁴⁵) Arctic Climate System Study (ACSYS), Initial Implementation Plan, WCRP-85, September 1994

- Arctic Ocean hydrographic survey
 - Arctic Ocean shelf studies
 - Arctic Ocean variability project
 - Historical Arctic Ocean climate database
- 2) Arctic sea-ice program (a main task is to establish a climatology of ice thickness and ice velocity: data to be provided by the WCRP Arctic Ice Thickness Project, the International Arctic Buoy Program, sonar profiling, airborne oceanographic lidars, polar satellites)
- Generation of an arctic basin-wide sea-ice climatology database
 - Monitoring of the export of sea ice through the Fram Strait
 - Arctic sea-ice process studies
- 3) Arctic atmosphere program (builds on a number of existing and planned field programs, like ARM, BASE, FIRE III, etc.)
- Encourage and promote field campaigns to provide a basis for improved physical parameterization schemes
 - Promote a re-analysis of arctic historical data
 - Develop a polar clouds and radiation program (improved techniques for satellite retrievals of cloud and radiation properties).
- 4) Hydrological cycle in the arctic region
- Compilation of an arctic hydrological database - APDA (Arctic Precipitation Data Archive)- containing daily, monthly and annual total precipitation data (both liquid and solid). APDA will cover a period of at least 15 years (1978 onward) and will draw on existing data collections. ACSYS will also include a Solid Precipitation Climatology Project (includes the development and assessment of satellite remote sensing methods for determining snow-water equivalent, snow depth and snow extent)
 - Development of hydrological models of selected arctic regions. Macroscale modeling will include atmospheric and surface (catchment) components.

5) ACSYS modeling program

AEROCE (Atmospheric/Ocean Chemistry Experiment)

An international long-term trace-gas, aerosol, and precipitation monitoring project centered on the Atlantic Ocean (within IGBP/IGAC).

AEROCONTRAIL²⁶⁴⁶⁾

An EC-funded campaign coordinated by the University of Strasbourg (P. Mirabel) and planned for the time frame of October 1996. The objectives are: 1) study of the interactions between subsonic aircraft emissions (gases and particles), cloud and particle formation (properties of contrails) and radiative energy transfer in the upper troposphere, 2) assessment of aircraft emissions on the physical and chemical processes in the upper troposphere, 3) realistic modeling of long-term regional climate effects. The region of investigation is an area of about 100 km x 100 km located to the west of Munich, Germany. In situ measurements will be conducted by: MISU (Sweden), UBP (Université Blaise Pascal, Clermont-Ferrand, France), University of Mainz, and DLR/IPA (Oberpfaffenhofen). Ground observations will be conducted by: Fraunhofer Institute (Garmisch-Partenkirchen), ONERA (France), CNRS/LPCA (U. of Strasbourg), DLR/IPA. Aircraft: Falcon (DLR) equipped with MASP (University of Mainz), (FSSP, OAP-2D-C, OAP-2D-P, all PMS laser spectrometers, see P.164), CVI (MISU), CCN chamber, Eppler pyranometer, CHOPPY, meteorological sensors.

AGASP (Arctic Gas and Aerosol Sampling Project)

NOAA aerial campaign series in Alaska: AGASP-I (1983), -II (1986), -III (1989) and -IV

²⁶⁴⁶⁾Information provided by P. Wendling of DLR/IPA

(1992), conducted with WP-3D aircraft, and the operation of a research and monitoring station at Barrow, Alaska. AGASP-IV was part of IGBP/IGAC's former PAC (Polar Atmospheric Chemistry), now PASC program, and in conjunction with LEADDEX. The objectives of AGASP-IV were: 1) to define the spatial distribution of pollution in the Arctic troposphere, and 2) to study the effect of open water (leads) on tropospheric composition. - Russia provided an AN-26 aircraft for AGASP-IV. The combined AGASP-IV and LEADDEX campaigns involved 120 scientists from the following countries: USA, Canada, Russia, Norway, Germany, Denmark, and Finland. Seven aircraft covered the Arctic from the New Siberian Islands, Russia to Barter Island, Alaska.

AGRISAR-86²⁶⁴⁷⁾

ESA/JRC coordinated campaign (participants: DLR, CNES, IGN, etc.) with the objective to collect SAR data during the growing season of representative agricultural test sites in Europe (crop/vegetation classification, pattern recognition, test of remote sensing techniques for agricultural and forestry applications). A CNES SAR instrument with the name of VARAN (X-band, two polarizations) was flown in a B-17 aircraft of IGN. A total of four flight campaigns were conducted (start of June, end of June, mid-July, and mid-August). Test sites: two in France, one each in Italy, Germany (Freiburg), Holland, UK and Ireland. Extensive ground truth collection took place (crop identification was done by many students, ground-based instruments were used for SAR calibration) in parallel to the aircraft overflights. In addition the Freiburg test area was 'underflown' with the DLR E-SAR (X-band, L-band) on a DO-288. Spaceborne data were collected from Landsat (TM).

AGRISCATT

ESA/JRC coordinated international microwave remote sensing campaigns that were conducted during the growing seasons of 1987 and 1988 in Europe. Objective: Collection of calibrated radar backscatter data over a number of representative European test sites for a variety of sensors and wave parameters, together with an appropriate ground data set. Standard ground data collection, compilation protocols and methodologies were defined and applied to the entire campaign to ensure data compatibility by all investigators. All campaign data are archived in EURACS (European Radar Cross Section Database) at ESRIN. Instruments flown: DUTSCAT [Delft University of Technology and NLR (operator on Be80 aircraft), see P.74], ERASME [CRPE and IGN (operator on B17 aircraft), France], VARAN-S [CNES and IGN (operator on B17 aircraft), France], and C/X-SAR [CCRS and Intera (operator on CV-580 aircraft, see P.61), Canada].²⁶⁴⁸⁾

Test sites: Feltwell and Reedham (UK), Flevoland (The Netherlands), Freiburg and Oberpfaffenhofen (Germany), Coulommiers (France), Oltrepo Pavese and Cerbaia, Fucecchio (Italy).

AIDJEX (Arctic Ice Dynamics Joint Experiment)^{2649), 2650)}

A US/Canadian cooperative research program, initiated by ONR and NSF, and conducted during 1970-1979 in the Beaufort Sea (Alaska). Participants: U. of Washington; Canada Center for Remote Sensing (CCRS) Ottawa; Naval Arctic Research Laboratory (NARL) at Barrow, CRREL, USGS, NSF, Columbia University, Oregon State University, McGill University, U. of Alaska, SIO, U. of California at Davis, NASA, NOAA, NCAR, Environment Canada, Canadian Geological Survey. The program was aimed at studying the mesoscale dynamic processes and response of sea ice to its environment in the region of the marginal ice zone (MIZ), and to develop numerical models. A series of campaigns were conducted.

- AIDJEX pilot study, spring 1974
- AIDJEX main experiment from March 1975 through April 1976.^{2651), 2652)} A comprehensive microwave sensing program was performed on the sea ice of the Beaufort Sea. Surface and airborne measurements with passive and active (L- and X-band SAR and scatterometer (SLAR)) sensors. Observation of ice features and types, estimation of deformations, average brightness temperatures (ESMR), dielectric constants, etc. Aircraft: CV 990 (NASA), C-47 Aerojet (CCRS). Satellite data from Nimbus-5.

The AIDJEX data archive is at NSIDC (National Snow and Ice Data Center) at Boulder, CO.

ALE/GAGE (Atmospheric Lifetime Experiment/Global Atmospheric Gas Experiment) ALE/GAGE began in 1978 as a global network program to provide continuous high-frequency gas chromatographic measurements of two biogenic (CH₄ and N₂O) and five anthropogenic gases (CFC-13, CF₂Cl₃, CF₂ClCFC12, CH₃CCl₃, CCl₄). The network includes observation stations positioned at different sites throughout the world: Cape Grim, Tasmania; Point Matatula, American Samoa; Ragged Point, Barbados; and Mace Head, Ireland; Cape Meares, Oregon. - The ALE phase (1978-84) utilized HP5840 gas chromatographs (data collection four times per day); the GAGE phase (1981 -) utilizes the HP5880 gas chromatographs (data collection 12 times per day). Newly installed AGAGE (Advanced GAGE) instruments use a fully automated system from SIO (Scripps Institution of Oceanography), La Jolla, CA.²⁶⁵³⁾

ALOHA (Airborne Lidar and Observations of the Hawaiian Airglow)

NCAR campaign in 1994 to study stratosphere-mesosphere dynamics, polar mesospheric clouds, and sporadic layering phenomena in the upper mesosphere and lower thermosphere. The Electra was used as an airborne platform for the large Rayleigh-sodium lidar of the University of Illinois (plus standard instrumentation). Mesospheric observations with the Ebert-Fastie spectrometer of the University of Michigan. Airglow measurements with an instrument of Lockheed. The Hawaii base was used for nighttime flight missions to map the near-equatorial region. Other missions included flight legs to Tahiti. Numerous ground-based instruments on Hawaii and Christmas Island provided concurrent data.

ALPEX (The Alpine Experiment)^{2654), 2655) ,2656)}

An international campaign (GARP subprogram on 'Air flow over and around mountains'), endorsed by WMO/ICSU, and participation by the following countries: Austria, Belgium, France, Germany, Hungary, Italy, Netherlands, Poland, Romania, Spain, Switzerland, USA, USSR, Yugoslavia and ECMWF. The campaign period of ALPEX lasted from September 1981 to October 1982, with 2 months of intensive observations in March and April 1982. During the intensive observation period the World Weather Watch (WWW) network was augmented in the inner experiment area from 5°W to 30°E and from 38°N to 50°N with observations from ships, aircraft, ground-based radars and balloons. The objectives of ALPEX were aimed at studying:

- The air flow, mass and moisture fields over and around the mountain range under various synoptic conditions

- The formation of cyclones in the lee of the mountain barrier with special emphasis on the subsynoptic nature of the associated processes
- The drag of the mountain range upon the atmosphere, including the vertical transport of horizontal momentum as a function of height and the dissipation of gravity-inertial wave energy over and downwind of the mountain range
- Local mountain winds such as Föhn, Bora, and Mistral
- Role of diabatic heating associated with lee cyclogenesis over the Mediterranean Sea
- The effects of the differential radiative heating produced by the mountain range
- The effect of the mountains on precipitation
- The physical processes responsible for the development of severe floods, wind storms and storm surges.

Aircraft observations from Electra (NCAR), P-3 (NOAA/AOC), and Falcon (DLR) with measurements of temperatures, humidities and wind profiles at different heights (some observations were performed by cooperating commercial airlines). Satellite observations by METEOSAT-2 (VISSR) and NOAA-7 (TOVS, MSU, HIRS). An oceanographic subcampaign MED-ALPEX was conducted in parallel to the ALPEX intensive observation period consisting of 9 R/V vessels, 36 coastal tide stations, 4 fixed near-shore platforms, 3 meteorological and 18 sub-surface buoys (study of air-sea interaction over the Mediterranean). The ground-based radar network provided information on the precipitation distribution. A microbarograph subprogram provided pressure field distributions. An upper-air sounding network (radiosondes, radiowind and piloted balloon observations) was part of the WWW network.

AMBIACE (Amazon Biogeochemistry and Atmospheric Chemistry Experiment)

A GEWEX campaign in the planning phase as of 1995. Objectives: Study of the consequences of forest conversion, agricultural practice and abandonment, and secondary succession, on regional and biogeochemistry and atmospheric chemistry. Field experiments, remote sensing observations, and modeling activities focus on understanding the ecological processes that regulate biosphere-atmosphere exchange in the tropical moist forest biome (influence on global distribution of greenhouse gases; factors that regulate the oxidizing power of the tropical atmosphere, including biogenic and anthropogenic processes).

AMEX (Australian Monsoon Experiment)²⁶⁵⁷⁾

AMEX is an Australian summer campaign conducted by BMRC (Bureau of Meteorology Research Centre) of Melbourne, Australia, and others (Monash University, Flinders Institute of Atmospheric and Marine Science), during the period October 1986 to February 1987. AMEX took place in the region of tropical oceanic North-Australia (Darwin), Papua New Guinea, and Indonesia, which is one of heavy rainfall associated with the summer monsoon. Objective: study of the physics and dynamics of tropical weather systems; in particular the interactions between cumulonimbus convection and the Australian summer-monsoon circulation. AMEX took place in parallel and in cooperation with EMEX and STEP; it is based on the collection of high-density tropical upper-air soundings and radar data during two seasonal phases in October 1986 and January/February 1987. A network of ground stations was installed for radar and atmospheric soundings.

Archimedes I, II, IIa (Coordinated European airborne campaigns, organized and sponsored by JRC (Joint Research Council) of Ispra, in the North Sea region).^{2658), 2659)}

Objectives: tryout of a suite of airborne instruments (passive and active microwave sensors and optic instruments) on hydrocarbons (pollution of oil slicks) and biogenic layers at sea; correlation study to compare the efficiency and merits of individual sensors. Archimedes I was conducted on October 21 and 22, 1983 in the southern part of the North Sea in Dutch coastal waters, of the coast of Hook of Holland. Archimedes II was conducted on October

1-2, 1985 in the German Bight, 25 miles North-West of the island of Helgoland. Archimedes IIA took place on April 21, 1988 in the southern part of the North Sea in Dutch coastal waters 20 miles off Hook of Holland.

Participants: RWS (Rijkswaterstaat) Netherlands, SBÖ (Sonderstelle des Bundes Ölfälle See/Küste, Cuxhaven, Germany), DLR (Oberpfaffenhofen), DHI (Hamburg), TUD (Technical University of Denmark), SSC (Swedish Space Corporation), CNR/IROE (Florence, Italy), CNES and IGN (France), U. of Oldenburg, U. of Hamburg (Germany), Eurosense (Belgium). - Aircraft observations of Archimedes II: Cessna 404 (of RWS with VV X-band SLAR and VV IR line scanner), B-17 (of IGN with VARAN S), DO-228 (of DLR with VV, HH X-band SAR, VV, HH L-band SLAR, MWR), DO-228 (of Eurosense with VV X-band SLAR and Daedalus scanner), Cessna 402 (of SSC with VV X-band SLAR, MWR), DO 228 (of U. of Oldenburg with LFS), Helicopter (U. of Hamburg, spreading of biogenic monolayers), C-130 (of TUD with VV, HH X-band SLAR, MWR). Ships: Scharhorn, Bottsand, Mellum and Nordsee (all of SBÖ), R/V Gauss (DHI), Volans and Smal Agt (of RWS). - Aircraft observations of Archimedes IIA: DO 228 (2 of DLR with X-SLAR, Ka-SLAR, L-SARSCAT, PMR, L-SAR), DO 228 (German AirForce).

ARESE (ARM Enhanced Shortwave Experiment)²⁶⁶⁰

A US DOE-supported multiagency campaign program (participation of NASA/ARC/LaRC/GSFC, SNL, NOAA, NCAR, SIO, BNL, SUNY at Stony Brook, University of Maryland, UC at Santa Barbara, Penn State University, University of Utah, etc.) with an IOP from September 22 through October 20, 1995. The ARESE campaign site is at SGP (Southern Great Plains) of the DOE ARM program near Billings, Oklahoma (CART site, see also: ARM). Project coordinator: John Vitko of SNL, Livermore, CA; chief scientist: Francesco Valero of ARC. The objectives of ARESE are to study shortwave absorption by clouds, since this information is not represented in atmospheric models. Particular goals are: 1) to directly measure the absorption of solar radiation by the clear and cloudy atmosphere and to place uncertainty bounds on these measurements, 2) to investigate the possible causes of absorption in excess of model predictions. Coordinated spaceborne (satellite overpasses), airborne and ground-based observations. Spaceborne data collection from the VIS channels of NOAA-GOES and Meteosat, AVHRR (NOAA-POES). Airborne instruments are flown on ER-2 aircraft (RAMS, MAS, cameras, CALS, etc.); G-520 Egrett (a high-altitude aircraft of Aurora with instruments: RAMS, CDL, MPIR, video camera, thermometer barometer, hygrometer, GPS/INS); Twin Otter (RAMS). Surface measurements are conducted with a ground RAMS, the baseline solar radiation network, micropulse lidar, millimeter radar, microwave water vapor radiometers, ozone sondes, standard sondes, RASS.

ARKTIS 1988 ²⁶⁶¹, ²⁶⁶²)

A German campaign from May 4-26, 1988, initiated and organized by the University of Hamburg (Meteorologisches Institut and Max-Planck-Institut für Meteorologie (MPIfM)) with participation from other institutes: AWI (Bremerhaven), DLR (Oberpfaffenhofen), GKSS (Geesthacht), Institut für Meereskunde (Hamburg), Institut für Meteorologie und Klimatologie (Hannover), Deutscher Wetterdienst (Hamburg), Institut für Geophysik und Meteorologie (Köln), Technical University of Braunschweig, University of Stockholm, Sweden. Objective: study of climatically relevant processes in the ocean-atmosphere-ice environment. The expedition took place in the Fram Strait in the area straddling the ice margin west of Spitzbergen (operation center at Longyearbyen on Spitzbergen). Spaceborne (NOAA/AVHRR, transportable station at Spitzbergen), airborne (Falcon-20, Polar-2, DO-128, DO-228), shipborne (RV Valdivia, RV Polarstern) and on-ice observa-

tions were conducted (study of energy and momentum budget of the polar ice and atmosphere and the conditions for the occurrence of certain cloud types).

ARM (Atmospheric Radiation Measurement)²⁶⁶³

A DOE-sponsored program (USA) with the goal of improving the parameterization of clouds and cloud-radiative interactions in general circulation models (GCMs). The ARM program is considering three ground-based highly instrumented primary measurement sites, for a program duration of up to 10 years, at land and ocean locations, to monitor on a continuous basis quantities like: longwave and shortwave radiation, spatial and temporal distribution of clouds, water vapor profiles, atmospheric wind, temperature; cloud physical and optical properties. Shorter observations campaigns will be conducted at additional sites. The field measurement component of ARM is **CART** (Cloud and Radiation Testbed). The ARM data archive is at Oak Ridge National Laboratory (ORNL). - Participating institutions: PNL, LANL, ANL (Argonne National Laboratory), NCAR, NASA/ARC, Colorado State University, University of Wisconsin, State University of New York (SUNY) at Albany, SIO, LLNL, Brookhaven National Laboratory (BNL), University of Maryland, UC at Santa Barbara, NASA/GSFC, SUNY at Stony Brook, ORNL, University of Denver, SNL, University of Massachusetts at Amherst, University of Utah, NOAA/ERL/ETL and AL, and CSIRO.

The ARM program also participated in observational campaigns in collaboration with other programs (pilot data), such as: FIRE-SPECTRE, WISP, PROBE, TOGA/COARE, BARFEX, ASTEX. The ARM preparation program was from 1990-1994, the experimental program at the selected three CART sites [SGP (Southern Great Plains), TWP (Tropical Western Pacific on Manus Island, Papua New Guinea) and NSA (North Slope of Alaska)] is to start in 1995.

ARMCAS (Arctic Radiation Measurements in Column Atmosphere-surface System)²⁶⁶⁴

A US (NASA/GSFC/ARC/HQ/JPL, U. of Washington, CSIRO, U. of Alaska, NOAA/NWS) campaign, funded by NASA, NSF and ONR, conducted from June 1-15, 1995 in the North Slope region of Alaska and the Beaufort Sea area. The objectives are:

- Collect cloud mask data for MODIS algorithm development
- Perform scale analysis for varying spatial resolutions
- Retrieve cloud properties over highly reflecting surfaces
- Obtain in-situ measurements for cloud retrieval validation
- Measure droplet spectral absorption with microphysics
- Measure aerosol light scattering and CCN (Cloud Condensation Nuclei) properties
- Study statistical properties of cloud microphysics
- Measure bidirectional reflectance of various surface types
- Serve as pilot study for FIRE-III and SHEBA campaigns

Spaceborne observation data from AVHRR (POES), ATSR and AMI (ERS-1/2). Airborne data with ER-2, deployed at Fairbanks, and the C-131A (U. of Washington), based in Prudhoe Bay. Ground-based observations in the Prudhoe Bay area. ER-2 carried the following instruments: MAS, AVIRIS, CALS, and RC-10 (Wild camera). Instruments on-board the C131-A: CAR, PMS probes (FSSP-100X, OAP-200X, OAP-200Y, OAP-2DC, OAP-2DP, FSSP-300), PVM-100A, etc.

APARE (Asia/North Pacific Regional Study)²⁶⁶⁵

An international campaign within the IGBP/IGAC program. The objectives of APARE are to quantify the oxidizing efficiency and atmospheric acidification by studying the emission, transport, chemical transformation and deposition of primary and secondary chemical spe-

cies over the east Asian continental rim region and northwestern Pacific Ocean (see also NARE). Subprograms of APARE are:

- **PEM-WEST** (Pacific Exploratory Mission - West)
PEM-WEST is an aircraft campaign conducted by NASA as part of the GTE (Global Tropospheric Experiment) program. The objectives of PEM-WEST are to:
 - Estimate the natural budgets of and the anthropogenic impacts on O₃ and its precursors, i.e. NO_x, CO, CH₄, and nonmethane hydrocarbons
 - Estimate the major sources of sulphur species over the western Pacific.

Two aircraft campaigns with the NASA DC-8 aircraft covered the latitudinal extremes of 60° N to 5° S. Major landing sites, from which one or more intensive flights were conducted, include Tokyo, Hong Kong, and Guam for Phase A, and Guam, Singapore, Hong Kong, and Tokyo for Phase B. The Phase-A campaign was conducted in September/October 1991, and the Phase-B campaign took place in February/March 1994. Ground-based measurements were also performed at several selected sites in a continuous mode during the campaigns to measure O₃, NO_x, SO₂, PAN, CO, etc. Several automated stations at remote islands were operated for the measurement of aerosols.

- **PEACAMPOT** (Perturbation by East Asia Continental Air Mass to Pacific Oceanic Troposphere)
An aircraft campaign coupled with ground-based observations sponsored by JEA (Japan Environmental Agency). Objectives:
 - Characterize the transport of acidic aerosols and their precursors in the marine air around Japan
 - Analyze the distribution and long-range transport of oxidative species such as O₃, PAN, and their precursors in the east Asian continental rim region.

The PEACAMPOT campaigns were conducted in parallel and in coordination with PEM-WEST Phases A and B in the fall 1991 and spring 1994, respectively.

APE (Airborne Polar Experiment)²⁶⁶⁶

APE is an international program, sponsored by ESF (European Science Foundation) and by PNRA (Italian National Program for Antarctic Research); the first campaign is to be conducted in the winter 1996/97 in the arctic region (base in Rovaniemi, Finland). Objectives: study of PSC (Polar Stratospheric Cloud) microphysics and chemistry. Participants: CNR/IROE, CNR/IFA, CNR/FISBAT, U. of Rome (all Italy), NASA/LaRC, MPIC Mainz (Germany), RAL (UK), SNCMP (France), CAO, IKI (Moscow), NILU (Norway), NOAA, U. of Cambridge (UK), U. of Stockholm (Sweden), etc. APE will be flown on the M-55 Geophysika of Russia. The instrument complement is described in chapter P.29. A second campaign period is planned for the antarctic winter in the time frame 1998 - 2000.

ASCOT (Atmospheric Studies in Complex Terrain)

A US-DOE program with campaigns in 1980 and lasting through 1994.

ASE (Automatic Air-Sampling Equipment), see description under P.40.4 on page 1574.

ASHOE/MAESA (Airborne Southern Hemisphere Ozone Experiment/Measurements for Assessing the Effects of Stratospheric Aircraft)

International campaign with participants from nine countries (NASA/GSFC and ARC, NOAA, NSF/NCAR, universities, New Zealand National Institute of Water and Atmospheric Research, UKMO, ECMWF, Cooperative Research Center for Southern Hemisphere Meteorology, Australia). The campaign was flown on ER-2 aircraft from Hawaii and Christchurch, New Zealand in 1994 (Deployment I was conducted in March 1994, deployments II and III were conducted in June and July; the final deployment was completed in October 1994). Objectives of ASHOE: study of the chemical and dynamic nature of the low-

²⁶⁶⁶ URL address: <http://www.area.fi.cnr.it/appe/aphtml.htm>

er stratosphere, investigate the causes of long-term reductions of ozone in wintertime mid-latitudes of the southern hemisphere. Objective of MAESA: to assess the possible ozone effects of aircraft exhausts on a proposed fleet of future supersonic aircraft. The experiment examines processes potentially affecting ozone and distributions of chemical tracers. Airborne instruments: OH/HO₂, CO₂ Analyzer, and ClO/BrO sensors (Harvard), MASP (NCAR), MMS (ARC), MTP (JPL), ATLAS (ARC), ARGUS (ARC), HIS (U. of Wisconsin), ALIAS (JPL), and others.^{2667), 2668)}

ASHOE/SPADE-II, this campaign was officially renamed **ASHOE/MAESA** by NASA²⁶⁶⁹⁾

ASTEX (Atlantic Stratocumulus Transition Experiment)^{2670), 2671)}

ASTEX is an international [USA (NASA, NSF/NCAR, NOAA, ONR, DoD, DOE, U. of Washington, etc.), UK (UKMO), France (CRPE/CNET), Russia (RAS), Germany (U. of Hamburg), Portugal, ECMWF, etc.] campaign conducted during May/June 1992 in the Azores/Madeira region of the eastern Atlantic. ASTEX is considered an element of the **FIRE** campaign as well as of **SOFIA** and of **MAGE**. The major objectives of ASTEX were the study of: a) the physical processes that are responsible for the break-up of sheets of stratocumulus clouds into shallow cumulus clouds, b) the physical processes that are responsible for the selection of cloud types and cloud amounts in an area, c) the consequences for the atmosphere and the ocean, cloud type and cloud amount. - Observations were conducted from instruments at island ground stations (including buoys), from aboard ships (Akademik Kurchatov, Le Suroit, Valdivia, Malcolm Baldrige, and Oceanus), from several aircraft (C-130, C-131A, ARAT Fokker F-27, Merlin IV, ER-2, Electra), from balloons, and from satellites (METEOSAT, NOAA POES, GOES, SPOT, Landsat, DMSP, ERS-1). Some airborne instruments were: CALS, CAR, MARSS, MAS, MCR, POLDER, TSCC, RAMS. Archiving of ASTEX data at GSFC.

BALTEX (Baltic Sea Experiment)²⁶⁷²⁾

A large regional European campaign program (combined observational and modeling approach) within the framework of WMO/WCRP/GEWEX. BALTEX is planned to extend over a ten-year period: preparatory phase 1992-1993; build-up phase from 1994 - 1996 (pilot studies, models, etc.); and a campaign phase from 1997 to 2001. The BALTEX region includes the entire water drainage basin of the Baltic Sea and covers an area of 2.1×10^6 km², or about 17% of the European continent. The Baltic Sea itself represents an area of 400,000 km². As of 1995 institutions from 10 nations are participating in this interdisciplinary research program (Belarus, Denmark, Estonia, Finland, Germany, Latvia, Lithuania, Poland, Russia, and Sweden). Science objectives:

- To explore and model the various mechanisms determining the space and time variability of energy and water budgets of the BALTEX region and its region's interactions with surrounding regions
- To relate these mechanisms to the large-scale circulation systems in the atmosphere and oceans over the globe
- To develop transport methodologies in order to contribute to basic needs of climate, climate impact, and environmental research.

The BALTEX International Secretariat is at GKSS, Geesthacht, Germany. BALTEX data centers are to be established at DWD in Offenbach, Germany (meteorology data), SMHI in

Norrköping, Sweden (hydrology data), and at FIMR in Helsinki, Finland (oceanography data). The basic program elements are:

- collection of in situ and remote sensing data
- re-analysis of existing data sets
- data assimilation
- numerical experiments and coupled modeling
- process studies, including field experiments

PIDCAP (Pilot Study for Intensive Data Collection and Analysis of Precipitation) is a BALTEX region precipitation pilot study scheduled for August to October 1995. - BALTEX observational data during the campaign phase are from spaceborne (all available sensors), airborne, and ground-based instruments (in particular weather radars).

BALTEX links to other programs: GCIP, MAGS, GAME, LAMBADA, NOPEX, ACSYS, and to the IGBP programs LOICZ and BAHC.

BASE (Beaufort and Arctic Storm Experiment)²⁶⁷³⁾

BASE is a Canadian GEWEX project that was conducted from September 1 through October 15, 1994 in Canada's Western Arctic ($\sim 70^\circ\text{N}$, 130°W). The objectives of BASE are to: 1) better understand and predict the weather in the Beaufort Sea and surrounding areas of the Arctic, and 2) to understand the implications of mesoscale weather systems on the regional climate. Participation: AES/NRC, U. of Toronto, CMC, NCAR, U. of Colorado at Boulder.

Ground-based observations: from automated weather stations (3 m towers) installed at three sites, Inuvik Town, Shell Lake, and Tuk; plus other weather station measurements. X-band Doppler radar equipment was installed at Inuvik. Spaceborne observations from NOAA-11 and -12 S/C (AVHRR, TOVS), airborne observations with CV-580 (NRC) aircraft for the measurement of microphysical and state parameters and dropsonde system. The NCAR C-130 aircraft (MCR, AIMR, etc.) was used to collect a suite of atmospheric state variables, cloud properties, radiation data, and surface imagery.

BATERISTA (Biosphere-Atmosphere Transfer and Ecological Research, In situ studies in Amazonia)

A campaign within the GEWEX umbrella and supporting LAMBADA (in planning phase as of 1995). The focus is on mesoscale/local-scale process studies to provide detailed information to support the formulation and validation of hydroclimatological, biogeochemical and ecological models. A number of selected sites within the Amazon Basin focus on surface-atmosphere exchange measurements and ecophysiological and soil process studies. They will serve also as calibration sites for satellite remote sensing and airborne flux measurements.

BATGE (Biosphere-Atmosphere Trace Gas Exchange in the Tropics)

An IGBP/IGAC program (start in 1992) involving short- and long-term studies of ecosystem and atmospheric processes carried out in areas of active land-use change in both savanna and humid tropical forest regions. Objectives:

- Determine the fluxes of trace gases between tropical biomes and the atmosphere
- Determine the factors that control these fluxes
- Assess the effects of land-use change, including agricultural expansion and forest harvesting, on the exchange of trace gases
- Develop the ability to predict the impact on these fluxes of both climatic and land-use change by describing the exchange of trace gases in terms of ecosystem properties.

BATGE field campaigns include ground-based, airborne and spaceborne observations. One such campaign planned is EXPRESSO (jointly with BIBEX).

BATS (Bermuda Atlantic Time-Series Study)

BATS is part of the IGBP/JGOFS program, an international and interdisciplinary inves-

²⁶⁷³⁾Information source: <http://www.on.doe.ca/BASE/>

tigation of the carbon and nutrient cycles in the upper ocean, with primary NSF funding. The campaign is projected over a 10 year period (1988-1998). The BATS measurements are made near the site of the Ocean Flux Program (31° 50' N, 64° 10' W). The data of BATS are reported to NOAA/NODC.

BIBEX (Biomass Burning Experiment)

An IGBP/IGAC program which commenced in 1990. The goals of the program are to:

- Characterize the production of chemically and radiatively important gases and aerosol species from biomass burning as to effects on the global atmosphere
- Assess the consequences of biomass burning on regional and global atmospheric chemistry and climate.

International subprograms of BIBEX are (see campaign description under the respective heading):

- STARE (Southern Tropical Atlantic Regional Experiment)
 - TRACE A (Transport and Atmospheric Chemistry near the Equator - Atlantic)
 - SAFARI (Southern African Fire-Atmosphere Research Initiative)
 - SA'ARI (SAFARI without Fire)
- FIRESCAN (Fire Research Campaign Asia North)
- SEAFIRE (South-East Asia Fire Experiment)
- FIREScheme (Fire Information Systems Research in the Socio-Culture, History and Ecology of the Mediterranean Environment)

BEERS (Baltic Experiment for ERS-1)

BEERS is a multiyear European program carried out jointly by Sweden, Finland Germany, and Canada [and is also part of PIPOR (Program for International Polar Oceans Research)]. The objectives of BEERS are to:²⁶⁷⁴⁾

- Demonstrate the possibilities of using ERS-1 SAR data for icebreaker services and as input to numerical forecast models
- Evaluate the possibilities to discriminate different ice characteristics, i.e., ice concentration, surface roughness, openings, and stage of development
- Investigate temporal and spatial data of the backscatter signature at C-band and like-polarization of low salinity sea ice.

Four extensive field experiments were conducted during three ice seasons from 1992-94.²⁶⁷⁵⁾ Due to light ice conditions during the winters of 1992 and 1993, icebreakers could be used for ground truth collection (Bay of Bothnia). The BEERS-92 campaign employed the Swedish icebreaker Tor, while BEERS-93 used the Finish icebreaker Atle. The major ice types were fast ice, new ice, nilas, young ice with ridges, and jammed brash barriers.

Winter conditions in 1994 were normal. The BEERS-94 campaign (March) was an operational demonstration with near-real-time SAR images to the icebreaker and a field experiment to investigate ice ridge properties in the ERS-1 images. A further objective was to test two airborne sensors for sea ice mapping: CARABAS (of FAO, Sweden) and AEM (Aero-Electro-Magnetic of Geological Survey of Finland). Ground truth collection concentrated on four different sites (ice types: ice ridge, rubble field, frozen brash, level ice). The measurements included meteorological observations, snow and ice physics parameters (salinity of ice blocks, vertical profiles of ice temperature, density and salinity, and ice thickness), and ice surface roughness.

BOREAS (Boreal Ecosystem-Atmosphere Study) ²⁶⁷⁶⁾

The boreal forest, which extends across the central region of the North American continent, is one of the Earth's large ecosystems. BOREAS was first proposed in 1988; it started in late 1993, reached its peak of activity in 1994; follow-up studies will be conducted for several years (immediate observational phase is planned for the period 1993-96). BOREAS is a large-scale international investigation organized by NASA/GSFC and CCRS of Ottawa. Objective: interdisciplinary study of relationships between northern forests, the atmosphere and those relationships that affect the global climate (exchange of energy, water, carbon dioxide and other trace gases, to understand how the land's vegetated surface couples with the Earth's lower atmosphere to influence weather in the short term and climate in the long term). The study consists of 85 interlinked projects and an international team of more than 300 scientists. BOREAS is an element of ISLSCP, which is now part of WCRP-GEWEX. BOREAS also contributes to three IGBP projects: BAHC, GCTE, and IGAC.²⁶⁷⁷⁾, ²⁶⁷⁸⁾

From late 1993 to 1994 (over a 13 month period) BOREAS data was gathered across a 1000 km x 1000 km region covering most of Saskatchewan and Manitoba, Canada (domain of meteorological and satellite data acquisition and large-scale modeling). Two study areas (of about 10,000 km² each) are embedded within the large-scale domain with a focus of spaceborne and airborne data collection and meso-scale modeling. A major data collection period from February to October 1994 focused on two study sites: one near Prince Albert, Saskatchewan (near the southern, moisture-limited boundary of the boreal forest), the other in Thompson, Manitoba (near the temperature-limited boundary). Canadian involvement is through: Environment Canada, Forest Canada, Agriculture Canada, Natural Resources Canada, the National Research Council, and a number of universities.. US participation is through: NASA, NOAA, NSF, EPA, USGS, USDA, and US universities.

Measurements were from ground-based, airborne and spaceborne sensors. Satellite data were those from POES (AVHRR), ERS-1, GOES, Landsat, SPOT, DMSP (SSM/I) and the SRL-1 and -2 Shuttle SIR-C/X-SAR missions.²⁶⁷⁹⁾ Eleven aircraft - including an Aerocommander (soil moisture detection), C-130 (ASAS, TMS, ATSP, POLDER), Piper Chieftain (CASI), CV-580 (C/X-SAR), DC-8, ER-2 (AVIRIS, MAS), Helicopter (UH-1), LongEZ (B-Flux), Twin Otter (microwave radiometers), Electra, and King Air - were used to collect remote sensing and flux data. Within the study areas, ten towers were erected at specific test sites to measure radiation fluxes, sensible heat, water and carbon dioxide, and some meteorological parameters (e.g., temperature, pressure, humidity, wind speed, etc.) at the boundary layer between the forest canopy and the lower atmosphere. Additionally, about 80 auxiliary and process study sites were established for gathering in situ ground data to complement remote sensing data. Subcampaigns within BOREAS:

- FFC-W (Focused Field Campaign - Winter) was carried out from February 2-18, 1994. Aircraft: Twin Otter (NRC) flying GSFC microwave radiometers; Aerocommander (NOAA) with gamma ray sensors; Chieftain (Canada) with an imaging spectrometer and CASI; ER-2 (NASA/ARC) with MAS
- FFC-T (Thaw) took place from April 11 to May 2, 1994 targeted at studying the forest thaw. The prime interest is in how the sun's energy heats the vegetation, snow, and underlying soil to produce melting and release gases, including carbon dioxide and methane, into the atmosphere
- IFC-1 (Intensive Field Campaign) took place from May 24 to June 16, 1994. Nearly a hundred missions were flown

- IFC-2 was from July 19 to August 10, 1994
- IFC-3 began on August 30 with a completion date of September 19, 1994

The BOREAS Information System (BORIS) is at GSFC for all the BOREAS investigators; BOREAS data will eventually become available to outside researchers.

For 1996 three intensive field campaigns (IFCs) are planned at BOREAS sites. In IFC (Feb./March, 1996) a C-130 will measure snow radiation. A further IFC is planned for July/August, 1996, with C-130 flying ASAS and ER-2 flying MAS and AVIRIS. The fall IFC is planned for ground-based measurements only.

CAFE (Central Australian Fronts Experiment)²⁶⁸⁰⁾

An Australian campaign (BMRC, Monash University, Australian National University, University of Munich, CSIRO) conducted from September 7 to October 4, 1991 with the objective to: a) investigate the structure and behavior of subtropical cold fronts that affect central and northeastern Australia; b) study the interaction of subtropical cold fronts with the developing nocturnal inversion and the generation of propagating borelike or solitary wave disturbances. Observations were made with a ground-based network of stations [radiosonde, automatic weather station (10), microbarograph station (12), 914 GHz wind profiler, upper air station (2)].

CAMAREX (Carbon in the Amazon River Experiment)

CAMEX (Convection and Atmospheric Moisture Experiment)²⁶⁸¹⁾

Airborne campaign conducted at NASA Wallops Flight Facility (WFF) in September/October 1993 (PI: J. R. Wang, GSFC) with the following science objectives:

- Measurements of temperature, water vapor, clouds, precipitation and electrical fields associated with tropical convection
- SSM/T-2 instrument validation and calibration
- Radiometric signatures of clear air and precipitation at high incidence angles
- High resolution vertical and horizontal measurements of the temperature and moisture field as well as top of the atmosphere radiances over WFF
- In-depth study of the low-level vertical temperature and moisture gradients and their relation to anomalous Radar propagation.

NASA ER-2 aircraft with the following sensors: HIS, AMPR, MIR, MTS, EDOP, LIP, and MAMS. Spaceborne observations from NOAA (MSU), DMSP (SSM/T2) and GOES-8. Ground-based observations with Raman lidar, AERI (ground-based HIS), rawinsondes, regional NEXRAD, etc. A **CAMEX-2** campaign was conducted in August 1995 with the same experimental setup as for CAMEX.

CaPE (Convection and Precipitation/Electrification Experiment)^{2682), 2683)}

A US campaign conducted in the central Florida region during the period July 8 through August 18, 1991. CaPE was sponsored by NSF, FAA, NASA, NOAA, and USAF [Participants: NASA (GSFC, WFF, MSFC, LaRC, ARC, HQ, KSC), NCAR, NOAA, AFGL, UCLA, U. of Washington, Colorado State University, U. of Miami, MIT, U. of Oklahoma, Florida State University, U. of North Dakota, U. of Nevada, SUNY at Albany, U. of Alabama, U. of Massachusetts, NSSL, etc.]. The objective of CaPE focused on the following research activities:

- Identification of the relationships among the co-evolving wind, water, and electric fields within the convective clouds

- Determination of the meteorological and electrical conditions in which natural and triggered lightning can (and cannot) occur, and understanding the initiation and propagation of lightning
- Development of mesoscale numerical forecasts (2-12 hour) of wind, clouds, and thunderstorms, employing data assimilation
- Improving techniques for performing short-period forecasts (nowcasts < 2 hours) of convection initiation, downbursts, and tornadoes
- Characterization of precipitation particles and remote estimation of rainfall.

Observational data was collected on three levels: spaceborne, airborne and ground-based. Spaceborne data: GOES-7 (VAS), POES (AVHRR, TOVS), DMSP (OLS, SSM/I), SPOT (HRV), Meteor-2-3. Aircraft: King Air (NCAR), U. of Wyoming (King Air), NASA [ER-2 with sensors: MAMS, AMPR, LIP, HIS, and MTS; Lear Jet (LaRC), T-39 (WFF)], NOAA/AOC (WP-3D with Doppler Radar), South Dakota School of Mines and Technology (T-28). A large ground-based network of stations was operated to measure meteorological parameters. In addition, there were numerous ground-based instruments such as NCAR's Mesonet, radars, upper air instruments (CLASS, rawinsondes, profilers). CaPE data management was coordinated by NCAR.

CAPTEX (Cross-Appalachian Tracer Experiment)

Conducted by SRI International and sponsored by EPA, 1983, with the objective to demonstrate the capabilities of the airborne lidar/FDP technique. CAPTEX was related to long-range transport of air pollutants.

CARIBIC (Civil Aircraft for Remote-Sensing and In-Situ-Measurements in Troposphere and Lower Stratosphere Based on the Instrumentation Container Concept), see P.40.3.

CASP (Canadian Atlantic Storms Program)²⁶⁸⁴⁾

The CASP field project was conducted by AES and other Canadian agencies from January 15 to March 15, 1986 over Atlantic Canada (Nova Scotia, Sable Island and Avalon peninsula Hibernia region) in conjunction with the US GALE campaign. The objective of CASP were to study the processes and mesoscale structure of east coast storms in order to produce models that may lead to better forecasts (description of airflow, temperature, moisture, and precipitation fields, mesoscale phenomena). Airborne and ground-based observations were conducted. Aircraft: Twin Otter of NAE, DC-3 of CCRS, Electra of AES. A ground-based radar network, rawinsondes, radiometers and other instruments were used. Further instruments on the ship RV Gadus Atlantica.

CEAREX (Coordinated Eastern Arctic Experiment 1988-1989)^{2685), 2686)}

An ONR-sponsored campaign carried out in the East Greenland Sea (west of Svalbard) and in the Norwegian Sea from September 1988 to June 1989. This interdisciplinary research program involved 210 scientists and technicians from USA, Canada, Germany, Norway, New Zealand and the UK. The objective was to obtain a better understanding of the structure and function of mesoscale to microscale processes in the Arctic ocean region of Greenland (dynamics and interactions of momentum, heat and biomass exchanges, development of improved sea-ice models). Observation data were collected by satellite, ship, aircraft, helicopter, and ice-floe-based sensors. These ground truth data were also used to calibrate satellite-derived data, in particular with regard to sea ice. CEAREX data are archived and available on CD-ROM at NSIDC, Boulder, CO. CEAREX encompassed the following seven distinct but complementary Arctic field operations:

- Winter drift operation September 4, 1988 to January 10, 1989). Focus on the mechanical behavior of sea ice resulting from drift and floe interactions, ice kinematics, heat

²⁶⁸⁴⁾R. E. Stewart, et al., "Canadian Atlantic Storms Program: The Meteorological Field Project," Bulletin American Meteorological Society, Vol. 68, No. 4, April 1987, pp. 338-345

²⁶⁸⁶⁾M. W. Douglas, et al., "Research Aircraft Observations of a Polar Low at the East Greenland Ice Edge," Monthly Weather Review, Vol. 123, No. 1, 1995, pp. 5-15

flux, under-ice turbulence, upper ocean characterization, passive microwave signatures of sea ice, and ambient noise measurements.

- Whaler's Bay operation (January 14 to February 4, 1989). Estimation of the absolute magnitude of the regional heat flux and the contribution of horizontal and vertical processes to ocean microstructure on the Svalbard shelf. Measurements of hydrogen peroxide production under winter conditions.
- Barents Sea operation (February 6 to March 4, 1989). A dual program for CEAREX and SIZEX. Passive and active microwave signatures of winter sea ice and adjacent waters; investigations of coupled air-ice-ocean processes.
- Greenland Sea Marginal Ice Zone operation (March 11 to April 2, 1989). Continuation of Barents Sea investigations into the Fram Strait and Greenland Sea. Investigation of the East Greenland Current and associated eddy structures, measurement of deep ocean convection in or near the Acoustic Tomography Array.
- Greenland Sea Biological Oceanography operation (April 5 to May 18, 1989). Studies of the influence of ocean eddies on nutrient flux and primary production of the marginal ice zone; relationship between biological and oceanographic processes; nutrient uptake rates and ocean gradients; detailed oceanographic investigation of warm core eddies and local circulation patterns in the upper 200 m of the ocean.
- Oceanographic Ice Camp operation (March 18 to May 1, 1989). Under-ice microscale to mesoscale investigation of oceanographic features; ice tilt and strain studies; under-ice surface mapping; bio-optical measurements in and under sea ice.
- Acoustics Ice Camp operation (March 21 to April 21, 1989). Focus on ambient noise mesoscale processes; mesoscale phenomena and statistics: ULF and VLF noise levels; coherence measured relative to time, space and environmental factors; acoustic back-scattering; seismic refraction and bottom interaction; physical oceanography of internal waves; ice diffusion; bio-acoustics; seawater chemistry.

A continuous remote sensing research program, with sensors positioned on shipboard, ice camps, helicopters and aircraft, was integrated into all seven CEAREX operations [CV-580 aircraft of CCRS with C/X-SAR, NADC P-3 aircraft with P-3/SAR, Royal Norwegian Air Force P-3, NOAA/AOC P-3; ships: Norwegian MV Polarbjorn, RV Hakon Mosby (University of Bergen)].

CEPEX (Central Equatorial Pacific Experiment)²⁶⁸⁷

An NSF-and DOE-funded project (USA) conducted by the Center for Clouds, Chemistry and Climate of the Scripps Institution of Oceanography (SIO), NASA/ARC, and UCAR, with the objective to examine the processes relating to the stability of the tropical sea surface temperature (SST) and its relation to climate variability and tropical to global climate implications (such as El Niño phenomena). The campaign was conducted in 1993 (March 7 to April 7) in the tropical Pacific. The NASA/ARC ER-2 and Aeromet Learjet aircraft (of Aeromet Inc. of Tulsa, OK) were based at Nadi on Fiji for missions flown to the northwest through the northeast of Fiji. The NOAA WP-3D and NCAR Electra were based at Oahu in Hawaii for missions flown near the equator southwest and southeast of Hawaii. The NOAA research vessel, Vickers, obtained surface measurements and vertical profiles from instrumented balloons as it sailed across the equatorial Pacific Ocean. Some ER-2 instruments: MAS, RAMS, CLS (CALS), WOX. Learjet instruments: RAMS, PMS FSSP (P.164) probes, dropsondes, and cameras. WP-3D instruments: Standard parameters (see Table 773), Doppler Radar System (P.153.1). NCAR Electra instruments: see P.151, SSSTR, etc. Specific science objectives: 1) the vertical structure of the water-vapor greenhouse effect, 2) the effect of cirrus clouds on radiation fluxes, 3) the east-west gradients of SST and the accompanying evaporative and sensible heat fluxes from the surface, 4) the east-west gradient of the water-vapor vertical distribution, 5) the microphysical factors contributing to the high albedo of the tropical cirrus layers.

²⁶⁸⁷) Information provided by P. Stephens of NSF, Division of Atmospheric Sciences, Arlington, VA

CHEOPS (CHEmistry of Ozone in the Polar Stratosphere)²⁶⁸⁸⁾

An airborne research program along with three campaigns that started in 1987 on the initiative of German and French scientists with the operations center at ESRANGE near Kiruna, Sweden. The objective was to look for a possible latitudinal difference in the vertical distributions of various minor constituents in the lower and middle stratosphere. CHEOPS-1 took place in February 1987, CHEOPS-2 (four payloads on balloons plus ground-based instruments) during winter 1987/88. The CHEOPS-3 campaign was conducted during winter 1989/90 (participation from France, Germany, Finland, Japan, New Zealand, Norway, Sweden, and USA). Several balloon experiments were launched, including chemiluminescent ozone sensors, NO_y, aerosol counters, and ion mass spectrometers; ground-based instruments were operated at Kiruna/Sweden, Ny Alesund, Spitzbergen/Norway, and Sondre Stromfjord/Greenland.

CINDE (Convection Initiation and Downburst Experiment)²⁶⁸⁹⁾

A US campaign (NCAR, NOAA, MIT Lincoln Lab, U. of Wyoming, U. of North Dakota, etc., with funding provide by NSF, NOAA and FAA) conducted in the Denver, Colorado area (85 km x 85 km) from June 22 to August 7, 1987. Objectives: Study of the kinematic and thermodynamic structure of the planetary boundary layer, emphasizing those processes that influence the development of convective storms, including terrain effects, and investigating the forcing and initiation of intense downdrafts known as microbursts. Ground observations with 6 Doppler radars, 87 Mesonet stations [46 PAM II (Portable Automated Mesonet) weather stations. Sounding systems: CLASS (Cross-chain LORAN Atmospheric Sounding System), three mobile sounding systems; three radars (NOAA X-band Doppler radars and NCAR C-band Doppler radar); wind profiler network]. Airborne observations: two Beechcraft King Air (NCAR and U. of Wyoming), Cessna Citation (U. of North Dakota). Satellite data from GOES-6.

CITE (Chemical Instrumentation Test and Evaluation), see GTE/CITE

CIVEX (Cloud Instruments Validation Experiment)²⁶⁹⁰⁾

A DLR campaign (participants: MPIfM/University of Hamburg, Free University of Berlin) conducted by the Institute of Atmospheric Physics from May 8 to May 19, 1995 in southern Bavaria, Germany. The major goal is to collect airborne measurements to further development of remote sensing techniques (retrieval of cloud top height, atmospheric water vapor, cloud microphysical parameters, and cloud radiative properties). Airborne observations with the Falcon 20 of DLR with the following instruments: OVID (high-resolution multi-channel spectral analyzer), H₂O-DIAL, PMS probes (FSSP-100, OAP-230X), Eppley Pyranometers, CHOPPY (Chopped Pyrgeometer). Ground-based measurements: standard meteorological surface data and regular radiosonde ascents at Munich and Stuttgart (from DWD). Spaceborne data reception of NOAA (AVHRR), METEOSAT (PDUS data), ERS-1 and ERS-2 (ATSR).

CLEOPATRA (Cloud Experiment Oberpfaffenhofen and Transports)²⁶⁹¹⁾

CLEOPATRA is a regional cloud system cooperative campaign (contribution to GEWEX/IGBP) that was conducted during the growing season (May 11 to July 31, 1992) in Southern Germany (50 km north of the Alps) by DLR, University of Frankfurt, University of Munich, University of Mainz, Technical University of Braunschweig, and IRE of Moscow. The objective of the campaign was to quantify elements of the hydrological cycle on a regional scale as a function of precipitation events and the vegetation state. Additional goals were to describe the mechanisms that force deep convective cloud systems, to compare theories and observations, and to compare observational data from ground, airborne and spaceborne

instruments. The following aircraft and instruments were used:

Falcon (DLR) with standard meteorological equipment, H₂O-DIAL, AADS1268 (Daedalus) scanner, in-situ ozone probe, and a humidity measurement device; Piper Chieftain (University of Frankfurt) equipped with standard meteorological sensors, cloud physics sensors, cloud water sampling device, aerosol sampling, particle and trace gas sampling; DO228 (DLR) equipped with standard meteorological sensors, trace gas sampling devices, and IRE microwave radiometers for upward and downward measurements; DO228 (DLR) with E-SAR²⁶⁹²; DO128 (Technical University of Braunschweig) equipped with standard meteorological sensors; Cessna 207 (DLR) was used for profiling for altitudes; three powered gliders (DLR) with standard meteorological sensors; Ilushin-18 (IRE) with some PRIRODA instruments.

Four ground-based radar systems were employed: a C-band polarization Doppler radar (POLDIRAD) of DLR; a C-band Doppler radar at Hohenpeissenberg (Deutscher Wetterdienst); a vertical-looking 1.23 GHz FM-CW Doppler radar (University of Hamburg).

A ground observational network was employed. In addition data was used from the following satellites: Meteosat, NOAA-11, Landsat-5, MOS-1, Olympus, Kopernikus, and Almaz.

CLIVAR (Climate Variability and Predictability)²⁶⁹³

A major WCRP initiative decided on at the 14th JSC (Joint Scientific Committee) of WCRP in 1993. The focus is on the variability of the “slow” climate system - the oceans, ice and snow masses, and land surface characteristics. It is a natural complement to GEWEX, which deals with the rapid fluxes of energy and water through the turbulent circulation of the atmosphere. CLIVAR is a 15-year research program (1995-2010) exploiting the results of TOGA by promoting studies of the dynamics of the global tropics - atmosphere, ocean and land. The overall objectives of CLIVAR are:

- To describe and understand the physical processes responsible for climate variability on seasonal, interannual, decadal, and centennial time-scales, through the collection and analysis of observations and the development and application of models of the coupled climate system, in cooperation with other relevant climate-research and observing programs.
- To extend the record of climate variability over the time scales of interest through the assembly of quality-controlled paleoclimatic and instrument data sets
- To extend the range and accuracy of seasonal to interannual predictions through the development of global coupled predictive models
- To understand and predict the response of the climate system to increases of radiatively active gases and aerosols and to compare these predictions to the observed climate record in order to detect anthropogenic modification of the natural climate signal.

The CLIVAR program is initially organized into three component programs: CLIVAR-GOALS, CLIVAR-DecCen, and CLIVAR-ACC. CLIVAR seeks cooperation with other national and international climate research programs, especially with the WCRP programs GEWEX, WOCE, ACSYS, and SPARC, and IGBP programs PAGES, JGOFS, and GAIM.

CLIVAR-GOALS (CLIVAR - Global Ocean-Atmosphere-Land System)

A WCRP (and major US) program of the meteorological and oceanographic community. The GOALS plan calls for a 15-year (1995-2010) research program that builds on TOGA. The overall goals are an expansion of observational, modeling, and process research to include the possible influences of the global upper oceans and time-varying land moisture, vegetation, snow and sea ice (addressing the variability and predictability of the coupled climate system). The scientific objectives are:

- To maintain the TOGA Observing System in the tropical Pacific and further develop the predictive skill for SST and concomitant climate variables in the Pacific

²⁶⁹²) C. Schmullius, J. Nithack, “Crop Monitoring with Multi-temporal Airborne DLR E-SAR Images,” IGARSS’95, Vol. I, pp. 719-721

²⁶⁹³) “CLIVAR, A study of climate variability and predictability,” Science Plan, WCRP-89, WMO/TD No. 690, 8/1995

- To expand the study of seasonal-to-interannual climate variability around the entire global tropics
- To study the interaction of monsoons with ENSO with a view towards improving the predictability of both phenomena
- To study the interaction between the tropics and extratropics with the intention of understanding variability, predictability and developing predictive skills for extratropical regions
- To study the existence of seasonal-to-interannual climate variability and predictability induced by ocean, land surface, or sea-ice processes in the extratropics.

CLIVAR-DecCen (CLIVAR - Decadal-to-Centennial time-scales)

The goals of this program are to examine the mechanisms of variability and to predict climate fluctuations on decadal-to-centennial time-scales by:

- Describing and understanding the patterns of global decadal-to-centennial climate variability in the instrument, paleoclimatic, and model records to the extent possible
- Extending the records of climate variability by concerted efforts of data recovery, re-analysis of existing atmospheric and oceanic data, finding new paleoclimatic indices, and instituting new oceanographic monitoring sites
- Developing, as necessary, appropriate observing, computing, and data archiving and dissemination systems needed to describe, understand, and predict global decadal variability.

It is expected that much decadal-to-centennial climate variability arises from the oceans. Hence, special efforts will be devoted to identifying these specific processes and regions responsible, in order to understand the mechanisms by which the ocean and atmosphere interact to produce this variability.

CLIVAR-ACC (CLIVAR - Anthropogenic Climate Change)

The program examines the nature of anthropogenic climate change in primarily a modeling context by:

- Simulating the response of the climate system to the anthropogenic increases in radiatively active gases and aerosols using state-of-the-art coupled atmosphere-ocean-land-cryosphere models
- Identifying the patterns of anthropogenic modification to the mean state and to the variability of the climate system
- Using these identifications for interpreting natural climate variability and for detecting the trends associated with greenhouse warming and the effects of anthropogenic aerosols.

COAST (Coastal Oxidant Assessment for Southeast Texas)

An ozone study of the US-EPA Las Vegas laboratory, supported by the Texas Natural Resources Conservation Commission. The UV-DIAL (NOAL as of mid-1994) instrument was installed in a CASA aircraft for flights over the Houston and Beaumont areas during July-August 1993. In 19 flights, about 70 hours of data were acquired. The ozone concentration profiles were taken over a variety of conditions including low and high ozone concentrations.

CODE (Coastal Ocean Dynamics Experiment)²⁶⁹⁴

Two US cooperative campaigns (CODE-1 and CODE-2), each of four months in length, conducted in 1981 and 1982, respectively, on the California continental shelf north of San Francisco and extending to Point Arena (participants: WHOI, USGS, NSF/NCAR, USCG). Objective: study of physical oceanographic variables for kinematic and dynamic descriptions of the response of continental shelf waters to wind forcing. The major observational elements of CODE were: 1) moored arrays instrumented to measure wind velocity,

²⁶⁹⁴)Special Section: Coastal Ocean Dynamics Experiment (CODE), Journal of Geophysical Research, Vol. 92, No. C2, February 15, 1987, pp. 1455 - 1851

air temperature, solar radiation, current velocity, water temperature, conductivity, and bottom pressure; 2) shipboard observations of water temperature, conductivity, current, velocity; 3) aircraft observations of wind velocity, wind stress, temperature, humidity, and sea surface temperature. In addition, surface drifters were tracked. Satellite data from CZCS of Nimbus-7 and AVHRR of NOAA-7.

COHMEX (Cooperative Huntsville Meteorological Experiment)
(aircraft campaign in 1986)

COPE (Coastal Ocean Probing Experiment)²⁶⁹⁵⁾

A multiagency campaign (of SCOPE heritage), led by NOAA's Environmental Technology Laboratory, Boulder, CO, from September 8 through October 7, 1995 at a site off the northern coast of Oregon between Tilamook Head and the mouth of the Columbia River. Other participants: SIO, WHOI, NRL, U. of Washington, U. of Colorado, IOS, APL, NPS, etc. Both campaigns (COPE and SCOPE) are part of ASAP (Advanced Sensors Application Program), an initiative of the US Navy. The overall objective is to develop optimal remote sensing methods for the retrieval of ocean surface strains and fluxes under varying environmental conditions. Observation of mesoscale processes to obtain data on oceansurface winds, currents, fluxes, stability, and ocean stratification in the area of the experiment. Shore-site X-band and Ka-band radars and lidars are employed to study the spatial distribution of backscatter: a) the cross-correlation coefficient of H and V polarized reflectivities, b) the ratio of the H and V polarized reflectivities, c) higher order Doppler spectral moments, d) the normalized variance ratio of the two polarizations.

Parallel measurements from FLIP (Floating Instrument Platform), a research vessel of Scripps Institute, with a variety of instruments (scatterometers, glint sensor, sonar, microstructure-current package, wave spectra package, laser wave spectra, surface radiometer, scanning radiometer, flux package, etc.). RV Snowgoose (U. of Washington). Airborne measurements (NASA DC-8, NOAA Twin Otter, Cessna 177) with a lidar, microwave radiometers and IR instruments. Beach-site measurements: CODAR (Coastal Ocean Dynamic Application Radar), Rawinsondes, Wind Profiler, Sodar, Mailbox (microwave radiometer) - all instruments of NOAA/ERL/ETL. Spaceborne data collection.

COPS-91 (Cooperative Oklahoma Profiler Studies-1991)²⁶⁹⁶⁾

A US interagency campaign (NOAA, NCAR, NASA) conducted in a region that includes Oklahoma, the Texas Panhandle, and southwest Kansas. Objective: study of the structure and evolution of the dryline meteorological environment, which is recognized as a major factor in the initiation of severe thunderstorms in the central and southern plains of the United States during the spring season. Observations (airborne and ground-based) were carried out from April 26 through May 30, 1991. The NOAA P-3 aircraft was equipped with a large array of in situ sensors, TDR (Tail-mounted Doppler Radar, X-band) and LFR (Lower Fuselage Radar, C-band). Ground-based observations by two NSSL mobile laboratories equipped with CLASS, continuously recording surface data systems, PAM-II (Portable Automated Mesonet) stations of NCAR, a Profiler Demonstration Network of NOAA/ERL, and S-band Doppler radars.

CRISTA/MAHRSI Campaigns. CRISTA (Cryogenic Infrared Spectrometer and Telescopes for the Atmosphere) and MAHRSI (Middle Atmospheric High Resolution Spectrograph Investigation) are two experiments that were flown twice on the ASTRO-SPAS free-flyer platform (J.1), deployed by Shuttle flights STS-66 (Nov. 3-14, 1994) and on STS-85 (Aug. 7-19, 1997). Both of these Shuttle flights were accompanied by parallel "ground campaigns" with the objective to validate/correlate the temperature and ozone measurements of the on-board instruments with those of ground-based stations, balloons, rockets, aircraft, and satellites.

²⁶⁹⁵⁾ "Coastal Ocean Probe (COPE) Experimental Plan," prepared by NOAA/ERL/ETL, May 1995

1) CRISTA/MAHRSI Campaign-1

- Rocket campaigns: ²⁶⁹⁷⁾ A campaign was conducted by NASA and the University of Wuppertal from WFF (Wallops Flight Facility, 37.5°N, 75.3°W). Meteorological rockets were launched (twice a day) furnished with a data sonde and a falling sphere to measure temperature, density and winds in the altitude range of 20 to 90 km. Others rocket campaigns were conducted by CAO (Moscow) from Volgograd (48°N, 44°E), Thumba (8.5°N, 76.9°E) and Moledozhnaya (68° S, 46° E), measuring temperature, density and winds in the 20-80 km range with M100B instruments. The Physics Research Laboratory of Ahmedabad (India) conducted rocket campaigns at Trivandrum (8.3°N, 76.6°E) and Balasore (21.5°N, 87°E) measuring temperature, density and winds in the range of 20-70 km with RH-200 instruments.
- Balloon experiments: Conducted by NASA and the University of Wuppertal from WFF. A radiosonde measured temperature, density and winds up to altitudes of 30 km. CNRS (France) conducted a balloon campaign from Aire sur l'Adour (44°N, 0°E) measuring O₃, NO₂, H₂O, and aerosol in the 10-30 km range with an optical sonde. DWD (Deutsche Wetterdienst) launched balloons from Hohenpeissenberg (48°N, 12°E) measuring ozone with the Brewer-Mast technique. CAO (Moscow) launched balloons from Molodezhnaya (68° S, 46° E), Kiev (50.3°N, 30.3°E) to measure ozone with ECC-5 instruments. Kazan University launched balloons from Kazan (56°N, 49°E) to measure temperature, density and winds up to 25 km. The University of Kyoto launched balloons at Jakarta (6°N, 107°E) and at Shigaraki (35°N, 136°E) to measure temperature, density with a radiosonde.
- Ground-based experiments: Over 30 institutes around the globe conducted measurements with their instruments from the ground observing various atmospheric parameters or constituents. The instrument types used were: Michelson and Fabry-Perot interferometers, lidars, spectrometers, radiometers, airglow photometers, wind radars, microwave instruments, etc.

2) CRISTA/MAHRSI Campaign-2.

Throughout the campaign there were a total of 49 sounding rocket launches, 74 balloon launches, and 49 ground stations monitoring CRISTA-MAHRSI overflights with their ground instruments. The ASTRO-SPAS platform was oriented in such a way to permit measurements from the platform and from the ground campaign instruments in the same volume (referred to as “zero miss distance”).

- Aircraft observations: Several underflights over central Europe were conducted by the DLR Falcon research aircraft, using THOMAS (THz OH Measurement Airborne Sounder), a FIR heterodyne spectrometer, for OH and H₂O measurements in the stratosphere and mesosphere. In parallel, in situ measurements with a Lyman Alpha hygrometer were obtained. ²⁶⁹⁸⁾
- Satellite observations: GOME instrument measurements from ERS-2 were taken from common areas of coverage. Simultaneous measurements with WINDII (observation of winds, airglow, and O) on UARS were taken with CRISTA in the mesosphere and lower thermosphere. Comparative measurements of HALOE, MLS and SOLSTICE (all of UARS) were conducted.
- Observations from Shuttle: The GLO (Arizona Airglow Experiment) instrument on STS-85 performed joint observations with CRISTA, searching for lightning-induced effects (sprites) in the middle atmosphere.
- Ground observations: at North-American cluster (at NASA/GSFC/WFF), also campaign HQ; at Scandinavian cluster (Kiruna, Sweden, Andenes and Tromsø, Norway, Juliusruh and Kühlungsborn, Germany); and at Russian/CIS cluster:

²⁶⁹⁸⁾ G. Lehmacher, D. Offermann, “CRISTA/MAHRSI Campaign-2, Handbook,” University of Wuppertal, Germany, June 1997

- Balloon soundings near Moscow and Kiev, Ukraine (temperature pressure wind up to 30 -35 km)
- Ground-based observations from about 50 stations in Russia and CIS (organized by CAO)

A global network of 33 ground stations conducted experiments in conjunction with ASTR-SPAS.

- Rocket campaign observations: A coordinated rocket campaign from WFF was conducted by USAF/PL and USU for ASTRO-SPAS overflights. The rocket payloads carried the following experiments: ATOX (resonance fluorescence observations), IR radiometers (OH emissions at 1350 nm and O₂ at 1270 nm), photometers (O₂ A-band at 762 nm, background at 700 nm, NO resonance fluorescence at 216 nm), Lyman-Alpha cell (Lyman-Alpha radiation), RF and DC probes (electron density structure), Meteorological falling spheres (radar tracking). Other rocket flights were from White Sands, NM (O₃, O₂, temperature, winds); Andenes, Norway: falling spheres (temperature, winds); Volgograd, Russia (temperature, winds, O₃).
- Balloon experiments (all equipped with radio sondes or ozone sondes) were conducted, from: WFF (VA, USA), Hohenpeissenberg (Germany), Marambio (Antarctica), Keflavik (Iceland), Izana and El Arenosillo (Spain), Reunion (France), Bandung (West Java, Indonesia), Moscow and Yakutsk (Russia, CIS).

CRYSYS (Use of the Cryospheric System to Monitor Global Change in Canada)²⁶⁹⁹

A Canadian long-term program initiated by scientists in 1988 and sponsored since 1993 by AES of Environment Canada (PI: B. Goodison) as an interdisciplinary science investigation in the context of the NASA EOS program. The objectives are to: 1) develop capabilities for monitoring and understanding the variations in cryospheric variables across a range of scales, 2) develop and validate local, regional, and global models of climate/cryospheric processes and dynamics to improve understanding of the role of the cryosphere in the climate system, and 3) to assemble, maintain, and analyze key historical, operational, and research cryospheric data sets to support monitoring and model development.

CRYSYS investigators use in-situ, airborne, and satellite data with a focus in five thematic areas: glaciers and ice caps, sea ice, lake ice, snow and permafrost. Collection of microwave satellite data from DMSP (SSM/I), ERS-1/2 (AMI), Radarsat (SAR), etc. for the development of algorithms for future sensors. Participants: AES, U. of Alaska, U. of Quebec, U. of Waterloo, U. of Sherbrooke, U. of Manitoba, McGill University, Environment Canada (Ice Center), CCRS, National Hydrology Research Institute (Saskatoon), Geological Survey of Canada, U. of Toronto, U. of Ottawa, Carleton University, McMaster University. A major campaign program in support of CRYSYS is **SIMMS**. CRYSYS contributes also to GEWEX programs like ACSYS and ARCSS.

DAISEX (Digital Airborne Imaging Spectrometer Experiment). ESA campaign in 1999.

DEBITS (Deposition of Biogeochemically Important Trace Species)

An IGBP/IGAC program which started in 1990. The long-term goal of DEBITS is the study of dry and wet deposition for atmospheric chemistry in tropical regions. DEBITS involves experiments of a range of species containing N, S, P and C, major sea-salt components, as well as species of special interest such as organic acids, organic nitrogen compounds, O₃, and H₂O₂.

DECAFE (Dynamics and Chemistry of the Atmosphere in Equatorial Forest)²⁷⁰⁰

A French program sponsored by CNRS which started in 1986. Three long-term research projects on ozone survey, precipitation chemistry, and methane sources and sinks in tropical Africa were initiated. In February 1988 a first experiment 'DECAFE88,' was conducted by French, German and Congolese scientists in the equatorial forest of the Congo river ba-

²⁶⁹⁹) Internet homepage URL: <http://www.on.doe.ca/CRYSYS/>

sin to investigate the influence of biomass burning on the region's atmospheric chemistry, and to characterize and quantify trace gas and aerosol sources. The 'FOS/DECAFE' (Fire of Savannas) campaign was carried out in Lamto (Ivory Coast) in January 1988. This experiment was followed by participation of DEFACE in the STARE/SAFARI experiment in September 1992 in South Africa.

DEGASP (Dye 3 Gas and Aerosol Sampling Program)²⁷⁰¹⁾

DEGASP is an international project within IGBP/IGAC (participants: USA, Canada, Europe) that was conducted from August 1988 to August 1989 with the objective to address processes influencing trace chemical constituents in the Greenland ice sheet. Samples of fresh snow were obtained from nearly all precipitation events at the Dye 3 site, and aerosol sampling was conducted at frequent intervals.

DYCOMS (Dynamics and Chemistry of Marine Stratocumulus Experiment)²⁷⁰²⁾

A US campaign (NCAR, Colorado State University, Drexel University, University of Rhode Island) conducted during the summer of 1985 over the eastern Pacific Ocean using the NCAR Electra aircraft. The objectives were to a) study the budgets of several trace reactive species in a relatively pristine, steady-state, horizontally homogeneous, well-mixed boundary layer capped by a strong inversion and b) study the formation, maintenance and dissipation of marine stratocumulus clouds that persist off the California coast (as well as in similar regions elsewhere) in summer. The Electra instruments measured air velocity components, air temperature, surface radiation temperature (PRT-5 radiometer), mean humidity, humidity fluctuations (Lyman- α hygrometer), liquid water (PMS), upward and downward radiation in UV, VIS and NIR, aerosol spectra, and cloud droplet spectra (FSSP), in addition to chemical measurements of trace gases.

EASOE (European Arctic Stratospheric Ozone Experiment)²⁷⁰³⁾

European-initiated campaigns coordinated by CEC and organized by EORCU (European Ozone Research Coordinating Unit, British Antarctic Survey, PI: J. A. Pyle, Cambridge, UK) and financed by the national funding agencies of the European Community. The objective was the measurement of ozone depletion in the arctic stratosphere (transport around the polar vortex), along with a study of trace gases, polar stratospheric clouds, dehydration of the arctic stratosphere, etc. EASOE-1 took place between November 1991 and March 1992 (over 200 scientists participated) at sites in Greenland, Iceland, Norway, Sweden, Finland, Russia - as well as in mid-latitude European countries. The participating countries in EASOE were: Belgium, Denmark, Finland, France, Germany, Greece, Iceland, Italy, Japan, Norway, Russia, Spain, Sweden, Switzerland, UK, and USA. EASOE measurements were made from 16 ground-based instruments, from three research aircraft [ARAT of IGN, Falcon (SUMAS, etc.) of DLR, Transall of Aerodata], from 43 stratospheric balloons launched in Northern Sweden (MIPAS-B) and from ozonesondes at 22 European sites. In addition, ground-based data from the total ozone monitoring network and from satellites (TOMS, TOVS) were available in near-real-time. These were complemented by meteorological data from ECMWF (European Center for Medium-Range Weather Forecast) and the UK Meteorological Office.

Several UV/VIS spectrometers measured the column amounts of O₃, NO₂, and in some cases OCIO, as well as aerosols and PSC extinction. Measurements with infrared instruments (5) gave information on: HCl, HNO₃, ClONO₂, and many source gases. Six lidars were operated, mainly giving information on scatterers in the lower stratosphere.

ECLIPS (Experimental Cloud Lidar Pilot Study)²⁷⁰⁴⁾

An international research program in support of ISCCP (International Satellite Cloud Climatology Project). ECLIPS uses intensive periods of lidar and ancillary measurements to categorize all clouds (low, middle, and high) present during NOAA POES overpasses. The main objective is to provide 'ground truth' (air truth) data on cloud properties (heights and coverage) for validation of cloud properties inferred from satellite radiance observations (AVHRR and HIRS). An additional objective was to provide detailed statistics on temporal variations of cloud base altitude. Two observational phases have taken place, in October-December 1989 (Phase I) and April-July 1991 (Phase II), with intensive 30-day periods being selected within two time intervals. The ECLIPS data are archived at NASA/LaRC. There is cooperation with the FIRE program. - The observational concept of ECLIPS involved the participation of numerous institutions with NOAA receiving stations around the globe, who conducted in parallel lidar (or other instruments) observations of cloud heights and properties during NOAA POES overpasses. Participants: CSIRO, Morialloc, Australia; York University, Canada; NASA/LaRC; CNR/IROE, Florence; NOAA/ETL, Boulder; CNRS/LMD, Palaiseau, France; Bureau of Meteorology, Melbourne, Australia; Georgia Institute of Technology, Atlanta, Georgia; Fraunhofer Institut (FhG/IFU), Garmisch-Partenkirchen, Germany; Lab. of Physics and Climate, Obninsk, Russia; Institute of Electronics, Sofia, Bulgaria; Institute of Atmospheric Physics, Beijing, China; U. of Utah, Salt Lake City, Utah; Institute of Atmospheric Optics, Tomsk, Russia; JMA, Yatabe, Japan; GKSS, Geesthacht, Germany; Institut für Troposphärenforschung, Leipzig, Germany; Macquarie University, Sidney, Australia.

EFEDA (European Field Experiment in Desertification-threatened Areas)²⁷⁰⁵⁾

A campaign conducted in central Spain in June 1991, sponsored by CEC and national agencies of the participating institutes. The EFEDA campaign built on the experiences of HAPEX-MOBILHY, LOTREX and HAPEX-Sahel (contributing to IGBP/BAHC). EFEDA is regarded a pilot study aimed at understanding the processes, including the impact of mankind, that may lead to land degradation and desertification. Specific objectives were:

- Experimental observation and modeling of area averages of available energy, and sensible and latent heat fluxes between the surface and the atmosphere
- Determination of the role of vegetation in these processes under relatively dry conditions
- Investigation of the changes in surface fluxes as land-use changes from one area to the other, and as weather changes from wet to dry conditions
- Testing and validation of algorithms to deduce relevant information from aircraft and satellite remote sensing data.

Observations were conducted at three sites in a southeastern direction from Madrid in a total study area of about 100 km x 100 km (central plateau of Spain, called the Meseta). Ground-based measurements were conducted with many micrometeorological stations and other instrumentation including mobile sensors and Doppler soundings. Airborne observations with Falcon 20 (H₂O-DIAL, turbulent fluxes, radiation up and down, meteorological parameters), DO-128 (meteorological parameters, fluxes, radiometric temperature), DC-8 (AIRSAR) and ER-2 (TMS, AVIRIS). Satellite data (Landsat-TM, NOAA-AVHRR, METEOSAT) were used to determine the albedo of the surface, the diurnal change in surface temperature and their variation during the growing season. Participants (about 150 scientists in 30 teams): DLR (Oberpfaffenhofen), CNRM (Toulouse), NASA/GSFC/ARC/JPL/HQ, INRA (France), INM (Spain), U. of Valencia, U. of Madrid, U. of Castilla-La Mancha (all Spain), Free U. of Berlin, U. of Paderborn, U. of Hannover, U. of Karlsruhe (all Germany), U. of Wageningen, U. of Amsterdam, (all Netherlands), U.

EISAC (European Imaging Spectroscopy Airborne Campaign)²⁷⁰⁶

An ESA/JRC-initiated campaign in May/June 1989 with participation from European national agencies and universities. Objective: evaluation of airborne imaging spectroscopy comprising a wide range of applications in agriculture, forestry, geology/soil science and oceanography/marine biology. Airborne data were acquired by the following instruments: FLI/PMI, GER-63, Zeiss camera RMK 15/23, and CASI (1990). Seven European test sites were chosen:

- Skagerrak (Norway) - chlorophyll distribution and pollution of coastal waters
- North Sea, Waddensea, Helgoland (Germany) - coastal ecology, monitoring sea water quality and algae blooms
- Northern Adria, Venice Lagoon, Sacca di Goro (Italy) - monitoring coastal ecology and sea water quality
- Upper Rhine Valley (Germany) - forestry and agriculture
- Somerset Levels (UK) - agriculture
- Almaden (Spain) - soil science, vegetation
- Ardeche (France) - soil science, land use

ELAC (European Lidar Airborne Campaign)²⁷⁰⁷

An ESA-initiated program with the objective to demonstrate the usefulness of a future spaceborne backscatter lidar, and to provide an input to the design of ATLID (Atmospheric Lidar) - a candidate instrument for the ENVISAT-2 mission. The campaign ELAC-90 was centered on cloud investigations (properties, statistics, and the synergism of active and passive spaceborne sensors). The instrumentation comprised the airborne backscatter lidars ALEX (DLR, on Falcon aircraft) and LEANDRE (CNES/CNRS, on Fokker F27 aircraft). Nine flights were carried out in October/November 1990 at the following sites: Irish Sea, Southern France, and Oberpfaffenhofen, Germany. In this context, a second campaign, referred to as **ELITE** (European LITE), was conducted during STS-64 (September 9-20, 1994), there were airborne underflights in support of the LITE payload on-board of Shuttle.

ELITE (European LITE Campaign), see under **LITE**

EMAC (European Multi-Sensor Airborne Campaign)

EMAC-94/95 is a collaborative ESA/JRC program (E. Attema, ESA/ESTEC) with the primary objective to provide user preparation support for future satellite missions, such as ENVISAT-1. The EMAC 1994 campaign utilized two SAR instruments (E-SAR and EMISAR) and the ROSIS imaging spectrometer. E-SAR flights within EMAC took place from April through September 1994 on the DLR Falcon aircraft (sites: Oberpfaffenhofen (7), Weilheim, Germany (1), Fontainebleau, France (4), Zwalm Catchment, Netherlands (3). Prior to the campaign, calibration flights of E-SAR and EMISAR took place in December 1993 (Oberpfaffenhofen site). The ROSIS calibration campaign took place near Marseille, France.

The following thematic groups were established for EMAC-94/95:²⁷⁰⁸

Earth's surface and the atmosphere. Test area is northwest of Uppsala, Sweden. Instruments: EMISAR in '94 and '95 supplemented with ERS-1 SAR data and passive microwave data (EMIRAD of TUD in 1995).

- **Agriculture and Forestry Study**; CI: W. Mauser, University of Munich. There is one agricultural test site at Oberpfaffenhofen (Germany) and a forestry site at Fontainebleau (France). Collection of multitemporal SAR data for agricultural applications (correlations with SIR-C/X-SAR data on 1994 Shuttle missions). Acquisition of imaging spectrometer data is included (ROSIS).
- **Vegetation and Soils Study**, CI: J. Hervas of JRC, Ispra. The test site is Zwalm Catchment (Belgium). For 1994 multitemporal E-SAR and ROSIS flights were conducted. There were coordinated experiments for soil moisture, forestry and modeling of land targets.
- **Ocean, Coastal and Inland Waters Study**, CIs: F. Montagner, ACRI, France, and A. Dekker, Vrije Universiteit Amsterdam). Test sites are at Ostende, Humber, Noordwijk and Dutch Lakes (all in the southern North Sea) and Skagerrak and Kattegat (western Baltic Sea). Objectives: Characterization of water quality parameters in coastal and open sea waters, and inland lakes. Some of these parameters are: ocean biomass and phytoplankton concentrations, dissolved organic carbon, suspended minerals, sediment transport, coastal morphology and erosion. The main instrument is ROSIS (hyperspectral imager); some measurements were made with E-SAR.
- **MACSI** (Microwave Airborne Campaign over Snow and Ice); CI: M. Hallikainen, Helsinki University of Technology). Campaign in March/April 1995. The goals of MACSI are to provide a) active and passive microwave data sets with extensive ground truth, b) modelling, and c) geophysical retrieval algorithms for the following applications:²⁷⁰⁹⁾
 - Snow (water equivalent, extent, water content)
 - Sea ice (concentration, ice type discrimination)

The effects of weather conditions and forest canopies were also investigated. The campaign site was northern Finland (Okstindan). Campaign participation: HUTRAD (radiometers at 6.6, 10.65, 18.7, 23.8 35, 93 and 94 GHz), UKMO (MARSS, Deimos), DLR (E-SAR) and TUD (EMISAR).²⁷¹²⁾

EMEX (Equatorial Mesoscale Experiment)²⁷¹³⁾

A cooperative campaign (NOAA, NCAR, NASA, CSIRO, U. of Washington, Penn State University, MIT, Colorado State University, Australian Bureau of Meteorology, etc.) conducted over the tropical oceanic region north of Australia in January-February 1987 during the southern hemisphere summer. Parallel campaigns of EMEX with AMEX and STEP. Objectives:

- To document the vertical profile of vertical velocity and other kinematic structures of mesoscale tropical convective cloud systems over the ocean near the equator with the most up-to-date instrumentation available
- To investigate the physical mechanisms responsible for the convective and stratiform components of the observed cloud systems.

Aircraft platforms: NOAA WP-3D with Doppler Radar System, Electra (NCAR), F27 (CSIRO), ER-2 of STEP program (NASA/ARC). A shipborne platform was the R/V Xiang Yang Hong (China) equipped with a NOAA C-band Doppler weather radar.

EPOCS (Equatorial Pacific Ocean Climate Studies)

ERICA (Experiment on Rapidly Intensifying Cyclones over the Atlantic)²⁷¹⁴

A US/Canadian program conducted under the Office of Naval Research (ONR). The field phase of ERICA began December 1, 1988 and ended February 26, 1989. Objective: determine the physical mechanisms and processes which lead to explosive wintertime storms developing over the Atlantic Ocean, with the focus on east coast winter storms. ERICA is a follow-up program to the GALE campaign conducted in the winter of 1986. Other contributors to ERICA include: US Navy and Air Force, NOAA/NWS, NOAA/NESDIS, NOAA/ERL, DOE, NSF/NCAR, AES (Atmospheric Environment Service) of Toronto, Canada, and universities and research organizations in the US and Canada.

Observation region: Northeastern USA, Southeastern Canada, and the Northwestern Atlantic (west of 50° W). Airborne campaigns (Air Force, Navy, NOAA, NCAR) in coordination with satellite observations (GOES-6, GOES-7, NOAA-10, and -11, DMSP-F8 and F9, and GEOSAT) and a meteorological buoy network (WHOI). Drexel University (Philadelphia) is the central archive and distribution center for ERICA data.

EUCREX'94 (European Cloud Radiation Experiment)²⁷¹⁵

A European campaign involving a multi-aircraft measurement program with the aim to study the dynamic, radiation and microphysical properties of cirrus clouds and model improvement, with specific cirrus objectives similar to those of FIRE-II, namely:

- To quantify the capabilities and limitations of various cirrus cloud retrieval techniques applied to satellite data
- To relate the microphysical and radiative properties of cirrus clouds with special emphasis on issues related to spatial averaging of inhomogeneous fields
- To test the capabilities of hybrid approaches based on a combination of passive and active remote sensing techniques to describe cirrus clouds
- To test the capability of multiangular observations of the degree of polarization of the reflected light to derive useful information of the structure and properties of cirrus clouds
- To validate new classification techniques designed for geostationary images (VISIR) to allow observations of the cirrus life cycle.

Participants from France: CNRS/LOA (University of Lille, coordination of campaign), CNRS/LMD (Palaiseau), CNRS/SA, University Blaise Pascal (Clermont Ferrand), INSU, Météo France (Toulouse and Brest). German participants: GKSS (Geesthacht), DLR (Oberpfaffenhofen), MPIfM (Hamburg).

The campaign took place from April 8-29, 1994 in the western part of Brittany; it was coordinated from Brest Guipavas Airport in France. Airborne observations from: Falcon of DLR (OVID, POLDER, PMS probes, radiation fluxes IR and solar, up and down; standard meteorological parameters); ARAT of INSU (POLDER, LEANDRE, radiation fluxes IR and solar, up and down; standard meteorological parameters); Merlin IV of Météo France (Fast FSSP, 2-D grey probe and FSSP-100, radiation fluxes IR and solar, up and down; standard meteorological parameters). Ground-based lidar measurements (GKSS, SA), interferometer (MPIfM); pyrometer, pyrogeometer, PRT-5, sun photometer (LOA). Satellite data from Meteosat and NOAA-11, -12 (AVHRR).

European Convair SAR-580 Experiment²⁷¹⁶

A campaign conducted in May-July 1981 at nearly 40 test sites in Europe with the objective to utilize SAR instruments and to analyze the images for potential agricultural applications. The SAR-580 radar instrument (X-, C-, and L-band) was flown on a Convair-580 aircraft

²⁷¹⁵) EUCREC 1994 Field Phase Report, Edited by G. Brogniez, Y. Fouquart, J. F. Gayet, September 1995

(operated by Intertech of Canada) obtaining dual-polarized imagery in two bands simultaneously. The German test sites were Oberpfaffenhofen and Straubing. Participants: DFVLR, ERIM, etc.).

EXPRESSO (Experiment for Regional Sources and Sinks of Oxidants)²⁷¹⁷⁾

A planned international campaign program within IGBP/IGAC/BIBEX (and BATGE) with participation from US (NSF, NCAR and universities), France, South Africa, etc., to investigate tropical biochemistry. The objectives are:

- To better quantify the exchange of fluxes of reactive trace gases and aerosols between the biosphere and the atmosphere in the tropics
- To analyze chemical interactions between the savanna and the tropical forest
- To isolate the perspective roles of photochemical and meteorological processes
- To characterize the effects of ecological processes on trace gas fluxes
- To assess the impact of tropical sources on the global troposphere. A broader ultimate goal is to assess the potential atmospheric impact of economic development and modifications in land use in tropical areas.

The campaign will take part in the African savanna and tropical forest (Central African Republic, and the People's Republic of the Congo, respectively) using ground-based, airborne (NCAR C-130, French Merlin and ARAT) and spaceborne instruments. Detailed characterization of vegetation, land forms, and soils (quantify fluxes of numerous chemical species over a range of spatial scales from the individual leaf, branch, and soil surface up to landscape and regional scales). The campaign will also focus on the fate of compounds released by the biosphere into the atmosphere, regional ozone formation, acid deposition, aerosol formation, etc. - The first intensive campaign will be conducted at the beginning of the wet season (May-June 1996). A second intensive campaign will take place during the dry season in January-February 1997. EXPRESSO observations and measurements include:

- Emission and deposition fluxes of methane, isoprene, and other hydrocarbons, as well as oxygenated organic compounds in the tropical forest
- Use of satellite imagery, aircraft and ground-based measurements in smoke plumes to determine trace gas fluxes from biomass burning
- Emission and deposition fluxes and concentrations of carbon monoxide which could be used as tracer during the dry season
- Emission and deposition fluxes of NO_x from soils and fires
- Concentrations of NO_x, nitric acid, and ozone and photochemical intermediates
- Particulate concentrations, chemical composition and interaction with other atmospheric species in various heterogeneous processes
- Deposition of ozone and NO_x on the forest canopy
- Energy and mass balance in homogeneous boundary layers over the savanna and forests
- Convective activity measurements from surface stations and airborne observations.

FASINEX (Frontal Air-Sea Interaction Experiment)²⁷¹⁸⁾

A US cooperative campaign (1984-1986), organized by ONR, and conducted in the subtropical convergence zone southwest of Bermuda. Participants: NOAA, WHOI, NCAR, ONR, NASA (GSFC, JPL.), SIO, NRL, US universities, etc. The overall objective was the study of sea-air interaction on 1 to 100 km scales in a region of the open ocean characterized by strong horizontal gradients in upper ocean and sea surface properties. The intensive period of the campaign was in 1986 (Phase 1, 2 and 3). Ship observations by R/V Oceanus, R/V Endeavor, and R/V Knorr (SST, winds, backscatter radar, XBT profiles, etc.). Long-term moorings: 2 subsurface, 5 surface, 4 PCM (Profile Current Meter). Aircraft observations in

Phase 2 (1 month) by Electra (NCAR), RP3A (NRL), C130, P3 and Electra (NASA), WP3D (NOAA). Satellite data from NOAA-8 and -9 (AVHRR), GOES (VAS), DMSP (SSM/I), and Nimbus (SMMR).

FASTEX (Fronts & Atlantic Storm Track Experiment)

An international campaign planned for 1996/97. Objectives:

- Study of the mesoscale dynamics and its application to weather forecasting
- Study of mid-latitude storm tracks within the climate system

FATE (FIRST ATSR Tropical Experiment)²⁷¹⁹⁾

An airborne campaign conducted by the UKMO in October/November 1991 to validate/calibrate the measurements (radiances and sea surface temperatures) of the ATSR (Along Track Scanning Radiometer) spaceborne sensor on ERS-1. A total of ten flights were carried out with the C-130 aircraft (sensors: MARSS, MCR, hygrometer, PRT-5, etc.) of UKMO in the tropical Atlantic near the Ascension Islands (8° S). In addition to the ATSR data, validation data was collected in support of the AMSU-B sensor (confirmation of model water vapor continuum values at microwave frequencies).

FIFE ^{2720), 2721)}[First ISLSCP (International Satellite Land Surface Climatology Project) Field Experiment]

An international land-surface-atmosphere experiment within WMO/WCRP (participants: NASA, NOAA, NSF, DOE, NRC of Canada, US and Canadian universities, US Army Corps of Engineers) which started in early 1987 and lasted through October 1989 with a series of IFCs (Intensive Field Campaigns) of 12 to 20 days, four in 1987 and one in 1989. The objectives of FIFE were to better understand the role of biology in controlling the interactions between the atmosphere and the 'vegetated' land surface, and to correlate existing satellite data and ground truth data (also airborne data) in an effort to detect climate-related fluctuations or man-induced changes on the land surface. - FIFE consisted of two major levels of activity: a) data collection and management in field experiments, b) data analysis and modeling. The primary area of the FIFE study was a 15 km x 15 km virgin tallgrass prairie site near Manhattan, Kansas (Konza Prairie in the Flint Hills of eastern Kansas). The operational strategy of FIFE was to acquire: a) simultaneous data sets of spaceborne, airborne, and ground-based sensors; b) multiscale observations of biophysical parameters and processes controlling energy and mass exchange at the surface; c) integrated analysis through a data system.

Satellite data sets for FIFE: AVHRR (LAC and GAC), GOES, Landsat (TM), SPOT (HRV). Airborne campaigns for the measurement of heat, mass, momentum and radiation fluxes from the surface and the atmospheric boundary layer. Aircraft: C-130 (NASA/WFF), King Air (NCAR), King Air (U. of Wyoming), Twin Otter (NCR, Canada), Helicopter UH-1B (NASA/WFF), U-2 (NASA/ARC). Some airborne instruments: AVIRIS, OCS, L-band SAR, TMS, TIMS, ASAS, PBMR, gust probes, X-band SLAR, etc. Use of balloons. FIFE data is archived at NSSDC at NASA/GSFC.

FIRE [First ISCCP (International Satellite Cloud Climatology Project) Regional Experiment]

Within the WCRP umbrella FIRE is a US multidisciplinary and multiagency research program to study the roles that clouds play in the global climate. FIRE project office at NASA/LaRC. Significant contributions are provided by NASA, NSF, ONR, NOAA, DOE, NOAA

²⁷¹⁹⁾Information provided by D. Jones of UKMO, Farnborough

²⁷²⁰⁾P. J. Sellers, et al., "An Overview of the First International Satellite Land Surface Climatology Project (ISLSCP) Field Experiment," *Journal of Geophysical Research*, Vol. 97, No. D17, November 1992, pp. 18,345-18,371

²⁷²¹⁾P. J. Sellers, F. G. Hall, G. Asrar, et al., "The First ISLSCP Field Experiment (FIFE)," *Bulletin American Meteorological Society*, Vol. 69, No. 1, January 1988, pp. 22-27

and DoD (USAF, AGFL).^{2722) 2723)} In addition, international contributions were provided by UKMO, and by CNRS of France. FIRE centers around two collective research efforts: ETO (Extended Time Observation) and IFO (Intensive Field Observation). The ETO studies include coordinated satellite and surface observations over both a limited and an extended area. The data utilized for ETO include those from AVHRR-HRPT and -GAC, TOVS, and 1 km GOES, also ERBE, SAGE II, Landsat, and DMSP. Some airborne instruments that participated in FIRE campaigns: CALS, CAR, HIS, MCR, RAMS, TSCC. NASA/GSFC NCDS serves as the central archive for FIRE data. The format for the archive is the FIRE Standard Data Format. - The FIRE strategy consists of three principal thrusts:

- A modeling program that encompasses general circulation models, process models, mesoscale models, and radiative transfer models
- A cirrus observing program consisting of several campaigns (1984-94)
- A marine boundary-layer cloud observing program with a field campaign in 1987 and a follow-on campaign ASTEX (Atlantic Stratocumulus Transition Experiment) in 1992.

FIRE Phase I (1984-1989)

The objective was to address fundamental questions concerning the maintenance of cirrus and marine stratocumulus cloud systems.

FIRE Phase II (1989-1994)

The objective was to study macroscale cloud systems and cirrus observational program, specifically:

- Expand the knowledge of how clouds and cloud systems interact with their environment and the climate
- Identify, quantify, and simulate the processes instrumental in the evolution of macroscale cloud systems
- Quantify the capabilities of current model for simulating macroscale cloud systems and the radiative properties of these systems, and improve cloud physics and radiation parameterizations used in general circulation models
- Assess and improve the reliability and currently used cloud/radiation monitoring systems from space and from the ground
- Assess the capability of future cloud/radiation monitoring systems, such as EOS

FIRE II encompasses the following subcampaigns:

- **Cirrus IFO-II** (Intensive Field Observation), a campaign conducted in November/December 1991 in southeastern Kansas. Collection of NOAA POES, GOES and Landsat satellite data (collection area: 25N - 50N and 65W - 135 W); instruments: AVHRR, TOVS, VAS, VISSR, TM, SSM/I, SAGE-II, ATSR (ERS-1). Four ground-based stations were used. Aircraft for airborne instruments: ARC ER-2, NCAR Sabreliner, NCAR King Air, and Citation of University of North Dakota.
- **SPECTRE** (Spectral Radiance Experiment) is a collaborative campaign in parallel to IFO-II. Objectives: Accurate measurements of the zenith infrared radiance (i.e. downwelling radiation) at high spectral resolution, simultaneously profiling radiatively important atmospheric parameters (temperature, humidity, aerosol, and cloud cover). ER-2 sensors: HIS and AVIRIS, CALS, MAS, etc.

FIRE III (also referred to as 'Arctic Cloud Campaign' - **FIRE/ACE**). FIRE/ACE is a two-phase field campaign in the Beaufort Sea with participants from the USA, Canada, Great Britain, and the Netherlands. Phase 1: from April 7 - June 13, 1998, phase 2 was conducted from July 6 -30, 1998. The objective of FIRE/ACE is to study the impact of Arctic clouds on radiation exchange between, surface, atmosphere, and space, and the influence of surface

²⁷²²⁾ "FIRE Cirrus Intensive Field Observations - II: Operations Plan," Prepared by the FIRE Project Office and the FIRE Cirrus Working Group, May 1991. Information provided by D. McDougal of LaRC

²⁷²³⁾ S. K. Cox, D. S. McDougal, D. A. Randall, R. A. Schiffer, "FIRE-The First ISLSCP Regional Experiment," Bulletin American Meteorological Society, Vol. 68, No. 2, February 1987, pp. 114-124

characteristics of sea ice, leads, and ice melt ponds in these clouds (cloud radiation feedback, changes in cloud fraction and vertical distribution, water vapor cloud content, cloud particle concentration and ice, cloud phase as atmospheric temperature and chemical composition change). Coordinated measurements of FIRE/ACE are conducted with instruments on the ground, on aircraft, and aboard satellites.

- Four instrumented aircraft: ER-2 of NASA/ARC, Convair CV-580 of the University of Washington, C-130 of NCAR, CV-580 of National Research Council (NRC) Canada to take remote and in situ measurements.
- The surface-based instruments for atmospheric measurements of clouds and radiation are at the SHEBA ice station (Des Grosielliers, Baeufort Sea) and at ARM (Barrow).
- The following S/C participated: NOAA-12, -14, DMSP F12 and F13, Landsat-5, Re-surs, and Radarsat.

FIRESCAN (Fire Research Campaign Asia-North)²⁷²⁴⁾

FIRESCAN is an international program under the IGBP/IGAC/BIBEX umbrella with the overall objective to investigate taiga and tundra fires and their impact on ecosystems, the atmosphere, and the climate. The first phase of FIRESCAN consisted of an international conference: "Fire in Ecosystems of Boreal Eurasia," held at the Forest Fire Laboratory of the Sukachev Institute of Forestry (Krasnoyarsk, Russian Federation) and organized in tandem with the "Bor Forest Island Fire Experiment," a large experimental forest fire conducted in July 1993.

Objective: investigation of a stand replacement fire in a boreal coniferous forest. Airborne observations were conducted with MI-8 helicopters (trace gas and aerosol sampling). Research institutes from the following countries participated: Austria (University of Vienna), Canada (Canadian Forest Service; University of Alberta, Edmonton), China (Northeast Forestry University, Harbin), Finland (Finish Forest Research Institute, Vantaa), Germany (MPICh, Mainz), Norway, Russia (Russian Aerial Fire Protection Service; Russian Academy of Sciences: Sukachev Institute of Forestry, Krasnoyarsk; Novosibirsk Institute of Chemical Kinetics and Combustion), Sweden (Swedish University of Agricultural Sciences, Umea), and USA (NASA/LaRC, USDA, University of Arizona, Duke University).

A second campaign within FIRESCAN (emission studies) is scheduled for June/July 1996 in a set of experimental fires in the Northwest Territories of Canada. Further campaigns in 1996/97 are planned for Siberia.

FIRESCHEME (Fire Information Systems Research in the Socio-Culture, History and Ecology of the Mediterranean Environment)²⁷²⁵⁾

A proposed Pan-Mediterranean research project within IGBP/IGAC/BIBEX (start in 1997). The aim of this regional project is to develop fire information systems which include the:

- History/prehistory of fire ecology in the Mediterranean Basin
- History of Mediterranean vegetation and vegetation treatment
- Socio-economical, cultural historical and political background of fires
- Present state of vegetation as related to, e.g., wildfire hazard, consequences of fire

GABLE (Global Atmospheric Backscatter Lidar Experiment)

A campaign (continuation of SABLE) conducted over the North Atlantic (Iceland, Azores, UK) by DRA (Defense Research Agency) of Malvern, UK and AFGL (Air Force Geophysics Laboratory), Hanscom AFB, MA. -For objectives and instrumentation see SABLE cam-

²⁷²⁴⁾J. G. Goldammer (editor), "Fire in Boreal Ecosystems of Eurasia: First Results of the Bor Forest Island Fire Experiment, Fire Research Campaign Asia-North (FIRESCAN)," World Resource Review, Vol. 6, No. 4, 1994, pp. 499-523

²⁷²⁵⁾K. Schrader, J. G. Goldammer, J. M. C. Pereira, "Fire Information Systems Research in the Socio-Culture, History, and Ecology of the Mediterranean Environment (FIRESCHEME)," Initial thoughts to the Development of a Pan-Mediterranean Fire Research Project. paign. The Iceland campaign (Keflavik, 63°N, 23°W) was from May 15-18, 1990 with the Canberra B57 aircraft (CO₂ lidar and particles probe sensors). The Azores (38°N, 25°W) campaign was from March 26-29, 1990 and from August 9-22, 1990. Ground-based and airborne instruments. - During the period October 1988 to August 1990 many flights were conducted over the UK and the Northeast Atlantic.

GAIM (Global Analysis, Interpretation, and Modeling)

An IGBP project (and encompassing the IGBP Core Projects) with the aim to advance the study of the coupled dynamics of the Earth system using as tools both data and models (GAIM Task Force Office at U. of New Hampshire, Durham, NH). Objectives: analysis of current models and data; assessment of the capability of current models and experimental programs to resolve key questions; improve our understanding of the biogeochemical cycles and their links to the hydrologic cycle and to the physical climate system as a whole.

GALE (Genesis of Atlantic Lows Experiment)²⁷²⁶

A US project/campaign initiated in 1982 by a group of US universities and supported by NSF, ONR, NASA, NOAA, US Army and Air Force and DOE. The field phase of GALE was conducted from January 15 to March 15, 1986 (GALE project office at NCAR). Science objectives:

- Describing the airflow, mass and the moisture fields in East Coast winter storms with special emphasis on mesoscale and air-sea interaction processes contributing to storms
- Understanding the physical mechanisms controlling the formation and rapid development of East Coast storms
- Development and testing numerical models for the prediction of East Coast storms.

Observation region: Eastern half of US (continental and marine effects). The inner GALE region is 500 km wide and centered on the coast from Virginia to Georgia (Investigation of convection, boundary layer fluxes and microphysical processes). The regional Gale area was 1000 km wide (west of the Appalachians to 500 km offshore) and extended from Florida to New England (Studies for cyclogenesis and frontogenesis). The outer GALE area extended from the Great Plains to 500 km offshore and stretched from New England to the Gulf of Mexico (Synoptic features of cyclones and jet stream circulations). Airborne campaigns (NOAA, NASA, NCAR, MIT, University of Washington) plus ground surface measurements (special GALE ground station network) and satellite data (GOES-6, NOAA-9, NOAA-6, DMSP F-6 and F-7, and Nimbus-7). Drexel University (Philadelphia) is the central archive and distribution center for GALE data.

GAME (GEWEX Asian Monsoon Experiment)²⁷²⁷

A broad and complex campaign program in Asia (combined observational and modeling approach) within the framework of WMO/WCRP/GEWEX. Participation of many institutions from Japan, Australia, Russia, China, and other nations. GAME focuses on the role of continental land-surface conditions on a seasonal cycle and the interannual variability of the Asian monsoon system. The objectives of GAME are:

- To understand the role of the Asian monsoon in the global energy and water cycle
- To improve the simulation and seasonal prediction of the Asian monsoon by global climate models and numerical forecasting models
- To understand multiscale interactions in the energy and hydrological cycles in the Asian monsoon region
- To assess the impact of monsoon variability on the regional hydrological cycle.

The central elements of GAME include intensive regional process studies, monitoring and observations from spaceborne platforms (NOAA-POES and GOES series, GMS series, RADARSAT, ERS-2, ADEOS, TRMM, EOS/AM-1, ENVISAT-1, ADEOS-2, EOS/PM-1,

²⁷²⁶) R. A. Dirks, J. P. Kuettner, J. A. Moore, "Genesis of Atlantic Lows Experiment (GALE): An Overview," Bulletin American Meteorological Society, Vol. 69, No. 2, February 1988, pp. 148-160

²⁷²⁷) GEWEX Asian Monsoon Experiment (GAME) Science Plan, October 1994, Japan National Committee for WCRP, T. Yasunari, Institute of Geoscience, University of Tsukuba, Japan

METOP-1, TRMM-2, HIROS-1, etc.), four-dimensional data assimilation routines are to be implemented in GCMs with a sophisticated land-surface scheme, and coupled, multi-scale hydrological and atmospheric models are to be developed. - The following time schedule is defined for GAME:

- Preparation phase (1994-95)
- Build-up phase (1995-96)
- Main observation phase I (1997-2000)
- Main observation phase II (starting in 2001)

Four domains of typical climatological and hydrological conditions have been defined for regional experiments:

- The tropical monsoon region of Southeast Asia (Indonesia, Thailand, Malaysia, The Philippines, the tropical ocean, etc.)
- The subtropical and temperate monsoon region in East Asia (the Huai-He river basin of China, the Chao Phraya river basin of Thailand, and the Lake Biwa basin of Japan are in this category)
- Tibetan Plateau and surrounding arid/semi-arid region
- The permafrost region (taiga and tundra) in Siberia

An AAN [Asian AWS (Automated Weather Station) Network] is being implemented by the end of 1995; in addition GAIN (GAME Archive Information Network) is being implemented to manage all observational and derived data. Planned regional experiments:

- HUBEX (Huai-He River Basin Experiment) - water budget, mesoscale- α cloud systems, atmosphere-land surface processes
- Lake Biwa Basin Experiment

Links of GAME to other projects: GCIP, MAGS, LAMBADA, BALTEX, CLIVAR, GOALS, ACSYS, SCSMEX, etc.

GARP/FGGE (Global Atmospheric Research Program/First GARP Global Experiment)²⁷²⁸⁾

GARP was organized by WMO and ICSU (International Council of Scientific Unions) in 1967 to study the dynamics of atmospheric behavior with the goal of improving the accuracy of weather forecasting. The first GARB experiment, **GWE** (Global Weather Experiment) was carried out from December 1, 1978 to November 30, 1979. It involved over 140 countries. Note: GWE is also referred to as **FGGE** (First GARP Global Experiment), it was the largest international atmospheric scientific experiment so far attempted. - The FGGE observing system consisted of the World Weather Watch (WWW) surface/upper-air network and voluntary observing ships, commercial aircraft, polar orbiting (NOAA-5, TIROS-N, NOAA-6, Nimbus-7) and geostationary satellites, drifting buoys (ARGOS data collection), etc. During special observing periods additional observing systems comprised tropical observing ships, meteorological reconnaissance aircraft and stratospheric constant-level balloons. - One of the objectives of GWE was to define the necessary elements of the future operational global observing system. See GCMD (Global Change Master Directory) at NASA/GSFC.

GATE (GARP Atlantic Tropical Experiment)²⁷²⁹⁾

A multinational campaign program (1971-1975) with contributions from 13 nations. A particular campaign of GATE from June 15 through September 1974, in the equatorial Atlantic, examined tropical convection processes from the ocean surface into the atmosphere, tropical cloud systems, etc. Satellite data from SMS-1. - Another GATE campaign studied Sahara dust clouds. Participation of the Geophysical Observatory of Leningrad (now St. Petersburg), Department of Atmospheric Science of Colorado State University, et al. The in-

²⁷²⁸⁾J. Noués-Paele, "GARP TOPICS - Summary of the National Conference on the Scientific Results of the First GARP Experiment," Bulletin American Meteorological Society, Vol. 67, No. 12, December 1986, pp. 1487 - 1492

²⁷²⁹⁾W. E. Egan, "Radiative Transfer Properties of the Sahara Region," Remote Sensing Environment, Volume 50, 1994, pp. 182-193

vestigation involved detailed quantitative ship, ground-based, and aircraft observations of Sahara dust clouds. Satellite imagery was used qualitatively to trace the origin and progress of the dust clouds. Satellite observations from ATS-1, and -6, SMS-1, NOAA-2 and -3. Aircraft data from four broadband Eppley hemispheric radiometers, both uplooking and downlooking, two in the spectral range of 0.285 - 2.8 μm , and two in the 4 - 50 μm region.²⁷³⁰⁾

GCIP (GEWEX Continental-Scale International Project)^{2731), 2732)}

A large international WMO/WCRP/GEWEX (in particular US) program. The study region of GCIP is the entire water discharge area of the Mississippi basin of North America. The study objectives are: 1) to determine the time/space variability of the hydrological and energy budgets over a continental-scale area; 2) to develop and validate macroscale hydrological models, related high-resolution atmospheric models, and coupled hydrographic/atmospheric models; 3) to develop and validate information retrieval schemes incorporating existing and future satellite observations, coupled with enhanced ground-based observations, and 4) to provide a capability to translate the effects of future climate change into impacts on water resources on a regional basis. The encompassing objective of GCIP can be judiciously expressed as a study of the terrestrial-atmospheric coupling in a regional, continental-scale climate context. The following time frame is considered for GCIP:

- Preparation phase: 1991 through 1992 (2 years)
- Build-up period: 1993 through 1994 (2 years)
- Enhanced observation period: 1995 through 1999 (5 years)

Due to its geographic focus the prime participation of GCIP is provided by US agencies and organizations (NOAA, NCAR, NASA, DOE, USGS, NWS, universities, etc.), international participants are from: Canada, UK, Germany, Australia, and other countries. Related projects to GCIP are: GCSS, ARM, USWRP, ISCCP, ISLSCP, SRB, GVap, BALTEX, MAGS, etc. - GCIP observations by meteorological and hydrological ground-based networks (Doppler radars (WSR-88D), wind profilers, automatic weather stations, etc.), and by commercial airlines providing wind and temperature profiles [ACARS (Aircraft Communication and Recording System)]. Atmospheric radiation measurements will be provided by the ARM program of DOE. - Satellite observations: GCIP uses data from existing satellite instruments to provide retrievals of atmospheric, hydrologic, and land surface parameters. In addition, the data collection capability, especially that provided by geostationary satellites, is essential for GCIP in collecting in situ measurements, such as for precipitation and stream flow [NOAA-GOES series, NOAA-POES (AVHRR, AMSU) series, DMSP (SSM/I), Landsat, Spot series, ERS-2, RADARSAT, ADEOS, TRMM, EOS-AM1, ADEOS-II, etc.]. - GCIP will make use of data collected during field campaigns and intensive observation periods. The first such field campaign is designated **CMESS-95** (Cooperative Multiscale Experiment spring/summer 1995).

The composite GCIP data set will include the following data types:

- Standard meteorological observations and analyzed fields (surface and upper air variables)
- Nonstandard meteorological observations of precipitation, wind, cloud, snow (cover and water content), and radiation measurements at other than standard resolution (temporal and spatial), systematically obtained.
- Hydrological measurements from existing observation networks that may also require special enhancement
- Geographical data (topography, soils, geology, and river basin location and characteristics)

- Vegetation information (time-, season-, and location-dependent data sets) combined from field surveys and satellite remote sensing
- Experimental data sets (ad hoc data sources and field campaigns).

GIMEX (Greenland Ice Margin Experiment)²⁷³³⁾

A ground-based glacio-meteorological campaign carried out in the margin (melting zone) of the Greenland ice sheet in the summers of 1990 and 1991. The campaign was initiated by a Dutch research program on land ice and sea level change. Participants: Utrecht University, Free University of Amsterdam, and Amsterdam University. Objectives: study of the relationship between surface energy balance, glacier mass balance, and ice flow. Data collection for modeling studies that simulate glacier mass balance based on the surface energy budget. - Seven meteorological stations were operated along a transect running from the tundra region up to 90 km onto the ice sheet. At the ice edge, humidity, temperature, and wind profiles were obtained with a tethered balloon. On the ice sheet, 90 km from the edge, a boundary-layer research unit (SODAR and RASS instruments) was established.

GLOBE (Global Backscatter Experiment)²⁷³⁴⁾

A NASA initiated interagency research program (started in 1986) to characterize the backscatter properties of atmospheric aerosols and clouds. The prime objective: support studies for the LAWS sensor design options (understanding the typical values of atmospheric backscatter cross section at various wavelengths, study of aerosol distributions and scattering properties). Two major field programs were conducted over the Pacific Ocean in November/December of '89 (GLOBE I) and May/June 1990 (GLOBE II). Flights were conducted on NASA DC-8 aircraft with a complement of lidar and aerosol instruments. Data from the GLOBE missions, collected by several sensors, are in a remotely accessible and interactive database at MSFC, Huntsville, Alabama.

GLOCHEM (Global Atmospheric Chemistry Survey)

An IGBP/IGAC program (under focus 6) with the goal to establish a global picture of the spatial and temporal distributions of key chemically reactive species and photochemically active solar radiation. The highest priority species to be measured are O₃, CO, NO, NO₂, the major reactive hydrocarbons (CH₄, and abundant reactive NMHC's) and water vapor, along with UV radiation fluxes in the relevant wavelength range. Campaigns in the context of GLOCHEM are: MLOPEX-I and -II, NATAC, [MOZAIC, CARIBIC, and ASE (see P.40)], MAPS (see J.11).

GOALS (Global Ocean-Atmosphere-Land System) see CLIVAR-GOALS

GOBEX (Gotland Basin Experiment)

GOBEX is an international pilot study of all riparian countries of the Baltic Sea carried out during 1994 and 1995. The campaign is considered as preparation for MAST-III activities (1996-99). GOBEX planning was funded by the European Committee on Ocean and Polar Sciences (EPOCS), which is sponsored by ESF and CEC. Objective: study of the water exchanges between coastal areas and the Eastern Gotland Basin and their effects on organic life within the Baltic Sea, (quantification of various past and present fluxes between different nonliving and living compartments, different ecological zones and food webs in the Baltic Sea). GOBEX expeditions consist mainly of shipborne and moored buoy observations (R/V Humboldt, R/V Gauss, R/V Livonia, R/V Oceania, R/V Vejas, R/V Aranda, R/V Logachov).

GORC (Global Ocean Carbon Research Program)

GTE/CITE (Global Tropospheric Experiment/Chemical Instrumentation Test and Evaluation)

²⁷³³⁾J. Oerlemans, H. F. Vugts, "A Meteorological Experiment in the Melting Zone of the Greenland Ice Sheet," BAMS, Vol. 74, No. 3, March 1993, pp. 355-365

NASA (ARC/WFF/LaRC), NOAA and NCAR campaigns. GTE is a major component of NASA's Tropospheric Chemistry Program, with field campaigns called ABLE. The CITE campaigns focus on testing and evaluating instruments which measure key tropospheric constituents (intercomparison of measurements).

- **CITE-1**²⁷³⁵) evaluated instruments for measurement of CO, NO, and OH. CITE-1 consisted of one ground-based and two airborne campaigns in fall 1983 and spring 1984. Aircraft: CV-990 of NASA.
- **CITE-2**²⁷³⁶) was conducted in August 1986. It focused on instruments for the measurement of NO₂, HNO₃, and PAN (peroxyacetyl nitrate). Aircraft: Electra. Measurement techniques employed: chemiluminescence, tunable diode laser differential absorption, UV absorption, gas chromatograph/electron capture, sample/gas chromatography, forward scattering spectrometer, photometers, etc.

GULFEX (Gulf Experiment)

A UKMO campaign conducted in the Persian Gulf (Kuwait) in March 1991 with the objective to study the smoke plumes of burning oil wells in Kuwait. A total of eight flights were carried out by the C-130 of UKMO. Environmental impact studies on: a) the long range transport of pollution, b) absorption and reflection of solar radiation on climate, c) photochemical smog.

GVaP (GEWEX Water Vapor Project)

GVaP addresses fundamental deficiencies in the present understanding of moist atmospheric processes and the modeling of these processes from a regional to a global scale. This GEWEX cooperative effort aims at providing a scientific basis for the application of global measurements of water vapor from spaceborne instruments and existing operational networks in order to determine the 3-D water vapor distribution in the atmosphere. The initial objectives of GVaP are to:

- Produce global water data sets using existing satellite and in situ data
- Establish a multisensor reference station to quantify the variability of atmospheric water vapor
- Compare the atmospheric water vapor measurement abilities of ground-based and spaceborne sensors
- Define and characterize a better water vapor sensor for use in radiosondes.

HALE (High Altitude Long Endurance)

HAPEX-MOBILHY (Hydrologic and Atmospheric Pilot Experiment - Modélisation du Bilan Hydrique)

A joint campaign in southwestern France conducted by a number of French institutes, among them: DMN (Direction de la Météorologie), PNEDC (Program National d'Etude de la Dynamique du Climat), and INRA (Institut National de la Recherche Agronomique) under the sponsorship of WMO, Free University, Berlin, and with cooperation from INSU, CNES, DLR, NCAR, NASA (and several US universities). The main objective was the study of hydrological budget and evaporation flux at the scale of the GCM grid, i.e., 10⁴ km² (subsurface and surface hydrology, watertable height, precipitation and stream runoff, land surface parameters, atmospheric processes). The observational site was 100 km x 100 km in size, located in southwestern France; the experiment began on April 1, 1985 and continued through 1986 (with a special observation period (SOP) from May 1 to July 15, 1986).

Observations from ground-based networks/sensors, airborne and spaceborne instruments. Surface networks measured evaporation by different methods including meteorological stations, 59 rain-gauge stations, radio-sounding of ABL, tropospheric radio soundings, a tower, etc. Aircraft observations during SOP with King Air (NCAR) and C-130 (NASA/

ARC with NS001, PRT-5 TIMS, PBMR, Camera). Satellite data from METEOSAT, SPOT, Landsat, and NOAA (AVHRR).^{2737), 2738), 2739)}

HAPEX-Sahel (Hydrologic and Atmospheric Pilot Experiment)^{2740), 2741)}

International cooperative campaign in the Sahel region of West Africa within the framework of GEWEX and with relevance to IGBP. Focus on soil-plant-atmosphere energy, water and carbon balance (land surface-atmosphere observation program, study of interaction between the Sahel and general atmospheric circulation, studies in hydrology and soil moisture, surface fluxes and vegetation, mesoscale modeling). The campaign was carried out in a 1° x 1° area of western Niger over a period from mid-1990 to late 1993 with an intensive observation period from August to October 1992 (three supersites were identified within the area). HAPEX-Sahel was funded by a number of agencies in seven participating countries (France, UK, USA, Netherlands, Denmark, Spain, Germany, Niger) and involved over 200 scientists.

Observations from ground-based, airborne and spaceborne sensors/platforms. Aircraft: ARAT (IGN France, POLDER, PORTOS), Meteo-France Merlin IV, C-130 (NASA/ARC with NS001 TMS, ASAS, TIMS, PBMR, etc.), Piper Saratoga (Sudan/Niger). Satellite data were acquired from: SPOT (HRV), Landsat (TM), NOAA-POES (AVHRR), METEOSAT, ERS-1 (AMI-SAR, ATSR, AMI-SCAT), DMSP (SSM/I). The HAPEX-Sahel data are archived at LERTS (Toulouse, France) in a database called 'HSIS (HAPEX-Sahel Information System).' HSIS data are compatible in format and structure with FIFE and BOREAS data, they are also available on CD-ROM and internet (www). HSIS data will be accessible to the public community on March 15, 1997.

HaRP (Hawaiian Rainband Project)

A meteorological study, July-August 1990 on the island of Hawaii, conducted with airborne instruments from NCAR; correlation of data from airborne sensors, spaceborne sensors (POES, GOES, DMSP, SPOT), and 50 portable weather stations. The main objective of the experiment was to focus on the offshore rainbands that form along the windward shore of the island of Hilo.

HESS (High-Latitude Ecosystems as Sources of Sinks of Trace Gases)

An IGBP/IGAC program (under focus 4) which builds on other international campaigns. The objectives of HESS are to:

- Estimate trace gas emissions and uptake in high-latitude ecosystems
- Determine the principal ecological and environmental characteristics that control an ecosystems' trace gas production, consumption and transport in high-latitude ecosystems
- Estimate the sensitivity of high-latitude sources/sinks of trace gases to environmental change.

Campaigns in the context of HESS are: NOWES, ABLE-3B.

ICE (International Cirrus Experiment)

ICE is the "European Regional Experiment" effort within the larger frame of ISCCP (In-

²⁷⁴¹⁾The Sahel occupies a narrow zone between the Sahara to the north and the Sudanian vegetation zone to the south, forming a strip about 400-600 km wide that stretches nearly 6000 km across the entire African continent

ternational Satellite Cloud Climatology Project) and analogous to FIRE (the US contribution to ISCCP). The science objectives are:

- To determine those physical processes which govern the life cycle of cirrus cloud sheets
- To develop parameterization schemes for use in circulation and climate models
- To improve remote-sensing methods
- To validate the results of the ISCCP.

The first ICE campaign took place during September/October 1987 over the eastern North Sea. Instruments on three aircraft were used to map up- and down-welling radiation fields, to measure vertical structures within cirrus with lidar, and also to measure directly the microphysical properties of cirrus. The airborne measurements were complemented by a network of ground-based instruments and by spaceborne measurements (Landsat, Spot, METEOSAT, NOAA POES series, and MOS-1 data).^{2742), 2743)} - A second ICE campaign took place in the fall of 1989 over the North Sea. Aircraft: Falcon, DO 228 (DLR), Merlin IV (France), C-130 (UKMO), etc.²⁷⁴⁴⁾ As of 1991 ICE activities have been reorganized under EUCREX (European Cloud Radiation Experiment).

IMAGES (International Marine Global Change Study)²⁷⁴⁵⁾

An IGBP/PAGES/PANASH long-term project (at least over a decade) with the overall objectives to quantify climate and chemical variability of the ocean on time scales of oceanic and cryospheric processes, to determine its sensitivity to identified internal and external forcing, and to determine its role in controlling atmospheric CO₂. A coordinated global program is proposed by IGBP to collect and study marine sediment records to address three fundamental questions:

- How have changes in ocean properties controlled the evolution of global heat transfer through the deep and surface ocean, and so modified the climate?
- How have changes in ocean circulation, ocean chemistry, and biological activity interacted to generate the observed record of atmospheric pCO₂ over the past 300,000 years?
- How closely has continental climate been linked to ocean surface and deep water properties?

IMAGES encompasses five elements: field programs, data acquisition, data and sample management, modeling, and program coordination. The program started in 1995.

INDEX (Indian Ocean Experiment), see under **MONEX**

INDOEX (International Indian Ocean Experiment).^{2746) 2747)} INDOEX is an extensive international program, involving several hundred scientists from India, Europe (France, Germany, Netherlands, Sweden, UK), USA, and the island countries Maldives, Mauritius, and Reunion. Objective: to study atmospheric pollutants, clouds, solar radiation, and interactions of clouds over the Indian Ocean (focus on the analysis of the direct and indirect effects of aerosols on the radiation budget in tropical regions and radioactive forcing modifications due to circulation associated with the intertropical convergence zone). INDOEX addresses these objectives by focusing on a region in the Arabian Sea and the Indian Ocean during several periods (Jan. to March), when the “polluted” air from the Indian subcontinent and the pristine air masses from the southern Indian Ocean meet over the tropical Indian Ocean

at latitudes between 0°-15° south. - Three pre-INDOEX campaigns were conducted during the Jan.-March periods of 1996, 1997 and 1998. This involved a variety of instrumentation from India, Europe and USA.

The intensive field phase of the campaign is from Jan. - April 1999, involving ship-borne airborne, spaceborne and ground-based measurements. Use of data from geostationary satellites Meteosat-5 (Eumetsat), INSAT (ISRO) and FY-2 (China) and polar orbiting S/C: NOAA-12, -14 and -15 and Resurs-O1-4 (ScaRaB). Participating research vessels are: Sagar Kanya (India) and Ronald H. Brown (USA). Aircraft: C-130, Citation and Mystere.

INDREX-96 (Indonesian Radar Experiment)^{2748) 2749)}

An international campaign initiated and coordinated by the Indonesian Ministry of Forestry and Wageningen Agricultural University (WAU) of Wageningen, The Netherlands. The objectives are to develop a 'remote sensing monitoring system for the support of sustainable forest management and land cover change in Indonesia and to investigate the complementary use of SAR data from high-resolution airborne platforms and from spaceborne platforms (ERS-1/2 data). A secondary objective is to provide a demonstration of how high-resolution radar images can replace aerial photography for forest monitoring applications. ESA provides some funding for airborne data acquisition and science coordination. Participants: Agency of Forest Research and Development, Litbang; Directorate for Forest Inventory and Land Use Planning, INTAG, Universitas Gadjah Mada (UGM), LAPAN, WAU, ESA, Dornier and DLR (Germany), CESBIO (France), JRC (Ispra, Italy), NASA, etc. The campaign is scheduled for July/August 1996. Two major test areas are identified: 1) East Kalimantan (on the island of Kalimantan), 2) Central Sumatra (Jambi). Observation of three forest types: production forests, conversion forests, and protected forests. The prime instrument for the campaign is DO-SAR (C-band and X-band), flown on an Indonesian Transall C-160 aircraft. Data acquisition for INDREX involved six different DO-SAR operating modes with spatial resolutions between 3 m and 0.8 m. DO-SAR collected also interferometric data using single-pass dual-antenna interferometry. Comparison of DO-SAR data with spaceborne ERS repeat pass interferometry.

ITEX (Island Thunderstorm Experiment)²⁷⁵⁰⁾

A cooperative Australian campaign conducted by BMRC (Bureau of Meteorology Research Centre) and Monash University (participation of NASA/GSFC) with the objective to study island thunderstorms and to obtain data for analytical evaluation. The campaign was conducted from November 20 to December 10, 1989 at Bathurst and Melville Islands, north of Darwin, Australia. Ground observations by weather stations, radar, upper-air soundings. Aircraft observations from a Nomad twin-engine aircraft. Satellite data from GMS, NOAA (AVHRR, TOVS, TOMS).

JGOFS (Joint Global Ocean Flux Study)

JGOFS is a core program of IGBP (International Geosphere-Biosphere Program of ICSU). The goal of JGOFS is to improve knowledge of the processes controlling carbon fluxes between the atmosphere, ocean surface, ocean interior and continental margins, and to monitor the sensitivity of these fluxes with respect to climate changes. - JGOFS is divided into several task teams including: global survey, process study, benthic processes, sedimentary record, time series, modelling, and data management. A global CO₂ survey is being carried out with WCRP and WOCE. Time series studies include BATS (Bermuda-Atlantic Time-series Study) and HOTS (Hawaii Ocean Time Series). Process studies include: **NABE** (North Atlantic Bloom Experiment), Equatorial Pacific Process Study, Arabian Sea Process Study, Southern Ocean Process Study.

JOWIP (Joint Canada-US Ocean Wave Investigation Project)²⁷⁵¹⁾

A campaign composed of surface truth oceanographic data, airborne SAR and other imagery data (July 21-August 6, 1983), conducted by APL, ERIM, NOSC (Naval Ocean Systems Center), TRW, CCRS, and DREP (Defense Research Establishment Pacific) in US and Canadian inshore waters adjacent to and in the Georgia Strait near the Pacific Ocean (BC). Objectives:

- To obtain quantitative measurements of surface modulations induced by natural and ship-generated internal waves, including determination of the phase relationship between SAR image roughness variations and internal wave amplitude
- To identify radar backscattering mechanisms as a function of incidence angle and surface wave conditions
- To obtain calibrated SAR images of internal waves in X- and L-band for different incidence and azimuth angles relative to the internal waves
- To investigate SAR imagery mechanisms for Kelvin wakes

Ground truth data from two ships: USS Quapaw and Endeavour (Canada). Airborne observations by two CV-580 (one with X- and L-band SAR, the other with nadir-looking IR scatterometer), a Cessna 310 (for stereo photography), a DeHavilland L-20 (with modular multispectral scanner), and a Bell helicopter (aerial photography).

JUSREX-92 (Joint US/Russian Internal Wave Remote Sensing Experiment)²⁷⁵²⁾

A US/Russian campaign conducted in July 1992 (13.-25.) with the objective to study sea surface hydrodynamic and electromagnetic processes associated with surface phenomena/features of oceanic internal waves. The campaign site was the US East Coast continental shelf, approximately 60 nautical miles south of the eastern end of Long Island. Packets of internal waves are generated by the semidiurnal tidal flow over the shelf break - these wave packets propagate to the northwest and eventually dissipate in the shallow waters near the shore. The surface current patterns and associated surface roughness variations induced by these internal waves can be measured by remote sensing techniques.

The campaign included ground in situ measurements (moorings, buoys), Akademik (a Russian research vessel, equipped with radiometers and scatterometers), two US and one Russian aircraft (TU-134 CX of IKI with side-looking RAR (NIT), microwave radiometers (NAMR), and an MKF-6 film camera). The US Navy/ERIM provided a P-3 aircraft with the P-3/SAR instrument (see P82.3), NASA provided the DC-8 with AIRSAR. In addition SAR imagery was collected from the SAR systems of ALMAZ-1 and ERS-1 satellites. PIs from JHU/APL, JPL, ERIM, IKI (Moscow), Shirshov Institute of Oceanology (Kalinin-grad), NPO Machinostroyeniya (Moscow), Institute of Applied Physics (Nizhny Novgorod). JUSREX data are archived at IKI (Moscow) and at JHU/APL.

Kamchatka-93²⁷⁵³⁾

A joint US/Russian airborne campaign conducted in August/September 1993 on the Kamchatka Peninsula, Russia (funding by NASA and RAS). The objectives were to provide an infrared multispectral imaging survey of the active volcanoes of the Eastern Volcanic Belt of the Kamchatka Peninsula, in particular concentrating on the Klyuchevskoy Group. A Learjet-25 from NASA/SSC was equipped with two principal instruments: TIMS and a Zeiss RMK (metric) camera. Two typhoons hit the peninsula in August, grounding the Learjet for two weeks. Observations were conducted during the first week of September, 1993. Participants: US [JPL, USGS, NASA, Arizona State University, SUNY, Buffalo], Russia [IVGG (Institute of Volcanic Geology and Geochemistry) and IV (Institute of Volcanology), both institutes are in the city of Petropavlovsk-Kamchatskii; IGEN (Institute of

Mining Formations Geology, Petrography, Mineralogy, and Geochemistry), Moscow]. Volcanoes surveyed: Klyuchevskoy volcano (4850 m), Klyuchevskaya group, Bezymianny volcano, Tolbachik volcanic field, Uzon caldera geothermal area and Geyser Valley, Avachinsky and Koriaksky volcanoes near Petropavlovsk-Kamchatskii, Gorely and Mutnovsky volcanoes, and the Ksudach caldera complex. Some ground-based measurements were performed in parallel to airborne observations. The campaign data was analyzed at NASA/ARC and JPL; they are available on CD-ROM and on internet at <http://www.geo.mtu.edu/eos/compiled.html>

KUREX (Kursk 1991 Experiment)²⁷⁵⁴⁾

A USSR/US energy-water-carbon exchange campaign (within ISLSCP) conducted in Kursk, Russia in July 1991. It is a FIFE follow-on campaign to further develop and test hypotheses concerning how the Earth's land-surface vegetation and atmospheric boundary layer interact to affect weather and climate. An intensive field campaign conducted on and near the Kursk Biospheric Reserve, which is located about 500 km south of Moscow, was accomplished by an international team of 134 scientists and technicians from eight countries (USSR, USA, China, Japan, Czechoslovakia, Poland, Belgium, and Cuba) and six Soviet republics (Russia, Ukraine, Byelorussia, Lithuania, Azerbaidjan, and Estonia), plus 31 students from the Moscow State University. Ground-based observations over natural and agricultural sites were coordinated with airborne (helicopter and aircraft) and spaceborne data from satellites (optical and microwave sensors of Landsat, NOAA (AVHRR), Cosmos-1939, ALMAZ-1, and Spot). The focus of the US team was to study steppe vegetation types, wherein different levels of vegetation productivity were evaluated for their influences on climate-related variables.

LAMBADA (Large-scale Atmospheric Moisture Balance of Amazonia using Data Assimilation)²⁷⁵⁵⁾

A campaign within the framework of GEWEX (in definition phase as of 1995, considered for 1998-2000). The campaign concentrates on understanding the regional-scale transport of energy and moisture over the entire Amazon Basin. The objective is to use a variety of large-scale observational techniques to extract different parameters for atmospheric, surface water and energy budget equations on a basin-wide scale. The data will provide diagnostic information on the atmospheric energy and water balance of the region and will improve understanding of some of the governing processes in tropical meteorology. A radiosonde network will be set in place around the perimeter of the basin; precipitation, hydrographic and surface meteorological networks will be established within the basin; there is a comprehensive satellite remote sensing program, and field observations.

LEADEX-92 (Arctic Leads Experiment)^{2756), 2757)}

A US campaign sponsored by ONR (participants: CRREL, NRL, ERIM, U. of Colorado, U. of Washington, NOAA) was carried out in March and April 1992 in the southern Beaufort Sea, 160 km north of Prudhoe Bay, Alaska. The campaign was dedicated to the study of sea ice growth and air-sea-ice interaction processes in Arctic **leads**. The campaign included in situ measurements (radiometers positioned on the ice) and concurrent observations from several spaceborne sensors [AVHRR (POES series), AMI (ERS-1), SSM/I (DMSP)]. Measurements of (multifrequency microwave) brightness temperature, emissivity of sea ice in leads, in situ radar scattering, physical properties; oceanographic and meteorological data were acquired.

LEWEX (Labrador-Sea Extreme Wave Experiment)

International campaign (researchers from eight North American and European countries)

²⁷⁵⁴⁾Information provided by D. W. Deering of NASA/GSFC, Greenbelt, MD

²⁷⁵⁵⁾Information from GEWEX homepage on www

²⁷⁵⁶⁾T. C. Greenfield, D. K. Perovich, "Analysis of Surface-Based Passive Microwave Observations during LEADEX-92," Proceedings of IGARSS '94, Aug. 8-12, 1994, Pasadena, CA, Volume II, pp. 1005-1007

²⁷⁵⁷⁾R. W. Fett, S. D. Burk, W. T. Thompson, T. L. Kozo, "Environmental Phenomena of the Beaufort Sea Observed during the Leads Experiment," Bulletin American Meteorological Society, Vol. 75, No. 11, 1994, pp. 2131-2145

conducted in March 1987 in the southern Labrador Sea to explore methods for measuring, predicting, and applying directional ocean wave spectra. The researchers were supported by ship, aircraft, and satellite estimates of wind and waves. ²⁷⁵⁸⁾

Surface ships: Canadian research vessel CFAV Quest, and the Dutch research vessel HNLMS Tydeman, they used wave buoys and their navigation radars. Aircraft: CV-580 (CCRS, Canada with C/X-SAR), NASA P-3 (SCR, ROWS, etc.), GEOSAT (Radar Altimeter for wind speed and wave height). A comprehensive data set of directional spectra in a common format is available.

LIMEX (Labrador Ice Margin Experiment)²⁷⁵⁹⁾

Canadian/US cooperative campaign during spring 1989 with the overall objective to establish a link between the status and evolution of ice and ocean properties in the Labrador Sea. LIMEX took place off the East Coast of Newfoundland between March 4 and April 4, 1989. Participants: CCRS, RADARSAT, Intera Technologies Ltd, JPL, AES of Canada, University of Kansas, University of Waterloo, NORDA, CRREL, NRC, IIP, Memorial University of Newfoundland, Canada Department of Oceans and Fisheries, Bedford Institute of Oceanography, etc.

Two ships (MV Terra Nordica and the icebreaker CCG Sir John Franklin), both supported by helicopters, served as research bases. Five aircraft and a shore-based helicopter participated, including: CV-580 (CCRS), NAY Electra (AES), HU-25 and HC-130 (IIP), King Air of Atlantic Airways Ltd. Satellite data from AVHRR (NOAA), SPOT, and SSM/I. Surface data from ships consisted of ice and snow properties that related to microwave and mechanical properties (ship-mounted scatterometers and radiometers). Measurements of dielectric properties, surface roughness, microwave reflecting facets. Measurements of snow properties included grain sizes, crystal structure, salinity, temperature, and depths. Measurements of ice included thickness, temperature, salinity, and cores for structure analysis. C/X-SAR (CCRS) measurements: large and intermediate scale phenomena, ice signatures, signatures of waves in ice, and mesoscale features at the ice pack.

LITE (Lidar In-space Technology Experiment)²⁷⁶⁰⁾

A US underflight campaign of Shuttle flight STS-64 which took place from September 9 - 20, 1994. The objective was validation and comparison of spaceborne lidar measurements from LITE (Lidar In-space Technology Experiment) on Shuttle with coincident measurements from underflight airborne and ground-based lidar instruments. Aircraft used were: P-3B Orion, and Electra (both of GSFC/WFF), Convair 580 (of AES, Canada). Lidar instruments flown: LASAL, LASE, and LARSEN (in addition to many other sensors). The P-3B aircraft flew from Wallops to: Barbados, Recife, Ascension Island, Cape Town, Ascension Island, Azores. The Electra flight track was: Wallops, Barbados, Venezuela, Barbados, Wallops, Lake Superior. In addition there were lidar measurements from numerous ground sites in the US, including the ARM/CART site in Oklahoma.

The European participation in the LITE campaign was named **ELITE** (European LITE Campaign).^{2761), 2762), 2763)} ESA provided coordination of the ELITE campaign. Coincident measurements from underflight airborne lidar instruments on two aircraft: Leandre of CNRS/CNES on Fokker ARAT F27 and ALEX on Falcon of DLR. Ground-based lidars were located at: CNRS/LMD (Palaiseau, France), DWD (Hohenpeissenberg, Germany), FhG/IFU (Garmisch-Partenkirchen, Germany), GKSS (Geesthacht, Germany), MPIfM (Hamburg, Germany), U. of Munich (Munich, Germany), CNR/IFA (Frascati, Italy),

LMOS (Lake Michigan Ozone Study)

LOTREX (Landoberflächen-Traversen Experiment)^{2764), 2765)}

A German campaign (sponsored by BMFT) in the Hildesheimer Börde ('HIBE,' a fertile agricultural region between the cities of Hannover and Braunschweig) with the objective to determine energy budgets/exchange between agricultural surfaces and the atmosphere. Participants: University of Hannover, Free University of Berlin, Ruhr University Bochum, University of Freiburg, University of Karlsruhe, University of Munich, University of Osnabrück, Deutscher Wetterdienst Offenbach, DLR Oberpfaffenhofen. Data collection from ground-based, airborne and spaceborne (Landsat, Spot, NOAA) sensors. Airborne observations were supported by several aircraft; Sensors: HELISCAT (Institute of Oceanography of the University of Hamburg, Germany) and E-SAR of DLR. The campaigns took place in 1988 and in July/August 1989.

LOWS (Lake Ontario Winter Storms)²⁷⁶⁶⁾

A ground-based project/campaign in January/February 1990, conducted and sponsored by a LOWS consortium of private industry, US/Canadian agencies, and universities with the objective to demonstrate and evaluate the potential for real-time mesoscale monitoring and location-specific prediction of lake-effect storms and freezing rain. LOWS focused on the eastern basin of Lake Ontario employing an array of atmospheric remote sensors with supporting observing systems and mesoscale numerical models. Instruments: X-band dual-polarization radar (NOAA/WPL), three-channel steerable microwave radiometer (NOAA/WPL), 915 MHz wind profiling radar (NOAA/WPL), two 404 MHz wind profiling radars (Penn State University and Tycho Technology Inc.), RASS (Radio-Acoustic Sounding System of Penn State University), Radar of AES at King City (Canada), mobile Rawinsondes (State University of New York); four GTS (Galson Technical Services Inc.) networks: microbarograph network, weighing precipitation gauge network, surface meteorology network, and snow observers network. A major sponsor of LOWS was the Niagara Mohawk Power Corporation.

MAC (Multiphase Atmospheric Chemistry)

An IGBP/IGAC program (under focus 6) with the objective to study in particular atmospheric aerosols. Note: the term 'multiphase chemistry' refers to the combination of physical and chemical processes that control the evolution and properties of the atmospheric aerosol, at least two mechanisms influence the global heat balance: 1) direct forcing of the radiative balance occurs mainly due to backscatter of solar radiation, and 2) indirect forcing occurs because some aerosol particles act as cloud condensation nuclei (CCN), thereby influencing the albedo of clouds. - Campaigns in the context of MAC and MAGE are: ACE-1 and ACE-2.

MAC-EUROPE (Multisensor Airborne Campaign - Europe)^{2767), 2768)}

MAC-Europe is a cooperative NASA/ESA campaign that was organized by NASA/JPL and ARC together with several national agencies from Europe (CNRS/CETP, INRA and CNES of France, ING of Rome, Italy, University of Rome, University of Florence, ASI, University of Munich, DLR, CEC, BNSC, ASA, etc.). The objectives were to investigate the potential of SAR and imaging spectrometer data and to derive biophysical parameters in different

environments. Related objectives were to stimulate applied and theoretical research in a variety of different fields. The campaign took place from June 14 to August 1, 1991 over sites in Austria, France, Germany, Iceland, Italy, Spain, Switzerland, The Netherlands, and the United Kingdom. European remote sensing aircraft and the DC-8 of NASA/ARC joined in the cooperative effort. The following instruments were flown: AIRSAR on a NASA DC-8; TMS (NS001) - the Thematic Mapper Simulator (TMS) - AVIRIS and a Wild RC-10 metric camera were flown on a NASA/ARC ER-2 aircraft; ERASME (CETP) was carried on a French helicopter (test site was in a watershed agricultural region near Paris, la Brie). In addition DLR provided aircraft for complementary data acquisition, and CNES flew POLDER. The ER-2 was deployed in Alconbury, UK for the following overflights:

- June 17: Iceland overflight: Hekla volcano region in Southern Iceland for the mapping of geological features, Surtsey, Krafla
- June 24 and 29; July 8 and 19: Italian test sites were Naples, the Strait of Messina, Stromboli, Oltrepo Pavese, Montespertoli, Florence, Matera, Etna Volcano
- June 24 and 28; July 16 and 17: French test sites were: Ardeche, Landes Forest, La Crau, Crau-Camargue
- June 29 and July 15: Castilla La Mancha, Serrania de Ronda, Carboneras (all in Spain)
- July 5: Germany (Freiburg), Switzerland (Rigi), Netherlands (Flevolands), France (Orgeval)
- July 17: Netherlands (Noordwijk)
- July 22 and 28: Germany [Augsburg, Oberpfaffenhofen (DC-8 (AIRSAR) underflights conducted with DO228 (E-SAR)), Freiburg], Austria (Tauern, Graz), France (la Brie)
- July 26 and 27: UK test sites were: Plymouth, Slapton Woods and Fenland
- July 29: Germany (Donauried), Austria (Tauern, Graz), France (la Brie).

The MAC-EUROPE data was analyzed by many teams for applications in a variety of fields: geology and topographic mapping, soils and hydrology, agriculture, forestry, land use mapping, calibration, and oceanography.

MACSI (Microwave Airborne Campaign over Snow and Ice); see MACSI under **EMAC**

MAESA (Measurements for Assessing the Effects of Stratospheric Aircraft)

NASA campaign (funded by High Speed Research Program) with the objective to provide information about stratospheric photochemistry and transport mechanisms for assessing the potential environmental effects of the proposed fleet of high-speed civil transports currently under study. The MAESA flights flew on NASA/ARC ER-2 (1) from California through Hawaii and Fiji to Christchurch (NZ) in March 1994, (2) from Christchurch during March-October 1994, and (3) from Christchurch through Fiji and Hawaii to California in October/November 1994.

MAESTRO-1 (Multiple Airborne Experiments Towards Radar Observations)

The Joint Research Centre (JRC) Ispra and ESA initiated and financed the deployment of the NASA/JPL C-, L-, and P-band polarimetric SAR instrument (AIRSAR flown on a DC-8 aircraft) in Europe in a mid-August 1989 campaign (7 days). The campaign represented an opportunity for European agencies and institutes to evaluate the state-of-the-art of multifrequency polarimetric imaging technology over European test sites. In addition the campaign gave some impetus for a European initiative (a joint CEC/ESA project) to build a European suite of sensors, entitled 'European Airborne Remote Sensing Capabilities' (EARSEC).

The objectives of MAESTRO-1 were the development of a number general applications for microwave data in the fields of forestry and agriculture. Development of models, selection of targets, analysis of data, etc. This resulted in a total of 35 studies, representing 15 nations who participated in the data analysis phase of the campaign.

Test sites: Les Landes (a forest region in southwest France), Freiburg (Germany, Black Forest region), Oberpfaffenhofen [E-SAR underflights of AIRSAR (for AIRSAR calibration,

about 20 corner reflectors of different sizes were provided)], Flevoland (The Netherlands, within the Flevoland test site were three test areas: Horsterwold, Speulderbos, and Flevo-polder), Thetford (UK, there were three areas: Thetford Forest, Feltwell, and Reedham). Standard ground data collection, compilation protocols and methodologies were defined and applied to the entire campaign to ensure data compatibility by all investigators. Measurements of the test sites were also conducted using a number of other sensors (CAESAR and SLAR by NLR for the Flevoland test site, Daedalus 1268 ATM, C/X-SAR of CCRS at Thetford site).^{2769), 2770)}

MAGE (Marine Aerosol and Gas Experiment)²⁷⁷¹⁾

MAGE is a multinational IGBP/IGAC (International Global Atmospheric Chemistry) effort in close collaboration with ASTEX (1992) to improve the capability for studying cloud-chemistry interactions and the air/sea fluxes that effect them. The specific goals of MAGE within ASTEX include:

- Develop and test a Lagrangian strategy for studying chemical and meteorological evolution in a tagged airmass, using ships, balloons, and aircraft.
- Develop and test new techniques for estimating trace-gas and aerosol fluxes across the air/sea interface by comparison with traditional approaches.
- Evaluate the impact of marine and continental aerosols on the formation and dissipation of stratocumulus clouds
- Compare the impacts of natural and anthropogenic sulphur, halogens, and hydrocarbons on marine aerosol chemistry.

Participants in MAGE were institutions that participated also in ASTEX, plus a number of universities. Aircraft platforms: NCAR Electra, C-131A of the U. of Washington, and the C-130 of UKMO. Ships: RAS Akademik Kurchatov, Le Suroit, UNOLS Malcolm Bridge, and NOAA Oceanus.

MAGS (Mackenzie River GEWEX Study)

MAGS is a series of large-scale hydrological and related atmospheric and land-atmosphere studies in the Canadian GEWEX program (Phase I from 1992 -98). The aim is to provide an improved understanding of cold region, high-latitude hydrological and meteorological processes and to study their role in the global climate system. Objectives:

- Conduct field “point” studies to understand physical phenomena such as snow and ice processes, permafrost, and arctic clouds and radiation interactions
- Relate these physical processes to variables which can be used in hydrologic and atmospheric models at the “basin” scale
- Incorporate parameterization schemes into hydrologic-atmospheric models.

BASE (Beaufort and Arctic Storms Experiment) is considered a first major field project of MAGS. MAGS is complementary to GCIP.

MAP (Mesoscale Alpine Program)²⁷⁷²⁾

A cooperative international campaign coordinated by the Swiss Meteorological Institute, Zürich (programme office) with WMO support and a steering committee by a number of institutes: ETH Zürich, Institute of Atmospheric Physics, DLR (Oberpfaffenhofen), University of Innsbruck, University of Vienna, CNR/FISBAT (Bologna), Météo (Toulouse), University of Munich, NCAR (Boulder, CO), Yale University (New Haven, CT), University of Reading (UK). The overall aims of the program are to further the understanding of the physical and dynamical processes that govern the precipitation over a complex topography and to determine 3-D circulation patterns in the Alpine region with a focus on key oro-

graphic-related mesoscale effects. The initiative and the need for MAP is based on the broad consensus of the international science community which emerged at a MAP workshop in Zürich, Switzerland, in September 1994. The MAP program builds on the previous ALPEX and PYREX campaigns. Phase I of MAP (1995-1998): preparatory program and testing of new observing systems. Phase II (1998): 13-month period of a coordinated MAP field campaign (including a 3-month special observing period) with data collection from numerous ground-based, airborne and spaceborne instruments. Phase III (1999-2000): data analysis and post-processing research activities.

MAST (Monterey Area Ship Tracks)

A US campaign (NASA/GSFC/ARC/LaRC, ONR) conducted off the coast of Monterey, CA in June 1994. Objective: study of marine stratocumulus clouds and the processes involved in association with ship tracks (measurement of radiative properties of extensive cloud layers, contaminated and uncontaminated by ship tracks). The ARC ER-2 aircraft carried instruments: MAS, CALS, LASE (vertical concentration profiles of water vapor and aerosols). - Within this context there are also MAST payloads by ONR carried on Shuttle missions (however, MAST has here the designation: "Military Applications of Ship Tracks;" it is in fact the same 5-year program). The first MAST experiment was flown on STS-65 in July 1994, the 2nd MAST experiment was on STS-70 (July 1995).

Background: the reflectivity of marine stratocumulus clouds is strongly influenced by the size of the water droplets in the cloud. This in turn is affected by the characteristics of the aerosol below the cloud. One of the most striking effects that illustrate this is the high-reflectivity tracks in clouds created by ships passing under them. These tracks are mostly seen in IR satellite data, which are more sensitive to droplet size, but quite often the tracks can also be seen in visible satellite data. The tracks can extend for several thousand kilometers and remain visible for two or three days.

MAST (Marine Science and Technology)

A long-term CEC-funded (Commission of European Communities) and coordinated program for European research organizations with the objective to foster scientific knowledge and technological development necessary to understand how marine systems function at basin scales, in order to prepare for sustainable use of the oceans consistent with the preservation of marine environmental quality and to determine their role in global change. The program comprises four areas of activity:

- Marine science (seas surrounding Europe - research on regional problems and marine environments)
- Strategic marine research (emphasis on coastal zones and socio-economic impact)
- Marine technology
- Supporting initiatives

The pilot phase of MAST was from 1989-92; the MAST-II program was from 1990-94, and MAST-III is planned for the period 1994-98.

MASTEX (Mediterranean Aircraft-Ship Transmission Experiment)

A UKMO campaign conducted in June 1990 in the vicinity of the island of Crete. Objective: study of atmospheric transmission in the infrared window region from 10-12 μm (water vapor) for global climate modeling and for sea surface temperature measurements from satellites. Survey flights were conducted by a C-130 (with MARSS) of UKMO in collaboration with the Research Vessel Alliance of NATO's SACLANT Undersea Research Centre, sailing from Crete.

MCTEX (Marine-Continental Thunderstorm Experiment) NCAR

MEDALUS (Mediterranean Desertification and Land Use)

A multidisciplinary EC-supported project under its EPOCH program with the aim to study the desertification (degradation) of the Mediterranean countries brought about by both human- and climatically-caused phenomena. The objectives are:

- To investigate physical processes in the soil and plants that determine how the environment will react to climatic and man-induced desertification over Mediterranean Europe
- To examine the likelihood of a worsening situation in the near future (next 50 years) as a result of both climatic and socio-economic changes
- To evaluate the impact such a worsening of conditions could have on physical conditions and society in Mediterranean countries.

MEDALUS-I project: January 1991 to December 1992, MEDALUS-II project: January 1993 to September 1995 (MEDALUS Office in Reading, UK).

MILOX (Mid-Latitude Ecosystems and Photochemical Oxidants)²⁷⁷³⁾

An IGBP/IGAC program (under focus 5) which started in 1993 with the overall objective to assess and understand the complex interplay between an urban-industrial society, natural and cultivated ecosystems, and atmospheric photochemical oxidants in the northern mid-latitudes.

MIST (Microbursts and Severe Thunderstorms)
NOAA

MIZEX (Marginal Ice Zone Experiment)^{2774), 2775), 2776), 2777), 2778) 2779)}

MIZEX was a large international field program carried out in several campaigns in the Fram Strait and Greenland Sea in June-July 1983, May-July 1984 (MIZEX-East), and March-April 1987, and in the Bering Sea (MIZEX-West) during February 1983. The objectives of MIZEX were to gain a better understanding of the mesoscale physical and biological processes occurring at the ice margin and to help improve existing ice-ocean-atmospheric models. The campaign was sponsored by the US Navy, NSF, NASA, USGS, as well as by ten countries: Canada, Denmark, Germany, Finland, France, Ireland, Norway, Sweden, Switzerland, and the UK. Specific objectives of this campaign were to study:

- Changes in acoustic refraction and coherence (changes in sound speed profiles due to fronts, ice-ocean eddies, and internal waves)
- Ice cracking noise mechanisms as related to ice-ocean eddies, winds, ice dynamics, gravity waves, and the presence of recently frozen thin ice
- Microwave electromagnetic reflectivity and emissive signatures of the winter MIZ and ice and ocean features
- Growth, propagation, and decay of ice-ocean eddies as affected by ice edge dynamic and thermodynamic processes, and their role in lateral heat transfer across the ice edge
- Heat, mass, and momentum transfer in the ice/upper ocean system at the ice margin
- Morphology, rheology, dynamics, and kinematics of the ice field created by forcing of intense incoming gravity waves, winds, and currents
- Winter ice edge meteorology, including mesoscale cyclogenesis (arctic lows) as influenced by large temperature and water vapor contrasts at the ice edge.

²⁷⁷⁹⁾Special issue on MIZEX, Journal of Geophysical Research, Vol. 92, No. C7, June 30, 1987

MIZEX-West²⁷⁸⁰) was a campaign that took place in the central Bering Sea from February 5-27, 1983 (scientists from USA and UK). Observation data were obtained by the NOAA ship Discoverer and the USCG icebreaker Westwind; aircraft: WP-3D (NOAA), CV-990 (NASA), and satellites: NIMBUS-7 and NOAA-POES.

The MIZEX 1984 operations (MIZEX-EAST) utilized seven ships, eight aircraft and four helicopters to support a multidisciplinary team of over 200 scientists and technicians. The remote sensing program had the objectives to obtain a synoptic picture of the morphology and evolution of the experiment area (regional context) and to gain a better understanding of the interactions of energy flux and the ice and ocean surfaces and the atmosphere. Satellite data from: NIMBUS-7 (SMMR), NOAA-POES (AVHRR), DMSP (OLS), and Landsat (MSS). Aircraft: CV-580 (CCRS), P-3 (NRL), P-3 (Norwegian Air Force), CV-990 (NASA), P-3 (NOAA), B-17 (CNES), Falcon 20 (DLR). Some of the sensors used: SAR, scatterometers, microwave radiometers, cameras, microwave imagers, AXBT, radar altimeters, CVI, etc. All MIZEX data are archived at NSIDC, Boulder, CO.

MLML (Marine Light-Mixed Layers)²⁷⁸¹

A long-term US program sponsored by ONR with the overall goal to predict the space/time variability of bioluminescence and optical properties of the upper ocean through the use of theoretical models and inferences from environmental data. Near-term objectives were: a) to identify the organisms responsible for bioluminescence; b) to study the distribution, production and loss of bioluminescence; c) to estimate the volume-specific bioluminescence potential (BPOT); d) to study the connections between bioluminescence and environmental forcing; etc. The observational program started in 1980 with the deployment of an instrumented bio-optical mooring site in the Irminger Sea, about 500 km south of Iceland. The mooring is referred to as the MLML site at location 59.5°N and 21°W. Campaign activities increased in particular during the 1990s. Shipboard measurements were conducted in parallel during numerous cruises to provide a seasonal context for the variation at the MLML site. The campaigns were conducted by many participants from US universities (Columbia University, U. of Rhode Island, UCB, U. of Hawaii, Johns Hopkins University, U. of Southern CA, UC at Santa Barbara, UC at San Diego, WHOI, U. of Southern Florida, U. of Washington, Oregon State University).

MLOPEX (Mauna Loa Observatory Photochemistry Experiment)²⁷⁸²

MLOPEX is a major component in NSF/NCAR's comprehensive GTCP (Global Tropospheric Chemistry Program) with participation from a dozen universities, NOAA, Brookhaven Laboratories, ANSTO (Australia) and INS (New Zealand). The primary goal of GTCP is to measure, understand, and thereby predict changes over the next century in the chemistry of the global atmosphere with emphasis on changes affecting the oxidizing capacity and radiative properties of the atmosphere and the atmospheric component of the biogeochemical cycles. The MLOPEX objectives within GTCP are:

- To evaluate the budgets and photochemical processes of ozone, odd nitrogen and some odd hydrogen species
- To build a climatology of the distributions of photochemically important short-lived trace species in the remote troposphere.

MLOPEX I occurred during May-June 1988 at NOAA's GMCC (Geophysical Monitoring for Climatic Change) site at the Mauna Loa Observatory on the island of Hawaii.

MLOPEX II (Sept-Oct. 1991, Jan.-Feb. 1992, April-May 1992, July-August 1992) at the Mauna Loa Observatory. Aircraft observations were added (NASA DC-8, King Air of U. of Wyoming). MLOPEX II was an experiment to test models of complex factors which control

²⁷⁸⁰)D. J. Cavalieri, et al., "MIZEX West: Bering Sea Marginal Ice Zone Experiment," EOS, Transactions of the American Geophysical Union, Vol. 64, No. 40, October 4, 1983, pp. 578-580

²⁷⁸¹)Special Section: Marine Light-Mixed Layers Program in the North Atlantic, Journal of Geophysical Research, Volume 100, No. C4, April 15, 1995, pp. 6521-6686

the chemistry of reactive gases and radical species in the remote troposphere. A wide range of trace gases, radical abundances and photochemical parameters were measured.

MOCE (Marine Optical Characterization Experiment)

A NOAA/NASA series of field experiments (MODIS-funded) conducted since 1992 and in parallel to the MOBY campaign (see chapter P.139). The objective of MOCE is to conduct experiments at sea (shipboard instruments) at specific sites to obtain a comprehensive set of bio-optical measurements such as radiometric parameters, pigment analysis, total suspended matter, beam transmittance, and physical properties. The data is being used for algorithm development (in pre-launch phase) for instruments such as MODIS, SeaWiFS, MERIS, etc. and for post-launch instrument calibrations in parallel overflights.

MOHAVE (Measurement of Haze and Visual Effects)

EPA project/campaign to study regional haze.

MONEX (Monsoon Experiment)²⁷⁸³

The international MONEX summer campaign, also referred to as **SMONEX**, was conducted within FGGE over the Indian Ocean and adjacent land areas from May to August 1979. The objectives of SMONEX were:

- Study of planetary-scale aspects: investigation of heat sources; onset of monsoon; breaks in the monsoon
- Study of synoptic-scale regional aspects: Arabian Sea Experiment (investigation of low-level monsoon flow, mid-tropospheric cyclones, components of heat sources, mechanisms of onset of monsoon); Bay of Bengal Experiment (development and structure of monsoon depressions, structure and energetics of monsoon trough; prediction of monsoon depressions)
- Interactions with atmospheric circulations (in the Pacific Ocean, southern hemisphere, northern midlatitudes, stratosphere)
- Numerical simulation and prediction (modeling, forecasting).

SMONEX participating countries: Afghanistan, Australia, Bangladesh, Burma, China, France, India, Iran, Japan, Kenya, Madagascar, Nepal, Oman, Pakistan, Saudi Arabia, Seychelles, Somalia, Sri Lanka, Thailand, USA, and USSR.

A SMONEX special observing system was embedded in the FGGE observing system consisting of the World Weather Watch (WWW) surface/upper-air network. Otherwise the SMONEX observing system consisted of research aircraft [Electra (NCAR), P-3 (NOAA), CV-990 (NASA), NRSA-AVRO (India)] and 16 ships, special minisonde upper-air stations, radiometer sondes, weather radars, constant low-level balloons, boundary layer measurement systems, and rocket soundings. Spaceborne observation by GOES (positioned at 60°E), GMS, TIROS-N, NOAA-6, and Meteor (USSR) series.

In this context **WMONEX** (Winter Monsoon Experiment) was conducted from December 1978 to February 1979 in the South China Sea. - The **INDEX** campaign (Indian Ocean Experiment, from 1975-1979) was conducted in parallel to SMONEX primarily along the East African coast and the equator. It served as the oceanographic component of SMONEX. The main objectives of INDEX were to study the time-dependent response of the Indian Ocean to variable wind forcing by the monsoons and the nature of the feedback that the ocean produces on the atmosphere and the monsoon regime itself.

MONSOON 90²⁷⁸⁴

A USDA-initiated (US Department of Agriculture) and sponsored campaign over semiarid rangelands in the Walnut Gulch Watershed in southern Arizona (31°43'N, 110°W), with the objective to investigate the effects of changing soil moisture on the surface radiation balance, the hydrologic cycle, and the feedbacks to the atmosphere. Two field campaigns were

²⁷⁸³J. S. Fein, J. P. Kuettner, "Report on the Summer MONEX Field Phase," Bulletin American Meteorological Society, Vol. 61, No. 5, May 1980, pp. 461-474

conducted, June 4-6, 1990 (dry season), and July 23 to August 10, 1990 (wet season). Ground-based observations included: eight sites with METFLUX (Meteorological - Energy Flux) stations, vegetation and soils information, soil moisture, soil temperature, evapotranspiration, radio soundings of atmospheric boundary layer. Spaceborne observational data from SPOT (HRV), Landsat-5 (TM), NOAA-11 (AVHRR) and GOES-6. Aircraft observations: Cessna (radiometer, multispectral video camera, thermal IR scanner), Aero Commander (of USDA with a multifrequency microwave radiometer of RAS/IRE Moscow, color video camera), C-130 (of NASA/ARC with NS001, TIMS, PBMR), DC-8 (of NASA/ARC with AIRSAR). Participants: USDA Remote Sensing Lab and Subtropical Agricultural Research Lab, USGS, LANL, NASA/JPL, RAS/IRE (Moscow), LERTS (France), U. of Arizona, U. of Maryland.

MOZAIC (Measurement of Ozone by Airbus In-Service Aircraft), see **P.40.1**

NARE (North Atlantic Regional Experiment)

An international program within IGBP/IGAC (participation of NOAA, NCAR, KfA Jülich, AWI, AES, Battelle Pacific Northwest Laboratory, UKMO, etc.) with the objective to examine the transport of tropospheric ozone and ozone precursors from populated and industrialized continental areas to the adjacent oceans. NARE started in 1991 with ground-based measurements, which were augmented by aircraft measurements in the summer of 1993. The initial emphasis of NARE is to determine the impact of emissions of pollutants which lead to the production of tropospheric ozone (O₃) in the North Atlantic Region. Aircraft flights between US East Coast and Newfoundland. Measurements of O₃, CO, nitric oxides, nonmethane hydrocarbons, and aerosols, in addition to state parameters and winds. - Parallel to NARE, NOAA/AL conducted the APARE campaign (Asian-North Pacific Regional Experiment) with the same objectives as NARE.

NATAC (North Atlantic Chemistry Experiment)

A ship-based campaign in 1991 carried out aboard the Russian vessel R/V Ernst Krenkel in the Mediterranean Sea, the mid-latitude North Atlantic and the North Sea. Several German (KfA, AWI), Ukrainian, and Russian research teams investigated the interactions of clean marine and polluted continental air masses. The studies included detailed measurements of trace gases related to photochemistry of the atmosphere (NO, NO₂, PAN, NMHCs, CO, O₃, etc.) as well as tracers for continental air masses (²²²Rn, ²¹²Pb). Meteorological observations, aerosol studies and precipitation sampling and analysis complemented the trace gas part of the program.

NBIOME (Northern Biosphere Observation and Modelling Experiment, PI: J. Cihlar)

The 10 year program for the 1990s is a cooperative Canadian effort involving CCRS, Forest Canada, Agriculture Canada, and a number of Canadian universities. It has been accepted as part of the Canadian Global Change Program, coordinated by the Royal Society of Canada. NBIOME's principal objective is to increase understanding of the role of terrestrial vegetation in the total Earth system and its changes with time. Its goal is to develop and adapt an observation system pertaining to a family of landscape and ecosystem models, to monitor, evaluate, and predict the impact of global change on boreal ecosystems, including forests, grasslands, wetlands and tundra. Use of satellite data from AVHRR, MODIS (EOS), TM and ETM+ (Landsat), Radarsat, ERS-1,-2.

NDTP (North Dakota Thunderstorm Project)²⁷⁸⁵⁾

NDTP was conducted by NOAA, NCAR, universities and state agencies on the northern High Plains in the vicinity of Bismarck, North Dakota, from June 12 to July 22, 1989. The objectives were studies in the areas of storm dynamics, cloud physics, radar meteorology,

2784) W. P. Kustas, et al., "An Interdisciplinary Field Study of the Energy and Water Fluxes in the Atmosphere-Biosphere System over Semiarid Rangelands: Description and Some Preliminary Results," *Bulletin American Meteorological Society*, Vol. 72, No. 11, November 1991, pp. 1683-1705

2785) B. A. Boe, et al., "The North Dakota Thunderstorm Project: A Cooperative Study of High Plains Storms," *Bulletin American Meteorological Society*, Vol. 73, No. 2, February 1992, pp. 145-160

atmospheric chemistry and electricity. Ground-based, airborne, and spaceborne observations were conducted. Participating aircraft: WP-3D (NOAA), Citation (U. of North Dakota), King Air (U. of Wyoming), Sabreliner (NCAR), etc. Spaceborne imagery from GOES was acquired. An extensive network of ground-based sensors was installed (boundary layer winds, soundings, Doppler winds, lightning detection, etc.).

NOPEX (Northern-Hemisphere Climate Processes Land-surface Experiment)²⁷⁸⁶⁾

NOPEX is an IGBP/BAHC-coordinated large land-surface project with the overall objective to investigate feedbacks between the biosphere and the atmosphere in a patchy landscape dominated by boreal forests but also including agricultural land, bogs, and lakes. NOPEX aims at quantifying the energy, water and carbon budgets for an area of 50 km by 100 km in central Sweden. The NOPEX region is also the target region of EMAC 1994/95. Planning started in 1987; two major field campaigns were carried out in 1994 and 1995; subsequent winter campaigns are planned for 1996/97 and for 1998/99. The continuous field activities started in early 1994 and will continue to the end of the century and beyond. The NOPEX central office is at Uppsala University, Sweden (S. Halldin).

NOPEX is comprised of around 100 subprograms divided into two major programs. A basic idea of the field-based activities within NOPEX has been to remedy the problems of a too-short time period that characterized previous experiments. The field programs in NOPEX are the CFCs (Concentrated Field Efforts - they are time-limited with a concentration of resources assigned during special intensive observation periods), and the multi-annual CCM (Continuous Climate Monitoring) program. The idea is to strike a balance between the two programs in such a way as to optimized the availability of resources.

NOPEX participants come from the following countries: Sweden, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Italy, Japan, The Netherlands, Norway, Slovakia, UK, and USA. Data from NOPEX are stored in SINOP (System of Information in NOPEX). The original SINOP, located at Uppsala University, Sweden, at the NOPEX Central Office, is closely following the information-system layout of previous experiments, like FIFE and HAPEX-SAHEL, and is biased towards time-series data. The final SINOP will include a GIS component integrated with the time-series component. Data are first available to researchers with accepted NOPEX subprojects, but later will be released for free use within the scientific community (tentatively on January 1, 2000).

- **CFE1** (Concentrated Field Effort 1), May 27 to June 23, 1994²⁷⁸⁷⁾
CFE1 consisted of 54 subprojects, organized in workgroups for local-scale, regional-scale, and remote-sensing studies. Measurements of evaporation, exchange of CO₂ and momentum, sensible heat flux and radiation, together with heat and water in soil and vegetation are central in the project. Ground-based, airborne (EMISAR) and spaceborne observations [ERS-1, JERS-1, DMSP (SSM/I), NOAA (AVHRR), Landsat, Spot].
- **CFE2** (Concentrated Field Effort 2), April 18 to July 14, 1995 with IOP1 from May 2-12 and IOP2 from June 19 to July 10, 1995.
There are 12 local-scale studies: transpiration, water relations and economy of large trees; CO₂ and H₂O transfer rates between forest floor and canopy; biogenic VOC fluxes from the forest; heat, momentum, and vapor fluxes, and profiles of wind at agricultural site; fluxes of latent and sensible heat and CO₂ from forest and field; energy balance and evaporation from a bog; water regime of plant canopies and the structure of their energy balance; simple parameterization of land-surface-atmosphere interaction; transport of water in the soil root zone; CO₂ and water vapor flux at the agricultural site; soil moisture, radiation, temperature and crop-related measurements; physiological responses at the leaf to atmospheric and soil factors; measurement and model-

²⁷⁸⁶⁾Information provided by S. Halldin of Uppsala University; information is also on www interface (homepage): <http://hydserver.hyd.uu.se/nopex>

²⁷⁸⁷⁾L. C. Lundin, S. Halldin, "NOPEX Experiment Plan," Part 1: 1994 and Part 2: 1994 from NOPEX Central Office

ing of the surface energy budget.

The seven regional-scale studies include: test and improvement of new parameterization scheme; airborne microwave measurements over NOPEX site; energy budget of a lake and its influence in the mesoscale; modeling of fluxes and PBL structure over inhomogeneous terrain; water-balance studies of Lake Tämnen; determination of regional surface fluxes; turbulent fluxes in the atmospheric boundary layer.

The 14 remote sensing studies are: radar profiling and scatterometry above forests; studies of biomass in temperate and boreal forest by SAR; water content of top soil layer; polarization and microwave radiative transfer of vegetation; validation of backscatter models; monitoring of soil erosion; data analysis from imaging spectrometers; regional mapping of leaf area index; relationship between topography and surface temperature; forest ecosystem radiation model; SAR and imaging spectrometer for parameter retrieval; land surface monitoring by passive and active microwave sensing; relationship between photosynthesis and energy budget of a lake; modeling of the energy fluxes over the NOPEX area; aerodynamic surface roughness and physical roughness using radar/optical remote sensing.

Some airborne sensors are: EMISAR, EMIRAD, MARSS, Deimos, DAIS-7915, AISA. Satellites: ERS-1, ERS-2, Spot, Landsat (TM), DMSP (SSM/I), NOAA (AVHRR, TOVS), METEOSAT (VISSR), JERS-1. - In addition 21 CCM subprojects participated actively during CFE2.

- **CFE3** (Concentrated Field Effort 3), a winter campaign in the planning phase. CFE3 will encompass the ordinary NOPEX region in Sweden as well as a second site in northern Finland. There will be a pilot study carried out in winter 1996/97, followed by a full-scale field campaign two years later.
- **CCM** (Continuous Climate Monitoring)
The CCM program is conducted within two main and two small meteorological sites and four small experimental catchments. The CCM program consists of three subprograms; these are: LTCS (Long-Term Catchment Studies), SVAM (Soil-Vegetation-Atmosphere Monitoring), and RCS (Regional Climate Survey). The LTCS and SVAM subprograms consist of 21 individual subprojects. The RCS subprogram handles data from external sources, eg., satellite data received as part of the pilot project on high-resolution data run by CEOS and IGBP-DIS, data from the Swedish Meteorological and Hydrological Institute, the Swedish Geological Survey, and the Swedish National Forest Inventory.

NORCSEX (Norwegian Continental Shelf Experiment)²⁷⁸⁸⁾

NORCSEX'88 was a pre-launch ERS-1 campaign carried out during a 25-day period in March 1988 on the continental shelf off the Norwegian Coast, centered at 64°N, with participation from Canada, France, Germany, Norway, and the USA. Objective: test of ERS-1 AMI (C-band SAR) and radar altimeter RA-1. Aircraft: CV-580 of CCRS with C/SAR, Geosat radar altimeter data, and a ship-mounted scatterometer. Complementary in situ measurements of parameters in the lower atmosphere and upper ocean were simultaneously collected from research vessels, moorings, and drifting buoys.

NORCSEX'91 (Norwegian Continental Shelf Experiment). ²⁷⁸⁹⁾ ²⁷⁹⁰⁾

NORCSEX'91 was an additional ERS-1 calibration/validation campaign (supported by ESA, Norwegian Space Agency, NERSC, ERIM, NPS, TNO, etc.) conducted from November 7 to 28, 1991 from a research vessel (Hakon Mosby of the University of Bergen). Site: operations were conducted off the west coast of Norway at a location 64° 30' N and 9° E,

centered on the Haltebanken, a sea mount which rises to 200 m above the coastal plane. The primary objective of NORCSEX was to demonstrate and validate the data (ocean state and features) of AMI-SCAT, the scatterometer instrument of the newly launched ERS-1 satellite. In situ scattering measurements were made from ship at 1.5, 5.25, and 9.38 GHz in VV or HH polarization at incidence angles of 23° and 50°.

NORSEX (Norwegian Remote Sensing Experiment)²⁷⁹¹⁾

NORSEX consisted of three field campaigns: 1) a sea surface temperature (SST) and wind campaign in the Norwegian and Barents seas in November 1978 (reception of Nimbus-7 data from SMMR); 2) dynamics of the Norwegian Coastal Current in the spring of 1979 (remote sensing methods); and 3) marginal ice zone investigations north of Svalbard from September 17 to October 12, 1979. - The last of these campaigns had international participation: NRSC (now NERSC), University of Bergen, NASA (GSFC, LaRC, JPL), ONR, USGS, University of Bern, AES (Canada). Objectives of NORSEX-79: study of interactive processes among air, ice, and water in the marginal ice zone (MIZ). Coordinated passive and active microwave observations from shipborne, airborne, and satellite instruments together with in situ measurements. Collection of Nimbus-3 SMMR data. Aircraft: C-130 and CV-990 (NASA); airborne sensors: airborne microwave scatterometer, stepped frequency microwave radiometer, multifrequency microwave radiometer, passive microwave imaging system, PRT-5, two cameras, L-band SAR. Ship: R/V Polarsirkel (platform for many surface observations). Deployment of four ocean drifting buoys (CTD type) and four ice floe drifters (all buoys were ARGOS-tracked).

NOWES (Northern Wetlands Study)²⁷⁹²⁾

A Canadian/US campaign within IGBP/IGAC coordinated by CIRAC (Canadian Institute for Research in Atmospheric Chemistry) was conducted in the Hudson Bay lowlands in the time frame from June 1 to the end of October 1990. Objectives: 1) to investigate the atmospheric chemistry of biogenic gases and related compounds in northern wetlands with emphasis on carbon gases, particularly methane; 2) to develop an understanding of the physical, chemical, and biological processes that influence biogenic gas production; 3) to determine the significance of northern wetlands as a source of biogenic gases to the atmosphere globally; 4) to characterize trace gas exchange in the context of the ecosystem. - The research activities were divided into four areas: 1) field studies of trace gas exchange in the Hudson Bay lowland, using enclosures, towers, and aircraft; 2) the scaling of flux measurements through modeling; 3) regional atmospheric chemical observations at Fraserdale; 4) field studies of the trace gas exchange in northern Labrador and Quebec in collaboration with ABLE 3B. NOWES concentrated its field effort along a 120 km x 40 km transect northwest of the town of Moosonee. The main aircraft activity took place along two transects: one from Kinosheo Lake to North Point, the other from Moosonee to Kinosheo Lake. In addition to the field program, another study site was established near Churchill, Manitoba. A second aircraft survey was done on a transect between Moosonee and Churchill.

OACES (Ocean-Atmosphere Carbon Exchange Study)²⁷⁹³⁾

A NOAA/AOML long-line study with the objective to perform repeat measurements along north-south transects in all major ocean basins to determine the change in total organic carbon with time. First estimate of the amount of CO₂ taken up from the atmosphere for estimating the role of the ocean in uptake of anthropogenic CO₂. The 1993 North Atlantic CO₂ cruise was part of the OACES long-line study.

OCOS (Ocean Climate Observing Study)

A program planned by Australia over the tropical Indian Ocean

OTTER (Oregon Transect Ecosystem Research)²⁷⁹⁴⁾

A cooperative project between NASA and several universities in the US and Canada with the objective to discern the ecology of western coniferous forests using remote airborne and ground-based observations. Six sites in Oregon across an elevational and climatic gradient were intensively studied (1990); the transect stretched from the Pacific Coast to 300 km east. Specific goals of OTTER were to simulate and predict ecosystem processes such as photosynthesis, transpiration, above-ground production, nitrogen transformation, respiration, decomposition, and hydrologic processes. Instruments flown on NASA aircraft include: TMS, NS001, AVIRIS, ASAS, TIMS, AIRSAR. Observations also from an ultra-light aircraft (Quicksilver GT500) from Oregon State University to measure aerosol concentrations and water vapor. Satellite data from AVHRR (NOAA-11). Ground observations include measurements of canopy chemistry, meteorological variables, and timber measurements. OTTER data are archived at the ORNL DAAC.

PANASH (Paleoclimates of the Northern and Southern Hemispheres)

An IGBP/PAGES focus 1 project (preparation phase as of 1995) with the overall objective to address the geographic imbalance in information that is available on the past history of the climate system, especially in the tropical regions and the southern hemisphere (understanding of interhemispheric climatic coupling). This will be accomplished through the development of a global framework of paleoscience sites organized in a series of continental and marine transects which will be closely tied into a global paleo-information grid. PANASH is comprised of the activities (or campaigns) of PEP-I, -II, and -III and the OCEANS.

- PEP-I (Pole-Equator-Pole), the 'Americas Transect.' PEP-I is an inter-American research program designed to address questions on the dynamics of transequatorial atmospheric linkages. PEP-I serves also to link the marine and terrestrial records along the eastern Pacific coast and to understand climatic linkages between the equatorial trans-Pacific and the Amazon Basin.
- PEP-II (Pole-Equator-Pole), the 'Austral-Asia Transect.' PEP-II incorporates the paleoclimate record of the Lake Baikal Drilling Project and other central Asian projects which have implications for the region's paleohydrologic and paleomonsoon history.
- PEP-III (Pole-Equator Pole), the 'Afro-European Transect.' Considerable research emphasis is on the African paleoclimate (terrestrial records of the late Pleistocene and Holocene, lake-level records of central Africa, etc.). Collaboration with the **IDEAL** (International Decade of East African Lakes) project. The paleomonsoon is a key objective of PEP-III. Further PEP-III long-term projects are: **ELDP** (European Lake Drilling Project), and **PMAP** (Paleoenvironment Multiproxy Analysis and Mapping Project), a Lake Rukwa (Tanzania) project.
- OCEANS.
 - Task 1: The North Atlantic Project is centered on climate variability of this region and surrounding land masses during the last millennium.
 - Task 2: Tropical Ocean-Atmosphere Systems. Cooperation with CLIVAR.
 - Task 3: IMAGES (International Marine Global Global Change Study) is directed towards the quantification of climate and chemical variability of the oceans with century-scale resolution.

PASC (Polar Atmospheric and Snow Chemistry)

An IGBP/IGAC program (under focus 3) with the following goals:

- To understand the role of the tropospheric chemistry of the polar regions in global change
- To establish the relationship between atmospheric chemical composition and glacial snow and ice in polar regions
- To document present and planned studies of the polar troposphere and of snow chemistry relevant to global change

²⁷⁹⁴⁾ M. Moghaddam, S. Durden, H. Zebker, "Radar Measurement of Forested Areas during OTTER," Remote Sensing Environment, Vol. 47, 1994, pp. 154-166

- To identify knowledge gaps in polar atmospheric and snow chemistry and encourage coordinated efforts to fill those that cannot be addressed by individual studies.

Campaigns in the PASC context are: PSE 1992, AGASP, DEGASP.

PEM-West (Pacific Exploratory Mission - West), see under APARE

PEM-Tropics (Pacific Exploratory Mission - Tropics)²⁷⁹⁵⁾²⁷⁹⁶⁾

PEM-Tropics is a NASA campaign in the planning phase; it is part of the GTE (Global Tropospheric Experiment) program (follow-on to PEM-West, see also ABLE and CITE) consisting of two subcampaigns: **PEM-Central** and **PEM-East**. PEM-Tropics involves the use of two aircraft (NASA/ARC DC-8 and NASA/WFF P3-B) during the time period of August - October 1996. The aircraft missions are designed to provide a latitude/altitude transect of atmospheric composition over the tropical Pacific Ocean. The DC-8 will survey the central and westerly portions of the South Pacific Basin while the WFF-P3-B surveys the easterly portion of the Pacific. The main objectives of PEM-Tropics are to study concentrations of photochemically active gases (in particular O₃, NO_x, NO_y, and CO) of the troposphere and to identify the processes regulating concentrations of these gases. A secondary objective is to provide data for constraining and evaluating global models of atmospheric CO₂, CH₄, N₂O, and OH (via CH₃CCl₃ -methyl chloroform - and ¹⁴CO proxies). Supporting measurements planned are: C₂-C₁₀ NMHCs, halocarbons, carbonyls, peroxides, aerosols, HCl, DMS, ⁸⁵Kr, ²²²Rn, ²¹⁰Pn, ⁷Be, and NH₃. Participation: NASA/LaRC/ARC, NCAR, U. of Michigan, NOAA, MIT, U. of Rhode Island, U. of New Hampshire, etc.

PMV&D (Plume Model Validation and Development)

A SRI International study, sponsored by EPRI (Electric Power Research Institute) with the objective to determine diffusion of emissions from coal-burning power plants. Tests were conducted during three field programs at Kincaid, Illinois and two field programs at Bull Run, Tennessee.

POLARIS (Photochemistry of Ozone Loss in the Arctic Region in Summer)²⁷⁹⁷⁾

A NASA/NOAA aircraft campaign with the objective to evaluate quantitatively the loss rate of stratospheric ozone over a range of altitudes and latitudes in the spring and summer season of the northern hemisphere. The campaign period is scheduled for 1997, aircraft deployment locations are at NASA/ARC, Moffett Field, CA and at Fairbanks, AK. Observations are conducted with the ER-2 aircraft (with a wing pod upgrade and new General Electric engines). In situ measurements of a wide variety of reactive nitrogen (NO_y), halogen (Cl_y), and hydrogen (Ho_x) reservoirs and aerosols will be made in the lower stratosphere. In addition there are measurements of long-lived tracers. The following sensors will be flown: ATLAS (N₂O), ALIAS (HCl, N₂O, CH₄), MASP (aerosols), ClO/BrO-Instrument (Harvard), etc. Collaboration with other investigators is invited making similar measurements from satellites, other aircraft or balloons.

POLINAT (Pollution from Aircraft Emissions in the North Atlantic Flight Corridor)²⁷⁹⁸⁾

An international campaign sponsored by the EC and coordinated by DLR/IPA (Institut Physik der Atmosphäre, Oberpfaffenhofen) with the objectives to measure and model the relative contribution of air traffic emissions to the composition of the upper troposphere and lower stratosphere, and to assess the effects of air traffic emissions (e.g. changes in ozone, oxidizing capacity, aerosol abundance, clouds). POLINAT campaign periods: 1) November 2-13, 1994; 2) June 21 to July 5, 1995; a further campaign is scheduled for February 1997. Participants: DLR, MPIK (Heidelberg), CNRS/LMD (Palaiseau, France), KNMI (The Netherlands), AEA Environment and Energy (Harwell, UK), UKMO (Bracknell, UK), NILU (Lillestrom, Norway), U. of Oslo and U. of Bergen (Norway), U. of Missouri

POLRAD (Polarimetric Radiometry Campaign in 1996).

http://www.estec.esa.nl/vrwww/VRS_POLRAD.html

PSE 1992 (Polar Sunrise Experiment 1992)²⁷⁹⁹⁾

An international campaign conducted at Alert, Canada, on northern Ellesmere Island (82.5° N, 62.3° W), from January 16 to April 20, 1992. The study involved 25 scientists from five nations and was part of IGAC (International Global Atmospheric Chemistry) project. Objective: study of the role of marine halogens and chemical destruction mechanisms in lower tropospheric ozone depletion at polar sunrise. The study involved several levels of intensification of ground-based observational activities at Alert. These included enhanced measurements throughout the campaign period and two intensive efforts of several weeks duration before and after polar sunrise. The dark-period campaign constitutes the first detailed characterization ever made of lower tropospheric composition in the absence of sunlight. - A light-period intensive in April permitted in parallel to the ground observations also aircraft observations (vertical profiles of air composition) provided by a Convair of the Canadian National Research Council (NRC, Ottawa). Participants: AES, York University, NRC, CIRAC (Canada), U. of Heidelberg, KfA Jülich, U. of Hannover (Germany), NIES Tsukuba, U. of Tokyo (Japan), U. of Stockholm (Sweden), U. of Illinois, Purdue U. (USA).

PYREX (Pyrenean Experiment)^{2800) 2801)}

A cooperative campaign initiated by the French (CNRS, CRPE, LA, LMD,) and Spanish (INM) Meteorological Services and conducted during October/November 1990 in the Pyrenean Mountains (participation of CNES, CNRM, DLR, IGN, INSU, Météo, SA). Objective: determination of the momentum budget for an improved model for 2-D mountain flow perturbation. A number of experiments were performed for synoptic situation description (meteorological soundings, constant-level balloons, wind profilers, upper air soundings) and local flow analysis (aircraft, radars, etc.). Also lidar observations (LEANDRE) of the perturbations induced on tropospheric flow and boundary layer structure. Aircraft: ARAT (Météo-France), Merlin IV and Piper Aztec (CNRM), Falcon 20 (DLR). Satellite data from METEOSAT and NOAA (AVHRR).

REBAL'92 (Radiation and Energy Balance for Imagery and Electromagnetic Propagation)

A cooperative campaign by DoD and USDA conducted by the US Army Atmospheric Sciences Laboratory and the USDA Research Service, at Bushland, Texas, during May and July 1992. Objectives: study of surface radiation/energy balance processes, characterization

²⁷⁹⁹⁾ Special Section: Polar Sunrise Experiment (PSE 1992), Journal of Geophysical Research, Vol. 99, No. D12, December 20, 1994, pp. 25313-25518

of surface-layer micro-meteorological processes over wet and dry soil surfaces. A wide variety of instruments were used for the ground observations. ²⁸⁰²⁾

REFLEX (Radiation and Eddy Flux Experiment)²⁸⁰³⁾

A cooperative campaign series conducted by AWI (Alfred Wegener Institut) of Bremerhaven and Potsdam, and GKSS of Geesthacht, Germany. Objective: study the effects of low level - mainly stratiform - clouds or arctic haze on the vertical radiative fluxes over various sea ice conditions in summer. Observation by two research aircraft: POLAR 2 and POLAR 4 of AWI (both aircraft are DO 228 turboprop). Instrumentation: both aircraft carried upward- and downward-looking pyranometers (Eppley PSP) and pyrgeometers (Eppley PIR) to measure radiation fluxes (vertical profiles during ascent and descent are also measured); FSSP (Forward Scattering Spectrometer Probe) for aerosol measurements; laser altimeter (PS-100EL) to measure surface roughness; downward-looking line scan cameras for synoptic information; collection of meteorological data (wind, temperature, humidity); GPS position; gust probe ‘Meteopod’ on POLAR-2 aircraft only. Flight altitudes up to 4.5 km. REFLEX-I was conducted in September/October 1991. REFLEX-II took place in March 1993. Both campaigns were primarily aircraft supported investigations of the lower atmosphere over the marginal ice zone of the Greenland Sea (field and numerical model investigations of turbulent and dynamic processes in the lower atmosphere and on the effects of the lower boundary layer conditions on the ocean surface). REFLEX-III is scheduled for June to August 1995. Further cooperation on REFLEX-III with the Technical University of Copenhagen and the UKMO is being considered (within the framework of EMAC). REFLEX-III is being jointly conducted with the AREOMAG’95 campaign (POLAR-2 will also conduct aeromagnetic measurements) for reasons of cost sharing. REFLEX-III is being flown from northern Greenland.²⁸⁰⁴⁾

RENE (Rehearsal ERS-1 Validation Northern Europe)

An ESA-initiated and organized campaign for the validation of ERS-1 wind- and wave data. The actual campaign took place from September 16 to December 10, 1991 off the coast of Norway (Haltenbanken area, near Trondheim). The experiments were carried out on board a number of aircraft, ships, and ocean buoys and represented a diverse collection of wind and wave measurements. In preparation of RENE ‘91 a rehearsal campaign was conducted in Feb. 1990.²⁸⁰⁵⁾

A NOAA instrument C-SCAT (C-band scatterometer) was flown aboard a WP-3 aircraft in the Gulf of Mexico for underflights of AMI (ERS-1 SAR instrument) passes.

In addition an ERS-1 field campaign for wind and wave data measurements was carried out (Grand Banks ERS-1 SAR Validation Experiment) by several Canadian institutions off the coast of Newfoundland. Research vessel: CSS Hudson (Bedford Institute of Oceanography), CCRS airborne instruments (C/X-SAR, Convair-580 C-band SAR, etc.).

RICE (Regional Interactions of Climate and Ecosystems)

An IGBP project with the objective to facilitate the integration of component models developed within IGBP into global change models. The goals of RICE with regard to PILPS (land surface intercomparison schemes) are:

- to facilitate the acceptance by physical modelers of the need for interactive vegetation and soils components
- to demonstrate the sensitivity to vegetation and soils components
- to examine the robustness of vegetation and soils components to climatic variables simulated by anticipated host models.

RITS (Radiatively Important Trace Species)

A NOAA/AOML field campaign program with the objective to measure ozone (O₃), its significant precursors, and related aerosols in the marine boundary layer of the world's oceans. Campaigns took place during cruises in the equatorial Atlantic (1986), equatorial Pacific (1987, 1990), South Atlantic (1991), and the North Atlantic (1992, 1993). The 1993 RITS campaign in the North Atlantic was in conjunction with NARE (North Atlantic Regional Experiment), an activity of the IGAC (International Global Atmospheric Chemistry) program.

ROCEW (Role of Clouds, Energy and Water)

NCAR campaign

SAAMEX (Surface and Atmospheric Airborne Microwave Experiment)²⁸⁰⁶⁾

In international campaign in northern Finland (northern Baltic) conducted during March 1990. Coordinator: Finnish Meteorological Institute. Participants: HUT (Finland) and UKMO, Farnborough. Primary objectives: a) to investigate the emissivity of various surfaces at a wide range of microwave frequencies, b) to study atmospheric transmissions in the microwave and infrared (1.0 - 2.0 μm and 10 - 12 μm) frequencies. Aircraft: helicopter (HUT) and C-130 (UKMO) both equipped with radiometers.

SABLE (South Atlantic Backscatter Lidar Experiment)^{2807), 2808)}

Airborne campaigns (aerosol measurement program) conducted by DRA (Defense Research Agency) of Malvern, UK, and the Phillips Laboratory (AFGL), Hanscom AFB, MA.

²⁸⁰⁶⁾ Information provided by D. Jones of UKMO, Farnborough

²⁸⁰⁷⁾ S. Alejandro, et al., "SABLE: A South Atlantic Aerosol Backscatter Measurement Program," Bulletin American Meteorological Society, Vol. 71, No. 3, March 1990, pp. 282-287

²⁸⁰⁸⁾ S. B. Alejandro, et al. "Atlantic atmospheric aerosol studies, 1. Program overview and airborne lidar," Journal of Geophysical Research, Vol. 100, No. D1, January 20, 1995, pp. 1035-1041

SABLE consists of two campaigns, the first was conducted in the period October 27 - November 10, 1988; the second one took place from June 23 to July 14, 1989. Objectives: collection of lidar measurements to determine atmospheric winds and the spatial and temporal variation of aerosol backscatter (and to obtain a database from a remote location far from industrial sources of aerosols). Both SABLE campaigns were flown out of Ascension Island (8°S, 14°W) on a Canberra (B-57) aircraft [sensors: coherent CO₂ lidar, particle probes, imaging]. Spaceborne data from ERBS with SAGE-II instrument (sunset occultations). Ground-based data from a direct detection lidar, a coherent lidar, and a sun-tracking photometer.

SAFARI (Southern African Fire-Atmosphere Research Initiative), see under STARE

SAGA 3 (Soviet-American Gases and Aerosols Experiment)²⁸⁰⁹

A cooperative campaign conducted in 1990 by researchers from Soviet institutes [MEPhI (Moscow Engineering Physics Institute), IAG (Institute of Applied Physics, Moscow), IAP (Institute of Atmospheric Physics, Moscow), IEM (Institute of Experimental Meteorology, Obninsk), LAM (Laboratory for Atmospheric Monitoring, Moscow, MGO (Main Geophysical Observatory, St. Petersburg)] and American institutes [NOAA (CMDL, PMEL), GSFC, WFF, US universities]. Objectives: study of trace gases (composition) and aerosols in the remote marine boundary layer. Detection of changes in the atmosphere's composition that may cause changes in the global climate. Study areas: concentration of gases in seawater and their air-sea flux, photochemistry in the marine boundary layer, distribution of aerosol particles in the marine boundary layer, measurement of latitudinal concentration gradients of trace species over the Pacific Ocean, stratospheric aerosol layers originating from both the constant influx of sulfur gases and the sporadic injections of volcanic SO₂. - Experiments were conducted aboard the Soviet ship R/V Akademik Korolev, which carried out five major transects through the Pacific Ocean. Satellite data from GOES.

SALSA (Semi-Arid Land-Surface-Atmospheric Program)²⁸¹⁰

A cooperative interdisciplinary campaign program (1996-1999) initiated by the Agricultural Research Service (ARS) of USDA (US Department of Agriculture) and supported by ORSTOM of France. The SALSA campaign region stretches from the Walnut Gulch Watershed in southeastern Arizona, as part of the Upper San Pedro River Basin (6500 km²), to Sonora, Mexico (spanning the US-Mexico border). The overall objectives are the study of arid and semi-arid regions and their sensitivity to climate variations (seasonal and inter-annual variations, land surface-atmosphere interaction studies). SALSA is conceived as a multidisciplinary monitoring and modeling effort to understand the complex hydrometeorological, biological, and ecological processes of this fragile semi-arid region. Specific objectives are:

- To estimate the spatio-temporal variations of surface energy and water balance over a heterogeneous region
- To assess the effects of changes in the surface properties across the US-Mexico border on the regional surface energy and water balance.

The concept entails long-term monitoring at many sites of the study area and the acquisition of remotely-sensed aircraft and satellite data on a target of opportunity basis. Participants: USDA/ARS (Tucson, and Beltsville); University of Arizona (Hydrology and Water Resources Department), Tucson; several NASA/EOS teams; CESBIO, Toulouse, France; ORSTOM, Montpellier, France; and CIDESON, Hermosillo, Mexico. During the summer 1996 the ORSTOM group (France) is setting up a transect of long-term surface flux stations on the Mexican side of the watershed. Acquisition of satellite data from POES (AVHRR), GOES, DMSP (SSM/I), ERS-1,-2 (AMI-SAR, AMI-SCAT, ATSR), SPOT (HRV, Vegetation), ADEOS (POLDER), Landsat (TM, ETM+).

²⁸¹⁰) Information provided by Y. Kerr of CESBIO, Toulouse, France

SAREX-92 (South American Radar Experiment)^{2811), 2812)}

ESA campaign flown at test sites in South America (Venezuela, Guiana, French Guiana, Brazil, Colombia, and Costa Rica) in April 1992. Acquisition of airborne and ERS-1 C-band data to evaluate the usefulness of spaceborne C-band SAR in a tropical forest environment. The scientific objectives include: physical backscatter modelling, empirical analysis of target/sensor relationships, cross-calibration and integrated analysis of ERS-1 and airborne data, satellite simulation studies. Applied objectives are: evaluation of radar for mapping forest from nonforest areas, differentiation of forest/vegetation types, mapping of clear cuts and different regrowth stages, identification of new roads and other forms of human activity, identification of flooded forest during the wet season.

Instruments: C/X-SAR (CCRS, Canada, flown on CV-580 at all test sites, see P.61 for description of instrument), the ERASME scatterometer [CRPE, France, now CETP] was flown over French Guiana and over Guiana (formerly British).

SARSEX (SAR Internal Wave Signature Experiment)²⁸¹³⁾

SARSEX was conducted in the New York Bight off the coast of Long Island (50 km square box test area) in late summer 1984 with the objective to investigate SAR imaging of oceanic (continental shelf) internal waves. During the phase I test period (from August 27 to September 7, 1984) oceanographic measurements (isotherm displacements) were made from two ships, the Bartlett (US Navy) and R/V Cape (APL). Echo sounding and internal wave horizontal currents were measured. Conductivity-temperature-depth (CTD) and XBT (Expandable Bathythermograph) profiles were made periodically throughout the test area. Airborne SAR observations in X-, L- and C-band with CV-580 aircraft (CCRS). During phase II (October 9-11, 1984), L-band SAR images of the test area were recorded from Shuttle during the SIR-B mission. SARSEX was sponsored by ONR with participants from APL, ERIM and CCRS.

SAXON-FPN (Synthetic Aperture Radar and X-band Ocean Nonlinearities - Forschungsplattform Nordsee)²⁸¹⁴⁾

A US/German cooperative program consisting primarily of a field experiment (Phase I, November 1990) in the North Sea on and around the German research platform FPN. Phase II of the field experiment took place in November 1991 (plus a series of workshops). The program had the objective to investigate radar backscatter phenomena and SAR imagery from ocean surfaces, and to study the relationship between acoustic and microwave scattering. - The campaign was conducted using FPN-based instruments (a number of microwave, optical, and acoustic experiments), in parallel to ship-mounted sensors (R/V Planet of the German Navy and the Marine Geophysics Research Institute (FWG), Kiel), and to airborne instruments. FPN location in the German Bight at 54° 42' 5.8" N, 7° 10.9' 9.2" E.

Aircraft in the Phase I campaign: 1) ERIM/Navy P-3 aircraft with P-3/SAR, 2) NRL P-3 aircraft with RAR, ROWS, and PRT-5, 3) DLR DO 228 aircraft with C-band SAR; 4) C-130 (Transall) aircraft of the Research Institute for Applied Natural Sciences, Wachtberg-Werthoven (FGAN) with a W-band microwave radiometer; 5) BO-105 helicopter (chartered by the University of Hamburg) with HELISCAT; 6) a second BO-105 helicopter was utilized for dropping frozen surfactants to produce slicks on the water surface.

Participants: Institute of Oceanography of the University of Hamburg, College of Ocean and Fishery Sciences of the University of Washington at Seattle, FGAN, MIT, WHOI, FWG, MIRS of University of Massachusetts, University of Kansas, University of Delaware, Federal Maritime and Hydrographic Agency of Hamburg, GKSS of Geesthacht, Ger-

many, Risø National Laboratory (RISO) of Roskilde, Denmark, NRL of Washington DC, DLR Oberpfaffenhofen, US Naval Air Development Center of Warminster, PA, etc.

SCAPE (Shenandoah Cloud and Photochemistry Experiment)²⁸¹⁵⁾

A US ground-based campaign (U. of Virginia, Harvard University, U. of New Hampshire, U. of Rhode Island, UC at Santa Barbara) conducted at a high-elevation forested site in central Virginia between September 1 and October 1, 1990. Objectives: a) study of the atmospheric chemistry in a forest with particular focus on the factors controlling concentrations of ozone, carbonyl compounds, and carboxylic acids; b) assessment of the relative importance of NO_x and hydrocarbons in limiting regional ozone production; c) investigation of sources and sinks for carbonyl compounds and carboxylic acids; d) examination of the dependence of droplet-size on solute concentrations and the thermodynamics of phase partitioning for carbonyl compounds and carboxylic acids in clouds. Most of the chemical species and physical parameters were measured from a 15 m tower on a mountain ridge at Pinnacles.

SCAR (Smoke/Sulfates Clouds and Radiation)

NASA-funded campaign series with the overall objective to study the physical and chemical components of the Earth's surface, the atmosphere, and the radiation field in the biomass burning/sulfate environment. Simultaneous observations from ground-based, airborne and spaceborne platforms, including in situ measurements from aircraft flying through haze and clouds. Other objectives include obtaining a database to be used to study the process of biomass burning and the presence of sulfate particles; their effect on atmospheric composition, radiative budget, and climate (J. T. Suttles, NASA/HQ).

Instruments flown on ER-2 aircraft are MAS (MODIS Airborne Simulator), AVIRIS, CAR, and TSCC. A C-131A research aircraft from the University of Washington carries a wide variety of sensors. In addition, a ground-based sun photometer network is installed, supplemented by roving ground stations and light aircraft carrying sun photometers.

SCAR-A (SCAR - Atlantic)²⁸¹⁶⁾

The campaign was completed in July 1993 (M. D. King, NASA/GSFC). Airborne instruments were utilized (from NASA/Wallops, VA) to collect information on the properties and effects of radiation on clouds and sulfite particles (measurements compared with those for aerosol particles and biomass burning). Airborne sensors included MAS (MODIS Airborne Simulator), AVIRIS, CAR, TSCC (EOC), etc. Spaceborne sensors: AVHRR, TM.

SCAR-B (SCAR - Brazil)²⁸¹⁷⁾

This campaign was conducted in August/September 1995 in selected areas of central Brazil in cooperation with INPE - coordinated flights of ER-2, C-131A and an INPE aircraft. The objective was measurement of the properties of smoke from biomass burning and the microphysical properties of clouds embedded in the smoke (emission rates of trace gases, properties of smoke particles, light scattering efficiency, interaction processes of smoke particles, effect of biomass burning on surface vegetation, etc.). Comparison and validation with data from other SCAR campaigns. Airborne sensors include: MAS, CALS, TSCC, AVIRIS, RAMS. Satellite data from POES (NOAA-12 and -14), GOES-8, Landsat, DMSP, and Meteor-3-7 (SCARAB). A ground-based network of 8-12 sun photometers were installed in Brazil, Bolivia, and Peru for several months before and during SCAR-B.

SCAR-C (SCAR - California)²⁸¹⁸⁾

NASA-sponsored campaign in September/October 1994 with coordinated flights of the AMES ER-2 and the C-131A of the University of Washington. The primary targets were controlled forest burns operated by the US Forest Service and agricultural burns managed

by the Air Quality Boards of Oregon and California (D. S. McDougal, NASA/LaRC). Objectives:

- Measure brightness temperatures at 11 μm , 3.95 μm , 3.75 μm and 1.6 μm of fires and surrounding areas (test and validation of MODIS fire detection algorithms).
- Characterize fire-produced smoke to validate remote sensing of aerosol algorithms, study biomass burning, and develop aerosol models for smoke particles (size, distribution, chemistry, black carbon, light scattering efficiency, optical properties, in situ measurements of absorption properties).
- Study the interaction of smoke aerosol with clouds
- Characterize background aerosol of the West Coast in order to further generalize the aerosol models developed from SCAR-A data.
- Measure emission factors for aerosols and a suite of trace gases, using the carbon-balance technique. Validation of atmospheric correction algorithms.

Ground-based sunphotometers (5) were located throughout Oregon and California. Airborne instruments include: MAS, AVIRIS, CALS, TSCC, RAMS. Satellite data from POES, GOES and Landsat.

SCCCAMP (South Central Coast Cooperative Aerometric Monitoring Program)²⁸¹⁹⁾

A US campaign sponsored by various California state and local agencies and by industry, and conducted by NOAA, NCAR, US-EPA, several universities, laboratories and industry. SCCCAMP is a comprehensive study of boundary-layer dynamics and photochemistry on a meso- β scale in the coastal and interior portions of south-central California encompassing the Santa Barbara Channel. The field measurement program was conducted from September 3 to October 7, 1985 over an area of approximately 20,000 km². The objectives were to investigate the physical mechanisms that infrequently create excessive concentrations of photochemical oxidant at ground level, and to provide a comprehensive database for the evaluation of a mesoscale photochemical simulation model. Measurements were made continually by surface and upper-air networks, and supplemented by aircraft, radar, rawinsonde, chemical and gas tracer measurements during four intensive operational periods (IOP).

The surface-based network included existing and enhanced meteorological stations, aerometric stations (denote both meteorology and air chemistry), rawinsonde sites, Doppler acoustic profilers, microwave radars, and the R/V Acania (ship). Surface measurements of air chemistry included: O₃, SO₂, NO, NO₂, total oxides of nitrogen (NO_x), reactive organic compounds, total and spatiated hydrocarbons, formaldehyde (HCHO), acetaldehyde (CH₃CHO), peroxyacetyl nitrate (PAN), CO, chlorinated hydrocarbons, and total suspended particulates (TSP). - Aircraft: Cessna 337 Skymaster, two Piper Aztecs, Beechcraft Queen Air (NCAR). Measurement of meteorological and chemical variables throughout the planetary boundary layer. Gas tracer studies were conducted. The SCCCAMP meteorological and air chemistry data are archived at SRI International, Menlo Park, CA.

SCMS (Small Cumulus Microphysics Study)

A US aircraft and ground radar campaign (NCAR, U. of Illinois, U. of Wyoming, U. of Chicago, U. of North Dakota, UCLA,) from July 17 to August 14, 1995 in central Florida. SCMS is aimed at studying the onset of coalescence growth in warm cumulus clouds, the evolution of droplet size distributions, as well as entrainment and mixing processes. Use of new aircraft instruments and NCAR CP-2 ground-based radar. An operational requirement is to obtain simultaneous measurements of airborne and ground-based instruments within a fairly close vicinity (radius of less than 30 km).

SCOPE (San Clemente Ocean Probing Experiment²⁸²⁰) - near San Clemente Island at 32.95° N, and 118.5° W, 100 km offshore from San Diego)

A US cooperative campaign conducted by NOAA/ERL/ETL and Scripps Institution of Oceanography (SIO, La Jolla, CA) in September/October 1993 with the objective to investigate environmental effects on microwave scattering and emission from the sea surface. Simultaneous measurements of X-band radar cross section and of atmospheric parameters that govern the radar scattering cross section, such as atmospheric surface layer stability, wind, and friction velocity. These measurements were made simultaneously with surface wave measurements from FLIP (Floating Instrument Platform), a research vessel of Scripps Institute, measurements from an airborne microwave radiometer, and images from airborne and spaceborne SARs. A NOAA King Air aircraft was equipped with ETL microwave and IR radiometers. One flight was obtained with AIRSAR (JPL). Three ERS-1 AMI overpasses were acquired during SCOPE. The ground measurements were conducted by the NOAA research vessel Titan (in-situ sensors for monitoring water and atmospheric surface-layer parameters, operation of a 915-MHz wind profiler and a RASS (Radio Acoustic Sounding System) for temperature profiling), by several ETL sensors (coherent X-band Δ -k radar, CO₂ Doppler Lidar, and by FLIP instruments (array of pressure transducers for gravity wave measurements, a microbarograph array for atmospheric surface-layer pressure measurements).

SCSMEX (South China Sea Monsoon Experiment)²⁸²¹)

A multilateral and international campaign program being planned/conducted by Chinese and US scientists (within WCRP/GEWEX: GAME, CLIVAR-GOALS, etc.). The primary goal of SCSMEX is to provide a better understanding of key physical processes for the onset, maintenance and variability of the monsoon over Southeast Asia and southern China, leading to improved predictions. Specific objectives are:²⁸²²)

- To describe the space-time evolution of large-scale atmospheric circulation, thermodynamic fields, as well as basic ocean flow patterns and thermohaline structures associated with the South China Sea (SCS) monsoon
- To identify the influence of heating contrasts between the South China Sea and the surrounding regions, and the role of early monsoon (April-May) convection and multi-scale processes in the SCS in the abrupt transition and subsequent evolution of the East Asian monsoon
- To elucidate physical processes in oceanic response to monsoon forcing and air-sea interaction in the SCS and relationships with the adjacent oceans
- To assess and improve the ability of regional and global models in simulations and prediction of the monsoon onset in Southeast Asia and in southern China.

A pilot study phase (devoted to analyzing and modeling climatological data) started in 1996, two years before the start of the full campaign phase in 1998 (covering the period April 15 to August 30 of each year). SCSMEX observations are planned on three levels: ground-based [upper air sounding, integrated sounding system, surface meteorological observations, ship-based and land-based radar, oceanic surface and subsurface observations from ships, TOGA/TAO moorings, etc.], airborne (balloons, etc.), and spaceborne [TRMM (PR, TMI, CERES), ADEOS (NSCAT), ERS-1,-2 (AMI scatterometer), DMSP (SSM/I, SSM/T-2), NOAA (AVHRR), GMS, TOPEX/Poseidon, FY-2, EOS/AM-1 (CERES, MODIS)]. Three IOPs (Intensive Observation Periods) are planned for each year (early to mid-May, mid-June, and mid-July).

SEADEX (Shoreline Environment Atmospheric Dispersion Experiment)

SEADEX was conducted in 1982 (SRI International, Palo Alto, CA) and was concerned

²⁸²⁰) R. A. Kropfli, S. F. Clifford, "The San Clemente Ocean Probing Experiment: A Study of Air-Sea Interactions with Remote and In Situ Sensors," Proceedings of IGARSS '94, Volume IV, pp. 2407-2409

with diffusion of accidental releases from nuclear power plants. Site: Shore line of Lake Michigan near Green Bay. The ALPHA-1 lidar was used to map the aerosol plume from a smoke release at the top of a reactor building.

SEAFIRE (South-East Asia Fire Experiment)²⁸²³⁾

An IGBP/IGAC/BIBEX campaign initiative planned for a time frame of 1997-99 in South-eastern Asia [Myanmar (formerly Burma), Thailand, Kampuchea (formerly Cambodia), Laos, Viet Nam, Malaysia, China, The Philippines, Indonesia]. The overall objectives are to investigate wildland fires and to identify the magnitude, patterns, quality, and the impacts of these fires on the local terrestrial and regional atmospheric ecology. Plans call for space-borne, airborne and ground-based observations.

SEMAPHORE (Structure des Echanges Mer–Atmosphere, Proprietes des Heterogeneites Oceaniques)

French airborne campaign in October-November 1993 near the Azores. Objectives: study of ocean-atmosphere exchanges at local- and mesoscales, with particular insight into the spatial variability of fluxes and related processes. It included an important network to document ocean circulation and thermal properties in a region characterized by the presence of spatial inhomogeneities (the Azores current). The experimental strategy involved research vessels, drifting buoys, as well as two research aircraft used for remote sensing and to document the marine boundary layer. The lidar ‘Leandre’ was mounted on the ARAT aircraft, and RESSAC was mounted on the MERLIN–IV of Meteo-France. Analysis of data from satellites (Meteosat, NOAA/AVHRR, TOPEX/Poseidon, ERS-1) in relation with in situ observations is also an important aspect of the campaign.

SERON (South Eastern (US) Regional Oxidant Network)

Field program to study atmospheric chemistry, July-August 1991

SESAME-79 (Severe Environmental Storms and Mesoscale Experiment)^{2824), 2825)}

A US interagency campaign program in 1979, also referred to as AVE-SESAME-79 (Atmospheric Variability Experiment), which consisted of six two-day campaigns during the period from April 10 to June 8, 1979. The primary objective was to study the structure and dynamics of mesoscale systems and to acquire sets of rawinsonde data during selected severe weather events (tornados) in the central part of the US for use in correlative and diagnostic studies with satellite and radar data obtained in parallel. Participants: NOAA, NASA, NSF (NCAR) and many other institutions. The experimental network utilized 20 supplemental rawinsonde sites meshed among 23 standard NWS (National Weather Service) sites. Airborne observations were conducted from 10 research aircraft. Satellite data from GOES-3, TIROS-N, and Nimbus-7.

SESAME (Second European Stratospheric Arctic and Midlatitude Experiment)^{2826), 2827)}

A large international follow-up EC campaign (coordinated by CEC and organized by EOR-CU) to EASOE (1991/92) concentrating more on mid-latitudes and spreading the measurements over a two-year period (1994/95) to study more the build-up and decay of the stratospheric polar vortex. The scientific goals are to study:

- The stratospheric chemistry of the chlorine, nitrogen, hydrogen and bromine families
- The roles of polar stratospheric clouds and of sulfate particles in abetting the chemical distribution of ozone
- The evolution of ozone concentrations through the two winters and to see exactly when and where ozone loss occurs

- The meteorological conditions most likely to favor ozone destruction.

Three intensive periods of study: Phase I in January/February 1994, Phase II in September/October 1994, Phase III from February 4 to March 6, 1995. Three aircraft are based at Kiruna during the campaigns: (Transall and Falcon from Germany, ARAT from France). In addition the campaign called for 57 large balloon launches (36 from ESRANGE near Kiruna, Sweden and from Andoya, Norway, and 21 from mid-latitude sites in France and Spain). Ground-based, aircraft and balloon-borne measurements include: O₃, NO, NO₂, HNO₃, ClO, HCl, ClONO₂, N₂O, CFCs, water vapor, polar stratospheric clouds, sulfate aerosol droplets etc. Three long-duration balloons (CNES) circled the globe. - Coordination of ground-based measurements with airborne, and spaceborne (TOMS and HIRS on NOAA S/C, UARS) instruments. Participating institutions in SESAME from the following countries: Austria (1), Belgium (3), Denmark (1), Finland (1), France (11), Germany (22), Greece (2), Iceland (2), Italy (4), Japan (2), Netherlands (3), New Zealand (1), Norway (5), Poland (1), Russia (3), Spain (2), Sweden (4), Switzerland (5), UK (11), and USA (10).

SHEBA (Surface Heat Budget in the Arctic)²⁸²⁸⁾

An international campaign [USA (U. of Washington, NSF/NCAR, NOAA, ONR, CRREL, and others), Russia (AARI), Canada, Norway] to be conducted on a drifting sea ice camp in the Arctic Ocean (Beaufort Sea) in combination with modeling and remote sensing analysis. The field campaign is scheduled for 16 months starting in April 1997, the SHEBA program has a time frame of 5 years. Objectives: 1) to study of the interactions of the surface radiation balance, mass changes of the sea ice, the storage and retrieval of energy and salt in the mixed layer of the ocean, 2) the formation and radiative properties of clouds and their interplay with the radiation balance, and 3) the relationships between the air-sea-ice system and the signals received by spaceborne and airborne remote sensors. Ground-based instrumentation includes: precision radiometers, multiband lidar, passive microwave sounders, cloud radar, ocean turbulence clusters, autonomous underwater vehicles, and photo-electric devices to measure subsurface radiation. The SHEBA modeling effort is focused on improving climate simulations. Coordination/cooperation with the FIRE-III campaign, the ARM program (NSA CART site near Barrow, Alaska), and RADARSAT. SHEBA is also coordinated with ACSYS of WCRP. The SHEBA project office is at the U. of Washington.

SIMMS (Seasonal Sea Ice Monitoring and Modeling Site)^{2829), 2830)}

A Canadian collaborative and interdisciplinary field project program which started in 1990. SIMMS was initiated by E. Le Drew of the U. of Waterloo and D. Barber of the U. of Manitoba; further participants: AES, CCRS, etc. The following field experiments were conducted in the Resolute Passage/Barrow Strait/Lancaster Sound area of the Arctic Archipelago: SIMMS '90 (May 15 to June 8, 1990), SIMMS '91 (May 13 to June 13), SIMMS '92 (April 3 to June 30 and October 2-9), SIMMS '93 (April 15 to June 30 and October 12 to October 28), SIMMS '94 (April 18 to July 1), SIMMS '95 (early April to early July). Major objectives are:

- To understand the physical nature of snow and sea ice over a continuum of space and time
- To understand how the major fluxes of energy and mass are partitioned between the ocean, sea ice and atmospheric interfaces
- To study the inversion of geophysical phenomena and energy flux from remote sensing data.

Ground-based measurements in parallel to spaceborne and some airborne observations (CV-580 aircraft with C/X-SAR in SIMMS '95 only). The spaceborne platforms are:

ERS-1,-2 (AMI), Radarsat, Landsat (TM), Spot (HRV), POES (AVHRR), DMSP (SSM/I).

SIZEX (Seasonal Ice Zone Experiment)^{2831), 2832)}

SIZEX 89 was a prelaunch ERS-1 program [sponsored by ESA, NSC (Norwegian Space Centre), ONR, and NASA] with the objective to perform ERS-1 type sensor signature studies of different ice types for the development of SAR algorithms. SIZEX 89 was a multidisciplinary international winter campaign carried out in the Barents Sea and the Greenland Sea in February and March 1989 (NERSC, ERIM, etc.). During the field experiment remote sensing, oceanographical, ocean acoustical, meteorological, and sea ice data were collected. SIZEX was a continuation of the MIZEX summer experiments in 1983 and 1984 (see MIZEX) and the winter experiment in 1987; it was carried out in coordination with CEAREX. SIZEX 89 employed the following platforms:

- Ships: R/V Polarbjørn with HELOSCAT L-, C- and X-band measurements, and R/V Hakon Mosby
- Bottom moorings: Aanderaa current meters, and acoustic buoys
- Drifting buoys (data collected by Argos): Toroids with current meters, simple position buoys, wave buoys.
- Aircraft: CV 580 of CCRS, contracted by NERSC with C-band SAR, P-3 of NADC/ERIM with C-band SAR, and a Norwegian P-3.
- Satellite data: NOAA (AVHRR), DMSP (SSM/I)

SIZEX 89 participants: NERSC, University of Bergen, ERIM, NASA/GSFC, NPS (Monterey), USGS, U. of Washington (Seattle), NDRE (Norway), U. of Texas, NORDA, Scott Polar Research Institute (UK), and ONR.

SIZEX 92. The campaign was a sea ice validation experiment for the ERS-1 SAR instrument conducted in the Barents Sea (75-80° N and 20-40° E) during the first two weeks of March 1992 using the vessel Polarsysse, a helicopter, and the research vessel Hakon Mosby. Participants: NERSC of Bergen Norway, ERIM of Ann Arbor MI, Environmental Research Institute of the U. of Michigan, ESA, NRL, etc.). In situ measurements of ice and snow were performed with a ship-based X-, C-, L-band scatterometer on the Hakon Mosby, and with a C-band scatterometer (V-polarized) from the Polarsysse. Aerial photographs and video records were obtained from different ice types such as multiyear, first-year, refrozen leads, pancake ice, grease ice and icebergs. Approximately 50 low-resolution SAR scenes (100 m) and 5 full-resolution SAR scenes (25 m) were obtained from ERS-1 during the campaign.

SOCEX (Southern Ocean Cloud Experiment)

US-sponsored campaign conducted by NCAR with participation by CSIRO (Australia). Objectives: Cloud study of southern summer (input of clouds in climate models). Seasonal changes in cloud condensation nuclei and the way in which these nuclei affect the properties of clouds.

SOFIA (Surface of the Ocean, Fluxes and Interaction with the Atmosphere, June 1-28, 1992). A research campaign carried out by France [CRPE, CMM (Brest), IFREMER (Brest), Service d'Aeronomie (Paris), LMD (Palaiseau) and CNRM (Toulouse)] in collaboration with the ASTEX campaign (Azores region). The objective is the study of energy transfer (heat, humidity and momentum fluxes) between the sea surface and the atmospheric boundary layer at scales ranging from the local scale to the mesoscale (50 km). The general concept of the program was to develop a measurement strategy based on nested boxes in which instrumentation is used to estimate and quantify fluxes. Ground-based and airborne measurements (F 27 from ARAT and Merlin IV from METEO) were comple-

ented with satellite data. - A second SOFIA campaign in the Azores region was realized in the October-November 1993 in parallel with the SEMAPHORE campaign.^{2833), 2834)}

SOS (Southern Oxidants Study)

A US urban campaign program consisting of two campaigns. The first SOS campaign was conducted in Atlanta, GA in 1992 (ground-based monitoring networks). - The second SOS campaign was conducted in Tennessee and 11 other states in the southeastern US (also referred to as the 'Nashville/Middle Tennessee Ozone Study') in June-July 1995 with the objective to conduct collaborative, policy-relevant air-quality research furthering understanding of tropospheric ozone air pollution and providing improved tools for the assessment and development of efficient ozone management strategies. Some specific objectives:

- Establish the relative importance of manmade and natural emissions of VOCs (Volatile Organic Compounds) and NO_x on urban and regional ozone production
- Determine the relative importance of VOCs and NO_x emissions
- Consider the role played by ozone or VOCs and NO_x transported from outside areas in fostering ozone production.

Participation of over 200 scientists and engineers representing more than 30 public, private, and academic institutions (TVA, North Carolina State University, NCAR, Georgia Institute of Technology, EPA, NOAA, NASA, U. of Alabama, BNL, U. of Michigan, U. of Miami, etc.). The resources include about 100 air quality and meteorological stations (90 level-1 stations operated by state and local regulatory organizations as well as industry; seven level-2 chemistry monitoring stations; one level-3 research chemistry station) across 12 eastern states and extensive observations with six research aircraft (TVA Bell-205 helicopter, P-3 Orion of NOAA/ERL/ETL, Grumman G-1 of DOE (BNL, PNL), Twin Otter of NOAA (B-Flux), CASA-212 of EPA, C-130 of NASA/JPL with AES).

SPADE (Stratospheric Photochemistry, Aerosols and Dynamics Experiment, PI: S. Wofsy) NASA/NOAA/NSF airborne campaigns in November 1992, April-May 1993, funded by NASA's High Speed Research Program. SPADE represents the first dedicated field experiment to acquire stratospheric data for the assessment of the potential chemical perturbations to the atmosphere from the proposed fleet of high-speed civil transports. The primary focus of this assessment was on the photochemistry of the lower stratosphere with emphasis on ozone production or loss from perturbations. The SPADE flights were flown from ARC. Measurement of HO_x radicals in the context of a complete suite of chemical observations including NO, HNO₃, NO_y, ClO, BrO, O₃, HCl, NO₂. In addition, CO₂, N₂O, CH₄, CFC's, CO, H₂O. Airborne instruments: OH/HO₂, CO₂ analyzer, and ClO/BrO sensors (Harvard), MMS (ARC), FSSP-300 (ARC), MTP (JPL), ATLAS (ARC), ALIAS (JPL), and others.²⁸³⁵⁾

SPECTRE (Spectral Radiance Experiment), see under FIRE

SPICE (Sensors Performance in Cloud Experiment)

NCAR campaign conducted on a King Air aircraft during November 1993. The objective was to evaluate a large array of cloud hydrometeor spectrometers, liquid water probes, and temperature sensors under various warm-cloud conditions. Cooperation of science investigators from AES (Canada), CNRM (France), RMS (UK), etc.

SRB (Surface Radiation Budget) Project

A GEWEX-related project concentrating on the exploitation of all available satellite measurements of the radiation budget components at the top of the atmosphere [ERB (Earth Radiation Budget)] and at ground level [SRB (Surface Radiation Budget)]. The initial outcome will be derived primarily from the ISCCP data sets, later also from direct radiation

budget measurements. The archives for the SRB will, in the future, contain various surface-based measurements from BSRN (Baseline Surface Radiation Network) required to establish ground truth and error estimates for such globally available information. The long-term objective of SRB is to produce and archive a global data set of shortwave and longwave surface parameters for a 12 year period from June 1983 through June 1995 using ISCCP and ERBE data.

SRL-1, -2 (Space Radar Laboratory) Underflight Campaigns

The two Shuttle missions (STS-59 and STS-68) with the SIR-C/X-SAR payloads were conducted during ten-day periods, April 9-20, 1994 (SRL-1), and September 30 - October 11, 1994 (SRL-2). A total of 19 supersites were selected (Table 849) for specific interdisciplinary research projects. All of these supersite investigations were (at the minimum) accompanied by field measurements in parallel to the Shuttle observations. In addition several 'underflight campaigns' were conducted (in parallel with the SIR-C/X-SAR overflights) at various supersites and with spaceborne, airborne, and ground-based instruments by a worldwide research community. Some campaign activity is reported here:²⁸³⁶⁾

- Gulfstream Supersite.²⁸³⁷⁾ A major multi-organizational series of experiments was conducted off the US East Coast (located within: 42° N, 75° W; 36° N, 65° W; 30° N, 73° W) with the objective to investigate oceanographic phenomena (emphasis on current-wave and air-sea interactions) in the Gulf Stream. Participant organizations: JPL, U. of Hamburg, NOAA, NAWC, NRL, U. of Miami, Navy ONR, USGS, NASA, etc. Extensive ground/sea/air truthing data were collected and eventually compared with the SRL data. NRL-P-3 aircraft with RAR, P-3/SAR (ERIM/NAWC), ROWS; DC-8 with AIR-SAR/TOPSAR, ERS-1 SAR imagery, AVHRR, NOAA/NDBC offshore buoys, RV Cape Hatteras, and stations. Specific objectives were: 1) to understand the dependence of SAR signatures of the supersite boundary on radar and environmental parameters; 2) to investigate the relationship between subsurface thermohaline circulation and near-surface atmospheric structure on the wave field responsible for the radar imagery signatures; 3) to optimize SAR sensor performance (polarimetric and interferometric radar collection modes) for detecting currents; 4) to understand imagery of the perturbation of Kelvin wakes by current and thermal fronts; and 5) to investigate the role of the hydrodynamic structure in the origin of "slick-like" features observed in near coastal regions by SAR imagery.
- The NASA/JPL AIRSAR/TOPSAR system (DC-8) was used in extensive underflight campaigns during both SRL missions. Observation sites during SRL-1 were: Stovepipe Wells (Death Valley), CA; Mammoth, CA; Chickasha, OK; Gulf of Mexico; Gulf stream; Duke Forest, NC; Mahantango, PA; Howland, ME; Racó, MI; Altona (Manitoba), Canada; Prince Albert, Canada; Bighorn Basin, WY. - Observation sites during SRL-2: Chickasha, OK; Gulf of Mexico; Duck Pier, NC; Duke Forest, NC; Howland, ME; Mahantango, PA; Racó, MI; Altona, Canada; Prince Albert, Canada; Yellowstone, MT; Bighorn Basin, WY; Davis, CA.²⁸³⁸⁾
- Beijing test site (G85). During SRL-1 a concurrent airborne underflight campaign was conducted by the Chinese Academy of Sciences (CAS) with its CASSAR instrument, operated by IRSA-CAS (Institute of Remote Sensing Applications of CAS). Objective: comparison with SRL-1 imagery.²⁸³⁹⁾

- Supersite Raco (Michigan, at 46.5°N and 84°30'W).²⁸⁴⁰ The University of Michigan was involved in the development of calibration procedures and precision calibration devices to quantify the complex radar images with an accuracy of 0.5 dB in magnitude and 5° in phase. A calibration campaign took place at Raco during the SRL-1, and -2 Shuttle overflights utilizing the following equipment: an array of point calibration targets including trihedral corner reflectors and PARCs (Polarimetric Active Radar Calibrators); distributed uniform target (for characterizing radiometric calibration) consisting of a field of grass, sometimes covered with snow; parallel measurements with ground-based polarimetric scatterometers.
- Supersite Oberpfaffenhofen. The DLR E-SAR instrument was flown on a DO-228 during each of the SRL-1 and -2 Shuttle missions (five times for each SRL flight) addressing such topics as calibration, agriculture, forestry and hydrology. Researchers from seven German institutes collected in parallel ground truth data during the two missions. In between the two SRL missions E-SAR participated in the EMAC (see EMAC) campaign, establishing a multitemporal and multifrequency SAR-dataset from the beginning of April to the end of October 1994 for the Oberpfaffenhofen supersite.²⁸⁴¹
- Supersite Altona, Manitoba, Canada (CRSS site at 49° 4.9'N, 97°39.6'W).²⁸⁴² Underflights were conducted with C/X-SAR in a Convair-580 aircraft (CRSS) and AIRSAR/TOPSAR on a DC-8. In addition acquisition of SIR-C/X-SAR data. Collection of ground truth data. The objectives were to evaluate the multitemporal and multifrequency SAR data and to estimate soil moisture for a variety of soil types.²⁸⁴³

Disciplines supported	Supersites	Backup Supersites
Calibration	Flevoland (Netherlands), Kerang (Australia), Oberpfaffenhofen (Germany, Western Pacific rain experiment)	Matera (Italy), Sarobetsu (Japan), Palm Valley (Australia), Eastern Pacific
Ecology	Manaus (Brazil), Raco (Michigan), Duke Forest (North Carolina)	Amazon Survey (Brazil), Prince Albert (Canada), Howland (Maine), Altona (Canada)
Electromagnetic Theory	Safsaf (Sudan)	
Geology	Galapagos Islands, Sahara, Death Valley (California), Andes Mountains (Chile)	Kilauea volcano (Hawaii), Saudi Arabia, Hotien East (China)
Hydrology	Chickasha (Oklahoma, The Little Washita River Watershed), Ötztal Alpes (Austria), Bebedouro (Brazil), Montespertoli (Italy)	Mahantango (Pennsylvania), Mammoth Mountain (California)
Oceanography	US East Coast, Gulf Stream, Southern Ocean	Equatorial Pacific, North Sea

STARE (Southern Tropical Atlantic Regional Experiment)²⁸⁴⁴, ²⁸⁴⁵)

STARE is an internationally coordinated campaign program under the IGBP umbrella. It is part of IGBP/IGAC/BIBEX (Biomass Burning Experiment. Overall objectives of STARE are to investigate the chemical characteristics of the ozone-enriched air masses over the southern tropical Atlantic and to study the sources of trace gas emissions (fires related to

deforestation in South America, especially in Brazil, and savanna fires in South America and Africa). Specific aims are to characterize the emissions from biomass burning in the source regions on either side of the Atlantic, to study the transport of the air masses from these source regions and to analyze the chemical transformations in the air masses. The STARE campaign activities consist of two subcampaigns, namely TRACE-A and SAFARI. Both programs analyze satellite data from AVHRR, TM, TOMS, SAGE.

- **TRACE-A** (Transport and Atmospheric Chemistry near the Equator - Atlantic)
The TRACE-A campaign was conducted in August-October 1992 and involved some 200 scientists from institutions of the following countries: Brazil, Congo, South Africa, UK, and USA. TRACE-A is a major component of NASA's GTE (Global Tropospheric Experiment) chemistry program, addressing the source regions in Brazil and the long-range transport and large-scale distribution of pyrogenetic pollutants over the southern tropical Atlantic. Aircraft observations: NASA DC-8 was used for ozone profiles, trace gas and aerosol measurement transects. The DC-8 flew out of Johannesburg and Windhoek from October 4-20, 1992.
- **SAFARI** (Southern African Fire-Atmosphere Research Initiative)
SAFARI-92 was conducted in parallel to TRACE-A involving 150 scientists from the following countries: Germany, Swaziland, South Africa, Zimbabwe, Zambia, Namibia, Congo, Brazil, Belgium, France, UK, Canada, and USA. Objectives: investigation of the emissions from savanna fires (atmospheric chemistry) in southern Africa and their atmospheric transport across the African continent and of the relationship between fires and the savanna ecology. Controlled burns took place within Kruger National Park (South Africa) and two controlled savanna fires (each 2000 ha in size). Ground-based and airborne (DC-3, Cessna 310, and helicopter) observations of emissions. Emission measurements were also conducted in the plumes from many savanna 'fires of opportunity.' Satellite data from AVHRR on NOAA-11, TM on Landsat 5, and OLS on DMSP.
- **SA'ARI** (SAFARI without Fire)
Investigation of the background atmosphere in southern Africa outside of the burning season. In May 1994 a first survey was conducted by MPIC (Mainz) using the South African Cloudquest Learjet 24; a repeat campaign took place in April/May 1995.

STEP (Stratosphere - Troposphere Exchange Project)²⁸⁴⁶⁾²⁸⁴⁷⁾

NASA-funded airborne campaigns in the 'Upper Atmosphere Research Program' with the objective to better understand the processes by manmade and natural chemicals that are transported into the stratosphere and, once there, to the ozone layer. Because any exchange process must be consistent with the very low relative humidities observed in the lower stratosphere, STEP also emphasizes the study of mechanisms that could dehydrate air entering the stratosphere.

STEP was managed by NASA/AMES (P. B. Russell). There were three major STEP field campaigns out of a total six: Two mid-latitude field experiments in April-May of 1984 (on NASA U-2 aircraft) and spring 1986, and a tropical field campaign in the Australian summer (January and February (base at Darwin, see also AMEX and EMEX) 1987. The NASA ER-2 aircraft carried 15 instruments [measurement of meteorological variables, stratospheric tracers (O₃, NO_y), tropospheric tracers (H₂O, CO, radon), particles (aerosol and cloud particles), radiation fluxes]. STEP data are available at NASA/ARC on CD-ROM.

STERAO (Stratosphere-Troposphere Experiments: Radiation, Aerosols, and Ozone)²⁸⁴⁸) A planned/proposed US campaign series by NCAR/NSF, NOAA, and NASA, utilizing the NCAR WB-57F and the NOAA WP-3D aircraft. The campaign investigations are divided into three related areas and are considered as separate subcampaigns or experiments of STERAO, spread over a period of several years:

- Deep convection and the composition of the upper troposphere and lower stratosphere
- Aerosol and cirrus cloud properties
- Photochemistry in the near-tropopause region

The ‘deep convection experiment’ is planned for spring/summer 1996. The objectives are to investigate the chemical and physical nature of thunderstorms over North-Eastern Colorado, and to gauge the effect they have on the composition of the upper troposphere and lower stratosphere. The WP-3D aircraft observes at or below ~ 6 km with emphasis on the boundary layer, while the WB-57F instrument payload investigates the upper troposphere and lower stratosphere. Major objectives are to characterize the chemical and thermodynamic inflows and outflows of storms. The airborne observations are complemented by parallel ground-based observations such as NEXRAD, CHILL (Colorado State University), etc. and spaceborne observations (GOES-8, -9, etc.).

The ‘aerosol and cirrus cloud experiment’ is planned for 1997 (two phases). The objective is to improve understanding of aerosol and cirrus cloud processes for estimates of the Earth-atmosphere radiation budget. A further objective is to improve the physical and chemical characterization of aerosols. The WB-57F aircraft will be instrumented for this purpose.

Parameter/Species	Method	PI (Affiliation)
NO/NO ₂ /NO _y /O ₃	Chemiluminescence	B. Ridley (NCAR)
N ₂ O/CO (time response of 1 s)	TDL absorption	M. Coffey, W. Mankin (NCAR)
CO	UV resonance fluorescence	F. Fehsenfeld (NOAA)
Whole Air Sampler (WAS)	Pressurized canisters	E. Atlas (NCAR)
H ₂ O/CH ₄	TDL absorption	R. May (JPL)
H ₂ O	UV fluorescence, cryogenic frost point	K. Kelly (NOAA), NCAR
H ₂ O/HDO (3-5 samples at constant altitude)	Ice crystal impact collection cryogenic vapor collection	R. Smith (Yale University)
O ₃	UV absorption	M. Proffitt (NOAA)

u, v, w wind components	Inertial navigation	NCAR
State parameters	Standard techniques	NCAR
Aircraft position	GPS	NCAR

Table 850: Instrumentation on the WB-57F aircraft

The ‘photochemistry in the near-tropopause region experiment’ is planned to start in 1998 and contains modeling and field campaigns over a period of two years. The overall objectives are:

- To obtain a quantitative understanding of the photochemistry of O₃ and HO_x under a wide variety of ambient conditions, including different seasons in the near-tropopause region
- To accumulate simultaneous observations of active and tracer species for testing and improving atmospheric models. The goal is to build a ‘climatology’ that will give models the capability of addressing science/policy issues.

STOIC (Stratospheric Ozone Intercomparison Campaign)²⁸⁴⁹⁾

A campaign organized within NASA's UARP and conducted at JPL's TMF (Table Mountain Facility, in the San Gabriel Mountains, CA) during July and August 1989. Objective: inter-comparison of ozone-measuring instruments (performance assessment) and provision of a validation/long-term calibration standard for satellite sensors, such as: SUBV-2 (POES series); CLAES, MLS, HALOE, ISAMS (all on UARS). Ground-based instruments employed: JPL lidar for ozone profiles between 20 and 50 km; GSFC lidar for ozone profiles between 20 and 45 km; LaRC microwave instrument (20-64 km); Dobson spectrophotometer of NOAA; and a Brewer spectrophotometer of AES Canada. Balloon-borne instrument: ECC (Electrochemical Concentration Cell) ozone sondes of WFF. Sounding rockets: ROCOZ-A (rocket ozone sonde) of WFF for measurements between 20 - 60 km. Spaceborne data from SAGE-II on ERBS and TOMS on Nimbus-7.

STORM-FEST (Stormscale Operational and Research Meteorology - Fronts Experiment Systems Test)^{2850), 2851)}

A US (NASA/NCAR/NOAA/NWS, U. of Washington, Naval Postgraduate School, Monterey, CA, etc.) campaign program as part of the US Weather Research Program (USWRP). The overall goal of STORM-FEST is to implement and integrate all research and operational aspects of USWRP for the decade-long program. Specific objectives are: a) to investigate the mesoscale structure of fronts and other mesoscale phenomena associated with winter storms that occur in the central United States, b) to test and evaluate the utility of the various observing networks and systems, and c) to investigate mesoscale weather prediction capabilities and limitations in active frontal regions with the goal of improving forecast and performance. - An array of ground-based operational instrumentation was set up in a limited region within the central United States. The first STORM-FEST field campaign (satel-

lite-, airborne- and ground-based data) was conducted from February 1 to March 15, 1992. During this observation period a major continental cyclone developed over the Rocky Mountains and the Mexican Plateau that affected the central United States from March 8-10 and which was named ‘Super Tuesday’ storm, an IOP (intensive observation period) of STORM-FEST.

STRAT (Stratospheric Tracers of Atmospheric Transport)

A NASA campaign with the objective to establish climatological distributions for long-lived tracers and dynamical quantities as functions of altitude and season in order to help determine rates for global-scale transport and future distribution of high-speed civil transport (HSCT) exhaust emitted into the lower stratosphere. Measurements of trace gases with contrasting sources, sinks and lifetimes (e.g. CO₂, N₂O, O₃, H₂O, CFCs CH₄, NO_y and CO) by in situ techniques and by whole air sampling. Also measurement of dynamic parameters (temperatures, winds) in the upper troposphere and lower stratosphere. A STRAT test flight series was conducted at ARC from May 1-18, 1995. The following instruments were flown on ER-2: MTP (JPL), MMS (ARC), NOAL, ATLAS, [CO₂ Instrument, O₃ Instrument, H₂O Instrument (all of Harvard)], WAS (NCAR). Further flights are planned on the ARC ER-2 starting in late 1995 and in 1996.

STREAM (Stratosphere and Troposphere Experiments by Aircraft Measurements)²⁸⁵²⁾

A cooperative EC-funded (Dutch, German, Swedish) campaign program coordinated by J. Lelieveld of U. of Wageningen [as of 1996: IMAU (Institute for Marine and Atmospheric Research Utrecht, The Netherlands)]. Participants: IMAU, MPIK (Heidelberg), MPIC_h (Mainz), Technical University of Delft (TUD) and Wageningen University, MISU (Meteorological Institute of Stockholm University, KfA Jülich (Institute for Stratospheric Chemistry), University of Frankfurt (Institute for Meteorology and Geophysics), KNMI (The Royal Netherlands Meteorological Institute), De Bilt, The Netherlands, ECMWF (Reading, UK).

STREAM-I: A winter campaign which took place from Kiruna, Sweden, in February 1993. The objectives were to study: a) wintertime chemistry in the lower arctic stratosphere, in particular O₃ depletion and signatures of transport processes related to the presence of a polar vortex important for O₃ loss, and b) convective transport and cross-tropopause transport associated with synoptic scale disturbances and fronts. - Three flights were carried out on February 16, 17, and 18, 1993 with a twin-jet Cessna Citation II aircraft of B. V. Heerema Offshore, Rotterdam.²⁸⁵³⁾

Parameter/Species	Method/Instrument	PI (Affiliation)
N ₂ O	TDLAS (FAST)	H. Fischer (MPIC _h), Mainz

O ₃	Chemiluminescence	B. V. Geosens, Rotterdam
O ₃ total column	Fabry Perot spectrometer	SRON, Groningen, NL

Table 852: STREAM-I aircraft instruments

STREAM-II: A summer campaign carried out from Amsterdam (Schiphol airport) in July 1994. The objectives were to: a) study the processes that control stratosphere-troposphere exchange in the mid-latitudes, b) investigate the convective transport between lower and upper troposphere of anthropogenic ozone precursors and sulfide dioxide by thunderstorms and deep convection associated with synoptic scale disturbances, and c) estimate the longterm effects of aircraft exhausts on the chemistry in the upper troposphere and lower stratosphere. - Five flights were carried out by the Citation II aircraft (TUD) between July

Aerosols and cloud elements	CN counter, optical particle counter, and CVI	J. Ström (MISU)
Water vapor	Lyman- α hygrometer	
O ₃ NMHC, halocarbons	Chemiluminescence Whole air sampling, GC-FID/ECD	J. Lelieveld, U. of Wageningen

Table 853: STREAM-II aircraft instruments

Two STREAM-III campaigns are scheduled for April/May 1996 over western Europe (from Shannon Ireland, mostly east-west flight directions to study the influences of extra-tropical cyclones on mixing processes), and for winter/spring 1997 over northwestern Europe (February/March from Kiruna, Sweden flight tracks mostly in the north-south direction to study the southward transport of O₃-depleted air in the lower stratosphere after break-up of the polar vortex). The objectives are:

- To improve understanding of the processes that control stratosphere-troposphere exchange in mid-latitudes, notably cross-tropopause transport of air associated with synoptic disturbances and fronts
- To study the chemistry of the mid-latitude lower stratosphere, in particular the role of nitrogen oxides in local production/destruction of ozone
- To collect experimental information about the background atmospheric chemical composition in the tropopause region (modeling of the roles of aircraft exhausts and long-range pollution transports).

STREAM combines in-situ observations with modeling studies (process studies and model validation).

Parameter/Species	Method	PI (Affiliation)
CH ₄ , CO NO _y CO ₂ /N ₂ O, CO ₂ /CH ₄ correlations	TDLAS (FAST) Chemiluminescence IR CO ₂ analyzer (Li-Cor)	H. Fischer (MPICh)

Table 854: STREAM aircraft instrumentation

SUCCESS (Subsonic aircraft: Contrail and Clouds Effects Special Study)²⁸⁵⁴⁾

A NASA-initiated campaign within SASS (Subsonic Assessment) program and AEAP (Atmospheric Effects of Aircraft Program), scheduled for March to May 1996. The general campaign site (airborne measurements) is planned to be over SGP (Southern Great Plains) in northern Oklahoma (an ARM program, CART site of DOE) with excursions to Colorado and Kansas. The CART site provides in addition ground-based measurements. The

²⁸⁵⁴⁾Information provided by R. Friedl of NASA/HQ

overall goal of SUCCESS is to estimate the impact of the current and future subsonic aircraft fleet on the Earth's radiation budget and climate. Study of contrails (impact on cirrus clouds) and their effect on the radiation budget. An understanding of the mechanisms of contrail formation will aid in understanding the role of aircraft debris in impacting cirrus clouds. Interaction with past and current campaigns is foreseen (FIRE, ARM, etc.) - The following NASA aircraft are planned to participate in SUCCESS: DC-8, ER-2 and T-39. DC-8 parameters to be measured: Aerosol composition and size, CN number and volatility, CCN versus supersaturation, ice particle sizes, ice particle scattering phase function, ice water content, ice nuclei composition and concentration, temperature, winds, turbulence, temperature profiles, water vapor, NO_x, NO_y, HNO₃, tracers (CO, CO₂, CH₄, N₂O), H₂SO₄, SO₂, net flux of solar and IR radiometers. ER-2 payload: water vapor lidar, cloud lidar, high-spectral resolution VNIR radiometers, imaging spectrometers, netflux solar and IR radiometers, microwave radiometer. The T-39 will be used to perform studies in the exhaust plume of the DC-8 aircraft; the T-39 is also employed to create contrails to be sampled by the DC-8.

SWADE (Surface Wave Dynamics Experiment, February - March 1991)²⁸⁵⁵⁾

The primary scientific goals of SWADE are 1) to understand the dynamics of the evolution of the wave field in the open ocean, 2) to determine the effect of waves on the air-sea transfers of momentum, heat, and mass, 3) to explore the response of the upper mixed layer to atmospheric forcing, 4) to investigate the effect of waves on the response of various airborne microwave systems, including radar altimeters, scatterometers, and synthetic aperture radars, 5) to improve numerical wave modeling. Major sponsors of SWADE are: ONR, NASA, NOAA, DOE, and CCRS. Site: East Coast of USA (Virginia and Maryland). Collection of buoy data, and airborne sensor data (including AXBT, see P.153.6).

Up to seven different aircraft were used during the intensive periods of SWADE (NASA P-3, T-39, and C-130, NRL RP-3A and Airship) with remote sensing instruments: a scanning altimeter (the Surface Contour Radar 'SCR' from NOAA/WPL, now called MARA (Multi-mode Airborne Radar Altimeter), a lidar (AOL), radiometers (PRT-5, see P.153.5), two ocean wave spectrometers (ROWS and RESSAC), several wind-scatterometers, NUSCAT (JPL), C-SCAT (C-band), and others, C/X-SAR from CCRS.

TAMEx (Taiwan Area Mesoscale Experiment)^{2856), 2857)}

TAMEx is a cooperative campaign conducted in May and June 1987 by scientists from Taiwan (Central Weather Bureau, universities) and the USA (NCAR, NOAA, several US universities, ONR, NRL) with the aim to improve the forecasting of heavy precipitation events, known as 'Mei-Yu' fronts, leading to flash floods. The scientific objectives regarding the mesoscale convective systems (MCS) were to:

- Describe the kinematic and thermodynamic structures of subtropical storms
- Identify the mesoscale triggering mechanisms (i.e. low-level jets, outflow boundaries, mesoscale frontal forcing) of the storms
- Study the microphysical structure of active convective cells as well as of anvil stratiform clouds, and to examine their precipitation processes (i.e. 'warm' rain processes, ice physics).

The TAMEx observational program consisted of an upper-air network, a surface network, a radar network, an aircraft program, and a satellite program. The upper-air network provided meso- α scale coverage over an area of 500 km x 500 km centered over Taiwan; the network consisted of rawinsonde sites (nine on land, three ship-based) and pilot-balloon stations (10); release of dropsondes from aircraft. The surface network consisted of 75 sta-

tions, 126 rain gauges, 21 wind towers, and three shipboard stations. The radar network consisted of five conventional radars and three C-band Doppler radars. Aircraft observations by NOAA/AOC P-3 (radar reflectivity data, Doppler radar data, cloud-microphysical data). Satellite data during TAMEX were collected from GMS-3, NOAA-9 and -10. TAMEX data are archived at the Central Weather Bureau in Taipei and at NCAR, Boulder, CO.

TIPEX (Tibetan Plateau Experiment)

TIPEX is an international campaign within the framework of GAME (GEWEX Asian Monsoon Experiment), which was initially planned as a Chinese national program.

TOGA (Tropical Oceans and Global Atmosphere)

The program was initiated in 1985 by WMO (jointly sponsored by WMO, ICSU, IOC) with major contributions from USA and many other nations including, UK, Russia, Japan, France, Australia, India, Chile, and China. TOGA is a component of WCRP (World Climate Research Program) with a focus on ENSO. Coordination of the program through the International TOGA Office in Geneva, Switzerland. TOGA is a 10-year international program 1985-95. TOGA aims to establish an operational climate prediction capability and an observing network to support it. Major science objectives are:

- To gain a description of the tropical oceans and the global atmosphere as a time-dependent system, in order to determine the extent to which this system is predictable on time scales of months to years.
- To study the feasibility of modeling the coupled ocean-atmosphere system for the purpose of predicting its variations on time scales of months to years.
- To provide the scientific background for designing an observing and data transmission system for operational prediction.

The major elements of the TOGA program plans are modeling, empirical studies, process studies and long-term observations. Three types of models are being used:

- Oceanographic models, in which the wind stress and heat flux at the air-sea interface are prescribed and the time-dependent response of the upper layers of the tropical ocean is simulated
- Atmospheric models, in which the global circulation is simulated given various prescriptions of the tropical SST field
- Coupled atmosphere-ocean models, which are integrated forward in time from a prescribed set of initial conditions.

Empirical studies are focusing on interannual and intraseasonal variability, along with statistical analysis of lead-lag relationships that may have relevance to seasonal climate prediction. - Process studies involve intensive, short-term, regional measurements focusing on specifically targeted processes. These include TOGA/COARE, largely a US program in the tropical Pacific, and SEQUEL/FOCAL, a US-French cooperative effort in the tropical Atlantic (emphasis on the annual cycle).

US involvement by NOAA (PMEL, AOML, GFDL, CMDL, NOS), NASA, NSF/NCAR, ONR, etc. - The observing network consists of two polar-orbiting satellites and the full array of geostationary weather satellites (GEOS, METEOSAT, GMS), ships, buoys and surface stations. TOGA data centers include the WDC (World Data Centers) for Meteorology and Oceanography: the Sub-Surface Data Center in Brest, France, the Sea-Level Data Center at the University of Hawaii, the Marine Climatology Data Center at Bracknell, UK, the ECMWF (European Center for Medium Range Weather Forecasting) in Reading, UK, and the NOAA/CAC (Climate Analysis Center) in Washington, DC.

TOGA/COARE (Tropical Oceans and Global Atmosphere Experiment/Coupled Ocean Atmosphere Response Experiment)

A research program aimed at investigating the scientific phenomena associated with the ocean, atmosphere and the interaction between the two in the warm pool region of the western Pacific Ocean. The program is international in scope (16 countries, ECMWF,), participating US agencies are (NASA, NOAA, NCAR, universities, etc.). The TOGA/COARE

International Project Office (TCIPO) is at UCAR, Boulder, CO. The specific COARE objectives are to describe/understand:

- The principal processes responsible for the coupling of the ocean and the atmosphere in the western Pacific warm-pool region
- The principal atmospheric processes that organize convection in the warm-pool region
- The oceanic response to combined buoyancy and wind-stress forcing
- The multiple-scale interactions that extend the oceanic and atmospheric influence of the western Pacific warm-pool system to other regions, and vice versa.

The intensive observation period (IOP) of the program took place from November 1, 1992 through February 1993 (site: 10° N to 10° S, and 140° E to 180° E) with the participation of some 700 scientists, technical and logistical specialists. One NASA aspect of TOGA/COARE is associated with concept demonstrations for TRMM (Tropical Rainfall Measuring Mission) and an understanding of convection in general. The TRMM objectives are in the areas of tropical ocean precipitation climatology, vertical structure of precipitation, water budget estimates and water cycle aspects.^{2858), 2859), 2860), 2861)}

- Ground-based observations: by ships (R/V Alis, R/V Franklin, R/V Hakubo-Maru, R/V Keifu-Maru, R/V Kaijo, R/V Le Noroit, R/V Maleita, R/V Moana Wave, R/V Nat-sushima, R/V Onnuri, R/V Kexue-1, R/V Shiyan-3, R/V Vickers, R/V Wecoma, R/V Xiangyanghong-5), buoys (TOGA/TAO and TOGA/WOCE), a land-based network of atmospheric sounding stations, island radars, ship radars, etc.
- Aircraft observations: ER-2 and DC-8 of NASA+, WP-3D (2) of NOAA, Electra of NCAR, C-130 of UKMO, Cessna 340A of Flinders University, Australia. Some airborne instruments: AMMR, AMMS, AMPR, ARMAR, CALS, EDOP, ELDORA, ESMR, ESTAR, LIP, MARA, MIR, MTS, RAMS, SSTR, TSCC, and VIRL.
- Satellite observations: GMS (VISSR), POES (AVHRR, TOVS), DMSP (OLS, SSM/I, SSM/T2), ERS-1 (ATSR, AMI, Altimeter), TOPEX/Poseidon (ALT, TMR, SSALT).

The TOGA/COARE data are archived at the following data centers:

- NOAA/NODC [oceanographic data, e.g. SEASOAR, ADCP (Acoustic Doppler Current Profilers), PROTEUS, CTD (Conductivity-Temperature-Depth profilers), XBT (Expendable Bathy-Thermograph), drifter, mooring], Washington, DC.
- NCDC (atmospheric data), Asheville, NC
- NCAR/DSS (oceanographic and atmospheric data), Boulder, CO
- MEDS (drifter data), Ottawa, Canada
- NOAA/PMEL (mooring data), Seattle, WA
- GSFC/DAAC (sensor data from aircraft and satellites), Greenbelt, MD

TOGA/TAO (TOGA/Tropical Atmospheric Ocean)²⁸⁶²⁾

TAO is a NOAA program within TOGA (Eulerian observations), consisting of an array of wind and upper ocean thermistor mooring ATLAS (Automated Temperature Line Acoustic System) buoys in the equatorial Pacific. The ATLAS mooring program started in December 1984 (NOAA/PMEL) with the deployment of the first buoy (19 buoys as of 1990), and has been complemented and upgraded ever since. The ATLAS mooring system is a taut-wire surface mooring with a toroidal float, measuring surface wind, air temperature, SST, ten subsurface temperatures to a maximum depth of 500 m, and two subsurface pressures. All data are monitored by ARGOS (see chapter G.15.4 and C.1) on NOAA-POES

satellites. TOGA/TAO represented a major component in the ground truth measurements of the TOGA/COARE campaigns.

TOGA/WOCE (World Ocean Circulation Experiment)

TOGA/WOCE is a subcampaign of the TOGA/COARE program, with so-called Lagrangian drifters (provision of ocean current data). During TOGA/COARE 130 drifters were deployed in the tropical Pacific and tracked via ARGOS. Some of these drifters were SEACAT buoys and operated by SIO (Scripps Institution of Oceanography, La Jolla, CA); others were Bogeda drifters operated by ORSTOM, Montpellier, France; Marisonde G drifters were operated by Meteo/France; eight drifters from the Maritime Safety Agency of Japan.

TOTE/VOTE (Tropical Ozone Transport Experiment/Vortex Ozone Transport Experiment)²⁸⁶³⁾ A US (NASA/HQ/ARC/GSFC/LaRC/JPL, NCAR, Penn State University, U. of Michigan, MIT) airborne pair of campaigns to be conducted from December 1995 through February 1996 (with test flights in June/July 1995). The main objective of TOTE/VOTE is to examine the production and dispersal of filaments (small-scale streamers of air) from the tropical and polar vortex regions (quantitative assessment of exchange process). Additional objectives are: examination of ozone/methane mixing ratios in the ozone loss region at the edge of the arctic vortex, and the study of denitrification processes associated with high cold cirrus near the tropopause. - Flights are conducted with the ARC DC-8; tropical deployment is from Hawaii, polar deployment from Anchorage, Alaska. Instruments: LASE (LaRC), MASP (NCAR), ATHOS (Penn State), MTP (JPL), FSSP-300 (ARC), ARL.

TRAGEX (Trace Gas Exchange: Mid-Latitude Terrestrial Ecosystems and Atmosphere)

An IGBP/IGAC long-term program (under focus 5) which started in 1990 (redefined in 1992; measurement and modeling activities are to start in 1995) with the goals to 1) document contemporary fluxes of CO₂, CH₄, N₂O and CO between the soil and the atmosphere, and 2) to determine the factors controlling these fluxes and improve the ability to predict future fluxes. - A sampling ground-based network is to be established at many sites on each continent representing the major ecosystems/land-use types of the mid-latitude zone (forests, rangeland, agriculture, urban, etc.).

TREES (Tropical Ecosystem Environment Observation by Satellites)^{2864), 2865)}

A joint CEC (Commission of the European Communities) JRC and ESA program/study for the development of Earth-observation techniques in support of global approaches to the problem of tropical forest assessment (long-term monitoring of global forest cover and the rate of deforestation). Participation of investigators from Europe, Brazil (INPE), China, and Australia. The program started at the end of 1993 and continued throughout 1994 by using optical data from the following satellites: NOAA-11, -12 (AVHRR), Landsat-5 (TM), Spot (HRV). Within TREES there was a special study, referred to as TREES/ERS-1, with the objective to assess the relevance and usefulness of ERS-1 SAR data in the framework of the TREES overall objectives. A total of 19 study areas were selected in Southeast Asia, Africa and Central/South America. The TREES project sites were selected to examine main forest features in three categories:

- Those related to forest canopy characteristics (in terms of forest/nonforest discrimination, forest type, seasonality, phenology, etc.)
- Those related to environmental effects upon the backscatter signal (such as topography, meteorological or overall hydrological conditions)
- Those related to the particular operation of the instrument and to SAR data analysis (in terms of selection of bio-windows for optimal analysis, type of products, data processing, analysis techniques, etc.).

VENTEX (Venting Experiment)

Sponsored by EPA, conducted in 1985 by SRI International with the objective to determine the vertical transport of pollutants in convective cloud regions. ALPHA-1 was used to map fluorescent dye particle transport near clouds.

VORTEX (Verification of the Origins of Rotation in Tornadoes Experiment)^{2866), 2867)}

A US campaign initiated and conducted by NOAA's National Severe Storms Laboratory (NSSL), Norman, Oklahoma, in collaboration with researchers from numerous universities and other federal agencies. The objectives were to study: a) interactions between tornadic storms and their environments, b) tornado-genesis and the roles of meso-cyclones and low-level boundaries, and c) tornado flow structure and dynamics. Two VORTEX campaigns were conducted from April 1 to June 15 in 1994 and during the same period in 1995. The study area covered the southern half of Kansas, most of Oklahoma, parts of the Texas panhandle and northern Texas. Ground and upper-air observations from five mobile mesonet vehicle, four mobile ballooning laboratories, TV cameras, portable Doppler radars, and an array of fixed (ground-based) WSR-88D radars. Aircraft observations from NOAA P-3 (Doppler radar) and NCAR ELDORA. VORTEX data archive at UCAR, Boulder CO. Study of the Tuskahoma/Talihina, OK tornado of April 25, 1994 and of the Gainesville, TX tornados of April 26, 1994.

WASHITA-92 (Little Washita River Watershed Campaign)^{2868), 2869)}

Washita-92 was a large-scale study of remote sensing and hydrology conducted on the Little Washita River watershed in southwest Oklahoma (participants: USDA, NASA/GSFC/JPL/ARC, U. of Massachusetts at Amherst, etc.). The campaign took place during the period of June 8-18, 1992. A large number of field experiments were conducted [routine data (rainfall, runoff, meteorological data), special data (eddy correlation, boundary layer profiling, land cover and vegetation mapping, surface roughness, bulk density measurements, reflectance and emissivity, L-band radar on truck, salinity and lake water temperature, etc.)]. Satellite data from Spot, ERS-1 and NOAA-POES (AVHRR). Two NASA aircraft were used: the C-130 flew TIMS, NS001, ESTAR, cameras, a 37-GHz radiometer and a USDA Laser Profiler; the DC-8 flew AIRSAR.

WENPEX (Western North Pacific Cloud-Radiation Experiment)

A Japanese WCRP campaign (Nagoya University, Tohoku University) with observations conducted over the southwest island area of the East China Sea from January 12-27, 1991. Objectives: a) cloud climatology; b) distribution of clouds and their bulk radiative properties; c) radiative properties of marine low-level clouds; d) formation of marine low-level clouds. Two aircraft (Cessna 404 Titan) carried microwave radiometers to determine the air truth of the total vertical liquid water path. Aircraft A flew above the clouds with a 37-GHz microwave radiometer (Dike-type, measurement of brightness temperature, estimation of liquid water path in optically thin clouds) and two pyranometers (measurement of upward and downward fluxes at 0.3-2.8 μm). Aircraft B flew inside the clouds with a cloud droplet spectrometer (FSSP-100), a thermometer and a dewpoint hygrometer.

WESTEX (West Coast Ship Tracks Experiment)

WESTEX is a cooperative NASA/DoD (ONR) campaign with the objective to determine the radiative, optical and microphysical properties of extensive cloud layers, both contaminated and uncontaminated by effluents of ships. Measurement of scattered radiation at multiple wavelengths with MAS and CALS. A further objective is to analyze and compari-

sons with ancillary and coordinated radiation data sets obtained from other aircraft platforms.

WINDOS (Western Indian Ocean Study)

A planned campaign of IGBP/IGAC/BIBEX to investigate the large-scale distribution of fire-impacted air masses over the southern hemisphere with emphasis on East Africa and the Indian Ocean.

WISP90 and 91 (Winter Icing and Storms Project, Feb. 1 to March 31, 1990; Jan. 15 to April 5, 1991)²⁸⁷⁰

Campaigns organized by NCAR with funding by FAA, NSF, and NOAA (U. of Wyoming, NOAA, Colorado State University, U. of North Dakota) and conducted in the Colorado Front Range region. The main goals of the campaign were to study the dynamic and microphysical processes leading to the formation and depletion of supercooled liquid water in winter ice storms and to improve forecasts of aircraft icing. Aircraft: King Air (U. of Wyoming) and Citation II (U. of North Dakota). Parallel measurements with ground-based equipment (radars, radiometers, sounders, wind profilers, etc.). Simultaneous spaceborne data acquisition from GOES. Data of campaigns is archived at NCAR.

WISPIT (Winter Icing and Storms Project, Instrument Test)

An NCAR/NOAA/Colorado State University campaign in February 1993 with the objective to test and verify the instrument observation capabilities for WISP94. The following tests were conducted:

- Measurements of ice nuclei, cloud condensation nuclei (CCN), and characteristics of aerosol populations
- Remote measurements of ice crystal characteristics with multiple-polarization radar
- Measurements of small ice crystals
- Diagnosis of cloud layers and icing hazard altitude (remote measurements)

WISP94 (Winter Icing and Storms Project)²⁸⁷¹

A multiinstitutional campaign organized and managed by NCAR (with participation by U. of Wyoming, Colorado State University, U. of Illinois, U. of Nevada, U. of Massachusetts, NOAA, etc.) and sponsored by FAA and NSF. WISP94 was a comprehensive winter research program conducted in eastern Colorado. Objectives: study of ice origins (ice nucleation, small ice and ice evolution), cold surges, multiparameter radar measurements, large supercooled droplets, and precipitation evolution. Observations were conducted from ground-based and airborne platforms. The NCAR Electra aircraft (Feb. 1 to March 25, 1994) measurements centered around wave clouds and upslope clouds. A King Air (U. of Wyoming) flew APDOR-95.

Q.2 International Research Programs

A major objective of international organizations like ICSU, IOC and WMO is to provide a framework within their organizations for the initiation, definition, coordination, standardization, promotion, and management of international research programs, which in turn require the combined efforts of the research agencies of many countries, in order to provide some degree of useful detail. Earth-System research of the atmosphere, the oceans, the climate, the biosphere, in short - the environment of humankind - is of such fundamental and vital interest (because the value of accurate climate forecasts can be high in many fields), and of such magnitude and complexity, that it requires the attention, dedication, and ingenuity of all involved, including considerable resources over a long period.

²⁸⁷⁰) R. Rasmussen, et al., "Winter Icing and Storms Project (WISP)," Bulletin American Meteorological Society, Vol. 73, No. 7, July, 1992, pp. 951-974

²⁸⁷¹) Internet information from NCAR

Q.2.1 International Geosphere-Biosphere Program

IGBP (International Geosphere-Biosphere Program) was established in 1986 by ICSU (International Council of Scientific Unions) - IGBP's International Secretariat is in Stockholm, Sweden. Overall objective: To describe and understand the interactive physical, chemical and biological processes that regulate the total Earth system, the unique environment that provides for life, the changes that are occurring in this system and the manner in which they are influenced by human activities. - The IGBP core projects with their principal questions, objectives, and research foci are:²⁸⁷²⁾

BAHC (Biospheric Aspects of the Hydrological Cycle)²⁸⁷³⁾, start of BAHC in 1993. - How does vegetation interact with physical processes of the hydrological cycle? Objectives of BAHC are:

- To investigate the biospheric controls of the hydrological cycle, and their climate, hydrological, and environmental significance
- To improve understanding of the exchanges of water, carbon, and energy at the soil-vegetation-atmosphere interface
- To assess ongoing changes in land-surface properties due to climatic and other changes that effect the interactions between the biosphere, atmosphere, hydrosphere, and lithosphere at different scales
- To estimate the role of plant communities, terrestrial and freshwater ecosystems in the fluxes of energy, water, carbon, and other substances between land and air, and land and river systems
- To improve our capability to model all processes at different scales from the micro- to the 1-50 km-scale in past, present and expected future conditions, considering climate explicitly
- To provide comprehensive and simplified ecohydrological models to be implemented as components of other sophisticated models
- To provide improved parameter estimation techniques
- To test and validate model simulations and data-processing algorithms for remote sensing data
- To simulate for specific climatic conditions a) the behavior of terrestrial ecosystems and freshwater ecosystems in view of the fluxes of energy, water, carbon, and other substances between land and air, b) changes in biospheric characteristics, and c) changes in surface and subsurface hydrology.

The research foci of BAHC are:

- 1) Development, testing, and validation of 1-D soil-vegetation-atmosphere transfer (SVAT) models
- 2) Regional-scale studies of land-surface properties and fluxes
- 3) Diversity of biosphere-hydrosphere interactions: Temporal and spatial variability
- 4) The weather generator project

GCTE (Global Change and Terrestrial Ecosystems),²⁸⁷⁴⁾ started in 1992. - How will global changes affect terrestrial ecosystems? The overall objectives of GCTE are: 1) to predict the effects of climate, atmospheric composition, and land use on terrestrial ecosystems, including agricultural and production forest systems, and 2) to determine how these effects lead to feedbacks to the atmosphere and the physical climate system. Research foci are:

- 1) Ecosystem physiology
- 2) Change in ecosystem structure
- 3) Global change impact on agriculture and forestry
- 4) Global change and ecological complexity

²⁸⁷²⁾Note: the IGBP projects are defined by scientists for scientists

²⁸⁷³⁾IGBP Global Change Report No. 27, The Operational Plan, 1993

²⁸⁷⁴⁾IGBP Global Change Report No. 21, The Operational Plan, 1992

IGAC (International Global Atmospheric Chemistry) project.²⁸⁷⁵) - How is the chemistry of the global atmosphere regulated, and what is the role of biological processes in producing and consuming trace gases? - IGAC has three main objectives:

- To develop a fundamental understanding of the processes that determine the chemical composition of the atmosphere
- To understand the interactions between atmospheric chemical composition and biospheric and climate processes
- To predict the impact of natural and anthropogenic forcing on the chemical composition of the atmosphere.

The research foci of IGAC are:

- 1) Natural variability and anthropogenic perturbations of the marine atmosphere. Campaigns: NARE, MAGE, APARE
- 2) Natural variability and anthropogenic perturbations of tropical atmospheric chemistry. Campaigns: BATGE, DEBITS, BIBEX
- 3) The role of polar regions in changing atmospheric composition. Activity: PASC.
- 4) The role of boreal regions in biosphere-atmosphere interactions. Activity: HESS.
- 5) Trace gas fluxes in mid-latitude ecosystems. Activity: MILOX, TRAGEX.
- 6) Global distributions, transformations, trends and modeling. Activity: GLONET, GLO-CHEM, GLOCARB, MAC, GEIA, GIM
- 7) Fundamental activities: ICIC, ACE

JGOFS (Joint Global Ocean Flux Study).²⁸⁷⁶) - How do ocean biogeochemical processes influence and respond to climate change? - JGOFS has the following objectives:

- To assess large-scale carbon fluxes, obtained from a greatly increased network of observations
- To develop a set of models that express an understanding of the processes controlling large-scale fluxes
- To establish a procedure for observing the ocean in a routine, synoptic manner to detect possible changes in the ocean carbon cycle in response to climate change
- To maintain a well-cared-for data set, comprising observations made according to standard protocols and a system for making subsets of these data easily available to researchers
- To increase knowledge and understanding of fluxes across the continental margins, to provide reliable boundary conditions for global models
- To increase the number of countries with an interest and skill in planning JGOFS-type activities and making the appropriate measurements and global-scale inferences.

The research foci of JGOFS are:

- 1) Study of processes controlling the fluxes of carbon and related biogenetic elements in the ocean and its exchanges on a global scale
- 2) Prediction: response of oceanic biogeochemical processes to anthropogenic perturbations, particularly related to climate research.

LOICZ (Land-Ocean Interactions in the Coastal Zone),²⁸⁷⁷) started in 1990. - How will changes in land-use, sea level and climate alter coastal ecosystems, and what are the wider consequences? The overall objectives of LOICZ are:

- To determine at global and regional scales:
 - the fluxes of materials between land, sea and atmosphere through the coastal zone
 - the capacity of coastal systems to transform and store particulate and dissolved matter, and
 - the effects of changes in external forcing conditions on the structure and functioning of coastal ecosystems

²⁸⁷⁵)IGBP Global Change Report No. 32, The Operational Plan, 1994

²⁸⁷⁶)IGBP Global Change Report No. 23, JGOFS Implementation Plan, 1992

²⁸⁷⁷)IGBP Global Change Report No. 25, Science Plan, 1993

- To determine how changes in land use, climate, sea level and human activities alter the fluxes and retention of particulate matter in the coastal zone, and affect coastal morphodynamics
- To determine how changes in coastal systems, including responses to varying terrestrial and oceanic inputs of organic matter and nutrients, will affect the global carbon cycle and the trace gas composition of the atmosphere
- To assess how the responses of coastal systems to global change will affect the habitation and usage by humans of coastal environments, and to develop further the scientific and socio-economic bases for the integrated management of the coastal environment.

The research foci of LOICZ are:

- 1) The effects of changes in external forcing or boundary conditions on coastal fluxes
- 2) Coastal biogeomorphology and sea level rise
- 3) Carbon fluxes and trace gas emissions
- 4) Economic and social impacts of global change on coastal systems

PAGES (Past Global Changes).²⁸⁷⁸ - What significant climatic and environmental changes have occurred in the past, and what were their causes? - The objectives are to improve our understanding of the significant environmental variations that have occurred in recent geological time. The initial effort is directed at obtaining a worldwide chronology of climate fluctuations, with emphasis on the sequence of events during periods of rapid change.

- Stream I aims: To reconstruct the detailed history of climatic and environmental change for the entire globe for the period since 2000 BP (Before Present), with temporal resolution that is at least decadal and ideally, annual or seasonal.
- Stream II aims: To reconstruct a history of climatic and environmental change through a full glacial cycle, in order to improve understanding of the natural processes that invoke global climatic changes.

The research foci of PAGES are:

- 1) Global paleoclimate and environmental variability. Activity: PANASH
- 2) Paleoclimate and environmental variability in polar regions. Activity: Arctic and Antarctic programs
- 3) Human impacts on past environments
- 4) Climate sensitivity and modeling
- 5) Cross-project analytical and interpretive activities

Q.2.2 World Climate Program

The World Climate Program (WCP) was initiated in 1979 at the World Climate Conference (WCC) and subsequently established as a joint program by ICSU and WMO (IOC is co-sponsor since 1993). The objective of WCP is to provide an authoritative international scientific voice on climate change and to assist countries to apply climate information and knowledge. WCP in turn is supported by GCOS (Global Climate Observing System) of WMO/UNEP/IOC/ICSU. WCP has four major elements:

- WCDMP (World Climate Data and Monitoring Program) - WMO responsibility
- WCASP (World Climate Applications and Services Program)
- WCIRP (World Climate Impact Assessment and Response Strategies Program) - UNEP responsibility
- **WCRP** (World Climate Research Program) - joint responsibility of WMO/ICSU/IOC (of UNESCO). The purpose of WCRP is to develop the fundamental scientific understanding of the climate system and climate processes that is needed to determine to which extent climate can be predicted and the extent of human influence on the climate.

²⁸⁷⁸PAGES Project Status and Work Plan (1994-1998), IGBP, November 1994

WCRP focuses on the four major components comprising the physical climate system, namely:

- 1) the global atmosphere
- 2) the world oceans
- 3) the cryosphere (continental ice sheets, ice caps, glaciers, sea ice and snow cover)
- 4) the land surface

WCRP has instituted a number of major projects to investigate the climate change processes, such as GEWEX, TOGA, WOCE, ACSYS, CLIVAR and SPARC. Each of these international projects consist in turn of other international and national projects or programs. There is considerable interproject cooperation and cross-fertilization on all levels. The development of global climate models is an important component of WCRP.

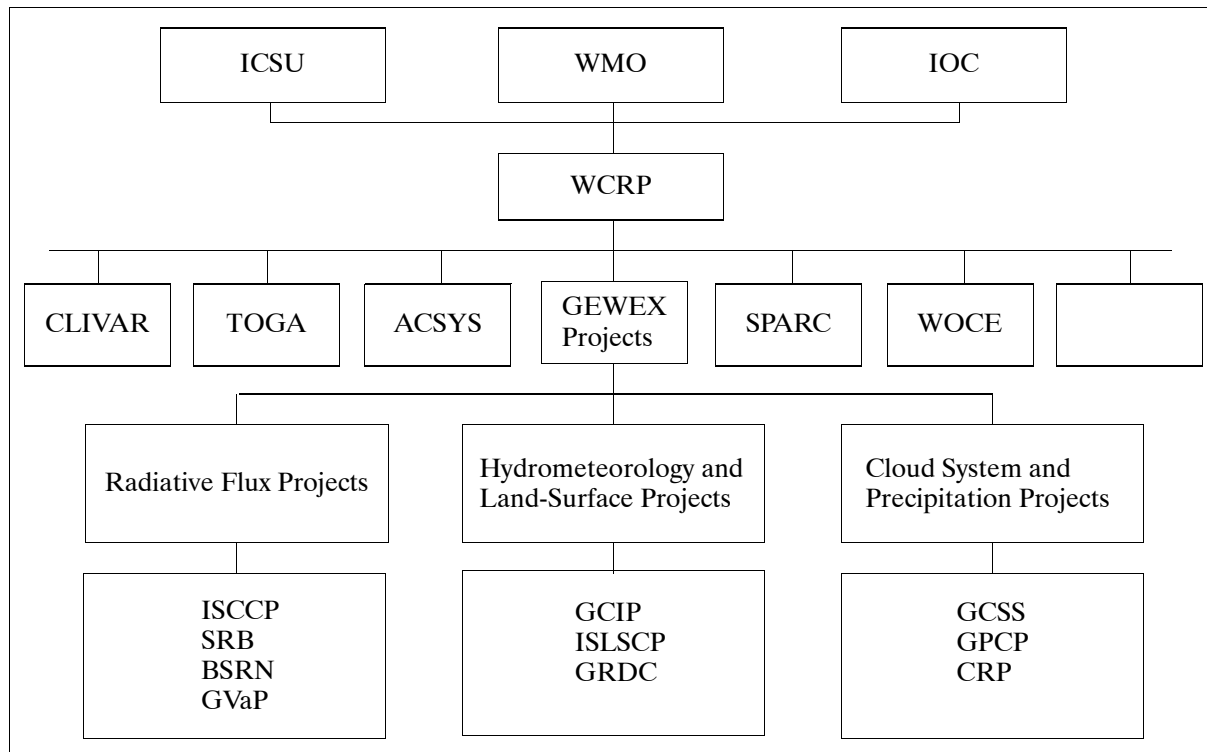

Figure 520: WCRP and GEWEX project structure

GEWEX (Global Energy and Water Cycle Experiment)^{2879), 2880)}

GEWEX was initiated in 1988 under the WCRP (World Climate Research Program). The objectives are to observe and model the distributions of water (hydrological cycle) and energy fluxes in the atmosphere (meteorological cycle), at the land surface and in the upper ocean layers. The ultimate goal of the program is to acquire the necessary knowledge to predict variations in the global hydrological regimes as well as changes in regional hydrological processes and water resources.

The magnitude of the task requires GEWEX to draw on information from a number of major campaigns and studies and also to initiate investigations of its own to improve modeling accuracy and surface-atmosphere coupling in general circulation models (GCM). Deployment of the spaceborne US EOS (Earth Observing System) platforms starting in 1998, and other observing systems by the world's space agencies, is considered part of the GEWEX

²⁸⁷⁹⁾ M. T. Chahine, "The hydrological cycle and its influence on climate," *Nature*, Vol. 359, October 1992, pp. 373-380

²⁸⁸⁰⁾ "The GEWEX Cloud System Study," *Bulletin American Meteorological Society*, Vol. 74, No. 3, March 1993, pp. 387-399

observing phase. The core of these studies will tie into **GCIP** (GEWEX Continental-Scale International Project). GCIP is designed to provide the parametric formulation of clouds, radiation and surface forcing factors. The goals of GCIP are to determine the variability of hydrological and energy budgets over a continental scale, to develop and validate coupled atmosphere-surface hydrological models and to provide a basis for translating the effects of future climate change into impacts on water resources on a regional basis.

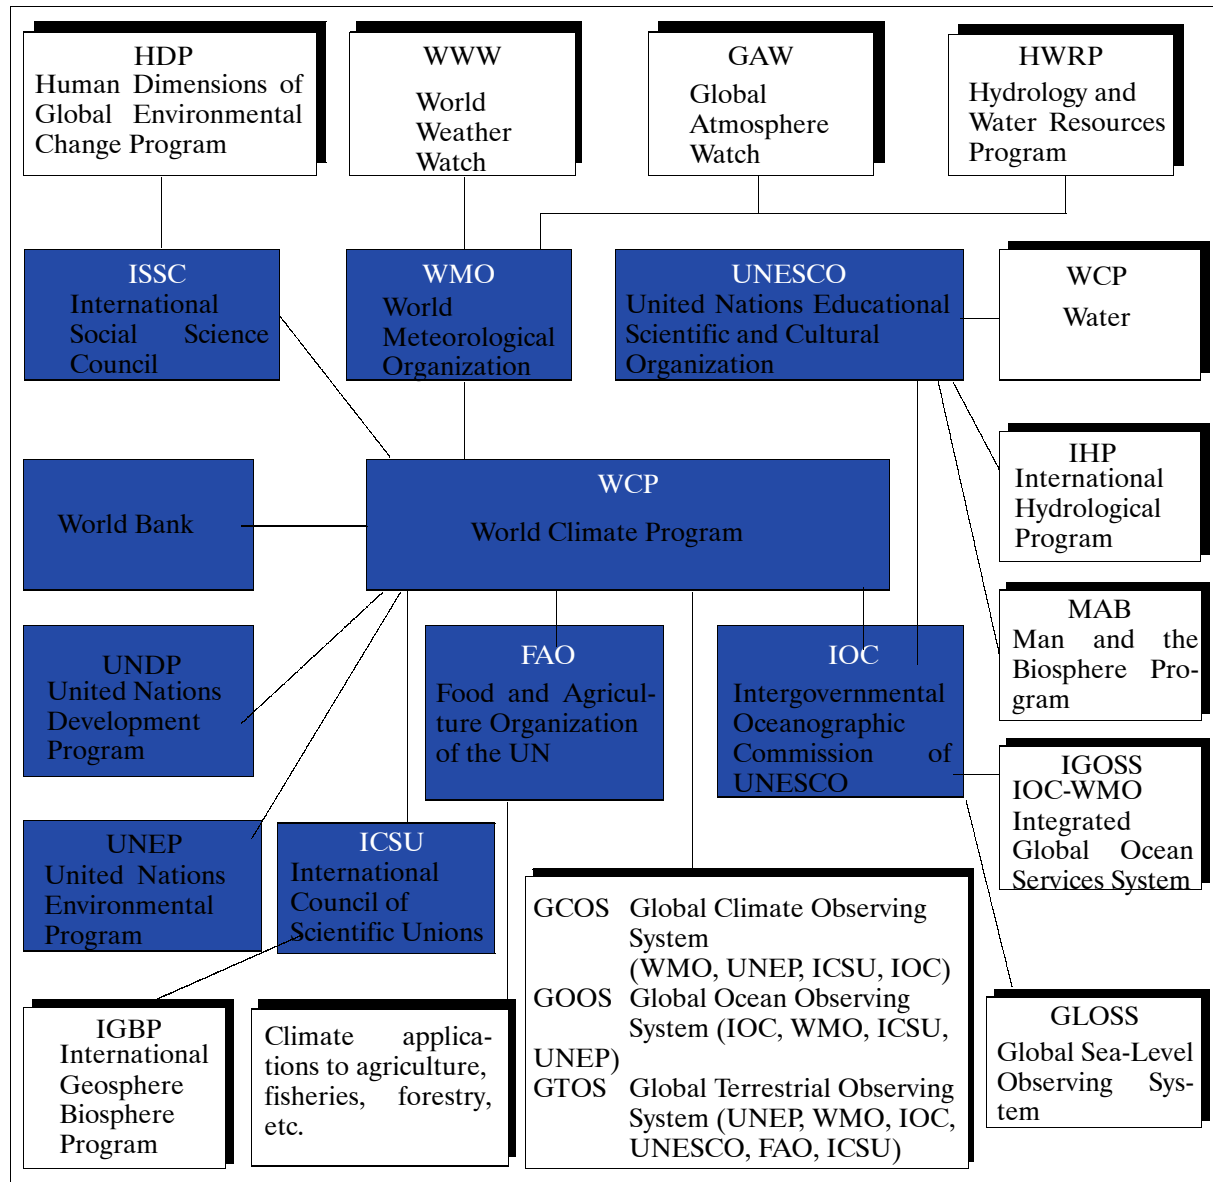

Figure 521: International organizations and their programs related to WCP

In 1992 WCRP approved a new long-term program called **GCSS** (GEWEX Cloud System Study). The focus of GCSS is on cloud systems spanning the mesoscale rather than individual clouds (modeling of cloud system life cycles, better parameterization of cloud systems and understanding of the physical processes). Many campaigns on the national and international level addressing cloud system problems have or will be part of the GCSS initiative. The objectives of GCSS are:

- To develop the scientific basis for the parameterization of cloud processes with due regard to physical and morphological identity among cloud system types
- To coordinate the acquisition and assimilation of observations and the use of cloud-resolving models to derive cloud systems for parameterization schemes in macroscale models

- To promote the evaluation and intercomparison of parameterization schemes for cloud processes.

GPCP (Global Precipitation Climatology Project)

A GEWEX project with the objective to provide global data sets of area, time-averaged precipitation for a minimum period of 10 years (1986-1995). GPCP merges geostationary and polar-orbiting satellite microwave and infrared data with rain gauge data from more than 6000 stations. GPCP data are used to validate atmospheric general circulation models and for the study of the hydrologic cycle. GPCP data are distributed by NOAA/NCDC, Ashville, NC.

GRDC (Global Runoff Data Center)

GRDC (of GEWEX) is located at the Bundesanstalt für Gewässerkunde (Federal Institute of Hydrology) at Koblenz, Germany. GRDC has compiled a global data base of stream flow data. One of its data application objectives is the development and verification of atmospheric and hydrologic models. The data base, which is updated continually, contains daily and monthly discharge data information for over 2900 hydrologic stations in river basins located in 143 countries.

Some campaigns/projects within **WCRP/GEWEX** are:

- **BALTEX** (Baltic Sea Experiment)
- **BASE** (Beaufort and Arctic Storm Experiment)
- **GAME** (GEWEX Asian Monsoon Experiment)
- **GCIP** (GEWEX Continental-Scale International Project)
- **GCSS** (GEWEX Cloud System Study)
- **GPCP** (Global Precipitation Climatology Project)
- **GVaP** (GEWEX Water Vapor Project)
- **ISCCP** (International Satellite Cloud Climatology Project)
- **ISLSCP** (International Satellite Land-Surface Climatology Project)
- **LAMBADA** (Large-scale Atmospheric Moisture Balance of Amazonia using Data Assimilation)
- **MAGS** (Mackenzie River GEWEX Study)
- **SRB** (Surface Radiation Budget) Project
- **PILPS** (Project for Intercomparison of Landsurface Parameterization Schemes)

SPARC (Stratospheric Processes and their Role in Climate)

SPARC is a new program of WCRP (start in 1993) extending its studies from the troposphere into the stratosphere. SPARC comprises four major research foci:

- The influence of the stratosphere on climate
- Process studies associated with stratospheric ozone changes
- Stratospheric variability and monitoring
- Monitoring and modeling of UV radiances changes

SPARC seeks cooperation with the following IGBP core projects: IGAC, GCTE, JGOFS, and LOICZ.

GCOS (Global Climate Observing System)

The GCOS program was initiated by WMO, IOC, UNEP and ICSU which set up two bodies: JSTC (Joint Scientific and Technical Committee, at WMO HQ in Geneva) and JPO (Joint Planning Office, also at WMO in Geneva) with the overall objective to develop plans and a framework/strategy for GCOS with the capability to monitor and predict climate variations and change and to coordinate all GCOS activities with other international programs. GCOS utilizes relevant UNEP programs such as GEMS (Global Environment Monitoring System) and GRID (Global Resource Information Database). Major subprograms of GCOS are:

- **GOOS** (Global Ocean Observing System, since 1991) - GOOS is conceived as a global framework for systematic ocean observations to meet the needs for forecasting climate variability. The objectives are:

- Monitoring and assessment of marine living resources
- Monitoring of the coastal zone environment and its changes
- Assessment and prediction of the health of the ocean
- Marine meteorological and oceanographic services.
- GTOS (Global Terrestrial Observing System) land/ecosystem observations

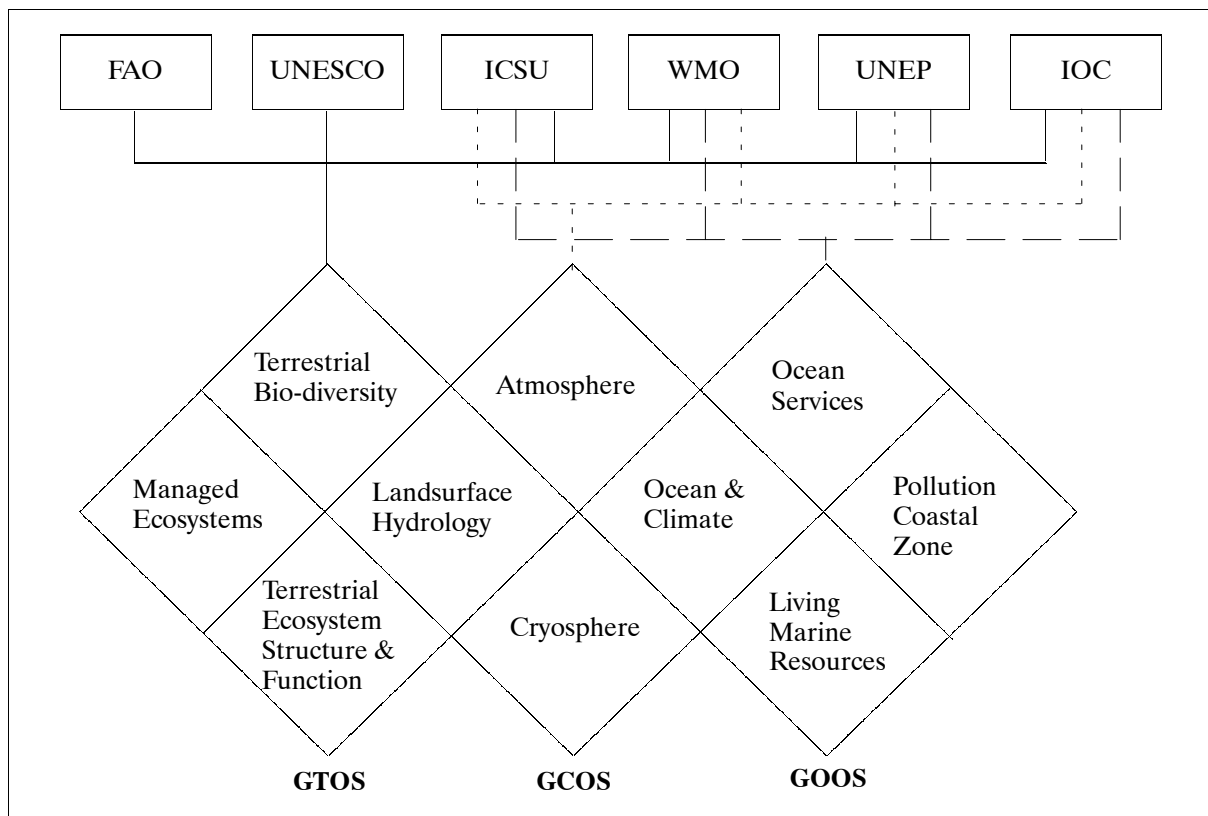

Figure 522: Interrelation of programs/functions/applications of organizations

Data centers and organizations participating in GCOS (1995):

- Environment Canada, Climate Information Branch, Downsview, Ontario, Canada
- Carbon Dioxide Information Analysis Center, ORNL, Oak Ridge, TN, USA
- Global Collecting Center for Marine Climatological Summaries, DWD, Hamburg, Germany
- Global Precipitation Climatology Center, DWD, Offenbach, Germany
- Global Runoff Data Center, Federal Institute of Hydrology, Koblenz, Germany
- Climate Prediction Center, Camp Springs, MD, USA
- National Meteorological Center, Melbourne, Australia
- EROS Data Center, Sioux Falls, SD, USA
- DAACs of EOSDIS Program (9 DAACs at distributed locations), USA
- Global Change Master Directory, NASA/GSFC, Greenbelt, MD, USA
- NCAR, Boulder, CO, USA
- NOAA/NGDC, Boulder, CO, USA
- NOAA/NSIDC, Boulder, CO, USA
- NOAA/NODC, Washington, DC, USA
- NOAA Satellite Active Archive, Camp Springs, MD, USA

Parameter	Coverage	Accuracy	Horizontal Resolution	Frequency of Observation
Sea surface temperature	global, ocean	0.2 K	100 km	5-10 days
Solar radiation		0.1 W/m ²	TBD	1 day
Snow cover	global, land/ice	TBD	100 km	5-10 days

Parameter	Coverage	Accuracy	Horizontal Resolution	Frequency of Observation
Land surface temperature	global, land	1 K	100 km	3 hours
Ocean surface wind vector	global	1 m/s	200 km	12 hours
Snow/water equivalent soil moisture	global, land/ice	1 mm	100 km	5-10 days
Ocean surface topography	global, ocean	3 cm	100 km	5 days
Land use assessment	global, land	TBD	TBD	TBD
Sea ice cover	polar ocean	1-5%	100 km	1 day
Multispectral albedo	global	1%	TBD	5-10 days
Ice thickness	polar ocean	10%	100 km	1 day
Precipitation	global	0.5 mm/day	100 km	5-10 days
Vegetation type, structure, hydrological function	global, land	TBD	TBD	TBD
Ocean color	global, ocean	TBD	100 km	1 day
Ice sheet and ice streams topography	polar regions	3 cm	10 km	1 year

Table 855: Preliminary list of GCOS data requirements for the Earth's surface

Parameter	Coverage	Accuracy	Horizontal Resolution	Vertical Resolution	Frequency of Observation
Wind profile	global	1 m/s	100 km	15 levels	1-2 hours
Cloud amount	global	10%	100 km	total column	3 hours
Temperature profile	global	1 K	25 km	15 levels	6 hours
Humidity profile	global	5%	50 km	10 levels	6 hours
Liquid water or ice	global	5%	100 km	3 km	3 hours
Top of atmosphere radiation budget	global	1 W/m ² (absolute 10 W/m ² , rms)	100 km		3 hours (or non-sun-synchronous sampling)
Cloud top height	global	1%	100 km	TBD	3 hours
Cloud top temperature	global	3 K	100 km	TBD	3 hours
Total ozone/profile	global	5%	50 km		6 hours
Aerosol optical depth	global	0.05	100 km	1 km	3 hours

Table 856: Preliminary list of GCOS data requirements for the upper air

Coverage	GCOS missions (7)	Principal Observations
Global	Global radiative properties	Cloud amount; cloud drop size distribution; solar irradiance; surface fluxes (heat, water); Earth radiation budget; surface radiation fluxes; multispectral albedo; aerosols
	Ocean characteristics	Ocean color; ocean topography/geoid; sea ice cover; sea surface temperature; ocean salinity
Oceans	Ocean/atmosphere boundary	Sea surface temperature; ocean wind vectors/speed; sea ice cover (as tracer); ocean wave height spectra; atmospheric surface pressure
	Atmospheric thermodynamics	Temperature profile; cloud clearing; wind profile; liquid water/ice; precipitation; humidity (profile/total)
Atmosphere	Atmospheric composition and chemistry	Constituents (total/profile); atmospheric dynamics; ozone (total/profile); aerosols (total/profile)
	Land/atmosphere boundary	Vegetation characteristics; soil moisture; snow cover; ice sheet topography; land surface temperature
Land	Land, biosphere, climate response	Vegetation change; land use change

Table 857: Principal observation parameters of GCOS missions

A total of seven 'GCOS spaceborne missions' have been formulated, providing a context of observational parameter requirements. These are:

ISCCP (International Satellite Cloud Climatology Project)

A (GEWEX) systematic international meteorological data collection phase that started in 1983 with the following science objectives:

- to collect and validate satellite radiance measurements from which a global cloud climatology can be derived
- to develop and use cloud extraction algorithms for the determination of cloud fractional coverages and altitudes of cloud fields, and other parameters for improving the parameterization of clouds in climate models
- to promote relevant research to improve knowledge of clouds within the climate system (radiation budget, precipitation).

Prime data sources of ISCCP are the operational radiance measurements of meteorological geostationary satellite series (GOES, GMS, METEOSAT) and POES series.

ISLSCP (International Satellite Land-Surface Climatology Project)²⁸⁸¹,

ISLSCP was started in 1983 under the UNEP umbrella to address research problems associated with interpretation and exploitation of satellite data over the Earth's land surface (methods for modeling and observation for land-surface-atmosphere interactions on regional and global scales). ISLSCP is part of WCRP-GEWEX as of December 1992. ISLSCP has served as a major forum for international consultations on planning, organization and scientific exploitation of land-surface process studies such as the:

- First ISLSCP Field Experiment (FIFE) which took place in 1987 and 1989 on the grassland prairies of Kansas
- Hapex-Sahel in the Sahelian zone of Africa (1992)
- KUREX, which took place in Siberia (1991)
- BOREAS, which took place in 1994 through 1996 in the boreal forests of Canada
- LAMBADA/BATERISTA/AMBIACE, which is planned for 1998 in the Amazon Basin.

This series of field experiments was designed to provide data to develop and test:

- regional and global carbon/energy/water process models
- algorithms for processing satellite data in order to initialize and evaluate process models.

ISLSCP has also taken the lead in producing a five-volume CD-ROM set of the major land parameters required to initialize and validate global energy/water/carbon process models.

CPR (Cloud Profiling Radar)²⁸⁸²

A GEWEX program with the objective to provide a global 3-D distribution of cloud parameters from satellite observations. A simple nadir-pointing millimeter-wave cloud radar is thought to provide a suitable sample of large-scale cloud information on a monthly mean-time scale and on a spatial scale of ~ 250 -500 km, adequate for determining large-scale cloud variability of significance for climate.

BSRN (Baseline Surface Radiation Network)

A WCRP/GEWEX coordination project with the objective to establish a worldwide network to continuously measure radiative fluxes at the Earth's surface. Over 25 stations located throughout the world are planned for BSRN. Many of these stations began operation in 1992 and each year more are added to the network. These stations provide data for the calibration of the SRB project and other spaceborne measurements of radiative fluxes. The data are archived in WRMC (World Radiation Monitoring Center) in Zürich, Switzerland. BSRN objectives:

- To monitor the background (least influenced by human activities) shortwave and long-wave radiative components and their changes with the best methods available
- To provide data for the calibration of spaceborne instruments whose data can be used to estimate surface radiation fluxes
- To provide high-quality observational data to be used for validating the theoretical computations of radiative fluxes by models.

²⁸⁸²Information from GEWEX homepage on [www](http://www.gewex.org)

PILPS (Project for Intercomparison of Landsurface Parameterization Schemes)²⁸⁸³⁾

PILPS is a WCRP/GEWEX program (since 1992) with the objective to improve understanding of the parameterization of the interactions between the atmosphere and the continental surface in climate and weather forecast models. The first phases of the project included documentation of land surface parameterization schemes (phase 0) and intercomparisons. Phase 2 includes the identification of datasets for stand-alone evaluations or off-line intercomparisons of land surface scheme calculations. Phase 3 comprises the diagnostic subproject of AMIP (Atmospheric Model Intercomparison Project).

WOCE (World Ocean Circulation Experiment)

The WOCE program is a cooperative international effort (WCRP initiative of 1983) involving scientists from 40 nations. The observational program started in 1990 and is expected to continue through 1997; it is supported by data from several satellites, by many airborne instruments, by dozens of ships, and by thousands of surface sensors to take a comprehensive global ‘snapshot’ of the physical properties of the ocean. The goal is to develop a very large data set for use in developing numerical models of ocean circulation and physical processes. Then, as these ocean models are improved, they will be coupled with atmospheric models to simulate and perhaps predict, how the oceans influence the global and regional climate over long periods.

Three satellite missions are pledged (Paris 1988) for WOCE support (ERS-1, -2, TOPEX/Poseidon, and ADEOS).

- Measurements of sea surface topography, sea surface temperature, and sea surface winds by the satellite missions.
- Collection of water samples
- Direct measurements of currents (worldwide array of ocean surface instruments)
- Estimates of air-sea fluxes (observation from ships, aircraft, etc.)

Major WMO cooperative programs are:

- WWW (World Weather Watch)
- WCP (World Climate Program)
- WCRP (World Climate Research Program)
- GCOS (Global Climate Observing System)
- AREP (Atmospheric Research and Environment Program)
- HWRP (Hydrology and Water Resources Program)
- ETP (Education and Training Program)

²⁸⁸³⁾ A. Henderson-Sellers, et al., “The Project Intercomparison of Land Surface Parameterization Schemes (PILPS): Phases 2 and 3,” BAMS, Vol. 76, No. 4, April 1995, pp.489-503

Appendix A Glossary

Only brief definitions are given to provide a quicklook reference for the reader with regard to terminology. Bold face type within a definition refers to a subject-related entry.^{2031) 2032) 2033)}

Aberration. Geometrical errors in imagery whereby a perfect image is not formed. Typical aberrations include spherical aberration, astigmatism, coma, and chromatic aberrations. Lens bendings, locations, powers, materials, and increasing the number of lenses and aperture stop positions are all used to minimize aberrations.

Absorption band. A range of wavelengths, or frequencies, in the electromagnetic spectrum within which radiant energy is absorbed by a substance (gas, liquid or solid). In the gaseous phase, absorption lines are much narrower than in liquids or solids. In a polyatomic gas, an absorption band is actually composed of discrete absorption lines which appear to overlap. Each line is associated with a particular mode of vibration and rotation induced in a gas molecule by incident radiation. Examples:

- Ozone (O₃) has several absorption bands. They are: a) the Hartley bands (2000-3000 Å in UV with max absorption at 2550 Å); b) the Huggins bands (weak absorption between 3200-3600 Å); c) the Chappuis bands (weak and diffuse at 4500 Å and at 6500 Å in VIS); d) IR bands at 4.7, 9.6, and 14.1 μm.
- Molecular oxygen (O₂) also has several absorption bands. They are: a) Hopefield bands (between 670 and 1000 Å in UV); b) diffuse between 1019 and 1300 Å (UV); c) the Schumann-Runge continuum (between 1350-1760 Å); d) Schumann-Runge bands (between 1760 - 1926 Å); e) the Herzberg bands (between 2400-2600 Å); f) the atmospheric bands (between 5380-7710 Å, VIS); g) IR at about 1 μm (=10⁴ Å).

Absorptivity. Ratio of the absorbed to the incident electromagnetic radiation on a surface.

Accuracy. Refers to an estimate of how well a certain parameter or measurement is known; it is a measure of the absolute truth of a measurement requiring absolute (traceable) standards. Accuracy is a quality that characterizes the ability of a measuring instrument to give indications equivalent to the 'true value' of the quantity measured. The quantitative expression of accuracy may also be given in terms of uncertainty. The actual or 'true value' of a quantity cannot be determined; it can only be said to exist within tolerance limits of a measured value. The measurement error is the algebraic difference between the measured (or indicated) value and the true value. Hence, accuracy is by its very nature only an estimation of the true value, taking into account all aspects of measurement.

Acid rain. Rain that is more acid than normal because the raindrops contain dissolved acid gases and/or dust particles (aerosols) from the atmosphere. The principal gases responsible for increased acidity are oxides of sulfur and nitrogen. Generally, rain with a pH below 4.5 is considered environmentally harmful.

Actinometer. A generic term for any instrument used to measure the intensity of radiant energy, in particular that of the sun.

Active sensor. A sensor having its own source of EMR (Electromagnetic Radiation); it transmits a series of signals to the target and detects the echo. A SAR instrument, a lidar, a radar altimeter, etc., are examples of active sensors.

Actuators. Refer to a class of on-board devices or techniques employed in particular for attitude control. Some examples are: reaction wheels, momentum wheel, magnetorquer coil/

rod, permanent magnets, gravity-gradient boom, nutation damper, control moment gyros, cold gas thrusters, solid thrusters, ion thrusters, mono- or bi-propellant engine, etc.

Adaptive optics. A technique which tries to compensate for the atmospheric degradation of the incoming signal of optical imaging systems. However, the compensations achieved, regardless of method, are never “perfect.” The following approaches are in use:

- An on-line adaptive optics system (hardware solution). In this version, the adaptive optics system is capable of compensating for the distortion of electromagnetic radiation as it passes through the turbulent atmosphere and the optical system. Elements of an adaptive optical system are a high-speed wavefront sensor (sensing the turbulence-induced aberrations), a flexible mirror system whose surface can be electronically controlled to correct for aberrations, and a computer controller that converts the wavefront measurements into deformable mirror commands. - More economic solutions are suggested by the use of LCPM (Liquid Crystal Phase Modulator) to deform the mirror, and by the use of the pupil masking technique.²⁰³⁴⁾²⁰³⁵⁾
- A post facto approach (software solution), where the data are acquired by an imaging instrument and processed off-line with suitable iterative algorithms to increase the overall resolution obtained by the optics system. Speckle imaging is an example of such a technique.²⁰³⁶⁾
- A hybrid approach using an adaptive optics system in combination with post facto processing.

Advection. Refers to a change in property of a moving air parcel from one region to another (say, from a warm region to a cool region, thereby changing its temperature). Commonly, advection is divided into horizontal and vertical components; it differs from convection only in scale. Convection is transport by random thermally induced currents, whereas advection is transport by steady vertical currents.

Aerosol. Aerosols are a suspension of fine (solid or liquid) particles such as dust, smoke particles, water droplets, etc. in the atmosphere. The smallest aerosols are the atoms of the various atmospheric gases. The range of sizes varies from a few nanometers (molecules) to tens of micrometers (wind-driven sand). Some aerosols (sea salt and haze) occur naturally and some (smoke) are man-made (anthropogenic). The ocean is a significant source of natural tropospheric aerosols. Once in the atmosphere, aerosols may be transported away from their place of origin, sometimes over great distances. - Aerosols can directly and indirectly affect the radiation budget of the atmosphere. Their direct radiative effect is due to their scattering, absorption, and emission properties. Their indirect effect is a result of their ability to act as condensation nuclei in the formation of clouds. Both tropospheric and stratospheric aerosols play an important role in global climate change.

Airglow. A nighttime glow from the upper atmosphere, occurring over middle and low altitudes, due to the emission of light from various atoms, molecules, and ions.

Albedo. The fraction of the total solar radiation incident on a body (or a natural surface such as the ground, ice, snow, water, clouds, etc.) that is reflected by it (commonly expressed as a percentage, see also **planetary albedo**). Measured albedo information may be applied to cloud analysis, it may also serve in calculations of inherent contrast between targets and background. By definition, white surfaces (i.e. an all reflective Lambert surface) have albedos close to 1, black surfaces have albedos close to zero.

Aliasing. A term in data processing referring to two or more distinctly different signals having identical sample values.

Altimetry. Altimetry can be described as run-of-time distance measurements taken from a vertically tracking satellite to the geoid. A spaceborne radar altimeter maps the sea surface, which is complex, but which largely conforms to the equipotential surface known as the geoid. The ocean surface departs significantly (at the meter level) from the geoid - this departure is of great interest to the science community (oceanographers, meteorologists, geophysicists, etc.) for it reflects the global circulation patterns and also, in the form of tides and changes in sea level, fundamental climatic and solid Earth phenomena. Furthermore, altimetry provides approximate estimates of the geoid itself, in the form of a mean surface obtained by averaging measurements taken over many satellite passes over the same locations. More detailed explanations on altimetry are given below.

- A radar altimeter on-board a satellite permanently transmits signals at high frequency to the Earth's surface, and receives the echo from the sea surface. This is analyzed to derive a precise measurement of the round-trip time between the satellite and the sea surface. By averaging the estimates, say, over a second, this produces a very accurate measurement of the satellite-to-ocean range. However, as electromagnetic waves travel through the atmosphere, they can be decelerated (by water vapor) or accelerated (by ionization). Once these phenomena are corrected for, the final range R is estimated within 2 cm.²⁰³⁷⁾
- Satellite orbit: The ultimate aim is to measure sea level relative to a terrestrial reference frame. This requires independent measurements (accurate tracking) of the satellite orbital trajectory, i.e. exact latitude, longitude and altitude coordinates. The critical orbital parameters for satellite altimetry are altitude, inclination and period.
- Sea surface height (SSH): SSH is the range at a given instant from the sea surface to a reference ellipsoid. SSH is simply the difference between the satellite height (S) and the altimetric range (R): $SSH = S - R$. The SSH value takes account of such effects as:
 - The sea surface height which would exist without any disturbances (wind, currents, tides, etc.). This surface, called the **geoid**, is due to gravity variations around the world, which are in turn due to major mass and density differences on the sea-floor. For example, a denser rock zone on the sea-floor may deform the sea level in the order of tens of meters; this is visible as a hill on the geoid.
 - The ocean circulation, or dynamic topography. The ocean circulation, which comprises a permanent stationary component (permanent circulation linked to Earth's rotation, permanent winds, etc.) and a highly variable component (due to wind, tides, seasonal variations, etc.). The mean effect is on the order of one meter.

Amplitude modulation (AM). The baseband signal is caused to vary the amplitude of the carrier wave to create the wanted information content.

Analog data. Data represented in continuous form, as contrasted with digital data having discrete values.

Ångström (Å, after A. J. Ångström, a Swedish physicist). A unit of length used in the measurement of short wavelengths (X-rays, gamma rays, etc.) and in the measurement of molecular and atomic diameters. $1 \text{ Å} = 10^{-10} \text{ m}$ or 10^{-4} μm .

Antenna. A sender and receiver system of electromagnetic radiation (in remote sensing terminology the antenna may be part of the sensing instrument, or may be regarded as a coupling device between the target and the sensing instrument). The term antenna refers a) to that part of a transmitting system that converts electrical energy to electromagnetic waves; and conversely b) to that part of a receiving system that converts electromagnetic waves to electrical energy (current) in the receiver (a duplexer automatically switches the antenna from a transmitting function into a receiving function). Physically, an antenna consists of metal surfaces that provide conducting paths for oscillating electric currents and charges. The radiated power of an antenna depends on the shape and size of its geometric contour and on the amplitude and frequency of its oscillation. Some antenna designs:

²⁰³⁷⁾ http://www-projet.cnes.fr:8170/HTML/information/frames/general/sitemap_uk.html

- **Dielectric rod antenna.** An antenna consisting of a dielectric cylinder that is partially inside a circular waveguide (pipe). It is possible to have an electric field applied to this device - no currents flow through it - although energy passes from one end to the other, thereby generating electromagnetic waves.
- **Dipole antenna.** A thin metal cylinder or wire excited by an alternating current generator at its center so that the ends are oppositely charged. - A dipole antenna is a form of open circuit in which the current oscillates between the ends of the conductor. A dipole antenna may also be a type of array consisting of a system of dipoles. A dipole antenna differs from a dish antenna in that it consists of many separate antennas that collect energy by feeding all their weak individual signals into one common receiving set.
- **Helix antenna.** A helical wire wound with a circumference of about one wavelength and a pitch of $1/4$ wavelength over a ground plane with a 1 wavelength minimum diameter.
- **Lens antenna.** Several types are in use: a) dielectric lens - the aperture of the antenna is equal to the projection of the rim shape; b) artificial dielectrics; c) strip antenna - metal strips are used as waveguides to increase the phase velocity by acting as parallel-plate waveguides.
- **Loop antenna.** The current circulates around or oscillates within the closed loop. The most important application of the loop antenna is reception. The shielded loop antenna is useful as a probe for measuring the magnetic field.
- **Microstrip patch antenna.** A printed circuit antenna consisting of a radiating patch supported by a dielectric layer over a ground plane.
- **Monopole antenna.** A thin metal cylinder or wire erected vertically over a conducting plane and excited by an alternating current generator connected between the base of the cylinder and the conducting plane.
- **Pencil beam antenna.** An antenna whose radiation pattern consists of a single main lobe with narrow principal plane beamwidths and sidelobes having relatively low levels.
- **Phased-array antenna.** Phased arrays are inherently random-access devices consisting of multiple antenna elements (fixed dipoles) which are fed coherently and use variable phase- or time-delay control at each element to scan a beam to given angles. Arrays are sometimes used in place of fixed aperture antennas (e.g. reflectors or lenses) because the array arrangement allows more precise control of the radiation pattern (lower sidelobes). The primary reason for using arrays is to produce a directive beam that can be scanned (repositioned) electronically in two dimensions without any mechanical movement (see also **Phased-array Technology**).
- **Stick antenna.** Also referred to as a fan-beam antenna, it produces a major lobe whose transverse cross section has a large ratio of major to minor dimensions.
- **Slot antenna.** A slot in a metal sheet with dimensions $\lambda/2$ in length and width w ($w \ll \lambda$) provides a means for achieving efficient directional energy radiation and reception. The radiation leaving the slot antenna is polarized in the direction normal to the major slot dimension (if the slot is horizontal, then the polarization is vertical, and vice versa). Array arrangements of slots permit the radiation of higher energies and consequently the illumination of larger target areas.

Antenna reflectors. A reflector antenna is a large-aperture (gain) directional antenna. A parabolic reflector (mirror) has the property of transforming rays emerging radially from a point source at its focus into a bundle of parallel rays. The reflected parallel rays are all in phase in any plane perpendicular to the axis of the parabola. The laws of optics apply with respect to the radiation geometries and projections (focusing, bundling, redirection of energy, diffraction effects, etc.). Characteristic parameters of a reflector antenna are a func-

tion of the properties of the feed and the ratio of the reflector's focal length (F) to the diameter (d) of its circular aperture.

Reflector antennas are widely used in the microwave range of the electromagnetic spectrum in the fields of remote sensing, telecommunication, and radio astronomy. Reflectors are inherently broadband instruments; the bandwidth and polarization are determined by the feed antenna. Reflector examples: paraboloidal, parabolic cylinder, dual (Cassegrain, Gregorian), offset-fed, corner, dichroic.

- **Cassegrain dual-reflector antenna (telescope).** N. Cassegrain, a French scientist, proposed the design in 1672. The basic properties of the Cassegrain dual-reflector are determined from the principles of ray optics. A small convex hyperboloidal subreflector is placed between the point source feed and the prime focus of the parabolic dish. Rays from the feed are transformed by the subreflector into rays that appear to be emerging from the paraboloid focus. The rays reflect from the parabolic reflector parallel to its axis.
- **Offset aperture reflectors.** The blocking of portions of the aperture of a reflector antenna by its feed, supporting structures, or by the subreflector generally degrades the radiation distribution. Hence, high-performance systems employ offset-fed antennas to eliminate the effects of aperture blocking.
- **Horn antenna.** A horn is an aperture antenna fed from a waveguide mode in an expanded waveguide. The bandwidth is determined by the feed waveguide.

Figure 418: Some antenna geometries

- **Dichroic reflector.** The term dichroic (chros = color in Greek) implies selective absorption in crystals of electromagnetic radiation vibrating in different planes. - Refers to frequency-selective surfaces designed to exhibit different ratio-frequency properties. In its simplest form, a dichroic surface is virtually perfectly reflecting at one fre-

quency and virtually transparent at another. The most common application of dichroic reflectors has been as subreflectors in Cassegrain antenna systems. Besides reflectors the dichroic principle is also applied to beamsplitters and filters.

- **Antenna retroreflector.** Retroreflection is defined as radiation that is returned in angular directions which are very close to those angular directions from which it came. This (incoming/outgoing) property is maintained over wide variations of the incident radiation. Retroreflector devices come in a variety of forms and have many uses. In remote sensing, a retroreflector uses total internal reflection from three mutually perpendicular surfaces. This kind of retroreflector is usually called a ‘corner cube retroreflector’. A corner cube reflector is normally used for radar measurements having a known radar cross section.

Antenna aperture. Surface area (size) of a reflector or horn that is illuminated by the outgoing and/or incoming radiation.

Antenna bandwidth. Range of frequencies within which the performance of an antenna, with respect to some characteristic, conforms to a specified standard. There are many different types of bandwidths, including gain, VSWR (Voltage Standing Wave Ratio), and polarization. For example, a typical bandwidth specification might be: The antenna gain with isotropic must be $> 10 \text{ dB} \pm 10 \text{ MHz}$ from a center frequency of 2090.0 MHz.

Antenna beamwidth. A planar cut through the radiation pattern containing the direction of the maximum of a lobe, the angle between the two directions in which the radiation intensity is one-half the maximum value and one tenth the maximum value, or in which zero is defined to be the half-power (3 dB), tenth-power (10 dB), or null beamwidth.

Antenna depression angle. The angle between the local horizontal and the center line of the antenna beam pointing at the target.

Antenna directivity. Directivity is a measure of the concentration of radiation in the direction of the maximum. It is the ratio of the radiation intensity in a given direction from the antenna to the radiation intensity averaged over all directions.

Antenna feed. The device in an antenna system that transmits or receives energy to or from the antenna aperture and the radio system.

Antenna footprint. Instantaneous projection of a directional antenna beam illumination on a surface.

Antenna gain. Ratio of the transmitted radiation intensity in a given direction to the radiation intensity that would be received if the power accepted by the antenna were radiated isotropically. In this context, ‘peak antenna gain’ refers to the maximum radiated intensity expressed as a ratio to the radiation power intensity of a hypothetical isotropic antenna fed with the same transmitting power.

Antenna - intermediate frequency (IF). In microwave systems, a frequency that is common to all channels at which amplification takes place, interconnections are made, and/or automatic gain is adjusted.

Antenna - isotropic. A theoretical antenna of infinitesimal size in which it is assumed that all of the energy is radiated (point source). This concept serves as a reference basis for other antennas of finite dimensions.

Antenna noise temperature. Refers to the increase of the receiver input noise temperature of an antenna system.

Antenna polarization. Spatial orientation of the electric/magnetic field radiated by an antenna. The vector electric/magnetic fields of free space traveling waves are perpendicular to

the direction of travel. Polarization describes how fields behave in time and space. For example, a “circularly polarized” wave can be thought of as having the electric field rotating about the direction of travel. The direction of the field rotates one turn per period of the wave. A “linearly polarized” wave radiated from an antenna into a specific direction has the electric field direction fixed with time - the only variations are in the instantaneous magnitudes of the electric/magnetic fields.

Antenna scanning techniques.²⁰³⁸⁾ For SAR observations the antenna beam casts an elliptical footprint on the ground with an effective rectangular aperture antenna of typical size 10 m (along-track) and 3 m (across track).

- **Electronic scanning.** Defines a method of positioning an electromagnetic beam in space or scanning across a target surface by electronic means. The antenna aperture remains fixed; no mechanical mechanism is involved in the scanning process.
 - Phase scanning (moved the beam by controlling the phase of the antenna illumination, using phase shifters or delay lines - see also **Phased-array technology**)
 - Frequency scanning (moves the beam by changing the carrier frequency of the transmitter and receiver)
 - Electronic feed switching
- **Mechanical scanning.** Defines a method of positioning an electromagnetic beam in space by mechanical rotation or angular positioning of the radiating aperture of the antenna system.
- **Electronic/mechanical scanning.** A hybrid method that employs electronic scanning in one dimension, say in elevation, and mechanical scanning in azimuth.

Antenna sidelobes. Undesired directions in which a directive antenna also receives or radiates power. Sidelobes are generally much weaker than the main beam in the desired direction.

Antenna waveguide. Usually a hollow metal structure (pipe or other profile) intended to guide or to conduct along its path an electromagnetic wave in a given microwave range (a waveguide is usually attached to a horn; it may also directly serve as a feed for a reflector). The internal dimensions of a waveguide are related to the transmission efficiency of specific frequencies. The cutoff frequency refers to that frequency below which a particular waveguide cannot satisfactorily transmit the wave.

Antenna waveguide modes. Refer to the wave propagation distribution patterns that may exist within a waveguide. They depend on the shape and size of the waveguide with respect to the length of the wave traversing the guide. Each mode has a specific topology, velocity, and energy distribution along and across the guide cross section. The cross section of the waveguide may be square, rectangular, circular, or elliptical.

Anthropogenic gases. ‘Human-induced’ gases emitted into the atmosphere and interacting with the environment. In a wider sense the term refers to all gases emitted as a result of human activities (e.g., chlorofluorocarbons from technical combustion processes, carbon dioxide and methane from livestock farms, rice paddies, biomass burning, etc.).

Aperture. Refers to the maximum diameter of a radiation beam that can pass through a system (either an optical lens or mirror system or an antenna system) on a telescope or satellite. The radiation-gathering power of such a system is proportional to the square of the diameter (or aperture) of the lens (mirror or antenna). Hence, sensors with wider apertures are able to capture more information. Apertures are used to restrict the field of view (FOV) of the responsive element (such as a detector). This is often done to reduce noise (cooled detectors are photon-noise limited) from extraneous sources.

²⁰³⁸⁾ P. J. Kahrilas, “Electronic Scanning Radar Systems, Design and Architecture,” in ‘Practical Phased-Array Antenna Systems,’ E. Brookner, Editor, Artech House, Boston, MA

Aperture stop. Location within a lens system where the principle ray passes through and crosses the optical axis. The presence of a mechanical limiting aperture (hole, slot, etc.) typically creates a limiting size.

Aperture synthesis. A technique (pioneered in radio astronomy) of generating high spatial resolution images by dividing the collection area of a telescope (or antenna) into smaller apertures spread out in a pattern covering several baselines. In microwave radiometry the concept employs an interferometric technique in which the product from antenna pairs is sampled as a function of pair spacing. Substantial reductions in the antenna aperture needed for a given spatial resolution can be achieved with this technique. However, the performance leap in resolution must be paid for with higher requirements for instrument precision sensing and stabilization. ESTAR (P.87) and MIRAS (P.132) are examples of airborne synthetic aperture microwave radiometers (both instruments operate in L-band).

Apodizing/unapodizing.²⁰³⁹⁾ The terms are used in the context of data processing in a FTS (Fourier Transform Spectrometer). The actual lineshape of a FTS interferogram is close to $(\sin x)/x$, which is a function with intense side-lobes (also referred to as “feet”). This is the shape that the spectrum of an intrinsically sharp line (e.g. a laser line) would have if the spectrum were untreated, or “unapodized”; to apodize means literally (Greek) “to cut off the feet”. Apodizing consists of treating the spectrum to reduce the sidelobes at the expense of degraded resolution (usually by a factor of about two). Apodizing can be done either by tapering the interferogram prior to transforming, or by algebraically filtering the spectrum after transforming.²⁰⁴⁰⁾

Area Array Camera. Refers to a solid-state imaging device (CCD technology) with an array (rows and columns) of pixels producing a 2-D image. The Area Array Camera is also referred to as Matrix Array Camera.

Figure 419: Sample illustration of an apodized and an unapodized radiation curve

²⁰³⁹⁾ Typical sources observed by a spaceborne or airborne FTS are extended such that (due to FOV) the rays through the interferometer are not collimated, leading to side lobes.

²⁰⁴⁰⁾ Courtesy of K. C. Chance of the Harvard-Smithsonian Astrophysical Observatory, Cambridge MA

Astigmatism. Refers to an aberration in which the light in one plane (for instance the plane of the paper) focuses at a different location from light in the orthogonal plane.

Atmosphere. The envelope of gases surrounding the Earth and bound to it by the Earth's gravitational attraction. Studies of the chemical and radiative properties, dynamic motions, and physical processes of the Earth-atmosphere system constitute the field of meteorology.

Figure 420: Atmospheric transmittance and radiance for UV to TIR regions

Atmospheric absorption. A process whereby some or all of the energy of electromagnetic radiation is transferred to the constituents of the atmosphere. Absorption by atmospheric gases is dominated by that of water vapor (H_2O), carbon dioxide (CO_2), and ozone (O_3) with smaller contributions from methane (CH_4), carbon monoxide (CO), and other trace gases. Water vapor is rather variable across the Earth's surface (location) as well as throughout the atmosphere (altitude). CO_2 and CH_4 are essentially uniformly mixed in the atmosphere, hence predictable in their effects (see also **Absorption bands**). - The sum effect of absorption results in atmospheric opaqueness in many spectral regions as illustrated in Figure 420. Hence, observational techniques must be tailored to utilize those atmospheric windows through which the surface can be viewed.²⁰⁴¹⁾

Atmospheric attenuation. A process whereby some or all of the energy of electromagnetic radiation is absorbed and/or scattered when passing through the atmosphere. The amount of radiant energy that the atmosphere either removes or adds to that emitted or reflected from the Earth's surface depends on:

- The constituents of the atmosphere
- The path length of radiation (a function of geometry of the source, surface, and sensor)
- The reflectance of the surface surrounding scene or target area

Atmospheric boundary layer (also referred to as **Planetary boundary layer, PBL**). This boundary layer includes the bottom part of the atmosphere within which the energy exchange processes (between the Earth's surface and the atmosphere) occur mainly through vertical transport mechanisms of momentum and heat (production of wind shear turbulence plus convective heat turbulence). The whole PBL is heated by convection. Temperature gradients are strongest near the surface, because there convective 'eddies' are relatively small and inefficient in carrying heat upward. The thickness of the daytime PBL is typically in the order of a kilometer; however, it may be three times as high with strong heating. The PBL may also be limited by a top inversion. On a clear day the whole PBL is turbulent; it increases rapidly in the morning and only very slowly after the time of maximum heating, until it decreases to a minimum during the night (sensitivity to diurnal cycle).

²⁰⁴¹⁾A. F. Goetz, J. B. Wellman, W. L. Barnes, "Optical Remote Sensing of the Earth," Proceedings of the IEEE, Vol. 73, No. 6, June 1985, pp. 950-969

Atmospheric correction. A problem with spaceborne surface observations is that a large portion of the received signal (about 80%) originates in the atmosphere. Much of this atmospheric signal is due to Rayleigh (or molecular) scattering, primarily from stratospheric ozone. Corrections attributed to Rayleigh scattering are normally estimated taking into account the geometry of a particular scene as well as the extraterrestrial solar radiation, ozone concentration, and atmospheric pressure. Aerosol scattering, primarily encountered in the marine boundary layer, represents another variable in the signal estimation. Since it is not possible to make direct measurements of these aerosols and their contribution to atmospheric optical properties, the remote-sensing community has relied on an indirect approach. The ocean is assumed as largely “black” in the VNIR portion of the spectrum; any radiance measured in this spectral region is assumed to originate in the atmosphere. The spectral dependence of aerosol scattering is in this manner propagated into the UV and VIS portion of the spectrum. Atmospheric correction algorithms try to account for all the various signal influences in their processing schemes.

Atmospheric refraction. As a signal (electromagnetic radiation) traverses the atmosphere, it experiences propagation delay and bending due to the variable characteristics of the medium through which it is passing. The Earth’s ionosphere introduces significant systematic perturbations on all microwave tracking data. At lower frequencies (150 MHz) daytime ionospheric biases can easily reach several kilometers in range, several meters per second in range rate, and up to two or three milliradians in position. Since most of the effects decrease as the inverse square of frequency, modern radiometric systems track at dual and well separated higher frequencies. As a signal traverses the troposphere it experiences a varying refractive index resulting primarily from spatial variations in atmospheric pressure, temperature and humidity. For radiometric technologies, variations in water vapor content is of chief concern. Optical signals have a much weaker dependence on water vapor. The varying refractive index influences the propagating signal in several ways. For optical signals, the most important effect is the varying group velocity where the pulse speeds up as it travels from the ground station to low pressure regions at higher altitudes. This change is a consequence of Snell’s law of refraction, which predicts the bending and speed of a light ray as it moves through atmospheric layers with differing refractive indices.²⁰⁴²⁾

Atmospheric sciences. Study of the dynamics and structure of the Earth’s atmosphere. There are three main areas:

- **Meteorology.** Primary concern is short-term weather variations in the lower regions of the atmosphere, in particular the troposphere.
- **Climatology.** Primary concern is long-term weather conditions on a global scale.
- **Aeronomy.** Involves research of the atmospheric regions above the lower stratosphere, dealing with such phenomena as ionospheric physics, photochemical processes of the upper atmosphere, aurorae, magnetospheric storms, etc.

Atmospheric window. Spectral bands for which atmospheric attenuation is relatively low (i.e., the bands for which the atmosphere presents minimal interference).

Aurora. Light radiated by ions in the Earth’s upper atmosphere, mainly near the geomagnetic poles, stimulated by bombardment of energetically charged particles of the solar wind. Aurorae appear about two days after a solar flare and reach their peak about two years after a sunspot maximum. The northern aurora is also referred to as the ‘aurora borealis’ while the southern aurora is also called ‘aurora australis.’²⁰⁴³⁾

For many centuries the aurora was referred to as the “northern lights” because it is a polar phenomenon and lies to the north when viewed from Europe. An aurora is a visible man-

2042) Ivan I. Mueller, S. Zerbini, “The Interdisciplinary Role of Space Geodesy,” Lecture Notes in Earth Sciences, Springer Verlag, 1989, p. 187

2043) L. J. Paxton, C.-I. Meng, “Auroral Imaging and Space-Based Optical Remote Sensing,” Johns Hopkins APL Technical Digest, Vol. 20, No 4, 1999, pp. 556-569

ifestation of “space weather” – the highly variable interaction between the sun and the Earth’s magnetosphere, upper atmosphere, and ionosphere. The aurora is visible because of interaction of electrons and protons that are accelerated along the Earth’s magnetic field lines from the magnetosphere (the cavity in the solar wind created by the Earth’s magnetic field) into the Earth’s atmosphere, where they undergo collisions with the background gas.

Auroral oval. Refers to the approximately circular band in the northern or southern hemisphere where aurora are most intense. The near-midnight portion of the oval, where some of the brightest emissions occur, is located about $\pm 65^\circ$ latitude. The mean diameter of the oval is about 4000 km.

Azimuth plane (direction). Observation by an instrument in the along-track direction, i. e. in the direction of the subsatellite track. In general the azimuth is the angle of horizontal deviation, measured clockwise, of a bearing from a standard direction.

Backscatter. Scattering of radiation (or particles) through angles greater than 90° with respect to the original direction of motion.

Band. A specification of a spectral range (say, from 0.4 - 0.5 μm) that is used for radiative measurements. The term ‘channel’ is also in common use with the same meaning as ‘band’. In the ITU convention (see Table 558) for the electromagnetic spectrum, the term ‘band’ refers to a specific frequency range, designated as L-band, S-band, X-band, etc.

Band-to-band registration (also referred to as co-registration). Refers to multispectral image resolution, i.e. how well the same scene is recorded in different spectral bands. Co-registration of spectral bands is measured by the displacement of corresponding pixels in two different bands from their ideal relative location. Two pixels are “corresponding” if their footprints should ideally coincide or if the footprint of one should ideally lie within a specific region of the footprint of the other.

Bandpass. Defined as the frequency band(s) over which a microwave radiometer detects radiation. The equivalent for IR radiometers is the filter response.

Bandpass filter. A filtering device that allows transmission of only a narrow band of frequencies (the other frequencies are blocked out). The spectral width of this filter is characterized by its bandwidth.

Bandwidth. Range of frequencies over which an instrument (or communication link) can be used. It is usually specified in terms of 3 dB points that is, frequencies at which the response has fallen by 3 dB or 30% from the mid-frequency response. Bandwidth may also refer to the width of a spectral feature as measured by a spectroscopic instrument.

Baroclinic waves (disturbances). Any migratory cyclone more or less associated with strong baroclinity of the atmosphere, as evidenced on synoptic charts by temperature gradients in the constant-pressure surfaces, vertical wind shear, and concentration of solenoids in the frontal surface near the ground.

Baseband. Band of frequencies, usually the lowest frequencies in a microwave communications system, where basic information is assembled. This spectrum is generally that provided to the microwave system to be delivered to a distant point in the same format and information content.

Bathymetry. Measurement of water body depths, in particular ocean floor surveys. Generally, bathymetry surveys cannot be directly performed from a satellite. However, there are some areas of satellite applications: - bathymetry surveys in coastal regions (with a SAR instrument) or of shallow bodies of water; the other method is the interpretation and correlation of radar altimeter data (the technique relies on the assumption that the relationship between the gravity field and bathymetry is uniform over relatively small areas ($\approx 200 \times 200$ km)).

Beamsplitter. A mirror, sometimes built into a prism, with the ability of reflecting part of a beam of radiation and transmitting the other part. The ‘splitting’ or diverting is performed on the energy level (frequency-selective surfaces), not on the spectral level (no spectral separation by dispersion). Such a partially diverted beam may be used in color separation cameras, or for the superposition of images in special cameras or in Fourier Transform Spectrometers (FTS), generating an interferogram in combination with an interferometer.

Bias. In electronics the term refers to the application of a voltage between two terminals (electrodes) resulting in current flow (also referred to as ‘forward bias’). The term ‘reverse bias’ refers to the application of a voltage in such a way that no current can flow. The term ‘unbiased’ designates that no voltage is applied.

Beat wave. A composite wave formed by the superposition of two waves having different frequencies (f_1, f_2) and wavenumbers (k_1, k_2). Beat waves form at the sum and difference frequencies ($f_1 \pm f_2$) and wavenumbers ($k_1 \pm k_2$). See also **heterodyne detection**.

Biological productivity. The amount of organic matter, carbon, or energy that is accumulated during a given time period.

Bioluminescence. Refers to the production of light from chemiluminescent reaction in living organisms. Although bioluminescence is very dim, it features prominently in the ecology of the seas, occurring in all oceans; it is produced by a wide variety of marine plankton and nekton.

Biomass. The total dry organic matter or stored energy content of living organisms that is present at a specific time in a defined unit (community, ecosystem, crop, etc.) of the Earth’s surface.

Biomass burning. A recognized major source of trace gases, including CO_2 , NO_2 , CO , CH_4 , and of aerosol particles. It takes on many forms: burning of forested areas for land clearing, extensive burning of grasslands and savannas to sustain grazing lands, burning of harvest debris, use of biomass fuel for heating, forest fires induced by lightning or other hazards. The emissions of biomass burning represent a large perturbation to global atmospheric chemistry, especially in the tropics.

Biosphere. The portion of the Earth and its atmosphere that can support life. The part (reservoir) of the global carbon cycle that includes living organisms (plants, animals,) and life-derived organic matter (litter, detritus). The terrestrial biosphere includes the living biota (plants and animals), litter and soil organic matter on land; the marine biosphere includes the biota and detritus in the oceans.

Bistatic system. The bistatic remote-sensing concept refers to a measurement arrangement in which the transmitter and receiver locations are separated by a distance comparable to that of the target distance. In contrast, monostatic radars employ a transmitter and receiver at the same location (often using the same antenna) and measure the backscattered radiation. The great majority of all radars (SAR instruments, Doppler radars, etc.) in use today are monostatic.

Blackbody (BB). An idealized body that absorbs all the radiation incident upon it and re-radiates it according to the Planck’s law.

Blaze wavelength. The wavelength of the highest efficiency for a ruled diffraction grating, the “blaze” being the controlled shape of the rulings on the grating.

Blooming. Refers to the saturation effect in image detection devices, like CCDs.

Body-pointing. Refers to the pointing technique of an instrument within the field of regard. The instrument is pointed along with its platform (satellite) into the desired direction.

Bolometer. A detector type making use of the change in electrical resistance of certain materials (with small thermal capacity) when their temperature is changed. The resistance of

most conductors varies with temperature, this change in resistance is measured by the bolometer. Bolometers are suitable detectors for the infrared and microwave regions.

Boresight. A technique for aligning sensors or detectors on a target.

Bragg scattering theory. According to this theory the normalized radar cross-section (NRCS) is proportional to the spectral energy density of the Bragg waves, i.e. of those surface waves with wave numbers k_B that satisfy the Bragg resonance condition:

$$k_B = \frac{4\pi \sin \theta}{\lambda_o} \quad \text{where } \lambda_o \text{ denotes the radar wavelength and } \theta \text{ the incidence angle.}$$

BRDF (Bidirectional Reflectance Distribution Function). Specifies the behavior of surface scattering as a function of illumination and view angles at a particular wavelength. BRDF is defined as being the ratio of the reflected radiance to the incident flux per unit area.²⁰⁴⁴⁾

Brightness temperature. A concept referring to the equivalent blackbody temperature for a given frequency (range) according to Planck's law. The term brightness temperature is often employed for data of radio/microwave observations where the radiation is in the Rayleigh-Jeans tail of the thermal distribution. It means that the source emits (at the frequency of interest) the same amount of radiation as a blackbody at the brightness temperature. Intensities are measured in terms of brightness temperature (that is, the temperature a blackbody would have if it emitted an equal intensity of radiation at the same frequency). Examples of brightness temperature applications:

- Measurement and/or computation of the 'top of the atmosphere brightness temperature' or 'troposphere moisture content' from data of particular channels of such sensors as: AVHRR, TOVS, etc.
- The measurement of ocean surface roughness at microwave frequencies (with a radiometer) permits estimates of ocean-surface wind speeds. The method employs the concept of brightness temperature anisotropy which increases with ocean-surface roughness. The SSM/I sensor of the DMSP series uses this principle to map ocean surface wind speeds.
- The Earth's surface brightness temperature can be measured by channel 6 (TIR) of the Landsat TM sensor, or by the MWR instrument of ERS missions.

Cadastre. An official (governmental) land registry defining the ownership of a parcel along with ancillary information (description of parcel location, boundaries, shape and size, inventory of actual features and structures, value for taxation, etc.). Positional accuracies are an important issue of such registries. - Cadastral mapping takes many forms around the world, based on current and historic land registry, land reform policies, and available funding levels. In Europe the cadastre is linked to the legal land registration system within the context of a national geodetic reference system. In the US and Canada there is no central land registry (land registry information is maintained at multiple levels). In all parts of the world, however, land ownership information plays a key role in defining local and national economies and in managing natural resources and handling environmental issues.

Calibration. Characterization of a sensor (radiometer, spectrometer, etc., see also chapter O.2) in the spatial, spectral, temporal and polarization responsive domains. The term 'calibration' is being used so often by different people that it has several additional meanings, such as:

1. The activities involved in adjusting an instrument to be intrinsically accurate, either before or after launch (i.e. 'instrument calibration').
2. The process of collecting instrument characterization information (scale, offset, nonlinearity, operational and environmental effects), using either laboratory standards, field standards, or modeling, which is used to interpret instrument measurements (i.e. 'data calibration').

²⁰⁴⁴⁾ See ERIM BRDF tutorial at URL: <http://www.erim.org/on-line-docs/GUIDE/guide.frm.html>

Candela (cd). A unit of luminous intensity equal to one sixtieth of the luminous intensity of one square centimeter (1 cm^2) of a blackbody surface at the solidification point of platinum.

Carbon cycle. A sequence of conversion processes from matter into energy. All reservoirs and fluxes of carbon; usually thought of as a series of the four main reservoirs of carbon interconnected by pathways of exchange. The four reservoirs - regions of the Earth in which carbon behaves in a systematic manner - are the atmosphere, terrestrial biosphere (usually includes freshwater systems), oceans, and sediments (includes fossil fuels). Each of these global reservoirs may be subdivided into smaller pools ranging in size from individual communities or ecosystems to the total of all living organisms (biota). Carbon is exchanged from reservoir to reservoir by various chemical, physical, geological, and biological processes.

Carrier. An electromagnetic wave in a communication path (basic center frequency of a signal) which does not carry information but is generally modulated by another wave (sub-carrier) which contains the information.

Carrier phase. Refers to the fraction of a cycle, often expressed in degrees (360° to a cycle). Carrier phase can also mean 'the number of complete cycles plus a fractional cycle.' In GPS terminology, carrier phase refers to a receiver capable of locking onto a GPS signal and keeping track of the whole number of cycles of the carrier; this method creates a cumulative phase of the signal which is also known as 'integrated Doppler.' Much higher ranging accuracies can be obtained with carrier phase than without carrier phase tracking.

Catadioptric telescope (see also Schmidt telescope under Telescopes). Refers to a telescope design with a large FOV to eliminate image distortions (a catadioptric telescope design incorporates the best features of both the refractor and reflector, i.e., it has both reflective and refractive optics. The Schmidt telescope has a spherically shaped primary mirror. Since parallel light rays, that are reflected by the centre of a spherical mirror, are focused farther away than those reflected from the outer regions, Schmidt introduced a thin lens (called the correcting plate) at the radius of curvature of the primary mirror. Since this correcting plate is very thin, it introduces little chromatic aberration. The resulting focal plane has a field of view several degrees in diameter.

Charge-Coupled Device (CCD). A CCD is a photosensitive solid-state imaging sensor (detector) implemented with large-scale integration technology (normally based on MOS technology). A MOS capacitor is a three-layer sandwich formed by positioning a metal electrode, insulated by a layer of silicon dioxide, onto a silicon substrate. Incident radiation into the system is sampled by photodetectors, converted into an electronic charge and trapped in the depletion region of the substrate. The isolated charge packets are transported by manipulating potential wells (place of minimum potential) within the substrate. The ability to store a charge is fundamental to the operation of CCDs. It corresponds to a memory device storing analog quantities. - CCD readout techniques employ clock-controlled circuits which transfer these charges to a matching grid of elements and shift all charges by one row at a time. - The CCD technology was first demonstrated in 1969 at the Bell Laboratories. See also chapter O.4.2.1.

Charge Injection Device (CID). A photo-sensitive image sensor (detector) implemented in large-scale integration technology. Charge packets are typically measured by injecting them into a substrate or by shifting charge packets under an electrode to induce a voltage on the capacitance formed by the electrode and the substrate. A CID can be randomly addressed. The pixel structure is contiguous with maximum surface to capture incident light which is useful for sub-pixel measurement (O.4.2.2).

Chemiluminescence. Emission of light as a consequence of a chemical reaction, the result of thermal generation of electronic excited states. Chemiluminescence can be seen when occurring in the dark. - A number of chemical reactions generate products not in their lowest energy states, but rather in upper levels. That is, some of the exothermicity of the reac-

tion is channeled internally into electronic, vibrational, or rotational energy of one or more of the products, rather than being released as heat. The excited product molecules may emit this energy as light, known as chemiluminescence because of the chemical source of energy. - The term of **surface chemiluminescence** belongs also into this context. In this scheme air is passed over a chemiluminescent plate causing the gas (eg., ozone) molecules to diffuse into the coating of the plate and in turn generating a chemiluminescent reaction. The reaction sequence causes the emittance of light (radiation) whose intensity is proportional to the ozone concentration.

Chirp principle. A microwave modulation technique in which the frequency of the transmitted microwave pulse is not constant but linearly changed in a positive sense (up-chirp) or in a negative sense (down-chirp). A frequency-modulated chirp is a signal with a (linear) increase in frequency or pitch.

Chlorofluorocarbons (CFCs). A family of inert, nontoxic, and easily liquefied chemicals used in refrigeration, air conditioning, packaging, and insulation, or as solvents or aerosol propellants. Because they are not destroyed in the lower atmosphere, they drift into the upper atmosphere, where - given suitable conditions - their chlorine components destroy ozone.

Chlorophyll. A green pigment essential for photosynthesis found in plants. It usually occurs in discrete bodies (chloroplasts) in plant cells, and is what makes green plants green. In remote sensing of aquatic ecosystems, the reflected radiance is related to the concentration of chlorophyll and other associated pigments. Since chlorophyll is green, the color of reflected light changes from blue to green as the concentration of chlorophyll increases. The concentration of chlorophyll is used to estimate the abundance of phytoplankton in ocean waters, and hence the abundance of ocean biota.²⁰⁴⁵⁾

Climate. The statistical collection and representation of the weather conditions for a specified area during a specified time interval, usually decades, together with a description of the state of the external system or boundary conditions. The properties that characterize the climate are thermal (temperatures of the surface air, water, land, and ice), kinetic (wind and ocean currents, together with associated vertical motions and the motions of air masses, humidity, cloudiness and cloud water content, groundwater, lake winds, and water content of snow on land and sea ice), and static (pressure and density of the atmosphere and ocean, composition of the dry air, salinity of the oceans, and the geometric boundaries and physical constants of the system). These properties are interconnected by various physical processes such as precipitation, evaporation, infrared radiation, convection, advection, and turbulence.

Climate change. The long-term fluctuations in temperature, precipitation, wind, and all other aspects of the Earth's climate. External processes, such as solar-irradiance variations, variations of the Earth's orbital parameters (eccentricity, precession, and inclination), lithosphere motions, and volcanic activity, are factors in climatic variation. Internal variations of the climate, e.g., changes in the abundance of greenhouse gases, may also produce fluctuations of sufficient magnitude and variability to explain observed climate change through the feedback processes interrelating the components of the climate system.

Correction/Calibration methods for sensor data (see chapters O.2 and O.2.2)

Cloud. A visible mass of condensed water vapor particles or ice suspended above the Earth's surface. Clouds may be classified by their visual appearance, height, or form.

Cloud albedo. Reflectivity that varies from less than 10 to more than 90 percent of the insolation and depends on drop sizes, liquid water content, water vapor content, thickness of the cloud, and the sun's zenith angle. The smaller the drops and the greater the liquid water content, the greater the cloud albedo, if all other factors are the same.

Cloud feedback. The coupling between cloudiness and surface air temperature in which a change in surface temperature could lead to a change in clouds, which could then amplify or diminish the initial temperature perturbation. For example, an increase in surface temperature could increase evaporation; this in turn might increase the extent of cloud cover. Increased cloud cover would reduce the solar radiation reaching the Earth's surface, thereby lowering the surface temperature. This is an example of negative feedback and does not include the effects of longwave radiation or advection in the oceans and the atmosphere, which must also be considered in the overall relationships within the climate system.

Cloud microphysics. Study of cloud and precipitation particles (individual or populations) and their interactions with the environment. Of key importance are mass exchange processes such as nucleation, growth, and fallout leading to the broad characteristics of clouds and precipitation.

Code Division Multiple Access (CDMA). Refers to an access scheme which employs spread-spectrum modulations and orthogonal codes to share a communication link among its users. In the CDMA scheme, all users transmit simultaneously and at the same frequency, with each being assigned a unique pseudorandom noise code. Usually, the data is first phase-modulated by a carrier and then the carrier is bi-phase-modulated with a pseudorandom noise (PNR) code. This concept generates a wide bandwidth, low-energy spread spectrum signal.

Coherence. A fixed relationship between the phases of waves in a beam of radiation of a single frequency. Two beams of light are coherent when the phase difference between their waves is constant; they are **noncoherent** if there is a random phase relationship. In active measurement systems like radars, coherence refers to the availability of phase and amplitude measurements of the radar cross section of the recovered signals. Coherence provides the ability to maximize SNR and to measure other features like target radial velocity.

Coma. An off-axis aberration whereby the outer periphery of a lens system has a higher (or lower) magnification than the central portion of the lens. The image typically is comet shaped.

Contrast. The ratio of a certain quantity of radiation between the brightest and darkest part of an image or between two arbitrary places of an image, where the contrast is to be determined.

Convection (meteorology). Vertical wind motions and associated horizontal circulations associated with buoyancy.

Convolution. Mathematical process, appearing in linear or circular form, that models the input-output filtering process.

Convolution filter. A linear filter type as used in digital image processing of which the window operation has a mathematically linear character (weighted summation). Examples are low-pass filter, high-pass filter, gradient filters, Laplacian filters, etc.

Corona. Refers to the outer atmosphere of the sun whose structure is controlled by solar magnetic fields. The corona has temperatures between one and three million degrees. It merges into the solar wind at its upper boundary about 1-2 solar radii above the visible surface of the photosphere.

Crossover (difference). A crossover is defined as the intersection points of the satellite ground track with itself (due to Earth rotation). At this location, the two crossing passes (one ascending and one descending) provide independent subsatellite ground track measurements at the same location but at different times. In altimetry crossover differences contain information about uncertainties in the satellite ephemeris and therefore enable correction of radial orbit error.

Crossover point. Refers to radar measurements concerning the curves showing the dependency of the radar backscatter behavior on the incidence angle of the radar transmission signals onto surfaces of differing roughness. The crossover point is the incidence angle where the diffuse region changes into a specular region on the curves (or: the incidence angle where the effect of soil roughness vanishes and the radar backscatter value is determined by the presence of soil moisture).

Cryosphere (from the Greek word ‘Kryos’, icy cold). The Earth’s cryosphere consists of four main elements: sea ice, seasonal snow on land, land ice (including glaciers, ice sheets, and ice shelves), and permafrost. The time scales on which these elements impact human activity range from daily to seasonal for sea ice and snow, while ice shelves respond in the range of 10-100 years, ice sheets (Antarctic and Greenland) have periods in the order of 1000-10,000 years. Land ice occupies about 11% of the continental surfaces. Sea ice and ice shelves spread around 7% of the total oceanic area.

Decibel (dB) - named in honor of Alexander Graham Bell. A measurement of signal strength, properly applied to a ratio of powers. For the signal power P compared by a ratio to a reference power P_{ref} , the definition is: $P_{\text{db}} = 10\log_{10} (P/P_{\text{ref}})$. As an example, the power ratio of 1/2 corresponds to “3 dB”, derived from: $\log_{10} (0.5) = -0.3010$.

Deforestation. The removal of forest stands by cutting and burning to provide land for agricultural purposes, residential or industrial building sites, roads, etc., or by harvesting the trees for building materials or fuel. Oxidation of organic matter releases CO_2 to the atmosphere, with possible regional and global impacts.

Densimeter. A photometer designed for measuring the optical density of a material, generally a photographic image by visual or photoelectric effects.

Depolarization ratio. The ratio of intensities of light scattered perpendicular and parallel to the E-vector of the incident radiation.

Detector. A device that detects and linearly transduces radiative power into an electrical signal. Direct detectors may be categorized as photon detectors (an electrical signal is produced by free charges on the detector surface from the incident photons) or thermal detectors (an electrical signal is produced due to the temperature change). Detectors may also be classified according to their arrangement: single line detectors, array detectors. Thermal detectors usually require cooling (active or passive). Infrared radiation is ‘thermal’ by nature, hence the detector is affected by the medium that is measured. As a rule of thumb, the longer the IR wavelength that is to be measured, the colder the detector must be. In the VNIR region the detector element temperatures rarely need to be below 200 K. From 1-17 μm , temperatures are typically in the range 50-80 K. The longer wavelengths of the microwave region usually demand temperatures below 20 K. The detectivity of a cooled detector is much higher than one operating at room temperature. The noise contribution from background radiation at 300 K is several orders of magnitude higher than that of the 4 K surroundings of the detector (see O.4).

Detector types for spectral ranges.²⁰⁴⁶⁾ From the UV to VNIR (0.3-1 μm), silicon photodiodes and photoemissive devices such as photomultiplier tube (PMT) are normally used.²⁰⁴⁷⁾ Between 1-12 μm , two technologies dominate: InSb (indium antimonide) from 1-5.5 μm , and HgCdTe (mercury cadmium telluride, also referred to as MCT). Both, InSb and MCT operate in a photovoltaic mode. For the spectral range of 12-35 μm , photoconductors or MCT are being used. Beyond 30 μm , the only available technology in use is the semiconductor bolometer.

Dewar [after Sir James Dewar (1854-1928) a Scottish chemist and physicist]. The term denotes a vessel to store hot or cold substances over long periods of time. It is a container with

²⁰⁴⁶⁾ R. Beer, “Remote Sensing by Fourier Transform Spectrometry,” John Wiley & Sons, Inc., New York, 1992, Chapter 4.1.2

²⁰⁴⁷⁾ Note: Silicon is transparent in the spectral ranges of 1.4 - 7 μm and from 25 μm to well beyond 100 μm

at least two walls and a space between the walls evacuated so as to prevent the transfer of heat. There are various techniques in use for minimizing the heat transfer in spaceflight for liquid helium, like: multilayer insulation, multiple reflective surfaces in vacuum, vapor-cooled shields, passive orbital disconnect struts, etc.

Dielectric. An insulating material or a very poor conductor of electric current. When dielectrics are placed into an electric field, practically no current flows in them because, unlike metals, they have no loosely bound, or free, electrons that may drift through the material. Instead, electric polarization occurs, reducing the electric field within the dielectric. A vacuum is the only perfect dielectric. - A dielectric gas is a nonconductor of electricity to high applied electrical stress; a gas with a high breakdown voltage.

Dielectric constant. A property of an insulating material (a dielectric) equal to the ratio of the capacitance of the capacitor filled with the given material to the capacitance of an identical capacitor in a vacuum without the dielectric material ($\kappa = C/C_0$).

Diffraction. A process by which the direction of radiation is changed so that it spreads into the geometric shadow region of an opaque or refractive object that lies in a radiation field. Diffraction is an optical “edge effect,” (differing only in degree from scattering) caused by particles with diameters of the same order of magnitude as, or larger than, the wavelength of radiation; scattering is caused by smaller objects. Diffraction causes a modification which light undergoes in passing by the edges of opaque bodies or through narrow slits or in being reflected from ruled surfaces, and in which the rays appear to be deflected producing fringes of parallel light and dark or colored bands.

Diffraction grating. A system of close equidistant and parallel lines or bars (also grooves) on a polished surface used for producing spectra by diffraction.

Diffraction-limited system. An optical system in which aberrations are negligible with respect to diffraction effects.

Diffuse radiation. Radiation propagating in many different directions through a given small volume of space (converse is ‘specular radiation’). The ideal form of diffuse radiation is isotropic radiation (uniform radiation in all directions).

Digital count. Refers to the total number of pixels occurring in an image for each possible data value.

Digital Earth. A vision/initiative of Vice President Al Gore, presented in a speech at the California Science Center in Los Angeles, on Jan. 31, 1998.²⁰⁴⁸⁾ The proposed concept model of “Digital Earth” refers to a multi-resolution, 3-D representation of Earth, into which geo-referenced data can be embedded. A “Digital Earth” could, for instance, provide a mechanism for users to navigate and search for geospatial information, etc. - Obviously, such an objective is so vast, that no one organization in government, industry or academia could undertake such a project. A vast standards infrastructure is needed to make it happen! The benefits of such a seamless system are apparent to the entire Earth Observation community.

Digital filter. A digital device (or a mathematical procedure) capable of altering the magnitude, frequency or phase response of a digitally encoded input signal (it may also selectively transmit digital signals).

Digital Terrain Model (DTM). Refers to a land surface represented in digital form by an elevation grid or tables of three-dimensional coordinates to form surface contours. The DTM definition is identical to that of a **DEM** (Digital Elevation Model). A DTM or DEM forms the basic building block for combining other data for analysis. For instance, digitized

²⁰⁴⁸⁾ G. W. Fuller, “A Vision for a Global Geospatial Information Network (GGIN) Creating, Maintaining and Using Globally Distributed Geographic Data, Information, Knowledge and Services,” ASPRS, May 1999, pp. 524-538

spatial data (images) can be draped onto a DEM and analyzed using a GIS. The quality of such a DEM depends on the spatial resolution (in particular the topographic accuracy) of image data available. Interferometric SAR data and/or altimeter data are currently the best sources for DEM generation.

Diode. A semiconductor diode consists of a crystal (two terminals), part of which is n-type (negative charge) and part p-type (positive charge). The boundary between the two parts is called a p-n junction. There is a population of holes on the p-type side of the junction and a population of electrons on the n-type side.²⁰⁴⁹⁾ The p-n junction of the diode conducts current with one polarity of applied voltage but not with the other polarity. Rectification (current flow only in one direction) is a very important characteristic of the p-n junction. Another characteristic of the p-n junction is its direct conversion capability of radiant energy into electrical energy (optoelectronic effect). An incident photon, striking a p-n junction, has the same effect as a hole (positive charge); it is absorbed thereby creating electron-hole pairs. The resulting current can be detected (see **photodiode**).

Dipole. An electric system composed of two equal charges of opposite sign, separated by a finite distance; e.g. the nucleus and orbital electron of a hydrogen atom. An ordinary bar magnet is a magnetic dipole.

Dipole antenna. A type of array consisting of a system of dipoles. A dipole antenna differs from a dish antenna in that it consists of many separate antennas that collect energy by feeding all their weak individual signals into one common receiving set.

Discrete Fourier Transform. A mathematical method of transforming a time series into a set of harmonics in the frequency domain and vice versa.

Dispersion of spectra. The following methods are used to separate radiation (light) into its component spectra (colors):

- Refraction. Historically, prisms were first used to break up or disperse light into its component colors. The path of a light ray bends (refracts) when it passes through the prism, i.e. from one transparent medium to another (from air to glass).
- Diffraction. Diffraction gratings are composed of closely spaced transmitting slits on a flat surface or alternate reflecting and non-reflecting grooves. - In any grating spectrometer, if a slit aperture is moved along the surface where the spectral lines are focussed, the lines are transmitted successively through the aperture.
- Interference. An interferometer divides a wave front by semitransparent surfaces. This allows the beams to travel different paths. The beams are then recombined generating interference patterns.
- AOTF (Acousto-Optic Tunable Filter). The AOTF principle is based on acoustic diffractions of light in an anisotropic medium. An AOTF device consists of a piezoelectric transducer bonded to a birefringent crystal. When the transducer is excited by an applied RF signal, acoustic waves are generated in the medium. The propagating acoustic wave produces a periodic modulation of the index of refraction. This provides a moving phase grating that, under proper conditions, will diffract portions of an incident beam. - In operation, acousto-optic tunable filters resemble interference filters and can replace a filter wheel, grating, or prism in many applications (see O.4.5).

Diurnal cycle (Lat. diurnalis). A 24-hour (daily) cycle associated with solar heating during the day and radiative cooling during the night. A periodic cycle affecting nearly all meteorological variables.

Doppler effect (after Christian J. Doppler, Austrian physicist, 1803-1853). The alteration in frequency of a wave of radiation caused by relative motion between the observer and the

²⁰⁴⁹⁾ Note: The term "hole" refers to a fictitious particle which carries a positive charge and moves, under the influence of an applied electric field (bias), in a direction opposite to that of an electron. The motion of electrons and holes in semiconductors is governed by the theory of quantum mechanics.

source of radiation.- The acoustic Doppler effect applies to the propagation of source waves; the optical Doppler effect depends on the relative velocity of the light source and the observer; the thermal Doppler effect causes a widening of the spectral lines.

Doppler radar. A radar system which differentiates between fixed and moving targets by detecting the change in frequency of the reflected wave caused by the Doppler effect. The system can also measure target velocity with high accuracy.

Doppler shift. Displacement of spectral lines (or difference in frequency) in the radiation received from a source due to its relative motion in the line of sight. Sources approaching (–) the observer are shifted toward the blue; those receding (+), toward the red. Used to determine radial distance.

Delay Doppler radar altimeter. An evolving technique which exploits signal processing algorithms borrowed from SAR processing schemes. When applied to an ocean-observing altimeter, real-time on-board processing achieves an integration level of the received signal that is about a magnitude higher (tenfold) than that achieved in conventional radar altimeters. This in turn translates into a tenfold reduction in required radiative power of the transmitter (or into a smaller radar antenna or a combination of both effects), improving instrument performance considerably.²⁰⁵⁰⁾

Downlink. Refers to the communication direction from a satellite (or aircraft) to a ground station. The prime information in this link is usually referred to as ‘telemetry.’ There may be different logical links in a downlink for instrument data and for the return (verification) of the telecommand data. In very elaborate communication systems with intermediate geostationary transmission satellites, the term ‘downlink’ is usually replaced by ‘return link’ to avoid confusion.

Dryline. A meteorological term referring to a boundary which separates moist and dry air masses. The dryline is an important factor in the frequency of severe weather in the Great Plains of the continental USA. It typically lies north-south across the central and southern high Plains states during the spring and early summer, separating moist air from the Gulf of Mexico and dry desert air from the southwestern states.

Dual spin. Refers to a spacecraft design whereby the main body of the satellite is spun to provide attitude stabilization. In this concept the antenna assembly is despun by means of a motor and bearing system in order to continually direct the antenna earthward. The dual-spin configuration thus serves to create a spin-stabilized satellite.

Duty cycle. Fraction of orbital period in which a sensor (or a sensor mode) is actually operational, determined by the overall power limitations of the payload. The concept of a duty cycle applies in particular to sensors with large power requirements such as active sensors, in particular SAR instruments.

Dwell time. The short period of time during which a detector collects radiation from a target area or volume. - A very short dwell time usually results in a low (i.e. poor) signal-to-noise (SNR) ratio with all its problems of proper signal recognition and discrimination. A small dwell time also implies ‘fast’ detectors and electronics.

Dynamic range. The dynamic range of a sensor system is determined by the ratio of the maximum observable energy (Q_{\max}) and the minimum still-useful energy (noise level Q_{\min}); it is defined in decibels (dB) as $10 \log (Q_{\max}/Q_{\min})$. All radiant energy $< Q_{\min}$ vanishes into noise, while the energy above Q_{\max} disappears into the saturation of the detector (see also **Signal-to-Noise-Ratio**).

Electromagnetic spectrum (EMS). The total range of wavelengths or frequencies of electromagnetic radiation, extending from the longest radio waves to the shortest known gam-

²⁰⁵⁰⁾G. H. Fountain, Robert E. Gold, et al., “A Technology Path to Distributed Remote Sensing,” Small Satellites for Earth Observation, 2nd International Symposium of IAA, Berlin, April 12-16, 1999, pp.189-193

ma rays. - EMS energy for passive remote sensing, as derived from the sun, is either **reflected sunlight** or **re-emitted thermal radiation**. The transfer mode of reflected radiation is dominant in the window associated with VNIR and SWIR, while the preferred mode of long-wave transfer (thermal radiation) is in the TIR window (see also Figure 422 on page 1365).

- In the VNIR and SWIR (0.4 - 3 μm) wavelength regions, the predominant mode of energy detection is that of reflected sunlight
- In the MWIR region (3-6 μm) the detected energy is a mixture of solar reflected and thermally emitted radiation
- In the TIR window (6-13 μm), practically all energy received (detected) is attributed to thermal emission.

Note: Although the sun, with a brightness temperature of about 6000 K, is much hotter than the Earth's surface at about 290 K, the dominance of the Earth's thermal energy at longer wavelengths is a result of geometry (the sun subtends only about 0.5° at the Earth - the sun's disk angle is actually about $32'$), and that the solar energy is subsequently scattered by the Earth's surface into 2π space.

Electron tube. The term is the generic name for a class of devices that includes: vacuum tubes, phototubes, gas-filled tubes, cathode-ray tubes, and photoelectric tubes. An electron tube typically consists of two or more electrodes enclosed in a glass or metal-ceramic envelope, which is wholly or partially evacuated. Its operation depends on the generation and transfer of electrons through the vacuum from one electrode to the other. Electron tubes have properties that cannot be surpassed by solid-state devices for particular applications. Their thermal ruggedness, operating efficiency, and high-power capabilities are features well beyond those of solid-state devices. As components of electronic systems, electron tubes are used as amplifiers, rectifiers, signal generators, and switches (in particular in the microwave region).

Electron volt (eV). A unit of energy used in atomic and nuclear physics; the kinetic energy acquired by one electron in passing through a potential difference of 1 volt in vacuum. $1 \text{ eV} = 1.602 \times 10^{-12} \text{ erg}$ (or $= 1.602 \times 10^{-19} \text{ Joule}$)²⁰⁵¹. An electron with an energy of 1 eV has a velocity of about 580 km/s. The wavelength associated with 1 eV is 12,398 Å. The eV is a convenient energy unit when dealing with the motions of electrons and ions in electric fields; the unit is also the one used to describe the energy of X-rays and gamma-rays. Nuclei in cosmic rays typically have energies ranging from about 1 MeV (or less) to many GeV per nucleon.

Electrooptics. An imaging technique which uses optics, such as the collimation of light beams and the magnification of images by lenses and mirrors, rectification by prisms, and diffraction by gratings (usage: generally in the VNIR spectrum). - The newer devices of electrooptics make use of more electronic components such as the generation of light by lasers and solid state devices, featuring electronic scanning of the images and data presentation on electrically activated displays. To an increasing extent, computers are employing electrooptical techniques for their own operation and display. See also chapter O.10.2.

Emissivity (ϵ). The ratio of radiative energy (power) emitted by a body to that emitted by a blackbody at the same temperature. For all cases: $\epsilon(\lambda) \leq 1$.

Energetic particles. These are electrons, ions, or atoms that have much higher energies than expected for the temperature of the gas in which they are transported (the solar wind is such a transport medium).

Energetic Neutral Atom (ENA). ENAs are created in the inner magnetosphere when charge exchange collisions occur between energetic ions and the cold neutral population of

²⁰⁵¹) The energy unit Joule is named in honor of James Prescott Joule (1818-1889), a British physicist who established that the various forms of energy - mechanical, electrical, and heat - are basically the same and can be changed into one another. Thus he formed the basis of the law of conservation of energy, the first law of thermodynamics.

the Earth's extended atmosphere. ENAs travel in approximately straight-line trajectories away from the charge-exchange sites (because gravitational forces are negligible for typical energies of interest and they are unaffected by the Earth's electric and magnetic fields) and carry with them valuable information about the pitch angle and energy distributions of the ion population from which they were emitted. As of the 1990s the ENA emissions can actually be sensed remotely by appropriate imagers. Several NASA missions have such instrumentation: POLAR, IMAGE, and TWINS.

ENSO (El Niño Southern Oscillation). ENSO is regarded as a large-scale interannual climate variability (anomaly) especially with regard to precipitation regimes and sea surface temperature (SST) changes in the tropical Pacific Ocean. The warming effect of ENSO can dramatically alter precipitation patterns over much of the Pacific basin. Its recurrence every three to seven years provides a clear signal of climate variability on a global scale. Its land surface manifestations are illustrated by heavy torrential rains on the west coast of South America and droughts in Sahelian Africa, southern Africa, Australia, and eastern Brazil. The forecasting of ENSO events can greatly benefit the peoples and economies of the impacted areas.

Scientists believe **El Niño** conditions between Australia and South America are sparked when the steady westward trade winds weaken and even reverse direction. This wind shift moves a large mass of warm water, normally situated near Australia, eastward along the equator, pushing it toward the coast of South America. The transportation of such a large body of warm water affects evaporation, causing rain clouds to form that, in turn, alter typical atmospheric jet stream patterns around the world.

Background: In the 16 century, the El Niño climatic phenomenon was first observed by Peruvian fisherman as a warm current running along the coast of Peru. Since this recurrent event happened around the Christmas season, they christened the warm current as El Niño (meaning Christmas in Spanish). This virtually periodic phenomenon appears at two- to seven-year intervals, it has economic and environmental consequences that are sometimes catastrophic. The entire climate is thoroughly disturbed. Due to the warming of the Peruvian waters, normally the most productive in the world, the ocean is depleted of nutrients, causing rarefaction of the phytoplankton. A consequence of the disappearance of the aquatic life is a massive destruction of oceanic bird life.

Eötvös experiment. An experiment performed in 1909 by the Hungarian physicist Roland Eötvös (1848-1919) to establish that the gravitational acceleration of a body does not depend on its composition - i.e. that inertial mass and gravitational mass are exactly equal (later a major principle of Albert Einstein's general theory of relativity). In Einstein's version, the principle asserts that in free-fall the effect of gravity is totally abolished in all possible experiments and general relativity reduces to special relativity, as in the inertial state. Today, the linear gradient of gravity is defined in units of Eötvös, where $1 \text{ Eötvös} = 10^{-9} \text{ s}^{-2}$; i.e. difference of 10^{-9} ms^{-2} acceleration per meter. The vertical gradient of gravity at the Earth's surface is about 3100 Eötvös.

Ephemeris. A tabular statement of the spatial coordinates of a celestial body or a spacecraft as a function of time.

Equatorial electrojet current. Current created around the Earth's equator by counter-rotating electrons and protons. This electrojet current causes ionization, and subsequently UV radiation, similar to auroral phenomenon usually associated with the Earth's F-Layer.

Equinox. Either of two points on the celestial sphere where the celestial equator intersects the ecliptic. At these two instances the sun is exactly above the equator and day and night are of equal length (see also **vernal equinox**).

Equivalence Principle (EP). A fundamental law of physics that states that gravitational and inertial forces are of a similar nature and often indistinguishable. EP in fact states that two

fundamentally different quantities, inertia and passive gravitational mass, always be exactly proportional to one another. This is usually interpreted as implying that the two quantities are equivalent measures for a single physical property, the quantity of **mass** of an object; hence, the term Equivalence Principle. A direct consequence of this Equivalence Principle is the 'universality of free fall' such that all objects fall with exactly the same acceleration in the same gravity field. EP turned out to be a major principle of Albert Einstein's general theory of relativity. The Strong or Einstein Equivalence Principle states that all of the laws of physics (not just the laws of gravity) are the same in all small regions of space, regardless of their relative motion or acceleration.

In the Newtonian form, EP implies that, within a windowless laboratory freely falling in a uniform gravitational field, experimenters would be unaware that the laboratory is in a state of nonuniform motion. All dynamical experiments yield the same results as obtained in an inertial state of uniform motion unaffected by gravity. Experiments with ordinary pendulums test the principle of equivalence to no better than about one part in 10^5 . The Hungarian physicist Roland Eötvös suggested (1909) that the attraction of the sun upon test masses could be compared with the inertial forces of the Earth's orbital motion about the sun. In the 1960s a series of careful observations (employing up-to-date methods of servo control and observation) were conducted by the American physicist Robert H. Dicke and his colleagues. They found that the weak equivalence principle held to about one part in 10^{11} for the attraction of the sun on gold and aluminum. A later experiment, with very different experimental arrangements, by the Russian researcher Vladimir Braginski, gave a limit of about one part in 10^{12} for platinum and aluminum. - A future NASA/ESA mission, called STEP (Satellite Test of the Equivalence Principle) or MiniSTEP, with a probable launch in 2005, has the objective to test EP to a precision of 1 part in 10^{18} .

Equivalent (or effective) Isotropic Radiated Power (EIRP). A measure of power radiated by an antenna in the direction of a receiver, expressed as the equivalent power that would have to be radiated uniformly in all directions.

Erlang. A measure of communication (telephone) traffic load expressed in units of hundred call seconds per hour (CCS). One Erlang is defined as the traffic load sufficient to keep one trunk busy on the average and is equivalent to 36 CCS. The measure is also used for DCS (Data Collection Satellite) access capabilities.

Figure 421: Definition of étendue

Étendue. The term (French for 'extent') describes a very fundamental property of an optical system, namely $A \Omega$, the product of the area A of a light beam and the solid angle Ω contained within a beam. The importance of étendue lies in the fact that it is one of the major factors in determining the SNR (Signal-to-Noise Ratio) of a system; it is in fact a design pa-

rameter which can be maximized by the proper choice of configuration. Étendue has the units: cm² sr. It is a property that is at best conserved through an optical train, i.e., the system étendue will be that of lowest value in any part of the system. ²⁰⁵²⁾

Excimer. In photochemistry a molecular aggregate formed by loose association of an excited state and a ground state of the same compound, where such association does not occur between two ground state molecules.

Extinction. The superimposed effect of two radiation effects that cancel each other, e.g. absorption and scattering.

F-Layer. One of the three regions (D, E, and F) of the Earth’s ionosphere. The F-Layer constitutes the highest region, ranging from about 160-500 km. Within the F-Layer precipitating electrons from the magnetosphere cause ionization critical to long-wave radio communication. This ionization is typically caused by electrons with a kinetic electron energy < 1 keV. Ionization within the F-Layer may be characterized by sensors designed to measure UV radiation. F-Layer electron density is usually two to four orders of magnitude higher than that of the D- and E-Layers.

False color. A color imaging process which produces an image that does not correspond to the true color of the scene (as seen by the eye).

Fast Fourier Transform (FFT). An algorithm that is often used to implement Discrete Fourier Transforms.

Feedback mechanisms. A sequence of interactions in which the final interaction influences the original one. Negative feedback: An interaction that reduces or dampens the response of the system in which it is incorporated. Positive feedback: An interaction that increases or amplifies the response of the system in which it is incorporated.

Layer	Altitude	Major Components	Production Cause
D	70 - 90 km	NO ⁺ , O ₂ ⁺	Lyman Alpha, X-rays
E	95 - 160 km	O ₂ ⁺ , NO ⁺	Lyman Beta, Soft X-rays, UV continuum
F	160 - 500 km	O ⁺ , N ⁺ , NO ⁺	HE II, UV continuum

Table 560: Ionospheric layers and physical causes of ionization

Field of Regard (FOR). The pointing capability of a sensor with regard to the cross-track direction and/or along-track direction may provide additional coverage to the sensor in its orbit. This can be an advantage for monitoring (or imaging) events that are outside the swath width [or FOV(Field of View)] of a regularly nadir-pointing instrument. - An imaging sensor with a cross-track and an along-track pointing capability may have the potential of stereo imaging by taking the same image from different along-track positions in the same orbit.

Field of View (FOV). The total range of viewing of a sensor into the direction of the target. The cross-track component of FOV is equivalent to the swath width (see also IFOV).

Filter (in optical sensors). A device that - by interference absorption or reflection - selectively modifies the radiation transmitted through an optical system (see also ‘convolution filter’).

Fluorescence. Refers to the absorption of a photon of one wavelength and re-emission of one or more photons at longer wavelengths (known as Stoke’s shift), especially the transformation of ultraviolet radiation into visible light. Plants re-emit a portion of the absorbed radiant energy in the visible region into the red and near-infrared region (0.65-0.75 μm). The distribution of wavelength-dependent emission intensity caused by a given wavelength

²⁰⁵²⁾R. Beer, “Remote Sensing by Fourier Transform Spectrometry,” John Wiley & Sons, New York, 1992

excitation is known as the emission spectrum. The method of fluorescence has its advantages over other spectroscopic methods mainly due to its high sensitivity (applications in cell biology, photochemistry and the environmental sciences). - Note, since lasers are used as the excitation light source to induced fluorescence, this active remote-sensing method has become known as the laser-induced fluorescence (LIF) technique.

Focal length (f). Distance measured along the optical axis from the image to the plane, where the axial imaging cone of light intersects the input light bundle. The F-number or F-stop is defined as f/d (the focal length divided by the diameter of the lens opening). In antenna design the term focal length refers to the distance from the center feed to the center of the dish.

Footprint. Refers to the projection of the instantaneous area of coverage of a sensor (or antenna) onto the Earth's surface. A footprint may also be the instantaneous area of visibility of a data collection platform on a satellite.

Forward error correction (FEC). A transmission scheme which adds unique codes to the digital signal at the source so errors can be detected and corrected at the receiver.

Fourier Transform Spectrometer (FTS). An optoelectronic (or an optomechanical) instrument, usually for the infrared region of the spectrum, providing high spectroscopic resolution and sensitivity for remote-sensing applications (Earth surface imaging, atmospheric soundings, etc.). The technique employs the Fourier series concept as a means of converting a detector signal output - referred to as the interferogram - into a form useful for spectral analysis. There are several ways in which the detector signal can be created from the incident radiation. The approach taken by the majority of FTS instruments is to use an interferometer (Michelson, Sagnac, Fabry-Perot, etc.) and corresponding foreoptics (lenses) to create the interference pattern in such a way that each optical frequency is coded as a unique electrical signal output of the detector. The amplitude of each frequency is proportional to the incident radiation (see also chapter O.9 on page 1258).

Frequency Division Multiple Access (FDMA). A process that shares a spectrum of frequencies among many users by assigning to each a subset of frequencies in which to transmit signals. Each user is assigned a unique center frequency within the operational bandwidth.

Full Width Half Maximum (FWHM). In the microwave region the resolution is often stated in terms of 'half-power points' or 'half-power response width' of the measuring system. The half-power width of a response is easier to describe than true resolution because the concept does not involve the contrast of the target. - The true resolution for targets of any character can be derived from the actual response and estimated from the half-power width (resolution) of microwave instruments.

Gain. A measure of the amplification of the input signal in an amplifier. The gain of an amplifier is often measured in decibels (dB), which is ten times the common logarithm of the ratio of the output power of the amplifier to the input drive power [$= 10 \log (Q_2/Q_1)$].

Galilei (Gal or gal). A unit of acceleration, $1 \text{ gal} = 1 \text{ cm/s}^2$; $1 \text{ milligal} = 10^{-3} \text{ cm/s}^2$. The term is commonly used in gradiometry.

Geocoding. Registration of images to the reference geometry of a map. In this process the imagery is corrected for all source-dependent errors and transformed to the desired map projection, and resampled to a standard pixel size. This is also called georeferencing.

Geodesy. The science of measuring the shape (and size) of the Earth, the geoid. A geodesic is the shortest line between two points on a mathematically derived surface (as a straight line on a plane or an arc of a great circle on a sphere). In general relativity the terms geodesic (noun) and geodetic (adjective) refer to paths followed by massive bodies ('geodesics') and light rays ('null geodesics') in curved four-dimensional space-time.

Geographical Information System (GIS). A combination of mutually referring data sets of various kinds of position-bound thematic data (database) and the necessary software to visualize this database, to manipulate it interactively and to analyze it in order to attain meaningful results.

Geoid. The Earth's conceptual gravitational equipotential surface (an ellipsoid) near the mean sea level, used as a datum for gravity surveys (a hypothetical ocean surface at rest). The geoid also serves as a reference surface for topographic heights, for example, as they are shown on maps. The geoid itself represents the surface of zero height.

Geomorphology (from Greek 'morph,' form). The explanatory science dealing with the form (shape) and surface configuration of the solid Earth (land and submarine relief features).

Geospatial information. Defined as information that identifies the geographic location and characteristics of natural or constructed features and boundaries on the Earth, including: statistical data; information derived from, among other things, remote sensing, mapping and surveying techniques; and mapping, charting and geodetic data, including geodetic products.²⁰⁵³⁾

Geosynchronous orbit. An orbit in which the satellite's orbital period is identical to the orbital period of the Earth. A geosynchronous orbit, unlike a geostationary orbit (with zero inclination, where the satellite motion relative to the Earth is at rest), does not impose any any restrictions on the orbit's eccentricity or inclination (see O.12.2 on page 1268).

Gradiometry. Study of the spatial gradient of the Earth's gravitational field.

Grating. See **diffraction grating**.

Grazing angle. Angle between the instantaneously transmitted signal of an active sensor (a SAR) and the local horizontal of the target. In other words, the grazing angle = $90 - \theta$, where θ is the incidence angle. Grazing incidences occur usually at very shallow angles. It's like skipping stones across a stream (the rock will skip only if it glances off the surface at a small angle).

Gravity-gradient boom. A deployable extension of a spacecraft (a rod fixed to the S/C with a small mass at its other end) intended to give the spacecraft elongated mass properties to contribute to gravity-gradient stability (the concept was first successfully demonstrated by JHU/APL on the Transit 5A-3 satellite with a launch on June 16, 1963). The principle: The attractive force F_1 of mass 1 (satellite) about the common center of mass exceeds the attractive force F_2 of mass 2. Hence, a torque arises to align the satellite to the vertical. - An elongated dumbbellshaped spacecraft is the most gravity gradient stable configuration with the long axis oriented vertically in orbit, i.e. (usually) the smaller mass is always pointing toward the center of the Earth. The gravity-gradient torque, small even for LEO S/C, decreases with the cube of the orbital radius. In GEO, gravity-gradient stabilization can barely be achieved.

Many gravity-gradient stabilized LEO S/C use extendable booms to achieve a favorable moment-of-inertia distribution providing two-axis (pitch and roll) attitude control. The addition of an actuator, such as a momentum wheel, to a gravity-gradient stabilized S/C provides gyroscopic stiffness to passively stabilize the third (yaw) axis. The advantages of gravity-gradient stabilization are simplicity of control, long life and low power requirements.

Gravity wave (or gravitational wave). A wave disturbance in which buoyancy acts as the restoring force on parcels displaced from hydrostatic equilibrium.

Greenhouse effect. Refers to the trapping of heat from the sun by the atmosphere (mainly by its water vapor, which absorbs and reemits infrared radiation), in the same manner that the sun's heat is trapped by the glass walls of a greenhouse. The atmosphere, like the glass, is largely transparent to the sun's radiation, but it absorbs the longer wavelength radiation from the Earth's surface into which the sun's radiation is converted.

Greenhouse gases. Those atmospheric trace gases, such as water vapor, carbon dioxide, methane, and CFC's that are largely transparent to solar radiation but opaque to outgoing longwave radiation. Their action is similar to that of glass in a greenhouse. Some of the long-wave (infrared) radiation is absorbed and reemitted by the greenhouse gases. The effect is to warm the surface and the lower atmosphere of the Earth.

Gridding. Use of a uniform system of rectilinear lines superimposed on imagery (such as photographs, mosaics, maps, charts, or other representations of the Earth's surface).

Ground pattern. Any specific identifying feature of the land surface which can be used for classification purposes.

Ground sampling distance (GSD). GSD is defined as the distance moved on the ground (in the along-track direction of the target area) during the integration period of the detector line array of an imaging instrument. Normally, the GSD is equated with the spatial resolution of a pixel or simply with IFOV (Instantaneous Field of View). However, this need not be the case. If the radiometric and electronic performance of a sensor allow, the GSD can be made smaller than IFOV to achieve better image quality because of the reduction of smear.

Ground track. Refers to the vertical projection of the actual flight path of a satellite (or aircraft) onto the surface of the Earth.

Ground truth. Reference data which is collected in the field (generally on or near the Earth's surface). The objective is to verify remotely-sensed primary sensor data against a typical 'reference.' Ground truth data is generally used in support of the analysis of remotely-sensed data. This ground truth may be gathered either by a single ground station, or by a network of ground stations (including buoys, remote terminals, etc.) whose data is collected by a 'data collection' satellite, or by airborne underflights of a spaceborne sensor. The ground reference that is being sought depends very much on the application. For instance, it may be a simple visual verification of the vegetation types in a particular scene, or it may be a particularly prepared ground patch with known radiative characteristics (reflectance, etc.) that is being used for the calibration of an airborne sensor. A very prominent ground truth station is for instance MOBY (see chapter P.139 on page 1731), which makes in situ measurements of ocean color near the Hawaiian island of Lanai.

Hall effect. Edwin H. Hall (1855 - 1938, American physicist) discovered what became known as the Hall effect in 1879 when investigating the nature of force acting on a conductor carrying a current in a magnetic field. Today, Hall effect measurements are used to characterize the electronic transport properties of semiconductors and metals. - In a model Hall effect measurement system, a uniform current density flows through a uniform slab of electrically conducting material in the presence of an applied perpendicular magnetic field. The Lorentz force then acts on the moving charge carriers, deflecting them to one side of the sample to generate an electric field perpendicular to both the current density and the applied magnetic field. The ratio of the perpendicular electric field to the product of current density and magnetic field is the Hall coefficient. The ratio of the parallel electric field to the current density is the resistivity. The Hall effect is also employed in Hall plasma thrusters (electric propulsion).

Heterodyning (see chapter O.4)

High-pass filter (in optical sensors). An absorption filter pervious to electromagnetic radiation above a certain wavelength only.

Humidity. The water vapor content of air. The term is commonly used to mean “relative humidity,” the dimensionless ratio of vapor that a given quantity of air can contain at a given temperature, expressed as a percentage. Perfectly dry air has a relative humidity of 0%; totally saturated air has a relative humidity of 100%.

Huygens’s principle (Christian Huygens, Dutch physicist, 1629-1695). A very general principle applying to all forms of wave propagation which states that every point on the instantaneous position of an advancing wave/phase front may be regarded as a source of secondary spherical ‘wavelets’. The position of the phase front an instant later is then determined as the envelope of all secondary wavelets. - This principle is extremely useful in understanding the effects due to refraction, reflection, diffraction, and scattering of all types of radiation. At his time, Huygens was the leading proponent of the wave theory of light.

Hydrological cycle. Virtually all the water of the hydrosphere is in constant circulation, moving through the hydrological cycle, a vast series of interchanges of geographic position as well as of physical state. Broadly speaking, the hydrologic cycle involves the transfer of water from the oceans through the atmosphere to the continents and back to the oceans. The processes involved are complex combinations of evaporation, transpiration, condensation, precipitation, runoff, infiltration, subterranean percolation, and others. The mean residence time of water in the atmosphere, on the land surface, and in the oceans is an important climate parameter.

Hydrometeors. These are cloud scatterers (when measured by a lidar or radar instrument) in different phases such as rain or frozen precipitation with a definite fall velocity.

Hydrosphere. All liquid and frozen surface waters (including the oceans, lakes and streams), groundwater held in soil and rock, and atmospheric water vapor. The Earth’s total water budget is estimated at roughly $1.385 \times 10^9 \text{ km}^3$. Over 97% of the Earth’s total water supply is contained in the oceans and other saline bodies of water. Of the remaining 3%, a little over 2% is tied up in glaciers and ice caps and, along with atmospheric (0.001%) and soil moisture, is inaccessible. Hence, approximately 0.62% of the total amount of water may be regarded as ‘freshwater’ in rivers, lakes and groundwater supplies.

Hyperspectral. In remote sensing the term implies a spectral signature of narrow, continuous and contiguous spectral bands per pixel, i.e. a fine spectral resolution ($\Delta\lambda/\lambda = 1 - 5\%$), over an extended spectral range. A hyperspectral sensor has a minimum of 20 spectral bands (normally 30 - 200 bands). On the other hand, “multispectral” usually implies fewer, spectrally broader bands, which may be noncontiguously spaced color bands per pixel. Hyperspectral imaging implies a hyperspectral signature for each pixel of the image. The detailed spectral information captured in a hyperspectral image allows detailed examination of the observed scene.

Image. Remotely sensed imagery (collected by CCD instrument, camera, or radar - in a wide range of the electromagnetic spectrum) is measured data which is transformed by numerical algorithms into an image. This is referred to as “computed imaging.”²⁰⁵⁴⁾ An image is a two-dimensional grid of data; each of its elements is a pixel (picture element) whose coordinates are known and whose light intensity has a DN (Digital Number) value. The coordinates of the pixels and their DN values describe the image in terms of rows, called ‘lines’, and columns, called ‘samples’. An 8-bit pixel provides up to 256 brightness levels (level 0 is set to black, while level 255 is set to white); the brightness levels are also referred to as ‘grayscale levels.’ In ‘false color image processing’, those pixels which have the same DN value are assigned an arbitrary color. This enhancement technique is used, for example,

²⁰⁵⁴⁾ Other forms of computed imaging (i.e. a restructured image of measured data) are in such fields as: tomography, x-ray crystallography, electron microscopy, seismic imaging, and radio astronomy.

to differentiate between various types of terrain or species of vegetation - to reveal changes which are otherwise not perceptible to the human eye.

Image correction. The adjustment of an image for errors: geometric, radiometric, etc.

Image correlation. The ability to locate or match a region of an image with a corresponding region of another image which can be taken with a different sensor at a different viewing angle.

Image degradation. Loss of resolution due to modulation transfer function defects including motion blur, nonlinear amplitude response, shading and vignetting and channel noise.

Image enhancement. The improvement of images to facilitate better interpretation (false color processing is an example), or further digital processing to develop a specific theme or to highlight certain features in an image series.

Image motion compensation. Algorithms (hardware and/or software) counteracting image motion during integration time, thereby reducing image blur. The blur effect increases when relative velocities of the sensor platform are noticeable with respect to the image integration time. The sensor platform attitude parameters are also important inputs for motion compensation. For low-flying aircraft motion compensation is normally in the forward direction. There are also algorithms in use for antenna motion compensation. For instance, the short-term scanning motion of the antenna is measured by IMU (Inertial Measurement Unit). This data is used as input to compensate the pulse-to-pulse phase of the radar to maintain coherence during synthetic aperture.

Image quality. Refers to the apparent central core size of the observed image, often expressed as an angular image diameter that contains a given percentage of the available energy. Sometimes it is taken to be the full width at half maximum (FWHM) value of the intensity versus the angular radius function. A complete definition of image quality would include measurements of all image distortions present, not just in size or projection. But this is frequently difficult to do, hence the approximations.

Image rectification. A process by which the geometry of an image area is made planimetric. Image rectification doesn't remove relief distortion or perspective distortion.

Image resampling. A technique for geometric correction in digital image processing. Through a process of interpolation, the output pixel values are derived as functions of the input values combined with the computed distortion. Nearest neighbor, bilinear interpolation and cubic convolution are commonly used resampling techniques.

Image space. The mathematical space describing the position (coordinates) of pixels in the image.

Imaging array. A solid-state imaging array consists of a 1-D or 2-D set of photodetectors onto which an image can be focused, together with an integral electronic readout scheme. The devices are classified according to the particular readout scheme and detector type. A linear array is an imaging array consisting of a single line of detectors. The introduction of detector arrays has resulted in a new type of spectrometer - the imaging spectrometer - capable of generating images in much narrower bands (hyperspectral imagers) than was possible with conventional spectrometers.

Imaging sensors. Instruments that produce a 2-D image of the target area. Imaging sensor systems may be subdivided into 'framing systems' (such as camera or vidicon) and 'scanning systems.'

Imaging spectrometry. The simultaneous acquisition of images in many contiguous spectral bands.

Incidence angle. Angle formed between the instantaneous line of measurement of a sensor to a target and the local vertical of the target (or object).

Inclination. In general the angle between two planes or their poles; usually the angle between an orbital plane and a reference plane (i.e. the equator plane). Inclination is one of the standard orbital elements specifying the orientation of the orbit plane (see also O.12 on page 1265).

Infrared radiation. Refers to electromagnetic radiation lying in the wavelength interval from 0.7 μm to 1000 μm (or roughly between 1 μm and 1 mm wavelength). Its lower limit is bound by visible radiation, and its upper limit by microwave radiation. Most of the energy emitted by the Earth and its atmosphere is at infrared wavelengths. Infrared radiation is generated almost entirely by large-scale intermolecular processes. The triatomic gases, such as water vapor, carbon dioxide, and ozone, absorb infrared radiation and play important roles in the propagation of infrared radiation in the atmosphere. - The phenomenon of infrared radiation was first discovered by the English astronomer Sir William Herschel (1738-1822) in 1800 (he dispersed the solar spectrum with a prism and found thermal effects of invisible radiation beyond the red).

In-situ soundings. An observation method (using sensors on such platforms as aircraft, balloons, ships, buoys, towers, spacecraft, on the ground, etc.) with the objective to measure parameters in the immediate environment. From a historical point of view 'in-situ' observation predated 'remote' observation by ages. Thermometers, barometers, thermocouples, hygrometers, air samplers, etc. are in-situ sensors, as are in fact most sensors in the fields of meteorology, atmospheric chemistry, hydrology, etc. By far the largest percentage of ground-truth observations are in-situ measurements (i.e., measurements of parameters at a particular location and at a particular time). Remote sensing data of a particular sensor and target area may be compared (calibrated) against in-situ data of that target area. Spaceborne data collection systems, like ARGOS on polar orbiting satellites, remotely collect data from many thousands of 'in-situ measurement systems' in the ground segment on a routine basis. Examples of spaceborne in-situ observations are: sensors measuring magnetic or electric field parameters, solar wind particles, etc.

By their very nature, in-situ measurements are local measurements; hence, they offer a very low observation efficiency with regard to coverage and timeliness (repeat periods). It would take a fleet of spacecraft to obtain in-situ data with sufficient spatial and timely resolution on a global scale.

Instantaneous Field of View (IFOV). A term denoting the (angular) aperture within which the sensor is sensitive to electromagnetic radiation. The IFOV may be expressed either as a small solid angle (in mrad or μrad , in this case the value is independent of the orbital altitude of the sensor), or as a unit area (e. g. 6 m x 6 m), or simply as the pixel size. Hence, the IFOV actually represents the spatial resolution of a sensor measurement.

Integration time. Refers to the short time period allocated for the radiative measurement of the instantaneous area of observation by the detector of a sensor (see also **dwelt time**). Depending on sensor type the integration time may be very short [as is the case with electro-mechanical scanning systems which measure each individual cell (IFOV) across the swath sequentially], while the entire swath width (FOV) is measured by a CCD detector array in a single measurement.

Interference. Signals that arise from sources extraneous to the measurement system and result in errors in the measured value.

Interference filter. A filter reflecting radiation selectively in a narrow spectral band.

Interferogram. An image of interference phenomena such as phase differences (as patterns of interference fringes) measured by an interferometer, FTIR spectrometers, or generated by SAR interferometry. Interference fringes form through the interaction of two beams. Hence, for a given wavelength, the signal on the detector is either strong or weak. Two cases are of interest:

- **Constructive interference.** This occurs when the optical path difference (OPD) between the two light paths from the collectors to the detector is zero or a multiple of the observing wavelength
- **Destructive interference.** It occurs when the OPD is a half-integer number of wavelengths. The destructive interference is also referred to as ‘nulling mode’.

Interferometer. An instrument class for dispersing spectra. The technique determines the relative phase of two (or more) wave fronts as a function of spatial location by observing interference fringes. Radiation is split into two or more beams which traverse different path lengths. The beams are reflected by mirrors and recombined for interference analysis. (see chapter O.10).

Interlaced scanning. Refers to a subsampling readout technique from a detector array of a camera or from some other high data-rate instrument. The advantage of such a measure is to reduce the bandwidth for image transmission. However, the disadvantage is a delay in total image recovery on the receiving side, resulting in distortions for fast moving objects in successive frames. The interlaced scanning technique is used for NTSC (National Television System Committee, a US TV display standard) television camera readout, in which each frame is scanned in two successive fields, each consisting of all the odd or all the even horizontal lines. The technique is also employed in other camera systems.

Intermediate frequency (IF). A common microwave frequency in an instrument (say, 80 MHz) for all channels at which considerable amplification takes place, interconnections are made, automatic gain adjustment is provided, and channels may be disabled upon command (squench). The IF concept of a relatively low frequency is used to simplify the design of all functions compared to performing them at much higher frequencies in the GHz region.

Interplanetary magnetic field. Designates the magnetic field carried out from the sun by the solar wind, which permeates the entire heliosphere.

Intertropical convergence zone. A low pressure trough and minimum east wind, lying between the trade regions of the two hemispheres, that are nearly continuous around the world on climatological charts.

Inversion (atmosphere). A positive temperature gradient or increase in temperature with elevation, resulting in adverse conditions for the dispersion of pollutants.

Ionosphere. Layer of the Earth’s atmosphere, between approximately 60 and 1000 km in altitude (a highly variable and complex physical system), that is partially ionized by solar x-rays, ultraviolet radiation, and energetic particles from space. The process of ionization is controlled by chemical composition and transport by diffusion and neutral wind. The region between about 160 to 1000 km, known as the F-region of the ionosphere, contains the greatest concentration of electrons (the peak electron concentration is around 250-300 km). The presence of the ionized zone disturbs the propagation of electromagnetic waves, particularly at the lower wave frequencies. Below at certain frequency, the wave may be totally reflected by the ionosphere. - At times, the F-region of the ionosphere becomes disturbed and small-scale irregularities develop. When sufficiently intense, these irregularities scatter radio waves and generate rapid fluctuations (or scintillation) in the amplitude and phase of radio signals.

The ionosphere was discovered in the early 1900s when radio waves were found to propagate “over the horizon.” If radio waves have frequencies near or below the plasma frequency, they cannot propagate throughout the plasma of the ionosphere and thus do not escape into space; they are instead either reflected or absorbed. At night the absorption is low since little plasma exists at the height of roughly 100 km where absorption is greatest. Thus, the ionosphere acts as an effective mirror, as does the Earth’s surface, and waves can be reflected around the entire planet much as in a waveguide.

Ionospheric disturbances. Refer to transient changes in ionospheric densities or currents, or the appearance of electron density irregularities, usually in association with the arrival of x-rays or UV bursts from solar flares.

Irradiance. Received radiative power per unit area (or the incident radiative flux onto a surface expressed in Wm^{-2}).

Isotropic radiator (antenna). A theoretical radiator of infinitesimal size in which it is assumed that all energy is distributed evenly (point source). Such a concept serves as a reference for other antennas of finite dimensions.

Lambertian radiator. A target or an object having the radiative property of directional independence of its (emitted and reflected) energy. With respect to reflection the object or target may be regarded to be a diffusely reflecting surface.

Langmuir probe. An instrument employed to measure the current-voltage characteristics of a plasma (single and double probes are in use) in order to determine plasma density.

Laplacian filter. A linear window operation (digital filter) concerning second derivatives of the pixel values within a window, either unidirectional or bidirectional (orthogonal).

Laser (Light Amplification by Stimulated Emission of Radiation). A source of light that is highly coherent (spatially and temporarily) and emitted in one or more wavelengths. A typical laser consists of two essential elements: gain and feedback. A beam of light passing through the gain, or amplifying, medium stimulates it to release its stored energy in the form of additional light that adds to, or amplifies, the beam. Feedback is achieved by placing the gain medium within the resonator (a set of mirrors that reflects the beam back and forth through the gain medium). The light from such a laser is composed of a number of discrete wavelengths corresponding to different resonant frequencies, or modes, of the resonator. There are two groups of lasers which operate either in a pulsed mode or in a continuous mode. The spectral range of lasers extends from the UV to the TIR (90 nm to 12 μm). Types of lasers:²⁰⁵⁵⁾

- **Gas lasers:** Usually receive their energy input via collisions of gas atoms with high-energy electrons. This energy is provided by applying a high voltage between electrodes located within the gaseous medium. The most common types of gas lasers are:

- **He-Ne laser:** Uses a gas discharge of helium and neon as the gain medium (this was the first laser to emit a continuous output beam).
- **Argon and krypton ion laser:** Uses a gas discharge containing ions as a gas medium. First lasers to operate in the blue and green regions of the spectrum.
- **CO₂ laser:** One of the most powerful lasers, operating mostly in the spectral region of about 10.5 μm . They range from small versions with a few mW of continuous power to large pulsed versions.

TEA (Transverse Excitation-Atmospheric pressure): These are generally pulsed CO₂ lasers; both the gas flow (about 1 atmosphere) and the electric discharge are transverse to the optical axis. Such conditions yield tremendous population inversions for short times. Commercially available TEA lasers deliver 100 to 200 ns pulses of several Joules/pulse at a repetition rate of 50 Hz; they are used for welding and cutting.²⁰⁵⁶⁾

- **Rare-Gas-Halide excimer laser:** Operate primarily in the UV region in mixtures of rare gases, such as argon, krypton or xenon, with halide molecules such as chlorine and fluorine.
- **Chemical lasers:** In these lasers the molecules undergo a chemical reaction. The hydrogen-fluoride laser fits into this class.
- **Metal Vapor lasers:** These lasers are actually a type of gaseous laser, since the laser action occurs in the atomic or molecular vapor phase of the species. The two best-known types are the helium-cadmium ion laser and the pulsed copper vapor laser.

Parameter	Laser type	Wavelength (nm)	Energy range
CW (Continuous Wave)	Argon Ion	488 and 514	1 μ W to about 1 W
	He-Ne	633	1 μ W to about 20 mW
	Diode	830	100 μ W to about 20 mW
	Nd:YAG	1064 1319	100 μ W to about 450 W 100 μ W to about 10 mW
	HeNe	1523	100 μ W to about 1 mW
	CO ₂	10600 (or 10.6 μ m)	1 μ W to about 1 kW
Pulsed	KrF Excimer	248	10 ⁻³ to about 200 mJ/pulse 50 μ W - 9W average power
	ArF Excimer	193	10 ⁻³ - 3 mJ/pulse 50 μ W - 3 W average power
	Nd:YAG	1064	1 - 50 mJ/pulse 10 nW - 100 μ W 10 ⁻³ - 10 nJ/pulse

Table 561: Overview of some laser characteristics ²⁰⁵⁷⁾

- **Solid-State lasers:** These laser generally consist of transparent crystals or glasses as “hosts” within which ionic species of laser atoms are interspersed or ‘doped.’ Typical host materials include aluminum oxide (sapphires), garnets, and various forms of glasses, with the most common lasing species being neodymium ions and ruby ions. - The energy input in these lasers is provided by a light source that is focused into the crystal to excite the upper laser levels. The light source is typically a pulsed or continuously operating flash lamp.
 - **Nd:YAG laser:** A laser whose gain medium consists of a neodymium-doped yttrium aluminum garnet crystal. The laser emits in the NIR region at 1.06 μ m.
 - **Ruby laser:** This laser is produced by implanting chromium ions into an aluminum oxide crystal host and then irradiating the crystal with a flash lamp to excite the laser levels.
 - **Color center laser:** This laser uses a different form of impurity species implanted in a host material (usually one part per ten thousand). Color lasers typically operate in the 0.8 - 4 μ m region and are tunable by using different crystals having different emission wavelengths.
- **Semiconductor lasers:** Semiconductor or diode lasers are the smallest lasers yet devised (about the size of a grain of salt). They consist of a p-n junction formed in an elongated gain region, typically in a gallium-arsenide crystal, with parallel faces at the ends to serve as partially reflecting mirrors. The light output of semiconductor lasers can be directly modulated using bias current, they can be tuned in wavelength using both temperature and bias current. Semiconductor diode lasers range in wavelength from 0.7 to 1.8 μ m with typically continuous output power of up to 10 mW. Two types of semiconductor diode lasers are in wide use: ²⁰⁵⁸⁾
 - **EEL (Edge-Emitting Laser).** A horizontal-cavity laser with an optical output beam emitting from the edge of the laser chip.
 - **VCSEL (Vertical-Cavity Surface-Emitting Laser).** A VCSEL's cavity is perpendicular to the wafer plane (the beam is guided in the vertical direction). The VCSEL is used for wavelength engineering, in optical fiber communications, etc.
 - **Quantum cascade laser (QC laser).** ²⁰⁵⁹⁾ Refers to a laser-based semiconductor sensor that operates at room temperature and at high power to detect minute amounts of trace gases (ppb) or pollutants by scanning for their optical-absorption “fingerprints.” The lasers’ high peak power, of 50-60 mW at 300 K, allows the use of uncooled detectors and enables LIDAR applications. They are particularly well suited for portable, robust sen-

sors in applications such as the point detection of trace gases and remote sensing applications.

The QC laser technology was invented by Jerome Capasso, Jerome Faist, Sivco, Carlo Sirtori, Hutchinson and Cho of Bell Labs (Murray Hill, NJ) in 1994, who demonstrated continuously tunable, single-mode, QC distributed-feedback lasers operating at mid-infrared wavelengths (5 and 8.5 μm) in pulsed mode. The single-mode tuning range is typically 50 nm in wavelength, and the peak powers are 60 mW.

QC lasers are made using the technique of MBE (Molecular Beam Epitaxy), featuring layered structures of only a few atoms thick. The QC laser's emission wavelength is determined initially by quantum-confinement effects: the fact that its layers are so thin that electrons are squeezed and change their quantum-mechanical properties, allowing a range of possible wavelengths. The distributed-feedback lasers incorporate a grating that makes it possible to further refine the laser's wavelength, making them continuously tunable. - The operation of a QC laser is unlike that of other laser types. They operate like an electronic waterfall: when an electric current flows through a QC laser, electrons cascade down an energy staircase; every time they hit a step, they emit an infrared photon. At each step, the electrons make a quantum jump between well-defined energy levels. The emitted photons are reflected back and forth between built-in mirrors, stimulating other quantum jumps and the emission of other photons. This amplification process enables high output power.

Bell Labs has built QC lasers operating throughout the mid-infrared region from 4.5 to 11.5 μm in both pulsed mode at room temperature and in continuous wave (CW) mode at temperatures up to about 110 °C.

- **Liquid (dye) lasers:** Dye lasers are similar to solid-state lasers in that they use a host material in which the laser (dye) molecules are dissolved. Different dyes have different emission spectra or colors, thus allowing dye lasers to cover a broad wavelength range (320 - 1500 nm). A unique property of dye lasers is the broad emission spectrum (typically 30-60 nm) over which gain occurs. The dye laser is tunable over a frequency range of 10^{13} Hz.
- **Dye laser:** Laser in which the gain medium consists of an organic dye dissolved in a liquid solvent. Applications in areas where tunability of the laser frequency is required. Dye lasers are also used for producing ultra-short pulses, a technique which is referred to as 'mode-locking.'
- **Free-Electron lasers:** These lasers are significantly different from any other type of laser in that the laser output does not result from discrete transitions in atoms or molecules of gases, liquids, or solids. Instead, a high-energy beam (in the order of 1 MeV) of electrons is directed to pass through a spatially varying magnetic field that causes the electrons to oscillate in a direction transverse to their beam direction. This laser type can be used over a wide range of wavelengths from the UV to FIR.

Lyman-alpha radiation. The radiation emitted by hydrogen at 1,216 Å, first observed in the solar spectrum by rocket-borne spectrographs.

Leads. Leads are transient areas of open water and/or very new ice, created in response to convergence/divergence phenomena (deformation processes) in the polar ice pack (see also **nilas**).

Limb/Occultation sounding. A horizon-looking (or edge-looking i.e. outer edge of the apparent disk of a celestial body) observation technique that uses a distant object [(for occultation sounding) sun, star, or a sensor on another satellite in a different Earth orbit, (see Figure 363)] as a source to observe the signal on its path through the atmosphere that is essentially tangential to the Earth's surface. Two types of occultation techniques have been used in the past to determine the composition and structure of the atmosphere:

- 1) **Extinctive occultations:** These occur because atmospheric constituents absorb or scatter the incoming radiation. Since extinction cross sections are generally wavelength-de-

pendent, spectral measurements - as the star (sun) sets deeper into the atmosphere - are diagnostic of the atmospheric composition. Hence constituent profiles may be determined from the relative transmission (i.e., the ratio of occulted to un-occulted spectra). As a result, extinctive occultation measurements are self-calibrating and ideal for long-term trend monitoring. - The technique provides measurements that are commonly referred to as trace gas monitoring. Examples of spaceborne instruments employing extinctive occultations are: SAGE (AEM-2, ERBS, Meteor-3M, ISS), POAM (SPOT-3,4,5), HALOE (ATLAS-1,2), ATMOS (ATLAS-1, Spacelab-3), ILAS (ADEOS, ADEOS-II), and GOMOS (ENVISAT).

- 2) **Refractive occultations:** They occur because density gradients in the atmosphere lead to refraction of the incoming radiation, causing it to follow curved paths through the atmosphere. Relative measurements of the degree to which the path of the incoming radiation is changed provide the bulk of atmospheric properties (density, pressure, temperature). Usually, this occultation technique employs dual-frequency carrier phase observations of retarded signals (atmospheric propagation delays) from GPS or GLONASS satellites which permit the derivation of atmospheric profiles of density, pressure, and temperature. The GPS/MET instrument of Microlab-1 and TRSR (TurboRogue Space Receiver) of CHAMP, SUNSAT, and other missions are examples of refractive radio occultation monitoring.

Very long atmospheric paths (up to 4000 km) with high sensitivities or dynamic ranges can be obtained in this 'limb-sounding' configuration. The refractive technique takes advantage of the precise knowledge of GPS satellite positions and timing of GPS radio signals. Instruments like GPS/MET and TRSR measure the extra time it takes for a GPS signal to enter Earth's atmosphere obliquely, pass through, and re-emerge to strike the LEO S/C - compared to an otherwise un-refracted direct ray path. The time delays of the GPS signal due to such atmospheric passage during the course of the occultation are used to derive the corresponding bending angles of the ray path, which in turn are converted to the refractive index profile of the atmosphere.

Some key advantages of limb sounding are:

- It maximizes the reception of the signal emitted by the atmospheric layer at the viewed tangent height provided that the receiver antenna has a very narrow beam
- The background temperature (that of the deep space) is much colder than that of the atmosphere, which guarantees very low biasing of the measured atmospheric emissions
- Vertical profiles with a high resolution can be obtained by limb scanning with a very narrow antenna beam
- A global coverage is achieved with LEO polar orbiting satellites.

A major disadvantage of limb sounding is: Low horizontal resolution due to the measurement geometry (long path-length) and high speed of the spacecraft (signal integration along the moving tangent point).

Lithosphere. Earth's outer rigid crust composed of rocks rich in silicon, aluminum, calcium, sodium, potassium, and some other elements, and hence less dense than the underlying mantle. The lithosphere varies from less than 30 km thickness under the ocean to over 100 km under continents.

Local oscillator (LO). A receiver oscillator that produces a reference sinusoid for comparison with the noisy received sinusoid.

Look angle. The direction in which an antenna is pointing when transmitting and receiving from a particular cell (for an active instrument). Refers to the instrument pointing direction from nadir. - In the current literature the terms 'look angle,' 'illumination angle,' 'pointing angle,' 'off-nadir angle,' and 'viewing angle' all have the same meaning.

Looks (in SAR imagery) see chapter O.8.4 on page 1252.

LORAN (Long-Range Navigation). A hyperbolic radionavigation system (the term ‘hyperbolic’ refers to the reflected ionospheric transmissions) which uses the difference in the time of arrival of signals from individual transmitters to establish position. Historically, LORAN was developed at MIT (DoD funded) during World War II as a navigation aid, known as LORAN-A. The operation of LORAN-A was in the 1850-1950 kHz radio band. LORAN-A had a range of 1000 km. Later LORAN-B was developed to improve the accuracy of LORAN-A. In 1958 LORAN-C became operational; it was used commercially for marine navigation. LORAN-C was transferred to civil authority (DOT) in 1974. Later, FAA extended LORAN-C coverage to include the continental USA. - LORAN-C is a long-range (in excess of 1850 km), low-frequency (90 -110 kHz) hyperbolic navigation system. Loran-C transmissions consist of groups of eight or nine accurately timed and phase-coded pulses at a carrier frequency between 90 and 110 kHz. Each chain consists of a master and a number of slave transmitters. - In the mid 1960’s LORAN-D (a low power transportable system with a range of 1100 km) was developed by the USAF. - Loran signals propagate as a ground wave, but sky waves reflected from the ionosphere are also received. - In the early 1990s, DoD declared that by the end of 1994, there would be no further military requirement for the system and authorized the transfer of LORAN-C assets to host nations for civil use. The USA plans to terminate Loran-C operations on Dec. 31, 2000.

A rebirth of LORAN-C in Europe was initiated in 1992 as result of an international agreement between the US and six European countries (Denmark, France, Germany, Ireland, the Netherlands, and Norway), known as NELS (Northwest European LORAN-C System). The NELS network, consisting of nine stations with a control center at Brest (France), started operations in 1999. The performance characteristics of the NELS network are: absolute location accuracy of 100-460 m; repeatable accuracy of 20-100 m; availability per station of 99.9%; and availability per chain of 99.7%. A policy recommendation of IALA (International Association of Marine Aids and Lighthouse Authorities) states that the future use of radionavigation be based on complementary satellite and terrestrial systems. ²⁰⁶⁰⁾

Low Noise Amplifier (LNA). A preamplifier between antenna and receiver. It is usually attached directly to the antenna receive port. Its main function is to reduce the thermal noise of the received signal.

LOWTRAN. LOW-resolution TRANsmittance - a computer code (model of USAF Geophysics Laboratory, also referred to as AFGL, Hanscom AFB, MA) which predicts the atmospheric transmittance and thermal radiation emitted by the atmosphere and the Earth. LOWTRAN programs are applicable for wave numbers ranging from 350 cm^{-1} ($28.5\text{ }\mu\text{m}$) in the infrared to $40,000\text{ cm}^{-1}$ ($0.25\text{ }\mu\text{m}$) in the UV region. The LOWTRAN code calculates atmospheric transmittance and radiance, averaged over 20 cm^{-1} intervals in steps of 5 cm^{-1} . The succeeding models are more advanced, building on the capabilities and options of the previous LOWTRAN models. ²⁰⁶¹⁾

- LOWTRAN-2 (1972)
- LOWTRAN-3 (1975)
- LOWTRAN-3B (1976)
- LOWTRAN-4 (1978)
- LOWTRAN-5 (1980)
- LOWTRAN-6 (1983) includes solar/lunar scattering, new spherical refractive geometry subroutines, and an improved water vapor continuum model. Other modifications include a wind-dependent maritime aerosol model, a vertical structure aerosol model, a cirrus cloud model, and a rain model.

²⁰⁶¹⁾F. X. Kneizys, et al., “Atmospheric transmittance/radiance: computer code LOWTRAN-6, Report AFGL-TR-83-0187, Bedford, MA, NTIS Report ADA137786

- LOWTRAN-7 (1988). This code has been extended to include the microwave spectral region.
- MODTRAN (1989)²⁰⁶² (MODerate-resolution LOWTRAN). MODTRAN is an extended version of LOWTRAN-7 (six additional subroutines) to increase its spectral resolution from 20 cm⁻¹ to 2 cm⁻¹ (FWHM). Further objectives were: a) to model molecular absorption of atmospheric molecules as a function of temperature and pressure; b) to calculate band model parameters for twelve LOWTRAN molecular species; c) to integrate LOWTRAN-7 capabilities into the new algorithms, maintaining compatibility with the multiple scattering option. For MODTRAN, molecular absorption is calculated in intervals of 1 cm⁻¹ bins, the other parts of the calculation remain unchanged. The molecular species affected are: water vapor, carbon dioxide, ozone, nitrous oxide, carbon monoxide, methane, oxygen, nitric oxide, sulfur dioxide, nitrogen dioxide, ammonia, and nitric acid. The MODTRAN spectral region is from 0 - 17,900 cm⁻¹ (with 2 cm⁻¹ spectral resolution), calculations at larger wave numbers, i.e. the VIS and UV regions, are performed at the lower spectral resolution of 20 cm⁻¹.

Magnetometer. An instrument for measuring changes in the Earth's magnetic field.

Magnetopause. The surface defining an interface between the magnetic field of a star and matter in the disk; a surface where the average magnetic pressure of the magnetic field is in pressure balance with the plasma pressure. Earth's magnetopause is the region in the ionosphere where the magnetosphere meets the solar wind (see Figure 408).

Magnetosphere. The region of space surrounding a rotating, magnetized sphere. Specifically, the outer region of the Earth's ionosphere, starting at about 1000 km above Earth's surface and extending to about 60,000 km (or considerably farther, such as 100 R_E on the side away from the Sun).

Marginal ice zone (MIZ). The critical region in which polar air masses, ice, and water masses interact with the temperate ocean and climate systems (an important geophysical boundary zone involving energy exchanges). The transition zone is characterized by large horizontal gradients in the properties of the ice, ocean, and atmosphere.

Maser. An amplifier utilizing the principle of 'microwave amplification by stimulated emission of radiation.'

Measurement mode - duty cycle. The fraction of available time during which an instrument is actively performing Earth measurements and producing meaningful data, including incidental calibration and overhead (such as scan retrace). High data rate, high power consumption, and steerable instruments may have small duty cycles. Daylight-only instruments may have measurement mode duty cycles averaging 50 percent.

Medium Earth Orbit (MEO). Refers to all satellite orbits between LEO and GEO. MEO orbits have larger and longer footprints than LEO orbits. Navigation systems, like GPS and GLONASS, are examples of MEO orbits. MEO orbits are also attractive to a number of communication satellite networks due to their relatively small transmission delay times (in the order of 0.1 s). The shorter radial distance (compared to GEO) translates into improved signal strength at the ground which means better reception and ultimately smaller terminals.

Mesosphere. Region of the atmosphere between approximately 50 and 85 km in altitude.

Meteoroid. A small particle in space (sources are comets, detritus from asteroid collisions, and interstellar dust). A meteoroid that survives the passage through the Earth's atmosphere and reaches the Earth's surface is known as a meteorite.

Microwave radiation. Electromagnetic radiation generally considered to be in the wavelength range from approximately 1 mm to 1 m (three orders of magnitude). In microwave radiometry polarization is often used as a discriminant parameter, because microwave antennas are easily built with a single polarization direction. - (On the other hand, most optical sensors are relatively independent of polarization; a special effort must be made to polarize the signal prior to detection). - The largest portion of the microwave region is also the 'radar' region, hence both terms are used interchangeably (this also applies to the microwave instruments), see also O.8.2 and O.8.1.

Microwave rainfall monitoring. Microwave radiation with wavelengths in the order of 1 mm to 3 cm results in a strong interaction between the raindrops and the radiation (the drop size is comparable to the wavelength). Passive microwave data is helpful in locating the leading and trailing edges of rain areas (extent), however, the actual measurement of rainfall and rain rates provides unsatisfactory results. So far passive microwave systems function promisingly over sea surfaces but not satisfactorily over land surfaces. The general consensus is that a passive (multichannel and multipolarized radiometer)/active (radar) instrument complement can provide a better characterization of rain systems.

Radar measurement of rainfall is based on Rayleigh scattering caused by the interaction of rain and the radar signals. The PR (Precipitation Radar) instrument on TRMM with a transmission frequency of 14 GHz (2.15 cm wavelength) is expected to improve on the problem of rainfall measurement.

Microwave signal penetration. Most natural terrain materials, with the exception of water, are partially transparent to microwave frequencies. The energy of a (radar) wave incident upon a terrain surface is partially scattered back into the atmosphere; the remainder is transmitted across the boundary into the terrain medium. - The most important parameters governing the depth to which microwaves can penetrate natural materials such as soil, snow, or vegetation are the wavelength, the moisture content of the material (soil), and the shape and sizes of the scattering elements (such as the leaves in a vegetation canopy, or ice crystals on a snow surface). Radar observations in L-band (2-1 GHz) and P-band (1.0 - 0.3 GHz) frequencies are providing first results in penetration measurements, in particular with regard to soil moisture content and canopy penetration. - Note: The microwave permittivity of water is an order of magnitude higher than that of any natural dry material. ²⁰⁶³⁾

Millimeter-Wave (MMW) region. Refers to the spectral region from 1 mm (300 GHz) to 10 mm wavelength (30 GHz). The MMW region is part of the microwave region of the spectrum which extends conventionally from 1 mm to 1 m wavelength. The MMW region is in particular of interest to radiometry (passive sensing) applications. Millimeter waves are able to penetrate many types of inclement weather, as well as opaque solids, and offers a lot of contrast. The emissivity of objects in this region is about 10 times higher than that in the infrared region.

Submillimeter-wave (SMMW) region. Refers to the spectral region from 0.1 mm (3000 GHz or 3 THz) wavelength to 1 mm (300 GHz) wavelength. The SMMW is also being considered as part of the microwave region. SMMW observations are of particular interest to atmospheric science. Submillimeter-wave limb sounding has some advantages compared with limb sounding in other frequency ranges. In the UV and VIS region only daytime measurements are possible, while in the infrared region some important species like ClO and HCl are not detectable.

Modeling. An investigative technique that uses a mathematical or physical representation of a system or theory that accounts for all or some of its known properties. Models are often used to test the effects of changes of system components on the overall performance of the system.

²⁰⁶³⁾ The penetration depth of microwaves decreases with increasing frequency. The atmosphere produces frequency-dependent distortions which set an upper frequency limit due to attenuation. This limit is about 90 GHz for airborne radars and about 15 GHz for spaceborne radars.

Modulation. A process of manipulating the characteristics (usually frequency or amplitude) of a carrier in relation to another wave or signal.

Modulation Transfer Function (MTF). ²⁰⁶⁴⁾ A function measuring the reduction in contrast from object to image (actually from each pixel), that is, the ratio of image-to-object modulation for sinusoids of varying spatial frequencies. The reason: any optical system reduces the contrast in the image compared to the contrast of the objects imaged; this is expressed as MTF. Thus, the MTF provides the response of an optical sensor as a function of object scene contrast and spatial frequency. MTF is also a measure of how accurately the actual radiance from a pixel (IFOV) is measured (a lower MTF indicates contributions from other pixels to the pixel of observation). A radiometrically accurate IFOV is one for which $MTF > 0.95$.

Note: EIFOV (Effective Instantaneous Field of View) is defined as the resolution corresponding to a spatial frequency (ground resolution) for which the system MTF is 50%.

Moire Interferometry. A method to determine 3-D profile information of an object or scene, using interference patterns. Two identical gratings of known pitch are used. The first create a shadow of parallel lines of light projected on the object. The second is placed in the imaging train, then superimposed on the shadow cast by the first grating, forming a moire fringe pattern. Varying the gap between the lines changes the sensitivity.

Mosaic. An assemblage of overlapping airborne or spaceborne photographs or images whose edges have been matched to form a continuous pictorial representation of a portion of the Earth's surface.

Multilook technique. A technique of averaging a number of independent samples per pixel. applied to radar in order to reduce speckle.

Multiple access techniques. There are three basic multiplexing schemes that allow a number of simultaneous transmissions over a single circuit. See also **CDMA**, **FDMA**, and **TDMA** in the glossary text.

- **Code Division Multiple Access (CDMA).** Refers to an access scheme which employs spread-spectrum modulations and orthogonal codes to share a communication link among its users.
- **Frequency Division Multiple Access (FDMA).** A process that shares a spectrum of frequencies among many users by assigning to each a subset of frequencies in which to transmit signals.
- **Time Division Multiple Access (TDMA).** A process that shares the time domain of a single carrier among many users by assigning to each time intervals in which to transmit signal bursts.

Multipath (GPS multipath). ²⁰⁶⁵⁾ The term multipath is derived from the fact that a signal transmitted from a GPS satellite can follow a 'multiple' number of propagation 'paths' to the receiving antenna. This is possible because the signal can be reflected back to the antenna off surrounding objects, including the Earth's surface (land and/or ocean). Some characteristics of the multipath signal are: a) a multipath signal arrives always at a later time than the direct-path signal, b) a multipath signal is normally weaker than the direct-path signal due to the reflection loss, c) if the delay of the multipath is less than two PRN code chip lengths, the internally generated receiver signal will partially correlate with it. If the delay is > 2 chips, the correlation power will be negligible.

Multiplet. A spectrum line having several components.

Multispectral. In remote sensing the term implies two or more broad spectral bands in which a sensor detects radiation (see also **Hyperspectral**). The multispectral concept im-

²⁰⁶⁴⁾ G. Joseph, "How well do we understand Earth observation electro-optical sensor parameters?" ISPRS Journal of Photogrammetry & Remote Sensing, Vol. 55, 2000, pp. 9-12

²⁰⁶⁵⁾ B. Townsend, J. Wiebe, A. Jakab, M. Clayton, T. Murfin, "Analysis of the Multipath Meter Performance in Environments With Multiple Interferers," ION GPS 2000, Salt Lake City, UT, Sept. 19-22, 2000, pp. 480-488

plies image analysis based on spectral characteristics. Note: The MSS (Multispectral Scanner System) sensor on Landsat-1 was probably one of the first spaceborne multispectral instruments with four spectral bands in VNIR.

Nadir. Direction toward the center of the Earth. Opposite of zenith.

Nilas. Thin and elastic ice sheets of a rather dull surface and up to a thickness of about 10 cm. Nilas form in quiet sea water and bend easily in swells. Transverse pressure causes nilas to pile up. **Leads** may be frozen over by nilas; but nilas are not bound to be present in leads; they may also occur outside of leads.

Noise. Any unwanted or contaminating signal competing with the desired signal. In a SAR instrument, two common kinds of noise are additive, receiver noise and signal-dependent noise, usually additive or multiplicative. The relative amount of additive noise is described by the signal-to-noise ratio (SNR). Signal-dependent noises, such as azimuth ambiguities or quantization noise, arise from system imperfections, and are dependent on the strength of the signal itself.

Noise-Equivalent-Equivalent-Width (NEEW) (sometimes shortened to ‘noise-equivalent-width’). A spectral resolution defining the smallest line area (in cm^{-1}) that can be measured, or the equivalent area of the average noise bump.

Noise-Equivalent Flux Density (NEFD), sometimes also referred to as ‘noise-equivalent irradiance.’ Defined as the in-band entrance aperture irradiance on one pixel, from a point source, that equals the sensor rms noise (units are W/cm^2). NEFD is related to a more familiar quantity, the Noise-Equivalent Radiance (NER), by the equation: $\text{NEFD} = \text{NER} \times \text{pixel subtends (in steradians)}$. NEFD can also be defined as the noise-equivalent power (NEP) per unit aperture area: $\text{NEFD} = \text{NEP}/A$.

Noise-Equivalent Radiance (NER). Defined as the in-band entrance aperture radiance ($\text{W}/\text{cm}^2/\text{sr}$) equal to the sensor rms noise. NER is the preferred figure of merit for an extended (pixel-filling) source. It is also defined as the noise-equivalent power (NEP) per unit aperture area, per pixel subtense ($\text{NER} = \text{NEP}/A/\Omega$).

Noise-Equivalent Spectral Radiance (NESR). Defined as the radiance ($\text{W cm}^{-2} \text{ sr}^{-1} \text{ cm}^{-1}$) density that corresponds to the rms value of the spectral noise of a calibrated spectrum (or: the radiance change corresponding to $\text{SNR}=1$). $\text{NESR} = \text{NEP}/(\mu \times \tau \times E \times (t)^{1/2} \times \Delta\sigma)$, with NEP = Noise Equivalent Power of the detector, μ = modulation efficiency, τ = optical efficiency, E = Etendue, t = scan time (1 instance), and $\Delta\sigma$ = spectral resolution.

Noise figure. Ratio of total output noise power of a system to that part of the output noise power due to the signal source.

Nonimaging sensors. Instruments which measure directly such quantities as radiant flux, irradiance, and radiance, which describe the intensity of a radiation field or the optical properties of a surface or a region of space. The sensors are nonimaging in the sense that they do not produce an image (a picture), but rather, integrate over time, space, and wavelength to produce a spectral curve, or a set of numbers that characterize the electromagnetic radiation. Typical measurement products are profiles, such as flux profiles, temperature profiles, moisture profiles, etc. Typical nonimaging instruments are: radar altimeters, sounders, scatterometers, spectroradiometers, radiometers, (note: there are also imaging radiometers which use scanning techniques, and imaging spectroradiometers using discrete filter-wheel systems), lidars, etc.

Nowcasting. The term is used in meteorology and refers to the development of atmospheric features on time scales between 0 and 3 hours over regional and local areas. Nowcasting is closely linked to very short-range-forecasting which covers developments over the time

scale of 3 to 12 hours over regional areas.²⁰⁶⁶⁾ A typical example of an application of now-casting is severe weather incidents, where small-scale features undergo rapid development. Nowcasting requires the (almost) continuous monitoring of the area(s) of interest. Furthermore, as many of the features to be observed are fairly small, quite high spatial resolutions are needed.

Nyquist sampling rate (Henry Nyquist, a US physicist and a pioneer in the field of communication theory, was borne in 1889 in Sweden).²⁰⁶⁷⁾ - Refers to a sampling rate above which a band-limited signal can be reconstructed from its sample value. If a signal $s(t)$ contains no frequency components at or above f_N Hz [$s(t)$ is then said to be band-limited to f_N Hz], then $s(t)$ can be completely reconstructed from its sample values, provided the samples are taken at a rate equal to or in excess of $f_s = 2 f_N$ samples/s. **This condition is known as the Nyquist or Shannon sampling theorem**; f_s is referred to as the Nyquist sample frequency, and f_N is sometimes called the Nyquist frequency. The Nyquist theorem essentially states that the sampling rate must be twice that of the highest frequency to be represented.

Observational reference frames and models:

- **Lagrangian experiments** (Joseph Louis Lagrange, 1736-1813, French mathematician and physicist). Refer to a physical system that changes as time goes on from one configuration to another as it is progressing along a particular evolutionary path (path with the smallest result). In this concept observer and observed object have zero velocity relative to each other (Lagrangian coordinates are also referred to as 'material coordinates;' they do not vary with time). The strategy is to observe a reference volume (a cell of air) of interest as it moves through space. All measuring devices move along with the reference object. The concept is generally very complex with respect to instrumentation. Drifting buoys in the ocean or constant-pressure balloons in the atmosphere are Lagrangian-type experiments of relatively small complexity.
- **Eulerian experiments** (Leonard Euler, 1707-1783). In Eulerian coordinates the properties of a fluid are assigned to points in space at a given time, without attempt to identify the individual fluid cells from one time to the next. The observer moves relative to the observed object. Example: observation of air masses. The vast majority of experiments, particularly in meteorology, are of the Eulerian type; a sequence of synoptic charts is a Eulerian data representation.
- **Transect experiments**. The observer takes snapshot measurements by transecting a large reference volume into different directions. Example: an aircraft or a ship observes many different small-scale air masses as it moves through them.

Occultation. Distortion or interruption of a direct observation path between the observer (sensor) and a target by an intervening medium (such as an atmosphere or a celestial body). The occultation technique may for instance be used to study the Earth's atmosphere (or planetary atmospheres) by remote sensing (in a limb-viewing configuration). The atmosphere causes signal propagation delay and bending [between a transmitter (a GPS satellite) and a receiver (a GPS receiver on a LEO satellite)] due to the variation in the index of refraction in different shells of the atmosphere. - In the conventional sense, occultation refers to light path obstruction by an astronomical body, such as a star, by another astronomical body, as seen from Earth. In this context, a solar eclipse is the occultation of the sun by the moon.

Ocean color. The color of the ocean reveals information on the presence and concentration of phytoplankton, sediments, and dissolved organic chemicals. By studying the color of the light scattered from the oceans, optical sensors can quantify the amount of chlorophyll and other constituents in the various regions of the ocean. - Ocean color gives a quantitative measure of the spectral radiance of light reflected from beneath the ocean surface. Since

²⁰⁶⁶⁾ "Meteosat Second Generation Programme Proposal," ESA/PB-EO (92), 57, 9 November 1992, p. 14

²⁰⁶⁷⁾ F. J. Taylor, "Digital Signal Processing," Encyclopedia of Physical Science and Technology, Academic Press, 1987, Vol. 12, p. 600

phytoplankton dominates the optical characteristics of most ocean waters, it permits the estimation of marine plant biomass, ocean optical properties, and marine photosynthesis (primary production), see also 'chlorophyll.'

Ocean mixing. Processes that involve rates of advection, upwelling/downwelling, and eddy diffusion and that determine, for example, how rapidly excess atmospheric carbon dioxide can be taken up by the oceans.

Oceans of the world and climate. The oceans play a decisive role in the evolution of the climate. Through irradiation of the sun and exchanges with the atmosphere, they receive considerable quantities of heat, in particular at the intertropical latitudes, which they store due to their high thermal capacity, and which the ocean currents redistribute from the equatorial regions to the polar regions. - Current estimates account for 30-50% of the meridian transport which makes the climate of the middle latitudes more hospitable. Fluctuations in the circulation and elevation of the average sea level, under the combined effect of thermal expansion and the melting of the icepack, are indicators of climatic anomalies. - Thus, the world's oceans represent a major regulating factor of the climatic system. Their circulation and evolution must be understood (via satellite altimetry or other means of observation) to account for the climate variability. Some figures of the oceans illustrate the importance of the oceans to our environment.²⁰⁶⁸⁾

- About 70% of the Earth's surface are covered with oceans, this amounts to a total area of 360×10^6 (million) km^2 , the total ocean volume is estimated to be 1.46×10^9 (billion) km^3 ; hence, the total mass is about 1.46×10^{18} metric tons.
- The average depth of the oceans is about 3800 m
- The mass of the oceans is about 300 times larger than the mass of the atmosphere; the heat storage capacity of the oceans is 1200 times the heat capacity of the atmosphere; the oceans provide 70 times the carbon storage capacity of the atmosphere. See also "altimetry" and "hydrosphere" in the glossary.

In addition to the normal ocean-atmosphere heat exchanges, the winds blowing on the sea surface, contribute to the productions of surface marine currents. These currents travel much more slowly than the winds; however, these ocean currents can store a large quantity of heat. This property enables the ocean to stabilize the Earth's temperature. An example of such an ocean current is the Gulf Stream which forms in the west Atlantic seaboard (mainly in the Gulf of Mexico) and travels in the direction of northern Europe.

Omega. A long-range, worldwide, all weather, day and night radionavigation system operating in the VLF (Very Low Frequency) band of the radio spectrum. The Omega network consists of eight atomic-clock-controlled transmitters transmitting sequentially on assigned frequencies between 10.2 and 13.6 kHz. The Omega network transmitters are located in Argentina, Australia, Japan, Liberia, Norway, Reunion, and USA (Hawaii and North Dakota). Users of Omega are commercial airlines, ships, land vehicles, meteorology (tracking of balloons), etc. Omega, like LORAN, uses phase differences of continuous-wave radio signals. The receiver of a user synchronizes to the transmitter frequency and measures the phase relationship of the receiver's location. Two or more 'line-of-position' measurements define the receiver location. Omega (of World War II vintage, developed by the USA) provides positioning within 2 to 4 nautical miles at a 95% confidence level with 95% availability. - The USA terminated permanently its Omega operations on Sept. 30, 1997.

Operational sensor. In Earth observation an instrument is said to be "operational" if the following services are provided: continuity of observations, timeliness of data delivery to the costumer, and several usable data products. A number of environmental/meteorological missions, like NOAA/POES and GOES, the METEOSAT series, etc., with their major instruments (AVHRR, etc.) and services, are considered "operational." Routine service

provision and regular use of the data by a user community are key ingredients for operability.

Optical depth. Refers to the negative logarithm of the extinction $[\ln I/I_0]$, where I is the radiation intensity at the back plane of the absorbing medium, and I_0 the incident intensity. The optical depth is the product of the extinction coefficient, the density of the medium, and the length of the transmitted medium layer (Lambert Beer Law).

On-orbit electric propulsion systems. (see chapter O.14)

Optical spectrum. Refers to electromagnetic radiation of frequency (or wavelength) that can be focused, dispersed, and detected using optical components such as lenses, mirrors, and gratings. This includes more than the narrow visible region; in general terminology the optical spectrum extends from 0.01 to 1000 μm (UV to FIR inclusive).

Optoelectronics.²⁰⁶⁹⁾ The term is a contraction of ‘optical electronics’ and refers to the photon effects (interaction/conversion, transmission) with a medium and vice versa. Optoelectronics is one of the foremost research fields affecting many areas of solid-state computer technology [microprocessors, data storage, communication (photon guidance between a source and a detector, optical fibers for signal transmission in optical communication, lasers), visual display methods using LEDs (Light Emitting Diode) and LCDs (Liquid Crystal Display)], energy detection and conversion [photon conversion into electrical energy (photodetection, photovoltaics), etc.]. Optoelectronics has also a wide field of applications in imaging sensor design.

Note: Often the terms electro-optical, electrooptical, and electrooptics are used with the identical meaning of optoelectronics. From a detection standpoint, the term optoelectronics seems to be more logical, because a detection sequence goes from the optics to the electronics.

Optoelectronic devices. Refer to systems in which the photon, the basic unit of light, is affected. There are four basic groups of optoelectronic devices:

- Photodetectors and solar cells - that convert photons into an electrical current
- Light-emitting diodes (LEDs) and semiconductor lasers - that convert an applied voltage into emitted photons
- Optical +s - that guide light between a light source and a detector
- Liquid-crystal displays - that use an applied voltage to change the reflection of light.

Optoelectronic detection (pushbroom scanner). The scanner uses a line detector to scan the cross-track direction of a scene, the total field of view is detected (imaged) simultaneously. The number of pixels is equal to the number of ground cells for a given swath. The motion of the platform (airborne or spaceborne) provides coverage in the along-track direction. When a 2-D line detector is used (several lines of detectors in the cross-track direction), then one dimension (cross-track) represents usually the spatial dimension, while the other is used for different spectral bands (multispectral imaging). Examples of pushbroom scanners are: HRV on SPOT series of CNES, LISS on the IRS satellite series of ISRO, AVNIR on the ADEOS S/C of NASDA, MSU on the RESURS series of Russia, ALI of the EO-1 satellite of NASA.

Optomechanical detection (whiskbroom scanner). A form of radiation detection, employing an oscillating or rotating mirror to a line-scanning whiskbroom scanner. On-axis optics or telescopes with scan mirrors sweep from one edge of the swath to the other. The FOV of the scanner can be detected by a single detector or an along-track line-detector. Typical examples of optomechanical scanners are: TM and ETM+ of the Landsat series, AVHRR on the NOAA/POES series, SeaWiFS on Orbview-2 (formerly named SeaStar), ASTER and MODIS of the Terra satellite.

²⁰⁶⁹⁾Special issue on Optoelectronics Technology, Proceedings of the IEEE, Vol. 85, No. 11, November 1997

Laser scanners (i.e. active lidar systems) utilize also **optomechanical scanner assemblies** just as many multispectral whiskbroom scanners. However, as active sensing systems, they are using a laser beam as a sensing carrier. Two optical beams must be considered, namely the emitted laser beam and the received portion of that beam.

Orbit types and terminology. See chapter O.12 on page 1265.

- LEO (Low Earth Orbit)
- MEO (Medium Earth Orbit)
- HEO (Highly Elliptical Orbit)
- GEO (Geostationary Orbit)
- Sun-synchronous orbit

Orographic phenomena. Meteorological events (precipitation, special winds, clouds, fronts, etc.) associated with the disposition and character of hills and mountain ranges (distribution effects the linked to the form of the terrestrial relief). Orographic precipitation results from the lifting of moist air over an orographic barrier; however, it is not limited to the ascending ground, but may extend for some distance windward of the base of the barrier. Orographic lifting refers to the deflection of an air current up and over mountains. Examples of orographic winds are: Föhn, Mistral, Bora, Santa Ana.

Orthographic projection. A projection in which the projecting lines are perpendicular to the plane of projection (also referred to as orthogonal projection).

Orthophotography. A digital orthophoto is a raster image, which has been accurately scanned and rectified with the aid of geodetic surveying and photogrammetry.

Orthorectification. (orthorectified imagery)

Ozone. A molecule made up of three atoms of oxygen (O_3). Ozone strongly absorbs UV radiation in the wavelength range of 290 - 300 nm. In the stratosphere, it occurs naturally and provides a protective layer (ozone layer between ~ 12 -30 km in which ozone is relatively concentrated $> 10^{12}$ molecules/cm³) shielding the Earth from ultraviolet radiation and subsequent harmful health effects on humans and the environment. In the troposphere, it is a chemical oxidant and major component of photochemical smog. Ozone is an effective greenhouse gas especially in the middle and upper troposphere and lower stratosphere. - The **depletion of ozone** in polar latitudes is attributed to a sequence of chemical reactions involving chlorine and bromine compounds. These sources are simple organic compounds containing chlorine, e.g. chlorofluorocarbons (CFCs), and/or bromine (e.g. halogens). Nearly all of the chlorine and about half of the bromine in the stratosphere originates from human activities.

Paleoclimatology.²⁰⁷⁰⁾ Science which deals with past climate periods of the Earth in very large space-time scales. Long-term baselines of past climate changes are studied and reconstructed to understand climate processes and predict future climate change (climate models). Paleoclimate data are derived from ice cores, tree rings, marine and lake sediments, fossil pollen, plant macrofossils, paleovegetation, past sea surface and lake level data, terrestrial ice sheet height and extent, land surface properties, etc.

Panchromatic channel. A channel of a sensor-detector system which covers the entire width of a spectral range, in particular the visible range (VIS).

Parallax. Apparent change in the position of an object due to an actual change in the point of view of observation. Example application: In optical stereo observation the parallax between two images, viewed from different angles, is used to derive the third dimension of altitude. This topographic information is used for map-making.

²⁰⁷⁰⁾ D. M. Anderson, R. S. Webb, J. T. Overpeck, B. A. Bauer, "The NOAA Paleoclimatology Program," NOAA Earth System Monitor, Vol. 3, No. 3, March 1993, pp. 6-8

Particle precipitation. Refers to the release of charged particles, stored in the Earth's magnetosphere, into the atmosphere. The particles follow magnetic field lines. They cause a glow (creating an aurora) when they strike the atoms of the upper atmosphere.

Passive sensor. A sensing system that detects or measures radiation emitted by the target. Such sensing systems do not emit any power to the target for purposes of measurement. Hence, passive sensors are sensitive to radiation of natural origin, usually reflected sunlight or energy emitted by an object. Examples of passive sensors are: cameras, multispectral scanners, and radiometers.

Peltier effect coolers. They work on the principle of the thermoelectric effect. Such coolers are thermodynamically reversible low impedance devices, operating at a high current from a DC power supply. A single stage cooler can typically achieve a temperature of -40°C , and lower temperatures can be achieved using several stages. A six stage device may achieve -100°C and give a cooling power of around 1 mW at -80°C . Peltier coolers are by their very nature vibration-free.

Perigee. The point in an orbit at which the spacecraft is nearest to the Earth.

Phase modulation (PM). Angle modulation in which the phase of a sine wave carrier is caused to depart from the carrier phase by an amount proportional to the instantaneous value of the modulating wave.

Phased-array technology. Phased arrays are random-access devices (antennas) employed for electronic beam-steering applications in the microwave and/or optical regions of the spectrum. The technology of electronic beam-steering overcomes many limitations of mechanical beam steering (in particular the motion of masses), offering such capabilities as very precise stabilization ($< \mu\text{rad}$), rapid random-access pointing over a wide field of regard (inertialess steering of beams), programmable multiple simultaneous beams, and other capabilities. In an active phased array system (such as a microwave antenna) individual transmit elements form and direct a beam into a particular direction (2-D steering). The field intensity across the aperture of an active microwave array is generally tapered at the edges to achieve low sidelobe levels. In some radar (SAR) applications the phased array concept is also referred to as **ScanSAR** with the capability to extend the regular swath width (see also **phased-array antenna** under **antenna**).

Photodetector. A semiconductor device that transforms radiation (light) into an electrical signal. There are two basic types of photodetectors: photodiodes and photoconductors.

Photodiode. Refers to a semiconductor diode which receives incident radiation thereby becoming a photodetector. Principle of operation: Photons (energy) incident on the photodiode (p-n junction) form electron-hole pairs in the detector material (silicon, for instance) when they are absorbed. Manipulation of the electron-hole pairs produce an output signal proportional to the amount of energy received. The time-varying signal represents the total amount of energy it receives. An important measure of how well the device converts photons to electrons is the **quantum efficiency (QE)**. - Silicon is virtually transparent to radiation in the IR range. However, in the UV and VNIR range ($0.2 - 1.1 \mu\text{m}$), radiation has enough energy (i.e. photon absorption can take place) to create electron-hole pairs.

Photoelectric cell (or photocell). A detector (transducer) which converts electromagnetic radiation from the UV, VNIR regions of the spectrum into electrical quantities such as voltage, current, or resistance.

Photogrammetry. A remote sensing application using image surveys (initially photographs) from airborne sensors and producing (topographic) maps from these images (along with position data). The ASPRS definition is: "Photogrammetry is the art, science and technology of obtaining reliable information about physical objects and the environment through processes of recording, measuring, and interpreting photographic images and patterns of

electromagnetic radiant energy and other phenomena.” 2071)

In the past, spaceborne imagery was not (or hardly) used for map making due to insufficient spatial resolution; this certainly changed with the availability of high-resolution imagery (<3m) starting from about 1998. Spatial imagery resolutions from satellites are classified as:

- Very low: for pixel sizes greater than or equal to 300 m
- Low: for pixel sizes between greater than or equal to 30 m and < 300 m
- Medium: for pixel sizes between greater than or equal to 3 m and <30 m
- High: for pixel sizes between greater than or equal to 0.5 m and <3 m
- Very high: for pixel sizes <0.5 m

Photomultiplier. A photoemissive detector in which amplification is obtained by secondary emission.

Photon. A particle description of electromagnetic radiation, which can exhibit the behavior of either waves or particles.

Photosphere. Refers to the layer surrounding the sun from which visible light is emitted into space.

Photosynthesis. The conversion of inorganic matter into organic matter by plants, using light as the energy source. Light energy absorbed by **chlorophyll** is used to manufacture carbohydrates (sugars) and oxygen from carbon dioxide (CO₂) and water. Photosynthesis is dependent upon favorable sunlight, temperatures, plant nutrients, and additionally, on soil moisture and carbon dioxide concentration for terrestrial plants. Increased atmospheric levels of carbon dioxide can increase photosynthesis in many land plants. Photosynthesis is responsible for the generation of all atmospheric oxygen. The photosynthetic generation of organic matter is also called ‘primary production.’

Photovoltaic effect, photoconductive effect. Refers to the direct conversion of radiation into electrical energy. The photovoltaic effect is achieved when a photon-produced electron-hole pair is separated by a space charge field (p-n junction diode) thus producing a photocurrent. Solar cells are photovoltaic devices. The photovoltaic effect was first reported by the French scientist Edmund Becquerel in 1839. He observed a voltage between two electrodes in a beaker of electrolyte when the beaker was exposed to sunlight. - The photoconductive effect occurs when a bias voltage is applied across a uniform piece of detector material. The photocurrent is then proportional to the density of electrons excited into the conduction band by the incoming photons.

Phytoplankton. The assemblage of microscopic algae (diatoms, flagellates, etc.) in aquatic ecosystems that drift passively with currents (plankton = wandering). The “grass” of the sea, upon which virtually all marine life depends (see also **chlorophyll**).

Pixel (Picture Element). The smallest area unit of an image which is generated by a single digital measurement (see also **image**). A pixel has a unique position within an image raster. Its numerical value is taken artificially from complete or partial resolution cells, sometimes also referred to as ‘image point.’

Pixel value. The digital radiation value of a pixel, expressed as a digital number (DN) or digital count (DC), radiance value, reflectance or other radiation value.

Planetary albedo. The fraction of incident solar radiation that is reflected by a planet and returned to space. The planetary albedo of the Earth-atmosphere system is approximately 30%, most of which is due to backscatter from clouds in the atmosphere.

Planetary Boundary Layer (PBL). Defined as the atmosphere between the Earth’s surface and the free atmosphere. It is directly affected by the properties of the Earth’s surface and

surface forcings, such as frictional drag, evapotranspiration, heat transfer, pollutant emission, and topography. See also **Atmospheric Boundary Layer**.

Plasma. A completely ionized gas (a low-density gas), the so-called fourth state of matter (besides solid, liquid, and gas) in which the temperature is too high for atoms as such to exist. A plasma is an electrically neutral gas consisting of charged particles such as ions, electrons, and neutrals. While the temperature of a plasma is very high, its density is very low.

Plasmoid. Bubble of plasma. Refers to the merging of magnetic lines in the magnetotail which is thought to produce a bubble of plasma, called a plasmoid that flows down the tail during active solar periods.

Polarimetry.²⁰⁷² Polarimetry deals with the vector nature of polarized electromagnetic radiation throughout the frequency spectrum. The electromagnetic field is a traveling wave (at the velocity of light) with electric and magnetic vector fields perpendicular to each other and to the direction of wave travel. A change in the index of refraction (or permittivity, magnetic permeability, and conductivity) causes the polarization state of a single frequency wave to be transformed, i.e. to be repolarized. Hence, a reflected (scattered) polarized wave from an object such as a radar target must contain some innate information about the object. The interpretation of the behavior of these complex signatures (in particular the direction of the electric field vector of the reflected polarized radiation) is in effect a major objective in polarimetry. In remote sensing polarization measurements are mostly performed in the microwave region of the spectrum. The incorporation of coherent polarimetric phase and amplitude into radar signal and image processing is indeed very promising.

Polarization. Defines the spatial orientation or alignment of the electric (and magnetic) fields of an electromagnetic wave (radiated by an antenna). Horizontal (H) / vertical (V) polarization refers to the electric field (magnetic field) vector's being parallel / normal to the surface of the medium that the wave is incident upon.

- Like polarization: HH or VV (one component for the transmit and one for the receive signal, as is the case for **active sensors**)
- Cross polarization: HV or VH. Cross polarization requires multiple scattering by the target and therefore results in weaker backscatter than like polarization.
- Alternating dual polarization: alternate transmit and/or receive polarization so that two polarization combinations are measured - e.g. HH and HV or HH and VV.

Polarization is established by the antenna, which may be adjusted to be different on transmit and on receive. Reflectivity of microwaves from an object depends on the relationship between the polarization state and the geometric structure of the object. Possible states of polarization in addition to vertical and horizontal include all angular orientations of the E vector, and time varying orientations leading to elliptical and circular polarizations.

Polarization knowledge offers an additional capability in detecting object characteristics and in discriminating between them, especially in the microwave region of the electromagnetic spectrum (for passive and active sensors). See also **Radar polarimeter**.

Although VV, HH, VH, HV are common terms in "polarimetric radar," the generally accepted terms differ in **polarimetric radiometry**. Here, the four scalar brightness temperatures are used that make up the complete (modified) Stokes' vector: $T_v = |E_v|^2$, $T_h = |E_h|^2$, $T_u = 2\text{Re}(T_v T_h^*)$, and $T_v = 2\text{Im}(T_v T_h^*)$.²⁰⁷³ The modified Stokes vector is related to the (unmodified) Stokes vector as follows: $T_1 = (T_v + T_h)/2$, $T_2 = (T_v - T_h)/2$. Some authors use T_3 and T_4 in place of T_u and T_v to eliminate confusion between the vertical (v) and fourth Stokes parameter (V) indices.

²⁰⁷³) Courtesy of Al Gasiewski of NOAA/ETL in Boulder, CO

Polar vortex. Refers to the swirling mass of air that appears each year over the Earth's poles.

Polynya. Polynyas (like leads) are openings in polar region sea ice, they range in size from a few hundred meters to hundreds of kilometers. Polynyas may be formed by two mechanisms: a) forming ice may be continually removed by winds or currents (an example is a shore polynya with offshore winds), b) oceanic heat may enter the region in sufficient quantity to prevent local ice formation.

Precision. The precision of a measurement is a measure of the reproducibility or consistency of measurements made with the same sensor. (The effect of random errors can be reduced by repeated measurement or by averaging, which increases the precision of a measurement).

Preprocessing. Commonly used to describe the correction and processing of sensor data prior to information extraction. For imaging data preprocessing includes geometric and radiometric correction, mosaicking, resampling, reformatting, etc.

Primary productivity. The rate of carbon fixation by marine photosynthetic organisms (phytoplankton). Primary productivity results in the reduction of dissolved inorganic carbon to form organic carbon, with concomitant release of oxygen.

Pseudolites. Refer to auxiliary ground-based transmitters that broadcast GPS-like signals to supplement those generated by the satellites. The transmitters were initially called "pseudo-satellites," which was abbreviated to "pseudolites." System developers used pseudolites as direct replacement for satellites that had not yet been launched, to facilitate system tests. A pseudolite transmits a signal with code-phase, carrier-phase, and data components with the same timing as the satellite signals. A GPS receiver acquires this signal and derives its measurements to be used in a navigation algorithm. Applications are particularly useful for equipment (receiver) tests for such functions as fault detection and isolation, for pseudorange correction (identical to DGPS), and many other practical solutions.^{2074) 2075)}

Pseudorandom Noise (PRN). Refers to deterministic binary sequences which are used in spread spectrum communication systems and in ranging systems such as GPS and GLO-NASS. Two PRN codes are continuously broadcast by GPS satellites: the C/A code and the P-code, both codes modulate the navigation signals. The modulation appears to be random but is, in fact, predictable; hence the term 'pseudorandom'. The PRN technique allows the use of a single frequency by all GPS satellites and also permits a broadcast of a low-power signal. [Note: The PRN technology was first employed in the 1950s by radio astronomers. With them researchers were able to measure the time delay in the weak radar reflections from the surface of a distant planet - by finding the instant, when the received signals and the transmitted PRN sequences seemed to match most closely.]²⁰⁷⁶⁾

Pseudorange. Refers to the range between the antenna phase centers of a GPS satellite and a receiver, measured by the receiver's delay-lock loop using the C/A-code or P-code. The range is biased by the offset of the clock in the receiver from that in the satellite and by atmospheric propagation delays.

Pulse Code Modulation (PCM). Any modulation that involves a code made up of pulses to represent binary information. This is a generic term; additional specification is required for describing particular cases.

Quantization. The process of converting continuous values of information to a finite number of discrete values. A 10 bit quantization means that the measured signal can be represented by a total of 1024 digital values, say from 0 to 1023.

2076) T. A. Herring, "The Global Positioning System," Scientific American, Feb. 1996, pp. 32-38

Quantum efficiency (QE). A measure of the efficiency with which incident photons are detected (such as a photodiode). Some incident photons may not be absorbed due to reflection or may be absorbed where the electrons cannot be collected. The QE is the ratio of the number of detected electrons divided by the product of the number of incident photons times the number of electrons each photon can be expected to generate. Visible wavelength photons generate one electron-hole pair. More energetic photons generate one electron-hole pair per each 3.65 eV of energy.

Radar (Radio Detection and Ranging). A method, a system, or a technique for using beam, reflected, and timed electromagnetic radiation to detect, locate, and track objects, to measure distance (range), and to acquire terrain imagery (see also chapter O.8.2). The term 'radar' in remote sensing terminology refers to active microwave systems (from about 1 GHz - 100 GHz; most current instruments operate below 10 GHz). The terms 'Doppler delay' (range), 'Doppler gradient' (range rate), and 'Doppler frequency analysis' are important parameters in the formulation of the range-Doppler radar imaging principles. The motion of the sensor-bearing vehicle provides the relative motion between sensor and target required to perform imaging.

Radar systems may be classified by the signal measurement technique employed - there is the pulsed radar class and the FM/CW (Frequency Modulation/Continuous-Wave) radar class. The pulsed radar is the most widely used type of radar systems. It is so called because the transmitter sends out pulses of microwave energy with relatively long intervals between pulses. The receiver picks up the echoes of the returned signals; the elapsed time (or run time) is a measure of the distance travelled.

FM/CW radar transmits continuous microwave energy - the resultant continuous echo cannot be associated with a specific part of the transmitted signal (hence, range information cannot be obtained). However, the system can determine the speed of a target by measuring the Doppler shift (change in frequency). A more sophisticated continuous-wave instrument, known as 'frequency-modulated radar,' is also able to measure range. This is done by tagging each part of the transmitted microwave signal (by continuously changing the frequency), rendering it recognizable upon reception. With the rate of frequency change known, the difference in frequency can be interpreted as a range measurement.

Radar instruments consist of the following major elements: RF electronics, antenna, digital electronics, and recorder. Radar instruments are built for a specific transmission frequency in the microwave spectrum, such as P-band, L-band, S-band, C-band, X-band, Ka-band, etc.; some very advanced instruments offer observation in multiple frequencies.

- **RAR (Real-Aperture Radar).** The term RAR is used because the along-track resolution of a surface image is determined by the actual length of the antenna aperture. In general, the larger the aperture of the antenna (in terms of wavelengths), the narrower will be the beam (along-track resolution is given by the width of the antenna sweep; across-track resolution is determined by the range-resolving capability of the instrument). RAR systems are usually much simpler than SAR systems in design and data processing. RAR-pulsed signals, based on the range-Doppler principle, are not required to be coherent (only the signal amplitude information is recovered and processed), representing and displaying backscatter characteristics from the surface sweep that are recorded on film or on magnetic tape. Microwave energy reflected from the surface terrain (target) is converted by the RAR instrument into electrical signals and recorded as a function of distance (along-track and across-track direction). The radar returns from the different positions in the sweep (and at the different ranges) are separated in time by the radar receiver (the across-track range measurement is a function of signal return time). After reception and recording of the previous pulse, a new pulse is transmitted for a new radar sweep.- The density of the image varies with the surface properties (roughness, moisture content, etc.). The image can be interpreted in terms of the topographical features of the terrain.

- **SAR** (Synthetic Aperture Radar), see also O.8.2. This radar type permits high-resolution imagery at long ranges (a SLAR device from a satellite orbit is of limited use due to the poor resolution obtained by the angular geometry constraints of the radar beam). A SAR instrument is also referred to as a ‘coherent SLAR.’ - SAR is a concept for complex signal processing techniques to recover an image by the coherent processing of all return signals of all targets (cells) in a single sweep. The cross-track Doppler range of all targets is determined by the signal return time. The pulse bandwidth determines the cross-track or range resolution. Coherence²⁰⁷⁷⁾ in this SAR context refers to the fact that the phase as well as amplitude information of the **radar cross section** is measured for all recovered signals. The SAR technique provides resolutions that would normally be associated with an antenna with an aperture far wider than that actually used. - A disadvantage of the SAR observation/processing technique is the generation of very high data rates (between 20 and 100 Mbit/s and more); this implies high communication rates and large storage volumes. On-board recorders are strained to their very limits to handle SAR data. First attempts are being made at real-time on-board preprocessing for the purpose of data reduction. The main elements of a SAR instrument are:
 - RF electronics. The RF portion of a SAR system consists of signal generators, high power transmitters (single or combined), low noise receivers, and the associated signal conditioning elements: amplification, filtering, and frequency conversion. Important RF characteristics to a SAR instrument are: large dynamic range with good linearity and low noise floor, good amplitude and phase stability over time and temperature, and high power efficiency.
 - SAR antenna. For an Earth observation SAR, the preferred antenna beam casts an elliptical footprint on the ground with an effective rectangular aperture of typical size 10 meters (along-track) and 3 meters (cross-track). Multi-polarization requires dual polarization antennas with good cross-pol isolation. Practically all SAR antenna designs feature a solid flat aperture (antenna and support structure are a dominant mass and volume factor of a SAR instrument).
 - Digital electronics. The main functions provided by the digital electronics in SAR are: radar configuration and timing control, radar signal digitization and formatting, radar housekeeping telemetry generation. Sometimes digital processing is performed to reduce the data, and the often coded radar illumination pulse is generated digitally.

Imaging radars (SAR instruments) operate at a specific wavelength or frequency in the microwave region. [This is different from optical instruments which observe radiation in a spectral band (a region of frequencies) or in many spectral bands]. A radar system records the signal response from the ground target at a single specific wavelength (e.g. 15 cm).

Background: The microwave region of the electromagnetic spectrum is generally considered from 1 mm to 1m wavelengths. In analogy to the optical band designations (red, green blue), the microwave spectrum was also given band designations in form of letter references. The military introduced these letter designations in the early days of radar research (mostly for reasons of security during World War II). The remote sensing community seems to adhere to these old “standards” as a means of “ball park reference” designation. Hence, the microwave region includes today such band designations as P, L, S, C, X, K, Ka, etc., for radar (SAR) instruments.

Naturally, the rule of specific wavelength (for frequency) operation of a SAR instrument is not affected by this scheme of letter band designations. Newer SAR instruments operating at multiple frequencies are actually an agglomeration of single-frequency instruments.

²⁰⁷⁷⁾ Note: As coherent pulses transmitted from the radar source reflect from the ground (target) to the advancing SAR instrument (on an aircraft or a spacecraft), the target acts as though in apparent (relative) motion. This motion results in changing frequencies which give rise to variations in phase and amplitude in the returned signals. - Offline processing of these data involves the analysis of the moderated pulses.

- **IFSAR** (Interferometric SAR) - see **Interferometric measurements**
- **SLAR** (Side-Looking Airborne Radar) - an active sensor with RAR technology.
- **Radar altimeter.** An active device observing the vertical distance between the instrument and the ground by measuring the elapsed time between the emitted and returned signals of electromagnetic pulses. Determination (mapping) of the height profile of the surface (topographic applications, in particular of ocean height surfaces).
- **Scatterometer.** A scatterometer is a nonimaging radar, distinguished from other radars by its ability to measure radiation amplitude. A radar scatterometer is an active device measuring the backscattering coefficient of the illuminated cell (area or volume under observation) at a specified configuration of incidence angles, wavelengths, and wave polarization orientations. The backscattering (or scattering) coefficient σ^0 describes the target backscattering characteristics (it is defined as the intensity of the power scattered by a 1 m² area of a target back toward the radar, relative to the incident power density) and varies as a function of surface roughness, moisture content, and dielectric properties. A rough ocean surface returns a weak pulse because sea surface waves scatter the energy of the microwave pulse in different directions. The scattering reduces the amount of energy which is received back at the satellite. On the other hand, a smooth ocean surface returns a strong pulse because there is very little wave effect. The surface roughness is related to the wind speed. High wind speeds disturb the smooth ocean surface and produce many waves of several cm in size while low wind speeds do not disturb the ocean surface as much and produce much smaller waves. In addition to windspeed, scatterometers (and SARs) measure the direction that waves are moving in relation to the satellite. The direction that the waves are oriented with respect to the radar pulse has an effect on the polarization of the returned signal. - Application: the surface backscattering coefficient may be used to derive the surface wind vector (in particular over oceans). See also **sigma naught**.
- **Lidar** (Light Detection and Ranging), see O.8.5. A lidar instrument is also referred to as an 'optical radar' [or a 'laser radar' - it also goes by the name of 'ladar' (laser detection and ranging)] since it utilizes the optical (and TIR) portion of the electromagnetic spectrum (0.3 - 10 μ m wavelength range, or a frequency range of about 1000 - 30 THz). A very narrow beam (pulse) of laser light is emitted, the echo is analyzed. Lidar beam divergence is two to three orders of magnitude smaller compared to conventional 5 to 10 cm wavelength radars. This characteristic permits unambiguous velocity measurements near clouds and surface features.
- **Radar polarimeter.**²⁰⁷⁸ This radar instrument type measures the complex (amplitude and phase) scattering matrix (i.e. the full polarization signature: VV, HH, VH and HV for transmit and receive signals) for every resolution element in an image. Radar polarimetry is therefore an extension of scatterometry, in which the received power of an echo is typically measured for one or more fixed polarization states and a single, or two orthogonal, transmit states. - Knowing the full scattering matrix permits calculation of the receive power for any possible combination of transmit and receive antennas; this process is called polarization synthesis. Hence, the information content derived from a polarimetric radar instrument is far superior to the information yielded by nonpolarimetric devices. Typical airborne polarimetric radar instruments are: ARMAR, CASAR, C/X-SAR, DO-SAR, EMISAR, HUTSCAT, MMW-SAR, NUSCAT, P-3/SAR, IMARC, RAMSES, PHARUS, etc. (see Table 8); a typical spaceborne polarimetric radar instrument is the L/C- Band SAR (JPL) of the SIR-C payload.
- Note: Conventional imaging radars operate with a single, fixed-polarization antenna for both transmission and reception of radio frequency signals. In this way a single scat-

²⁰⁷⁸) H. A. Zebker, J. J. van Zyl, "Imaging Radar Polarimetry: A Review," Proceedings of the IEEE, Vol. 79, Nr. 11, November 1991, pp. 1583-1606

tering coefficient is measured for a specific transmit and receive polarization combination for many thousands of points in a scene. A result is that only one component of the scattered wave, itself a vector quantity, is measured, resulting in a scalar characterization of the wave, and any additional information about the surface or volume contained in the polarization properties of the reflected signal is lost.

Radar albedo. Ratio of a target's radar cross-section in a specified polarization to its projected area; hence, a measure of the target's reflectivity.

Radar backscatter. Refers to the radar echo; a scattering process of microwave energy by an object/target in the direction of the radar antenna, after actively being irradiated by the radar source.

Radar cross section. A hypothetical area of an object of such an extent that if the power intercepted by this area were distributed isotropically over the space, it would render the same power density at the receiving antenna as the power density brought about in reality by the presence of the object or target. Usually, the radar cross-section concerning compound objects (distributed targets) is normalized: either as a radar cross section per unit area (differential scattering cross section or backscatter coefficient σ^0), or as a radar cross section per unit of area projected in the direction of transmission (gamma or scattering cross section).²⁰⁷⁹⁾

Radar meteorology. A discipline that uses backscattered electromagnetic radiation within the microwave band to gain information about the state of the atmosphere, especially with respect to clouds and precipitation. The return signal allows the interpretation of four fundamental properties of the spectrum: amplitude, phase, frequency, and polarization.

Radian. The size of angles in classical mechanics is expressed in radians. The concept of radians permits a simple mathematical relationship between the length L of the arc of a circle (i.e. a segment of the circumference) and the angle subtended (enclosed) at the axis by the arc. The arc length L is given by: $L = R \theta$. This means that when the length of the arc is equal to the radius ($L = R$), then θ is one radian (or the angle at the center of the circle subtended by an arc equal to the radius is one radian). In one revolution the arc length is equal to the circumference, so that $L = 2\pi R$, or $\theta = 2\pi$ radians, or 1 radian = $2\pi/360^\circ \approx 57.28^\circ$. Example: for $R = 1000$ m and $\theta = 0.2$ radians (FOV), then $L = 200$ m (in case of a sensor, the swath width).

Angular size with no distance information is usually the only information available in observational astronomy. Some sample angular sizes are:

- The full moon subtends 30 arcminutes
- The Andromeda galaxy subtends about five degrees

Radiance. Energy per unit area and solid angle. Measure of energy radiated by an object. In general, radiance is a function of viewing angle and spectral wavelength.

Radiation laws.

- **Planck's law** (Max Planck, 1858-1947). $E_{b\lambda} = 2 h c^2 \lambda^{-5} / [e^{(hc/\lambda kT)} - 1]$, where $E_{b\lambda}$ = monochromatic emissive power (or spectral radiance, or brightness) per unit wavelength interval, λ = wavelength, T = absolute temperature, h = Planck's constant, k = Boltzmann's constant, and c = speed of light.

In words, Planck's law states that the temperature of a blackbody is related to the

²⁰⁷⁹⁾ H. J. Buiten, J. Clevers, "Land Observation By Remote Sensing," Gordon and Breach Science Publishers, ISBN 2-88124-936-6, 1993, p. 608

emitted radiance as a function of the wavelength (or of the frequency). Planck's equation is plotted in Figure 422 for several temperatures.

Note: The term 'spectral radiance' is commonly used for remote sensing instruments operating at optical wavelengths, while the term 'brightness' is mainly used for the microwave region of the spectrum. Then Planck's law is expressed in units of power density per frequency bandwidth (Hz^{-1}) rather than per unit wavelength interval (m^{-1}). Spectral brightness B_f is related to spectral radiance $E_{b\lambda}$ by: $B_f = E_{b\lambda} |d\lambda/df|$, which results in: $B_f = 2 h f^3 c^{-2} / [e^{(hf/kT)} - 1]$.

In the microwave region ($f < 300 \text{ GHz}$), the term $hf/kT \ll 1$ for the range of physical temperatures commonly encountered in the Earth's surface and atmosphere. Consequently, the spectral brightness equation above reduces to a simpler form: $B_f = 2kT/\lambda^2$ which is known as the Rayleigh-Jeans law, a special case of Planck's blackbody radiation law (see also **brightness temperature**).

Figure 422: Hemispherical radiation emitted by objects at typical temperatures

- **Wien's displacement law** (Wilhelm Wien, 1864-1928). A law indicating that the wavelength at which the emitted amount of energy by a blackbody is maximal is inversely proportional to the absolute temperature of that body.
- **Kirchhoff's law** (Gustav Robert Kirchhoff, 1824-1887). A law stating that under conditions of thermal equilibrium, the absorption spectrum of an arbitrary body must be equal to its emission spectrum. Kirchhoff's identity: ϵ (emissivity) = α (absorptivity).
- **Lambert's law** (Johann Heinrich Lambert, 1728-1777). A law stating that the radiant intensity (flux per unit solid angle) emitted in any direction from a unit radiating sur-

face varies as the cosine of the angle between the normal to the surface and the direction of radiation. The radiance of a radiating surface is therefore independent of direction. This law is also satisfied (by definition) by the distribution of radiation from a perfectly diffuse radiator.

Radiation hardening. Exposed satellite and instrument components, such as detectors, are constantly subjected to space irradiation effects. In particular, long-term exposure may cause radiation damage to electronic components by altering the properties of a material arising from exposure to ionizing radiation (penetrating radiation), such as X-rays, gamma rays, neutrons, or heavy-particle radiation. With proper hardening processes applied, the components may be turned into radiation-tolerant products.

Radio beacon. A type of radio transmitter with wide-angle coverage. It may emit signals continuously or, like the transponder, may respond to input energy before operating. Beacons are used primarily in navigation and radio-detection finding. In meteorology a beacon is used in rawinsonde observations.

Radiodetermination. Refers to the determination of position, velocity and/or other characteristics of an object, or to obtaining information relating to these parameters, by means of the propagation properties of radio waves. The radiodetermination service has two parts to it: the **radionavigation service** and the **radiolocation service** (see also Figure 412).

- 1) **Radionavigation Systems.** Radionavigation is used for the purpose of navigation (aeronautical, maritime, land, and space), including obstruction warning.
 - LORAN-C (Long Range Navigation) operates on 100 kHz; it is used in maritime and aeronautical applications (see **LORAN**)
 - Omega is a worldwide CW system; it is used for maritime and aeronautical navigation. System operation in the VLF band (9-14 kHz) on four discrete frequencies. (see **OMEGA**)
 - VOR/DME (VHF Omnidirectional Range/Distance Measuring Equipment). VOR operates in the 108-118 MHz band, providing azimuth readings to aircraft. DME is collocated with VOR providing distance; it operates in the 960-1215 MHz band.
 - TACAN (Tactical Air Navigation) is the US military version of DME. It operates in the 960-1215 MHz band.
 - ILS (Instrument Landing System) for precision navigation. ILS consists of a localizer operating in the 108-112 MHz band and a glidescope operating in the 328.6-335.4 MHz band.
 - MLS (Microwave Landing System), operating in the 5000-5150 MHz range with associated DME in the 960-1215 MHz range. MLS was initially considered a successor to ILS. It probably may be succeeded by GPS systems.
 - GPS (Global Positioning System), a US satellite-based system operating in the 1215-1240 MHz and 1559-1610 MHz bands. GPS was officially integrated into the US National Airspace System on February 17, 1994. In the future, GPS is expected to replace such systems as Omega, LORAN-C, and perhaps VOR/DME.
 - GLONASS (Global Orbiting and Navigation Satellite System), a Russian satellite-based system operating in the 1215-1260 and 1559-1626.5 MHz bands. By the year 2005 the second bandwidth of GLONASS is expected to be the same as that of GPS. There is a major trend towards increased use of the GPS and GLONASS satellite-based system for many navigation applications.
 - etc.
- 2) **Radiolocation Systems:** The service is used by pulsed and CW radar systems for a number of applications, such as determining precise location, search or surveillance, target tracking, weapons control, ground mapping and target identification, or combinations

of these applications. The military is by far the largest user of this service, but there are also a number civil users (NASA, NOAA, CNES, CRC, Russia, etc.²⁰⁸⁰)

- S&RSAT (Search & Rescue Satellite, CNES/CRC) flown on NOAA-POES satellites. The S&R instruments consist of a 3-band (121.5, 243, and 406.05 MHz) repeater S&RR and a 406.025 MHz processor. The system may receive three types of radiobeacons, namely aviation ELTs (Emergency Locator Transmitter), maritime EPIRBs (Emergency Position Indicating Radio Beacon), and PLBs (Personal Locator Beacon). S&RSAT was declared operational in 1985. The COSPAS-SARSAT agreement was signed in 1988.²⁰⁸¹)
- COSPAS (Space System for Search of Vessels in Distress, Russian system). The system is flown on Cospas series satellites (named Nadezda) and administered by Russia, US, France, and Canada. Distress alert and location data to RCCs (Rescue Coordination Centers) for 121.5 MHz beacons within the area of COSPAS-S&RSAT ground stations (Local User Terminals - LUTs), and for 406 MHz beacons activated anywhere in the world.
- IVHS (Intelligent Vehicle Highway Systems) or ITS (Intelligent Transport Systems)
- etc.²⁰⁸²)

Radiometer. An instrument for the quantitative measurement of the intensity of electromagnetic radiation in some band of wavelengths in the spectrum. Usually a radiometer is characterized with a prefix, such as IR-radiometer, or microwave-radiometer, to indicate the spectrum to be measured.

Radiometer (absolute radiometer). An instrument based on the measurement of a heat flux by an electrically calibrated transducer. Optical radiation absorbed in a black cavity is substituted by electrical heating during a shaded reference phase. For practical use of the instrument, an electronic circuit keeps the heat flux constant by controlling the power fed to a cavity heater (this is also referred to as substitution radiometry - directly relating the optical watt to the electrical watt). Absolute radiometers are used to measure the Solar Constant or TSI (Total Solar Irradiance).

Note: electrical substitution radiometry at cryogenic temperatures is also the basis of detector calibrations in which a detector's response to optical flux is measured as a function of wavelength.

Radiometric resolution. See **resolution**.

Radiosonde. A balloon-borne instrument which measures (by means of transducers) and transmits meteorological data (temperature, pressure, humidity). Various types of transmission schemes exist.

- **Rawinsonde** (Radio-Wind-Sonde). A balloon-borne instrument tracked by radar or radio direction-finder and operating on the same principle as a radiosonde, but with the additional capability to measure wind speed and direction.
- **Dropsonde.** A radiosonde or a rawinsonde dropped by parachute from an aircraft for the purpose of obtaining soundings of the atmosphere below. The radio signals of the dropsonde/rawinsonde are tracked for data evaluation.

Radio occultation principle. Fundamentally, the technique relies on the simple fact that a planet's atmosphere acts much like a spherical lens, bending and slowing propagation of microwave signals passing through it tangent to the surface. The lens effect results from decreasing atmospheric density with altitude. If the positions of transmitting and receiving satellites are precisely known, then the atmospheric delay can be measured precisely, the

²⁰⁸⁰) US Spectrum Requirements, URL: http://www.ntia.doc.gov/openness/sp_rqmnts/radar4.html

²⁰⁸¹) NOAA S&RSAT homepage, <http://psbsgil.nesdis.noaa.gov:8080/SARSAT/homepage.html>

²⁰⁸²) COSPAS-S&RSAT homepage, <http://www.worldserver.pipex.com/cospas-sarsat/>

time derivative of which (Doppler) can be inverted to give atmospheric density versus altitude. See also **Limb/Occultation sounding** and **Occultation**. - Note: The radio occultation technique was first developed (in the 1970s) at Stanford University Center for Radar Astronomy and at NASA/JPL for the study of solar system planetary atmospheres (Venus, Mars, Jupiter, Saturn, Uranus and Neptune).

Raman spectroscopy.²⁰⁸³⁾ A technique to investigate molecular properties using scattered light resulting from photon-molecule collisions. When a monochromatic light beam is incident on systems such as transparent gases, liquids, or solids, most of it is transmitted without change. However, a very small portion of the incident light is scattered. Although most of the scattered light has the same wavelength as the incident radiation, a small part of it has different wavelengths. The scattering of light at different wavelengths is called **Raman scattering** (Indian scientist Sir C. V. Raman, who, with K. S. Krishnan, first reported the phenomenon in 1928). The physical origin of Raman scattering lies in inelastic collisions between the molecules composing the system (e.g. the liquid) and photons, the particles composing the light beam. 'Inelastic collision' means that there is an exchange of energy between the photon molecule with a consequent change in energy, and hence wavelength, of the photon.

Range. The distance between two objects, usually between an observation point and a target (object under observation). Slant range: same as range - the line-of-sight distance between two objects.

Range direction. Observation of an instrument in the cross-track direction (normal to the subsatellite track). See also **azimuth direction**.

Range error. The (small) error in radar range measurement caused by the propagation of radio energy through a nonhomogeneous atmosphere. This error is due to the fact that the velocity of radio-wave propagation varies with the index of refraction, and that ray travel is not in straight lines through actual atmospheres (see also **Atmospheric refraction**).

Range resolution. Resolution characteristic of the range dimension, usually applied to the image domain, either in the slant range plane or in the ground range plane. Range resolution is fundamentally defined by the system bandwidth in the range channel. See also **SAR**.

Raster image. Refers to a matrix of row and column data points. Each data point is a pixel.

Rayleigh criterion. It states that the resolution of a system is directly proportional to the wavelength. Thus, with perfect optics, an imaging system working at 50 nm (EUV wavelengths) would have an order of magnitude better resolution than one working with visible light (about 500 nm wavelength).

Rayleigh scattering. Scattering by particles small in size compared with the wavelengths being scattered (e.g., the blue color of the sky and ocean is caused by Rayleigh scattering of the air and water molecules respectively). Rayleigh scattering is also caused by density fluctuations in atmospheric gases (it increases toward the shorter wavelengths proportional to λ^{-4} where λ is the wavelength). In a sensor energy balance, Rayleigh scattering adds to the radiation received by a sensor; this is most pronounced at shorter wavelengths.

Reaction/momentum wheels. These are actuators (fly wheels) which may be used for three-axis reaction control or momentum bias applications. By adding or removing energy from the flywheel, torque is applied to a single axis of the S/C, causing it to rotate (reaction). By maintaining flywheel rotation (momentum), a single axis of the spacecraft is stabilized. Such an assembly provides a reliable source of reaction torque and angular momentum storage for attitude control of medium to large spacecraft. Accelerating or decelerating a flywheel with an integral motor provides a means of controlled momentum exchange with the spacecraft platforms, which is advantageous for a variety of attitude control schemes.

²⁰⁸³⁾ Encyclopedia of Physical Science and Technology, Academic Press, 1987

Real-Time Kinematic (RTK). Refers to a DGPS process where carrier-phase corrections are transmitted in real-time from a reference receiver at a known location to one or more remote “rover” receivers. RTK has become a preferred method for surveying applications since it provides real-time positions with high accuracy.

Reflectance. Refers to the fraction of the total radiant flux incident upon a surface that is reflected and varies according to the wavelength distribution of the incident radiation.

Reflection. The scattering of electromagnetic radiation by an object. Diffuse reflection causes the radiance of the reflected radiation to be equal in all directions (e.g. reflection from a rough surface). Specular reflection has a direction of preference (e.g. the reflection of a smooth surface). The use of the terms ‘smooth’ and ‘rough’ is independent of wavelength.

Reflectivity. A property of illuminated objects to reradiate a portion of the incident energy. For SARs, backscatter is the observable portion of the energy reflected. Backscatter, in general, is increased by greater surface roughness.

Refraction. A process by which the direction of energy propagation is changed due to a change in density within the propagating medium (smooth bending), or due to a discontinuity between two media (abrupt bending). - Atmospheric optical phenomena are produced by continuous and discontinuous refraction: scintillation, mirages, astronomical refraction, anomalous propagation of radio waves and the bending of sound waves are examples of refraction within a single medium.

Refractive index (in a medium). The inverse ratio of the wavelength (or velocity) of electromagnetic radiation in the medium to that in vacuum. A measure of the amount of refraction (a property of the dielectric constant). See also **Atmospheric refraction** and **Occultation**.

Registration. Geometric rearrangement of the pixels in an image for image matching by superposition - often to the reference geometry of a map (geocoding). Image registration is the process of matching (overlying) two or more images so that corresponding coordinate points in the images correspond to the same physical region of the scene being imaged. The technique is used for a number of applications.²⁰⁸⁴⁾

- Integration of information taken from different sensors (sensor or image fusion)
- Analysis of changes in images taken at different times (temporal registration and change detection).

In a wider sense image registration tries to combine image data with different spatial, spectral and radiometric characteristics to improve the information extraction process from available imagery. Typical registration processing steps are: feature identification, feature matching, spatial transformation, and interpolation.

Relative aperture. For a photographic or telescopic lens system, the ratio of the equivalent focal length to the diameter of the entrance slit. It is expressed as $f/45$ or $f/5.6$, and is also called the ‘f-number,’ speed of lens, or the ‘focal ratio.’

Renewable energy. Refers to energy technologies that generate electricity, fuels, and/or heat through the use of resources which are continually replenished, such as sunlight (photovoltaic), heat from the sun (solar thermal), wind, naturally occurring underground steam and heat (geothermal), plant and animal waste (biomass), and water (hydropower).

Repeat period (or cycle). Time interval between successive satellite observations of the same area of the Earth’s surface.

Resampling. The rearrangement of the resolution cells of each scanned line of an image into geometrically equal terrain elements (geometric rearrangement) by creating artificial

²⁰⁸⁴⁾L. M. G. Fonseca, B. S. Manjunath, “Registration Techniques for Multisensor Remotely Sensed Imagery,” PE&RS, Vol. LXII, No. 9, Sept. 1996, pp. 1049-1056

pixels whose spectral radiation data are computed from the original values proportional to the area coverage by the new pixels with respect to the resolution cells. In general a resampling process follows after a geometric rearrangement (registration) of the pixels because of the matching of two different images of the same region by means of a mathematical transformation. The resampling then involves the assignment of artificial pixel values to the newly formed pixels according to the selected sampling algorithm.

Resolution. A term defining the smallest discernable physical unit of an observed signal by a sensor.

- Spatial or geometric resolution defines the minimum (spatial) separation between two measurements in order for a sensor to be able to discriminate between them. Spatial resolution defines the size of an image resolution cell in the target area, or the size of pixels. The spatial resolving power is determined by the aperture dimensions of a lens or the antenna of a sensor. - Some spatial connotations are: GSD, IFOV, FOV, look angle of the sensor, shape and size of the object, position, site, distribution, texture.
- Spectral resolution refers to the resolving power of a system in terms of wavelength (or wavenumber) or frequency.
- Radiometric resolution refers to the resolving power of a system in terms of the signal energy [detection of energy differences (reflection and emission) in terms of temperature, intensity and power]. The radiometric resolution is the Noise Equivalent Delta Radiance (NE Δ R), or the Noise Equivalent Delta Temperature (NE Δ T), depending on the spectral measurement range. This can be defined as the minimum change in reflectance (or temperature) that can be detected by a sensor. The value depends on a number of parameters, such as SNR, the saturation radiance setting, and the number of quantization bits. The important parameter of an instrument is the SNR. The resolution capability of an instrument in terms of quantization does not necessarily give an idea of its precision or accuracy with which it can measure. Nevertheless, a higher number of bits increases the dynamic range of the instrument, permitting the measurement of very variable targets, without a gain change. See also **Full Width Half Maximum**.
- Temporal resolution concerns the time lapse between two successive images of the same area (by the same spaceborne sensor, at the next revisit time).

Rheology. A science dealing with the deformation and flow of matter.

S/A (Signal-to-Ambiguity ratio). In SAR instruments the ratio of the receiving power of the signal scattered and reflected from the observed (target) area to the power leaking into the observation area from the non-observed area.

SAR (Synthetic Aperture Radar), see SAR under **Radar**.

Satellite surface charging. All bodies which are placed in a plasma in thermal equilibrium acquire a negative electrostatic charge. The negative potential depends on the plasma temperature. At altitudes of 300 to 500 km, the average kinetic energy of the plasma is low (< 1 eV), hence, satellites become only weakly charged. At high altitudes (geostationary orbit and further out) the kinetic energy of the plasma is considerably larger (the plasma is referred to as 'hot'), hence, satellites acquire a high potential with respect to it (in the order of several keV). The electrostatic charge on satellite surfaces can pose a hazard, in particular when differential charging is leading to potential gradients. In some cases this potential build-up causes discharge arcing. Electrostatic charging by the natural space radiation environment is an accepted source of many anomalies of S/C electronics.

Satellite classes. Satellites may be categorized by a number of different criteria such as mass (large, small, mini, micro), or functions and services (EO, communication, space science, data collection, navigation, orbit, etc.), or by other criteria. Within the last years advances in digital microelectronics resulted in achieving sophisticated functions within ever smaller constraints of mass, volume, and power. This in turn brought about a miniaturization trend in platforms and instruments, and a demand for low-cost projects. The following classification has become widely accepted:

Satellite Class		Mass
Large satellite (observatory, etc.)		> 1000 kg
Medium size satellite		500 - 1000 kg
Minisatellite	Small Satellite Class (or LightSats)	100 - 500 kg
Microsatellite		10 - 100 kg
Nanosatellite		1 - 10 kg
Picosatellite		< 1 kg

Table 562: Satellite classification by mass criterion

Satellite Laser Ranging (SLR). Very precise range measurements from ground reference stations to geodynamic satellites (like Lageos, Starlette, Stella, Geo-IK, Etalon, EGS, etc.). The SLR technique employs short pulse lasers from the ground to retroreflectors on satellites. While the above listed geodynamic satellites are dense reflector-covered spheres (dedicated to laser ranging), there may also be configurations where a satellite flies a retro-reflector arrangement as an experiment. The quantity of interest is time-of-light (round trip) corrected for ranging system internal delay (calibration), atmospheric refraction (delay), retroreflector offset to the S/C center-of-mass, and network epoch synchronization. The short wavelengths of visible light result in a single-shot precision of about 2 cm. SLR techniques are a strong contributor to advances in precision orbit determination.

The applications of SLR data from geodetic satellites includes detection and monitoring of tectonic plate motion, crustal deformation, earth rotation, and polar motion; modeling of the spatial and temporal variations of the earth's gravitation field; determination of basin-scale ocean tides; monitoring of millimeter-level variations in the location of the center of mass of the total earth system (solid earth-atmosphere-oceans); establishment and maintenance of the International Terrestrial Reference System (ITRS); detection and monitoring of post-glacial rebound and subsidence; monitoring the response of the atmosphere to seasonal variations in solar heating.

Satellite structure: Basic Elements. Satellite structures must survive launch, meet outgassing and other mission-specific requirements, provide stiffness, dimensional stability and thermal control, and allow equipment mounting and containment. Remote sensing satellites are comprised of a number of subsystems. The actual number of subsystems depends on the complexity of the mission and the overall design of the spacecraft. The trend is in the direction of standardized modular subsystems with high functional autonomy.

- Satellite structure. Refers to the basic platform or “bus” (design, body, shape, etc.) and subsystem accommodation.
- Thermal control subsystem (passive and/or active). Orbital temperatures may vary considerably due to varying solar irradiation. The subsystem provides the proper thermal environment for a number of subsystems (in particular electronic or optical equipment). Thermal balance may be maintained by using an exterior finish that absorbs or emits radiation; this is referred to as a ‘passive system.’ An active system may use louvers to achieve a required environment
- G&C (Guidance and Control) subsystem. G&C is responsible for all functionality associated with spacecraft attitude (sensing and control), a basis for proper S/C pointing. G&C is sometimes simply referred to as ‘attitude control.’ See also **Spacecraft stabilization**.
- Power subsystem. The subsystem is responsible for providing continuous power for all subsystems throughout the mission. The two most common power sources are solar cells and high performance batteries. The solar energy may vary depending on satellite orbit (due to sun eclipses or varying sun elevation angles). Batteries (such as NiCd or NiH₂) are used as a supplemental on-board energy source.
- Power distribution. Refers to the spacecraft cabling system to all subsystems. Sometimes this electrical distribution function is integrated into the spacecraft bus.
- Antenna subsystem. The subsystem is responsible for receiving and transmitting telecommunication signals between ground and spacecraft (maybe in several bands).

- C&DH (Command and Data Handling) subsystem. The subsystem is responsible for command processing, data management, health and status management, telecommunications management, and power management.
- Spacecraft bus. A shared communications medium for all subsystems (like serial busses or parallel backplane busses). This requires a common interface definition. Some S/C series of agencies or companies offer standardized systems capable of accommodating a variety of payloads and subsystems. Newer designs consider the S/C bus as the physical structure for distribution of all on-board services (data, electricity, etc.) to the payload along with the integration of all service subsystems (attitude and control, timing, thermal control, etc.).
- Spacecraft computer. Depending on spacecraft complexity there may be a S/C computer and/or subsystem computers.
- Data recorder. Responsible for recording data streams during non-contact periods of the S/C. This may be an independent device (high volume and high data rate) or solid state memory storage in a S/C computer.
- Payload instruments. A suite of sensors performing assigned observations. Such instruments may be imagers, sounders, radiometers, etc.
- Timing subsystem. Responsible for giving a uniform time stamp to all required interfaces.
- GPS receiver. Ever more satellites are carrying such a system for orbit determination.

Scales (macro-, meso-, and microscales). See observational scales in modeling chapter O.13 on page 1278.

Scanning. The sweep of a mirror, prism, antenna, or other element across a track (normal to the direction of flight); the footprint may be a straight line, a circle or any other shape. In general, the process of scanning is a programmed motion that can be used either for measuring angular location of a target, or it can be used to extend the angular range of an antenna beam. There are two basic ways of classifying scanning methods:

- From the viewpoint of the type of beam motion introduced to scan a volume, the methods are described as: raster scan, helical scan, etc.
- From the viewpoint of beam steering, the methods are described as mechanical, electromechanical, or as electronic.

Scanner. An instrument that scans and by this means produces an image. A two-dimensional image is generated by the forward motion of the satellite platform. The addition of single pixels in combination with cross-track scanning (whiskbroom) or of a cross-track line of pixels (CCD line array) are the basic elements of such an image. Common scanner types are: a) whiskbroom (cross-track multispectral imaging with discrete detectors), b) pushbroom (cross-track multispectral scanner with CCD line arrays), c) hyperspectral scanning with area arrays (see chapter O.3).

ScanSAR. A SAR imaging technique permitting acquisition of a larger observation swath than what would normally be possible due to range-Doppler ambiguity limitations, but at the expense of reduced resolution. The technique, based on phased array antenna technology with a rapid electronic steering capability of the elevation beam pattern, permits a high degree of flexibility in ground observation coverage. The principle of this mode of operation is to illuminate an area on the ground long enough to acquire imagery (synthetic aperture) for the desired resolution and then move the illuminated beam to a different area across the swath to increase coverage. Hence, the operational time of the SAR beam pattern is shared between two or more subswaths in such a way as to obtain full image coverage of each. However, a contiguous subswath coverage implies shorter integration times for each footprint, resulting in shorter integration times – consequently, the resolution of the resulting image is degraded.

The ScanSAR technique may also serve to cover an event of interest, positioned close-by

but still outside the normal coverage of the current orbit. The required beam pointing for such an event can be done on command.

Scattering. Light absorbed and subsequently re-emitted by particles suspended in a medium in all directions at about the same frequency. In scattering no energy transformation results, there is only a change in the spatial distribution of the radiation. - Scattering varies as a function of the ratio of the particle diameter to the wavelength of the radiation. When this ratio is less than about one-tenth, **Rayleigh scattering** occurs in which the scattering coefficient varies inversely as the fourth power of the wavelength. At larger values of the ratio of particle diameter to wavelength, scattering varies in a complex fashion described by the Mie theory (particle size is comparable with the wavelength dimension). At a ratio of the order of ten, the laws of geometric optics begin to apply and this serves to mark the somewhat diffuse upper boundary of the realm of scattering (where diffraction begins). Primary scattering of the Rayleigh type, largely by air molecules, is responsible for the blue sky and the polarization of the sky's light. On the other hand, Mie scattering occurs by the interaction of radiation (light) with aerosols or cloud particles.

Scattering matrix. An array of complex numbers that describes the transformation of the polarization of a wave incident upon a reflective medium to the polarization of the back-scattered wave. See also **radar polarimeter** under **radar**.

Scatterometer types. There are two basic designs of scatterometers: the traditional fan-beam Doppler scatterometer (examples: NSCAT, AMI-SCAT), and the scanning pencil-beam scatterometer. The fan-beam Doppler scatterometer requires multiple antennas to achieve the target illumination pattern (sticklike antennas are used to broadcast long, narrow radar footprints). The FOV requirements of the antennas are very strict making fan-beam scatterometers very difficult to accommodate on S/C. - The design of the newer scanning pencil-beam instrument is more compact; they offer long dwell times which result in better SNRs. SeaWinds on ADEOS-II will be a scanning pencil-beam scatterometer.²⁰⁸⁵⁾

Schottky diode (named after Walter H. Schottky). A diode that has a metal-semiconductor contact (e.g., an Al layer in intimate contact with an n-type silicon substrate). The Schottky diode is electrically similar to a p-n junction, though the current flow in the diode is due primarily to carriers having an inherently fast response. It is used for high-frequency, low-noise mixer and switching circuits.

Scintillation. Variations in the brightness of starlight (i.e. 'twinkling') caused by turbulent strata very high in the Earth's atmosphere (ionosphere). Also, the emission of sparks or flashes. In general, scintillation refers to the fluctuation of amplitude and/or phase of a signal caused by the irregular structure of the propagating medium.

Scintillation counter. A device that uses a photomultiplier tube to detect or count charged particles (which produce scintillations of radiation when they impact upon phosphor) or γ -rays.

Sea Surface Salinity (SSS). SSS is an important variable in oceanography. In polar oceans, SSS intrusions with a low salinity influence the deep thermohaline circulation and the meridional heat transport. Variations in salinity also influence the oceans near surface dynamics in the tropics where rainfall modifies the buoyancy of the surface layer and the tropical ocean-atmosphere heat fluxes (warm surface pool dynamics).²⁰⁸⁶⁾ - The physical basis for SSS remote sensing is the microwave brightness temperature (low frequency range in L-band around 1.4 GHz) which is directly linked to the dielectric constant of the target area (i.e., moisture or salinity); hence, proportional to moisture or salinity. SSS retrieval requires

²⁰⁸⁶⁾G. Lagerloef, C. Swift, D. LeVine, "Sea Surface Salinity: The next remote sensing challenge," Oceanography, 8, 1995, pp. 44-50

knowledge of sea surface temperature and sea roughness and, additionally, it also requires a very high sensitivity from the sensor. ²⁰⁸⁷⁾

Semiconductor junctions. Semiconductors whose principal charge carriers are electrons are called n-type (negative). If the charge carriers are mainly holes (a vacancy with positive charge), the material is p-type (positive).

Sensor. An instrument (generic term), usually consisting of optics, detectors, and electronics that collects radiation and converts it to some other form. The form may be a certain pattern (an image, a profile, etc.), a warning, a control signal, or some other signal. - The photographic camera is one of the best known examples of a 'remote sensor' which has been around since the first half of the nineteenth century.

Sensor characteristics. The ability of a sensor to detect and to resolve incoming radiation. For imaging sensors a very prominent characteristic is 'ground resolution,' its ability to distinguish objects on the Earth's surface. Other sensor characteristics are: scene size, spectral range, spectral resolution, radiometric resolution, pointing accuracy (location knowledge), and timeliness (in which images are returned to the user, the frequency at which a given target can be revisited, the fraction of time that the sensor requires for taking an image).

Shielding. Refers to a technique of enclosing an object or a device within a container specifically designed to attenuate or otherwise exclude electromagnetic radiation.

Sidelobes. See **antenna sidelobes**.

Sigma (σ). The conventional measure of the strength of a radar signal reflected from a geometric object (the target area). Sigma designates the strength of reflection in terms of the geometric cross section of a conducting sphere that would give rise to the same level of reflectivity. See also **radar cross section**.

Sigma naught (σ^0). Scattering coefficient, the conventional measure of the strength of radar signals reflected by a distributed scatterer, usually expressed in dB. It is a normalized dimensionless number, comparing the strength observed to that expected from an area of one m². Sigma naught is defined with respect to the nominally horizontal plane, and in general has a significant variation with incidence angle, wavelength, polarization, as well as with the properties of the scattering surface itself.

Signal-To-Noise Ratio (SNR). The ratio of the level of information-bearing signal power to the level of noise power. The maximum SNR of a device is called the 'dynamic range.' In general, the higher the value of an instrument's SNR, the better the signal quality for recognition (detection) and interpretation.

Signature. The response of electromagnetic radiation to particular objects in the target area. Signatures may be used for pattern recognition which may in turn lead to target identification.

- The radar signature is the radar response (differential radar cross-section or the scattering cross section) of a particular material or object as a function of frequency, angle, polarization, or time.
- The **spectral signature** is the radiation response of an object as a function of wavelength.

Solar absorption technique. A method for measuring atmospheric constituents. As sunlight passes through the Earth's atmosphere, certain wavelengths are selectively absorbed by gaseous constituents. In the infrared region, nearly all gases have characteristic, discrete absorptions, whose positions and relative strengths are known from laboratory measurements of pure gas samples. This permits gaseous atmospheric constituents between the sun and an observer to be identified and quantified from high resolution solar spectra.

Solar cell. An optoelectronic device (invented in 1954) that converts the radiant energy of sunlight directly into electrical power, based on photovoltaic principles. The solar cell is a large-area photodiode that detects the solar emission spectrum rather than a specific wavelength, as do photodiodes. The solar cell is unbiased, the load is connected directly across the two terminals of the p-n junction. Conversion efficiency, radiation hardness, and EOL (End Of Life) power are very important properties of solar cells. They are usually arranged in arrays or panels for spacecraft powering. During the 40 years of space technology, three generations of solar cells have been introduced:

- Silicon (Si) solar cells dominated the field until the early 1990s
- Gallium arsenide (GaAs) solar cells arrived in about 1990. They have better conversion efficiencies and radiation resistance in comparison with Si cells. GaAs cells can be manufactured on lightweight germanium substrates.
- The third generation of solar cells is the multifunction cell, or cascade cell. Current multijunction cells are based on GaInP (Gallium Indium Phosphide) material and GaAs on Ge substrate.

Solar cycle. The 9.5 - 11 year period between maxima (or minima) of solar activity (usually measured by the number of sunspots on the solar surface). About every 11 years the magnetic field of the sun reverses polarity; hence the more basic period may be 22 years. It is generally accepted that the solar cycle is maintained by a dynamo driven by the differential rotation of the sun's envelope.

Solar sail. A low-thrust propulsion technology (in the experimental/demonstration phase at the turn of the century) whose concept relies on the momentum transfer of photons (solar radiation pressure) on large, highly reflecting sails in space for passive propulsion such as orbit transfer functions. The concept involves the deployment and control (orientation) of a large sail in orbit on lightweight structures. The technology of such solarcraft is of interest for interplanetary missions.

Solar wind. A radial outflow of plasma from the solar corona, carrying mass and angular momentum away from the sun (see chapter O.18). The solar wind consists of a flux of particles, chiefly protons and electrons together with nuclei of heavier elements in smaller numbers, that are accelerated by the high temperatures of the solar corona, or outer region of the Sun, to velocities large enough to allow them to escape from the sun's gravitational field. At 1 au (astronomical unit) the solar wind contains approximately $1\text{--}10\text{ protons/cm}^3$ moving outward from the sun at velocities of 350 to 700 km/s (or about 1.26 -2.52 million km/h); this creates a positive ion flux of 108 to 109 ions/($\text{cm}^2\text{ s}$), each ion having an energy equal to at least 15 eV (electron volts). During solar flares, the proton velocity, flux, plasma temperature, and associated turbulence increase substantially.

Sounder. A remote sensing instrument that measures state parameters (like temperature, pressure, moisture, etc.) in a particular plane of observation for the derivation of profiles. A sounder may be a passive device by measuring the incoming radiation, it can also be an active device, transmitting signals (echo sounding) and receiving the echo information. Two basic configurations are in use:

- In the nadir-viewing configuration the observation plane is the orbit plane of the platform (series of footprints along the suborbital track). The scan technique provides good horizontal resolution of the measurements, but usually poor vertical resolutions.
- Limb sounders look at the horizon (the limb) and scan vertically, producing good vertical resolution but poor horizontal resolution.

Sounding. To 'sound' (to find bottom) originally referred to the measurement of water depths by sounding methods (sounding line, echo sounding, etc.) in shallow coastal waters and in rivers. The technique was much later extended to measure also the conditions of another medium, namely the atmosphere, at various heights. The first devices used were

balloons with self-registering instruments (referred to as sondes) to record meteorological data. As new technologies became available, radiosondes, dropsondes from aircraft, rawinsondes, sounding rockets, ground-based, airborne and spaceborne instruments of a great variety appeared.

Spacecraft/platform attitude sensing and control devices.

- 1) A S/C attitude or pointing direction is determined by comparing information from various on-board sensors with the positions of known references. Attitude knowledge may be derived from the following orientation instruments:
 - Magnetometers (measuring the known magnetic field components)
 - Sun and/or star sensors or trackers (measuring of known celestial body directions)
 - Earth horizon sensors (various types, mostly in the IR region; a horizon crossing indicator may determine the attitude of a spin-stabilized S/C with respect to the Earth; another horizon sensor may measure one component of the attitude of a three-axis stabilized S/C with respect to the Earth; there are scanning IR Earth horizon sensors, etc.).
 - Gyroscopes (measuring inertial reference)
 - GPS receiver (capable of measuring attitude). These GPS attitude instruments provide attitude and attitude rate data to actuators for real-time, autonomous attitude determination.
 - Telescope (instrument guide telescope)
 - etc.
- 2) The following instruments (or combinations thereof), referred to as actuators, provide attitude control:
 - Momentum gyros
 - Reaction/momentum wheels
 - Thrusters (cold gas thrusters, solid thrusters, ion thrusters, mono- or bi-propellant engine, etc.)
 - Magnetic torque coil/rods (magnetorquers)
 - Permanent magnets
 - Gravity gradient boom
 - Nutation damper
 - etc.

The simplest attitude control system is passive stabilization, either magnetically (a magnetometer as sensor in combination with a magnetic torque rod as actuator) or by gravity gradient methods. Passive stabilization can also be combined with active components, e.g. gravity gradient systems with magnetic torquers are quite common. Simple spinners, and momentum biased satellites represent the next advanced level of attitude control system, requiring at least for the momentum biased system some active stabilization about the angular momentum axis (typically the pitch axis). Zero-momentum systems with either reaction wheels or thrusters are the most complex systems, they require constant stabilization and become unstable if control is lost only for a short period of time. Simple and passively stable systems have a low pointing performance, and complex systems using reaction wheels are highly accurate pointing systems. ²⁰⁸⁸⁾

Spacecraft/platform and instrument pointing. Good location knowledge of a target (of the ground surface, of a celestial body, etc.) by instrument pointing is an ever-present requirement of many missions (in particular for astronomy instrument pointing, also when imagery of the Earth's surface is used for cartographic applications). Precision pointing capability is the result of spacecraft stability through suitable attitude sensing and control mechanisms (some systems may include vibration control, elimination of alignment errors due to ther-

²⁰⁸⁸⁾H. J. Koenigsmann, G. Gurevich, "AttSim, Attitude Simulation with Control Software in the Loop," Proceedings of the AIAA/USU Conference on Small Satellites, Aug. 23-26, 1999, Logan UT, SSC-IIa-5

mal distortions, etc.). In general structural stiffness of the platform is an important prerequisite for a stable pointing environment. There are several classes of instruments with regard to pointing capability:

- Rigid-body instrument pointing or simply **body pointing**. This refers to a no-instrument-pointing capability relative to the platform. Most observation instruments on a spacecraft platform are fixed, they point into a constant direction (nadir, off-nadir, limb, zenith, etc.), their FOV (Field of View) provides a sufficient scan capability (for instance in the cross-track direction, and/or in the height direction) to measure all resolution cells in a swath.
- Some S/C with body-pointed (fixed) instruments are able to employ maneuvers to turn the entire S/C into a desired direction (example: IKONOS-1) thereby extending the field of regard considerably for observations outside of the normal swath width. S/C with relatively small masses (microsatellites) are most suited for this choice of pointing implementation.
- Instrument pointing relative to the platform. This class of sensors performs inertial pointing/tracking of a star or simply pointing/tracking of the sun or the moon. Some observation instruments need to be kept pointed for relatively long periods of time with extraordinary precision at faint celestial bodies. However, most instruments in this class are attitude sensors (such as: gyroscopes, magnetometers, horizon sensors, star or sun sensors, star trackers, accelerometers), their measurements serve as input for the on-board attitude control subsystem. The pointing knowledge bounds of a platform are always smaller than the actual pointing control bounds.
- Instrument pointing capability relative to the platform. These are observation instruments (imager, etc) performing fairly quick slew maneuvers, for instance in the along-track direction, to obtain stereo imaging.

Platform or Instrument	Pointing Knowledge	Pointing Accuracy (Control)
TIROS-N		0.1°
Spot-1 to -3		0.1°
ENVISAT	<0.03°	< 0.1° (3 sigma)
GP-B (relativity mission)		< 20 milliarcseconds (rms)
UoSAT		2-3° (rms) gravity-gradient boom system
DMSP (Block 5D-3)		0.01° (three orthogonal gyros)
SOHO		1 arcsecond (sun pointing over a period of 1.5 min)
TRACE		20 arcseconds (correction for pointing jitter)
Landsat-7	45 arcseconds	180 arcseconds
MSX		<0.1° (post-processing knowledge of 9 μrad)
GFO-1		0.25° (3 sigma)
Microlab-1		±2° gravity gradient boom system
IPS (Shuttle)		±1.2 arcseconds
CERES (on EOS)	180 arcseconds	
MISR (on EOS)	90 arcseconds	
SeaWinds	500 arcseconds	
OSA (on CRSS, also referred to as Ikonos-1)	Rms ground location accuracy: 2 m relative (with ground control points) 12 m absolute (without the use of control points)	

Table 563: Typical pointing parameters of a few satellites/instruments

SAR's capability to form good imagery relies significantly on the stability of the platform and, if the stability is not satisfactory, the precise knowledge of attitude information can be used to correct for orbital effects. On-board accurate and precise attitude/position determination is required, and in case of interferometry, most demanding. The baseline knowledge required is in the order of millimeter and the attitude of the baseline in the order of several arcseconds.

In an effort to achieve very precise aiming, ESA built a Spacelab system by the name of IPS (Instrument Pointing System - first flown on STS-51-F as Spacelab-2 in July/Aug. 1985).²⁰⁸⁹⁾ This three-axis gimbal pointing system provides precision pointing and tracking capabilities by establishing an inertially stable base from which stellar, solar, and Earth observations can be made (maintenance of pointing stability is within ± 1.2 arcseconds). - In the same context, MACE (Middeck Active Control Experiment) is a NASA precision pointing system (built by MIT, LaRC, LMSC, et al.) flown on Shuttle flight STS-67 in March 1995, with the objective to explore high precision pointing and vibration control of future spacecraft and satellites. MACE extends conventional rigid-body instrument pointing to include flexible modes. Tests were conducted on the free-floating MACE platform to measure how disturbances caused by a payload impacts the performance of another nearby payload which is attached to the same supporting structure. MACE accomplishments: a) About 50 LaRC control systems were experimentally evaluated on-orbit, b) a reduction of at least 19 dB was achieved in the vibration levels, and c) MACE was able to synthesize and evaluate new control designs during the STS-67 flight.^{2090) 2091) 2092)}

Spacecraft/platform stabilization. Techniques that control the orientation (attitude) of the spacecraft in orbit with respect to certain known references. Several of the methods in use are:

- **Single-spin stabilization.** The whole spacecraft body rotates about the axis of the principal moment of inertia (acting like a gyroscope). These satellites cannot have oriented antennas, a severe drawback for certain applications.
- **Dual-spin stabilization.** A configuration in which the spacecraft consists of two parts: the platform, which is oriented toward the Earth, and the rotor, which rotates about the principal axis of the S/C thereby providing gyroscopic stiffness (example: Meteosat).
- **Three-axis stabilization.** A configuration in which the entire spacecraft is oriented toward a particular direction (usually toward the Earth in one dimension and aligned to the flight path in the other dimension). The control torques for attitude control are provided by a combination of reaction/momentum wheels, magnetotorquers, torque rods, gimbal system, and/or thrusters. In this concept, the rotating **reaction wheels** are able to absorb torque and momentum, while magnetic torquers or thrusters are used of allowing the wheels to slow their rotation rate. The same attitude control function may also be provided by an all-thruster system.
- **Gravity gradient stabilization (passive stabilization method).** A spacecraft consisting of two masses (main mass and small mass) that are connected by a rod or a boom. This two-mass arrangement produces a gravity gradient along the boom axis and an associated small torque which is employed for spacecraft orientation. This technique is normally used along with magnetic torquing (yet another passive stabilization method) for better attitude control of small satellites (mini, micro, or nanosatellites).

Space weather. This term refers to the conditions in space that affect the Earth and its space environment. Space weather is a consequence of sun behavior, the nature of Earth's magnetic field and atmosphere (in particular the ionosphere and magnetosphere), and Earth's location in the solar system. The solar wind, propagating against the Earth's magnetic field and interacting with it, shapes the near-Earth space environment. The response of the Earth's space environment to the solar wind is termed 'space weather.' Space weather can influence the performance and reliability of spaceborne and groundbased technological systems (power and communication systems) and can endanger human life and health

(spacewalks of astronauts). Other effects are: aurora and changes of climate. The space environment hazards that spacecraft and mission designers and operators need to be concerned with are: ²⁰⁹³⁾

- **Solar environment.** The solar environment, directly or indirectly, effects all the other hazard environments. The solar activity levels, which follows an 11-year cycle, is a directly contributing factor which interacts to the radiation, thermal and plasma environments. The increased energy output from the Sun during its active periods heats the Earth's atmosphere and causes it to expand, which can effect the impact and neutral atmosphere environments, as well.
- **Magnetic environment.** The fields generated by the magnetic environment can directly interact with spacecraft. This is often taken advantage of in the attitude control subsystems, which can employ magnetometers and magnetic torque rods. The magnetic environment is also a major factor in determining the radiation and plasma environments around the Earth.
- **Radiation environment.** The radiation environment is principally composed of naturally occurring charged particles trapped in the Earth's magnetic field (also known as the Van Allen belts). Energetic solar particles and galactic cosmic rays also contribute to the natural radiation environment.
- **Thermal environment.** The thermal environment consists of thermal energy flux from the sun, the solar energy reflected back into space (and towards the spacecraft) from the Earth, referred to as albedo and the direct longwave thermal emission of the Earth due to its temperature, sometimes referred to as Earthshine.
- **Impact environment.** The impact environment consists of material from natural occurring micrometeoroids and from man-made debris flux. Due to the high relative velocities, even tiny particles can cause direct physical damage to the satellite structure and solar panels and can also induce damaging electrostatic discharges.
- **Plasma environment.** The plasma environment is mostly composed of charged particles (electrons) with energies too low to be a radiation hazard. However, these particles can strike and deposit themselves on external surfaces of the spacecraft or penetrate through the surface and deposit on internal components, causing electrostatic charge build-up. This charge can build up to high enough levels to create electrostatic discharge hazards that can damage spacecraft electronic components.
- **Neutral atmosphere environment.** The neutral atmospheric environment is the residual atmosphere remaining at spacecraft altitudes. The neutral atmosphere can contain atomic oxygen, which can damage the materials used on the spacecraft. Other residual atmospheric chemicals can also react with materials or be a source of contamination for optical systems.

Spatial frequency. Representation of an object or an image as a superposition of sinusoids (Fourier components).

Specific impulse. The specific impulse (Isp) of a thruster is the impulse (a force applied for a certain time) exerted with 1 kg of propellant. Therefore the units for specific impulse are Newton-seconds per kilogram (Ns/kg). By inserting the units of a Newton ($1\text{N} = 1\text{kgm/s}^2$), the numerical value of the specific impulse also corresponds to the effective exhaust velocity (**m/s**) of the gas exiting the thruster in a vacuum.

Speckle. Refers to the phenomenon of a strong variation of echo signals from one resolution cell to another occurring in radar imaging (it is sort of a granular noise that affects the SAR images). Speckle occurs because the echo received consists of the sum of contributions of point targets in a each resolution cell, in continuously changing combinations (see also chapter O.8.4). Speckle is caused by the random interference of wavelets scattered by the microscopic fluctuations of the object surface within a resolution cell. The presence of

²⁰⁹³⁾ M. Enoch, et al., "An Integrated Space Environment Analysis Tool (SEAT)," Proceedings of the 13th AIAA/USU Conference on Small Satellites, Aug. 23-26, 1999, Logan UT, SSC99-IIa-6

speckle in an image decreases the radiometric resolution, and thus reduces interpretability of the image (reduction in detail). Usually, filters are used to reduce the effects of speckle.

Spectra (of dispersion). Common methods are: (see also Table 812)

- Refraction: prisms are used to break up or disperse electromagnetic radiation into its component colors. The path of the radiation bends (refracts) when it passes from one medium into another.
- Diffraction: a lightwave breaks up into waves travelling in all directions as it strikes a surface. Diffraction gratings are composed of closely spaced transmitting slits on a flat surface (transmission gratings), or alternately reflecting and nonreflecting grooves on a surface (reflecting gratings).
- Interference: see **Interferometer**.
- Filter (electronically tunable filters)
- Filter (mechanical)
- Filter (mask)

UV	Ultraviolet: 0.01 - 0.38 μm
FUV	Far Ultraviolet: 90 - 125 nm
EUV	Extreme Ultraviolet: 40 - 90 nm (also abbreviated as XUV)
VIS	Visible: 0.4 - 0.7 μm
NIR	Near infrared: 0.7 - 1.3 μm
VNIR	Visible/Near infrared: 0.4 - 1.3 μm , - the predominant mode of energy detection is that of reflected sunlight
SWIR	Short-Wave infrared: 1.3 - 3 μm - the predominant mode of energy detection is that of reflected sunlight
MWIR	Mid-Wave infrared: 3 - 6 μm - the detected energy is a mixture of solar reflected and thermally emitted radiation
TIR	Thermal infrared: 6 - 14 μm (also referred to as LWIR) - practically all energy received (detected) is attributed to thermal emission
VLWIR	Very Long-Wavelength Infrared (14 - 30 μm)
FIR	Far infrared: 10 - 1000 μm (note: 1000 μm = 1 mm). The TIR range is practically the lower portion of the FIR range.
MW	Microwave region: 1 mm - 1 m (<300 GHz frequencies < 300 MHz) - the detected energy is of microwave (thermal) emissions. Since microwave sensors do not depend on solar illumination the observations are virtually independent of aerosols and also much less affected by clouds (cirrus) than sensors operating in IR or VIS.

Table 564: Spectral regions of frequently-used acronyms

Spectral and spatial purity. An evaluation of the quality of radiometric measurements in the spectral and spatial domains.

Spectral band. An interval in the electromagnetic spectrum defined by two wavelengths, two frequencies, or two wavenumbers. Note: The so-called **optical spectrum** extends from 0.01 μm to 1000 μm , i.e., from the UV to the FIR region inclusively. This is followed by the microwave region.

Spectral resolving power. Ratio of $\lambda/\Delta\lambda$ (see also an example under **Wavenumber**).

Spectral signature. Quantitative measurement of the spectral properties of an object at one or several wavelength intervals.

Spectrometer. An instrument connected to a telescope that separates the light signals into different wavelengths or frequencies, producing a spectrum (thus permitting an analysis of the spectral content of the incident electromagnetic radiation). Usually, only a relatively small portion of the spectrum is measured by an instrument. Some spectrometer types are:

- 1) **Dispersive systems:** A class of spectrometers using the dispersive principle to separate radiation into its narrow-band components (spectral discrimination). A dispersive imaging spectrometer can only support one dimension of imaging (along the slit); the

other dimension is used for spectral dispersion. Images are built up by making successive exposures; hence, images are stacked side by side. This is done either by using the motion of an aircraft or spacecraft (pushbroom imaging) or by the use of a sideways-scanning mirror (whiskbroom imaging). See also O.3 and O.6.

- Prism spectrometer. From a historical point of view, glass prisms were first used to break up or disperse light into its component colors. The path of a light beam bends (refracts) as it passes from one transparent medium to another, e.g., from air to glass. A prism is used, along with collimating and re-imaging optical and mechanical components, to disperse light for spectral discrimination.
 - Grating (diffraction) spectrometer. A grating is used (along with collimating and re-imaging optical and mechanical components) to disperse light by diffraction for spectral discrimination. The spectral dispersion is stated, for example 2-4 nm/mm at 300 nm, and the resolution is 0.5 nm.
 - In a wedge spectrometer spectral discrimination occurs in a focused beam
- 2) **Filter Spectrometers (nondispersive systems).** Filters are used to control the spectral bandwidth of the radiation that is allowed to reach the detector system. Narrowband filters are in the order of $1\text{-}2\text{ cm}^{-1}$.
- Filter-wheel technique. Allows the selection of up to n discrete spectral bands.
 - Bandpass filter technique. Allows the transmission of only a narrow band of frequencies (the other frequencies are blocked out). The spectral width of this filter is characterized by its bandwidth. A typical bandpass filter instrument is TM on Landsat
 - Filter mask technique in which the spectral separation filters are mated to the detector array to achieve two-dimensional sampling of the combined spatial/spectral information passed by the filter. A typical instrument of this type is WIS (Wedge Imaging Spectrometer)
 - Dichroic systems. A filter method allowing selective absorption in crystals of electromagnetic radiation vibrating in different planes (usually filtering is based on wavelength). The dichroic principle is applied to beam splitters and filters.
 - Interference filter. A filter reflecting radiation selectively in a narrow spectral band
- 3) **Fourier Transform Spectrometers (FTS, nondispersive systems).** An FTS system provides a conventional spectrum, but with greater speed, resolution and sensitivity. This class of spectrometers separates the incoming broadband spectrum into narrow-band components with the use of an interferometer. An incoming wavefront into the interferometer is divided by a beam splitter (semitransparent surfaces). Beams produced in this way travel two different paths, then recombine (superposition principle), creating an interferogram. This interferogram (a function of signal intensity versus time) is normally digitized and converted to an absorption spectrum by means of a Fourier transform. Instruments with high resolving power often use interferometers in series with grating instruments. FTS can be designed to cover all spectral regions from the radio frequency to the UV.
- 4) **Correlation Spectrometers**, also referred to as NDIR (Non-Dispersive Infrared) spectrometers. A correlation spectrometer is a device for a gas-specific investigation that correlates the spectral signatures of the species to be analyzed with reference spectra.
- 5) **AOS (Acousto-Optical Spectrometer).** The principle of an AOS is based on the diffraction of light at ultrasonic waves. A piezoelectric transducer, driven by the RF-signal (from the receiver), generates an acoustic wave in a crystal (the so called Bragg-cell). This acoustic wave modulates the refractive index and induces a phase grating. The Bragg-cell is illuminated by a collimated laser beam. The angular dispersion of the diffracted light represents a true image of the RF-spectrum according to the amplitude

and wavelengths of the acoustic waves in the crystal. The spectrum is detected by using a single linear diode array (CCD), which is placed in the focal plane of an imaging optics.

- 6) **Heterodyne Spectrometers** (nondispersive systems). See **Heterodyning**.
- 7) Lidar Spectrometers.
- 8) etc.

Spectrometry. In remote sensing the detection and measurement of radiation spectra of a target (area or volume). Each spectra has a characteristic pattern of absorption and emission bands. Comparison of these spectra against reference spectra provide information on the target's material composition. Imaging spectrometry refers to the simultaneous acquisition of images in many contiguous spectral bands.

Spectroradiometer. A combination of spectrometer and radiometer for measuring the energy distribution of emitted radiation.

Spectroscopy - differential absorption spectroscopy. A technique that uses two frequencies emitted by the same laser or by different lasers to perform measurements of the concentration of a gas along a given line of sight. The frequency of one laser signal is tuned to the frequency of the center line of the absorption feature; the frequency of the other laser signal is tuned aside from this feature. The difference in the amount of transmitted light at these two frequencies is the quantity that is being sought.

System Technology	Spectral Resolving Power $\lambda/\Delta\lambda$	Wavelength Range	Moving Parts	Simultaneous Acquisition of all spectral bands	Throughput
Grating (CCD detectors)	$10^2 - 10^5$	Narrow (optics-limited)	no	yes	low
Prism	$10^2 - 10^3$	Narrow (optics-limited)	no	yes	low
Fourier Transform Spectrometer (FTS)	10^6	Broad (detector-limited)	yes (no, depending on type)	yes	very high
Filter (electronically tunable)	10^2	Narrow (optics-limited)	no	no	very high
Filter (mechanical)	10^3	Broad (detector-limited)	yes	no	very high
Filter (mask)	10^2	Narrow (optics-limited)	no	yes	very high
Filter (mask) WIS	10^2	Broad (detector-limited)	no	no	very high

Table 565: Overview of some spectrometer technology characteristics

Spectroscopy - imaging. Imaging spectroscopy is the acquisition of images, where for each spatial resolution element (pixel) in the image a spectrum of the energy arriving at the sensor is measured. These spectra are used to derive information based on the signature of the interaction of matter and energy expressed in the spectrum.

Spectrum. Refers generally to the intensity distribution of electromagnetic radiation as a function of wavelength, wavenumber, or frequency (see Figure 413).

Spread-spectrum technology. A transmission technique that allows multiple senders and receivers to share the same portion of the spectrum (bandwidth) by having each sender encode its transmission in a unique way decipherable by only its intended receiver. Part of this technique is used in GPS (see chapter H.4) and GLONASS (see chapter H.3) communication. Spread spectrum technology is also used for PCS (Personal Communication Services) via satellite on such systems as 'Iridium' and 'Globalstar.' The spread-spectrum technology allows communication satellites to capture and transmit signals that normally would be lost because the original signals were too weak or had too much interference. The wide band-

width of the technology (about three orders of magnitude higher than normal radio frequencies) make it difficult to intercept the signal by an unauthorized party. The feature of low interception probability is attractive for many communication applications.

Squint. The term is used to describe an oblique pointing geometry of a sensor. For instance, a typical SAR pointing geometry is in the cross-track direction, normal to the flight path. Squinting occurs when the antenna beam is pointed forward or backward from this orthogonal direction.

Standing wave. A wave that is stationary with respect to the medium in which it is embedded, e.g., two equal gravity waves moving in opposite directions.

Station keeping. Refers to the maintenance of a geostationary satellite in its assigned orbital slot with regard to position and orientation (attitude). Orbital drifts are due to small gravitational effects of the sun and the moon as well as to an inhomogeneous Earth. The physical mechanism for station keeping is the controlled ejection of hydrazine gas by command from a control center.

Steradian (sr). A unit of solid angle measure in the International System, defined as the solid angle of a sphere subtended by a portion of the surface, whose area is equal to the square of the sphere's radius. The total solid angle about a point is 4π steradians. The term steradian is derived from the Greek for 'solid' and 'radian' - a steradian is, in effect, a solid radian.

Stereoscopy. The spatial three-dimensional or 'stereo' observation of related 2-D images, showing the same object under different viewing angles. Stereo images are very appropriate for map-making and for many other applications (flight simulators, etc.). The image combination of a target area may either result from, say, three cameras of an instrument pointing into the forward, nadir and aft directions, respectively, of a subsatellite track, or from a single gimbaled camera, performing along-track imaging by pointing into the forward, nadir and aft directions successively. Stereo images offer better surface relief mapping capabilities than do regular 2-D images.

Store-and Forward (S&F). A non-real-time communication technique between a LEO satellite and its ground segment (often used for Data Collection Systems, e-mail systems, etc.). In this setup the originating ground station (or terminal) sends a digitized message to the LEO satellite; the satellite intermittently stores the message in an on-board storage system, and the destination ground station later receives the message when the satellite footprint is in its view. Multiple small satellites in polar LEO increase the message traffic capacity and reduce delivery delays.

Stratopause. Stratosphere-mesosphere boundary (at about 50-55 km in altitude) where a relative temperature maxima is found (see Figure 410).

Stratosphere. Region of the atmosphere between the troposphere and mesosphere, having a lower boundary of approximately 8 km at the poles and 18 km at the equator, and an upper boundary of approximately 50 km. Depending upon latitude and season, the temperature in the lower stratosphere can increase, be isothermal, or even decrease with altitude, but the temperature in the upper stratosphere generally increases with height due to absorption of solar radiation by ozone. - The importance of the stratosphere stems from the absorption of the bulk of the solar UV radiation, in particular in the wavelength regions of 290-320 nm. Penetration of this UV radiation to the Earth's surface may be harmful to life. The component in the stratosphere absorbing the bulk of the UV radiation is ozone (O_3).

Subcarrier. Refers to a second signal "piggybacked" onto the main signal (carrier) to carry an information channel.

Sunspot. A temporary disturbed area in the solar photosphere that appears dark because it is cooler than surrounding areas. Sunspots are concentrations of strong magnetic flux (2000 - 3000 gauss), with diameters less than about 50,000 km and lifetimes of a few weeks.

Sun-synchronous orbit. An orbit is said to be sun-synchronous when the precessing rate of the orbital plane of a satellite, caused mostly by Earth flattening at the poles, is the same as the apparent motion of the sun in the celestial sphere, namely $0.9856^\circ/\text{day}$. Such an orbital configuration results in a (nearly) constant local time of ascending node (resulting in observations of a given area on the Earth's surface that are always made at the same local time of the day and the same solar incidence angle). See also chapter O.12.1.

Superconducting Tunnel Junctions (STJs). Initially under development as efficient detectors of x-rays, they are now being used as single photon detectors in the visible spectrum. STJ (developed at ESA/ESTEC) operates in the range 200 - 1000 nm with a spectral resolution of 45 nm. Unlike a silicon-based CCD, the niobium-based STJ generates a number of electrons (in the thousands) that depends on the incoming photon's energy. This property eliminates the need for filters or diffraction gratings that lower the overall efficiency.

Superconductivity is the ability of a material to carry electricity with no resistance. Superconductivity was discovered in 1911 by H. K. Onnes in Leiden, Netherlands, just three years after he had succeeded in liquifying helium. Onnes discovered the abrupt and complete disappearance of resistance in certain metals when they were cooled below the critical temperature T_c of 4.2 K using liquid helium. [Note: instrumentation at liquid helium temperatures is referred to as LTS (Low Temperature Superconductivity) devices]. - The value of T_c has changed ever since. The search for a higher T_c began in particular in the 1980s to save the enormous cooling costs at cryogenic temperatures leading eventually to **HTS** (High Temperature Superconductivity).²⁰⁹⁴⁾

- $T_c = 35\text{ K}$ (April 1986). Karl Alexander Müller and Johannes Georg Bednorz (IBM Research Laboratory, Switzerland) discovered superconductivity in $(\text{La-Ba})_2\text{CuO}_4$. In 1987, the Nobel Prize in physics was awarded to both researchers.²⁰⁹⁵⁾
- $T_c = 77\text{ K}$ (end of 1986). P. C. W. Chu (University of Texas at Houston) discovered superconductivity in the liquid-nitrogen temperature range.
- T_c above 90 K (January 1987). M. K. Wu, Chu's former student, achieved stable and reproducible superconductivity above 90 K in $\text{YBa}_2\text{Cu}_3\text{O}_{7-d}$ (Y123), with T_c close to 100 K.
- $T_c = 110\text{ K}$ and 125 K (1988) for bismuth and thallium superconducting systems respectively
- $T_c = 164\text{ K}$ (1993) for mercury-based compounds under pressure (University of Texas, Houston).
- etc.

The first SQUID (Superconducting Quantum Interference Device) instrumentation appeared in 1964 and was widely used in the field of cryogenics. In the late 1980's, the discovery of high-temperature superconductor materials opened the possibility of introducing the technology in superconducting instruments. Commercial applications of HTS technology in fields such as electric power, transportation, electronics and medicine are appearing in the 1990s. Current applications of HTS include thin-film technology, magnetic resonance imaging (MRI), wireless communication filters, and ultra-fast computer chips. Modern discoveries in superconductivity go far beyond piece-meal improvements in electric devices. They have opened the door on a totally new technology and stretch the imagination to the discovery of new applications.

Surface charge. A satellite immersed in an ambient plasma will come to equilibrium with that plasma by developing surface charges of the proper sign and magnitude to reduce the net current between the satellite and the ambient plasma to zero. The net current consists of a) currents from the environmental flux, b) secondary backscattered electrons and ions, and c) by photoelectrons from any illuminated areas on the spacecraft. As a result of these three processes contributing to the charged particle fluxes, a potential distribution exists about

²⁰⁹⁴⁾Special issue: "Superconductivity," Physics Today, March 1986

²⁰⁹⁵⁾<http://www.physnet.uni-hamburg.de/home/vms/reimer/HTC/HTC.html>

the spacecraft so that the net current to the satellite is zero. The potential distribution about a satellite may be rather asymmetric; this depends very much on the satellite geometry, it is also due to the anisotropic distribution of the particle fluxes. ²⁰⁹⁶⁾

Surface roughness. Variation in surface height within an imaged resolution cell. A surface appears “rough” to microwave radiation when the height variations become larger than a fraction of the radar wavelength.

Synchronization (sync). Refers to the process of orienting the transmitter and receiver circuits in the proper manner in order that they can be synchronized. Usually a data format is preceded by a sync pattern which is recognized by the receiver.

Synoptic view. A large (inclusive) scene of the Earth’s surface, or of an object/target under investigation, allowing a large-scale overview of features or phenomena or relations of a scene in a wider context.

Swath. Width of the imaged scene in the range direction.

Telemetry. A space-to-ground data stream of measured values (normally including instrument science data, instrument engineering data, and spacecraft engineering data) that does not include commands, tracking, computer memory transfer, audio, or video signals.

Telemetry, Tracking and Command (TT&C). Refers to the function of spacecraft operations (monitoring and control of all vital system parameters and tracking of the orbit) by a control center. These TT&C functions are normally completely separate from the spacecraft’s user signal (communication satellite) or the measured source (or instrument) data (in case of an Earth observation satellite). Hence, they are also transmitted in a separate band.

Telescience. A technique referring to the control of scientific and/or engineering experiments/instruments from a remote location. Applications include various configurations such as Earth-Earth connections as well as Earth-spaceborne support.

Telescopes (types). Optical telescopes are of two basic types, refractors or reflectors that use lenses or mirrors, respectively, for their light collecting elements. The Galilean (1564-1642) and Keplerian (1571-1630) telescopes are of the refractive type. The Cassegrain and Gregory telescopes are of the reflective type. Reflectors are used in the UV, VIS and IR regions of the electromagnetic spectrum. The name of this type of instrument is derived from the fact that the primary mirror reflects the light back to a focus instead of refracting it.

- **Cassegrain telescope** (design was proposed in 1672 by N. Cassegrain, a French scientist). A reflective telescope in which a small hyperboloidal secondary mirror reflects the convergent beam from the paraboloidal primary mirror through a hole in the primary mirror to an eyepiece in back of the primary mirror (see also Cassegrain antenna). The Cassegrain telescope design is the most frequently used two-mirror system.
- **Dall-Kirkham telescope.** A Cassegrain-type instrument where the primary mirror geometry is an ellipse, while the secondary mirror is a sphere.
- **Ritchey-Chrétien telescope.** A Cassegrain-type instrument. The telescope design reduces the ‘coma’ (image aberrations) by modifying the primary and secondary surfaces of a Cassegrain telescope. The Ritchey-Chrétien telescope employs a hyperboloidal figure for both the primary and secondary mirror thereby providing excellent resolution over a large FOV.
- **Gregorian telescope.** James Gregory (a 17th century Scottish mathematician) devised an arrangement of two concave mirrors. Gregory placed a concave secondary mirror

²⁰⁹⁶⁾E. A. Bering, III, R. Kabadi, B. McIntyre, “High Voltage Spacecraft Charging: Theory and Measurement,” Proceedings of the AIAA 2000 Space Conference and Exposition, Long Beach, CA, Sept. 19-21, 2000

outside the prime focus to reflect the light back through a hole in the primary mirror. The spacecraft of the SMM (Solar Maximum Mission), launched in 1980, flies a Gregorian telescope.

Type of Telescope	Primary Optic	Secondary Optic	Configuration 1 - Primary Optic 2 - Secondary Optic 3 - Eyepieces/Correctors 4 - Focus (usually also the image plane)
Newtonian Examples: ALF, UV-DIAL	Parabola	Diagonal Flat	
Gregorian Example: UVSP	Parabola	Ellipse	
Cassegrain Ex: ALISSA, GO-MOS, ALEX	Parabola	Hyperbola	
Dall-Kirkham Ex: CAR, CAMS, LASE, MCR	Ellipse	Sphere	
Ritchey-Chrétien Ex: SEVIRI, EIT, LEANDRE	Modified Parabola	Modified Hyperbola	
Schmidt Ex: LFS, OLS, HYDICE	Aspherical Refractor	Sphere	

Figure 423: Basic optical configurations for common types of reflective telescopes

Type of Image Defect	Description
Spherical aberration	Light focuses at different places along the optical axis as a function of radial position
Coma	Image size (magnification) varies with radial position in the focal region.
Field curvature	Off-axis images are not focused on the ideal surface, usually a plane
Astigmatism	Light focuses at different places along the optical axis as a function of angular position in the aperture
Distortion	Focused off-axis image is closer or further from the optical axis than intended
Chromatic aberration	Shift in the focused image position as a function of wavelength

Table 566: Definition of some basic image aberrations occurring in telescopes²⁰⁹⁷⁾

- **Newtonian telescope.** The primary mirror is of parabolic geometry; the secondary mirror may be a flat plate or a refractive prism. The light beam is diverted to one side for observation.
- **Schmidt telescope.** Bernhard V. Schmidt (1879-1935). In 1930, Bernhard V. Schmidt of the Hamburg Observatory in Bergedorf, Germany, designed a catadioptric telescope

2097) Encyclopedia of Physical Science and Technology, Academic Press, 1987, Vol. 9 pp. 730-732

with a large FOV to eliminate image distortions (a catadioptric telescope design incorporates the best features of both the refractor and reflector, i.e., it has both reflective and refractive optics). This design compensates for most of the spherical aberration by means of an aspherical refractor at the center of curvature.

Theodolite. A surveying instrument used to measure horizontal and vertical angles.

Thermal control system. An on-board system which maintains all satellite components within allowable temperature limits for all operating modes of the satellite when exposed to the varying thermal environments throughout its lifetime. Typical thermal loads (forms of environmental heating) are: a) direct solar radiation, b) reflected radiation from the Earth's albedo, c) emission of long-wave IR radiation from the Earth, d) free molecular heating, and e) charged particle heating.

Thermal Infrared (TIR). Electromagnetic radiation in the spectral range of 6-20 μm . Many remote sensing applications utilize the 6-12 μm range. TIR is emitted energy, whereas NIR (Near Infrared) is reflected energy.

Thermal noise. The 'noisy' detector signal of an infrared sensor caused by the thermal heating of the detector itself. Thermal noise occurs when the system is not sufficiently cooled.

Thermistor. A semiconductor device (sensor) whose electrical resistance varies with temperature. Its temperature coefficient of resistance is high, nonlinear, and usually negative.

Thermoluminescence. A property of certain minerals which causes them to emit light when moderately heated, after electrons are excited into traps by ionizing radiation.

Thermosphere. Outermost layer of the atmosphere, above the mesosphere.

Thin-film technology. Thin films are an important ingredient in all surface technology applications. Surfaces play an important role in nature as well as in technology where small-scale exchange processes take place. Nanotechnology offers a new realm for surface technology in which to operate, providing also new analytical methods for much clearer windows onto nanoscale surface structures. In solar cell applications, thin-film technology refers to dielectric layers for optical anti-reflective coatings, electrical passivation and diffusion barriers. Applications of thin-film technology abound in such fields as: lithography, deposition, etching, epitaxy, diffusion, optics, sensor technology, etc.

Time Division Multiple Access (TDMA). A process that shares the time domain of a single carrier among many users by assigning to each time intervals in which to transmit signal bursts. In this scheme, all users transmit on the same frequency, each is assigned the total available bandwidth for a limited amount of time. TDMA systems segment time into frames, each frame is further partitioned into assignable time slots.

Tomography (optical tomography).²⁰⁹⁸ A diagnostic technique permitting the mathematical reconstruction of 3-D images from a set of 2-D measurements. A typical application are the medical CAT (Computer Aided Tomography) scans which yield the structure of a human body from a set of X-rays. The tomography technique is also finding its way into high-speed applications (high temporal resolution), such as in aero-optical measurements of dynamic turbulent media (simultaneous measurements of the flow field and the optical field provide information of the flow structure in space and time). An application of this technique is the study of phenomena causing degradations in laser beam propagation through atmospheric boundary layer turbulence. In laser transmissions through turbulent media, adaptive optics systems are being used to correct for phase distortion. Adaptive optics systems rely on accurate measurements of the turbulent media and on its ability to distort the beam.

²⁰⁹⁸) Note: Tomographic methods were first formulated in the 1970s as a means of remotely mapping inaccessible regions of the human body.

Naturally, the microwave region of the spectrum may also be used for tomographic studies. For instance, the basic concept in CIT (Computerized Ionospheric Tomography) research is to use LEO satellites as moving transmitters and an array of ground receivers to measure TEC (Total Electron Content) in the ionosphere.

Total Solar Irradiance (TSI). The total solar irradiance along with Earth's global average albedo determines Earth's global average equilibrium temperature. Because of selective absorption and scattering processes in the Earth's atmosphere, different regions of the solar spectrum affect Earth's climate in distinct ways. To place the 11-year sun cycle into perspective, the sun's TSI is about 1370 Wm^{-2} in space (i.e. in low Earth orbits of spacecraft). Since the intercepted radiation is distributed over the surface of the Earth, the average solar radiation at the top of the atmosphere is $1/4$ of this, or about 340 Wm^{-2} ; hence, a variation of 0.1% corresponds to 0.34 Wm^{-2} .²⁰⁹⁹⁾ Planetary albedo scattering reduces this further to about 0.24 Wm^{-2} (approximately 20-25 % of the TSI is absorbed by atmospheric water vapor, clouds, and ozone, by processes that are strongly wavelength dependent. Ultraviolet radiation at wavelengths below 300 nm is completely absorbed by the Earth's atmosphere and contributes the dominant energy source in the stratosphere and thermosphere, establishing the upper atmosphere's temperature, structure, composition, and dynamics). Even small variations in the sun's radiation at these short wavelengths lead to corresponding changes in atmospheric chemistry. Radiation at the longer visible and infrared wavelengths penetrates into the lower atmosphere, where the portion not reflected is partitioned between the troposphere and the Earth's surface, and becomes a dominant term in the global energy balance and an essential determinant of atmospheric stability and convection. Thus it is important to accurately monitor both the TSI and its spectral dependence.²¹⁰⁰⁾

Trace gas. A minor constituent of the atmosphere. The most important trace gases contributing to the greenhouse effect are water vapor, carbon dioxide, ozone, methane, nitrous oxide, and chlorofluorocarbons. Other trace gases include ammonia, nitric oxide, ethylene, sulfur dioxide, methyl chloride, carbon monoxide, and carbon tetrachloride.

Tracking system. Tracking is the process of following a moving object. Tracking system is a general name for an apparatus, such as a tracking radar, used to follow and record the position of objects (airborne or spaceborne). A theodolite and an observer form, for instance, an optical tracking system which is used in pilot balloon runs.

Transceiver. A term made up of the words 'transmitter' and 'receiver' of a signal transmission system. Since each side of a two-way system requires both functions, they are provided in one unit.

Transducer. A device changing one form of signal energy into another, such as a microphone, a thermocouple, a photocell, etc.

Transmittance (transmissivity). The ratio of power transmitted through a layer of a medium to the power incident upon it.

Transmitter. An electronic device consisting of an oscillator, modulator and other circuits which produce a wave signal for radiation by an antenna.

Transponder. A combined receiver and transmitter system (usually part of a communications system of a satellite) whose function is to transmit signals automatically when triggered by an interrogating signal.

Traveling wave tube. A microwave power generating tube that accelerates electrons by varying a magnetic field between cathode and anode to set up waves of electron density.

2099) G. C. Reid, "Solar Variability and the Earth's Climate: Introduction and Overview," pp. 1-11 in *Solar Variability and Climate*, Editors: E. Friis-Christensen, C. Fröhlich, J. D. Haigh, M. Schüssler and R. von Steiger, Kluwer Academic Publishers, ISBN 0-7923-6741-3, 2000

2100) <http://laspl.colorado.edu/sorce/>

Tropical year. The interval of time between two successive vernal equinoxes. It is equal to 365.242 mean solar days.

Tropopause. Boundary between the upper troposphere and the lower stratosphere that varies in altitude between approximately 8 km at the poles and 18 km at the equator. The temperature gradient of the tropopause goes to zero (a relative temperature minima exists).

Troposphere. Lowest atmospheric layer, between the surface and the tropopause (lowest 8-15 km of the atmosphere, depending on latitude). The troposphere is characterized by decreasing temperature with height, large vertical motion, and large water vapor content. This is the region where most of the 'weather' occurs.

Uplink. Refers to the communication path direction from a ground station to a satellite. The information in this uplink is usually used for commanding of a subsystem (in general there are also uplinks in tracking systems, etc). In very elaborate communication systems with intermediate geostationary transmission satellites, the term 'uplink' is usually replaced by 'forward link' to avoid confusion.

Upwelling. The vertical motion of water in the ocean by which subsurface water of lower temperature and greater density moves toward the surface of the ocean. Upwelling occurs most commonly along the western coastlines of continents, but may occur anywhere in the ocean. Upwelling results when winds blowing nearly parallel to a continental coastline transport the light surface water away from the coast. Subsurface water of greater density and lower temperature replaces the surface water, and exerts a considerable influence on the weather of coastal regions. Carbon dioxide is transferred to the atmosphere in regions of upwelling. This is especially important in the Pacific equatorial regions, where 1 to 2 gigatons of carbon per year may be released to the atmosphere. Upwelling also results in increased ocean productivity by transporting nutrient-rich waters to the surface layer of the ocean. - The term 'upwelling' is also used in the context of 'upwelling radiation.' This refers to radiation (from the Earth's surface and from the atmosphere) observed from an airborne or spaceborne sensor.

UTM (Universal Transverse Mercator Projection). A widely used map projection which employs a series of identical projections around the world in the mid-latitude areas, each spanning six degrees of longitude and oriented to a meridian. The UTM projection preserves angular relationships and scale, it easily allows a rectangular grid to be superimposed on it.

Van Allen Belt. Regions or belts in the Earth's magnetosphere (at about 1.4-1.5 R_E and 4.5-6 R_E) where many energetically charged particles from the solar wind are trapped in the Earth's magnetic field.

Vegetation index. A mathematical algorithm of reflection values (reflectances, digital pixel values) in different spectral bands, used to estimate vegetation characteristics. Such an algorithm also serves to correct undesirable influences, such as differences of soil reflectance, atmospheric influences, etc. - In physical terms vegetation indices are radiometric measures of vegetation usually involving a ratio and/or linear combination of the red and NIR regions. Vegetation indices serve as indicators of relative growth and/or vigor of green vegetation, and are used as intermediaries in the assessment of various plant biophysical parameters, such as leaf area index, percent green cover, green biomass, and fractional absorbed photosynthetically active radiation (FPAR).

The spectral vegetation index concept and its universal generality has its roots in Landsat data interpretation.²¹⁰¹ As a consequence there are now a multitude of defined spectral vegetation and soil indices in existence. They are all derived, at least in part, by considering the contrast between visible (VIS) and near-infrared (NIR) spectral reflectance from land

²¹⁰¹)S. N. Goward, D. L. Williams, "Landsat and Earth Systems Science: Development of Terrestrial Monitoring," PE&RS, July 1997, pp. 887-900

surfaces. For typical broadband VIS/NIR measurements, green vegetation foliage produces stepped reflectance, with low VIS and high NIR reflectance, a result of pigment absorption in the VIS region and strong light scatter from cell walls in NIR.

Vernal equinox. The point of intersection between the ecliptic and the celestial equator, where the sun crosses from the south to the north (it is in fact the ascending node of the sun's orbit). The vernal equinox marks the beginning of spring for the northern hemisphere.

Very Long Baseline Interferometry (VLBI). In radio astronomy, the use of a system of two or more antennas placed several hundred or even several thousand kilometers apart, which are operated together as an interferometer. VLBI techniques are also employed in the field of Solid Earth Physics (geodynamics) for determining plate motions with accuracies of better than 1 cm/year. VLBI systems offer a superb tie to an inertial celestial reference frame based on extragalactic radio sources, which in turn is used to maintain the terrestrial reference frame.

Video. In general used to mean television, or a system used to communicate the television image. Specifically, pertains to the bandwidth and spectrum position of the signal which results from television scanning and which is used to reproduce a picture. Video images do not have the detailed resolution of film, but offer the advantage of immediate processing capability. This is particularly important in time-sensitive applications.

Vidicon. A generic name for a camera tube of normal light sensitivity. It outputs an analog voltage stream corresponding to the intensity of the incoming light.

Viewing angle. See **look angle**.

Water vapor. A very important constituent of the atmosphere. Its amount varies widely in space (vertical and horizontal) and time. The troposphere is the domain of water vapor, with about half of all the atmospheric water vapor in a layer below 2 km (only a minute fraction is above the tropopause). Water vapor is the major vehicle of atmospheric energy transport, a regulator of planetary temperatures and of rainfall. - The amount of water vapor in a given air sample may be determined in a number of different ways, involving such concepts as absolute humidity, mixing ratio, dew point, relative humidity, specific humidity, and vapor pressure.

Water-vapor absorption bands. Wavelength bands where water vapor - free or bound - absorbs radiation to a high degree. Absorption bands in the IR region are near 1.4 μm , 1.8 μm , 2.7 μm , 6.3 μm (strong), 11 μm , and 30 μm .

Wavefront. A three-dimensional surface in space for which the field radiated by the antenna has the same phase at all points. At a large distance R from the antenna, the wavefront is a spherical surface with radius R over the angular window established by the antenna pattern. For most geometries encountered in remote sensing, the wavefront may be approximated by a plane tangent to the spherical surface.

Wavenumber (ν). The number of waves per cm (the reciprocal of the wavelength). $\nu = 1/\lambda$. A wavenumber of 10,000 corresponds to a wavelength (λ) of 10^{-4} cm^{-1} , or to a wavelength (λ) of 1 μm . Conversion of a wavenumber resolution $\Delta\nu$ into a wavelength resolution $\Delta\lambda$:

$$\nu = 1/\lambda \Rightarrow |\Delta\nu| = |\Delta\lambda| / \lambda^2 \Rightarrow |\Delta\lambda| = |\Delta\nu| \lambda^2$$

Example: convert the wavenumber resolution $\Delta\nu = 20 \text{ cm}^{-1}$ into a wavelength resolution for the spectral range of 400-800 nm.

$$|\Delta\lambda| = |\Delta\nu| \lambda^2 = 20 \text{ cm}^{-1} \times (400 \text{ nm})^2 = 2 \times 10^{-6} \text{ nm}^{-1} \times 160000 \text{ nm}^2 = \underline{0.32 \text{ nm}} \text{ for } \lambda = 400 \text{ nm}.$$
$$|\Delta\lambda| = |\Delta\nu| \lambda^2 = 20 \text{ cm}^{-1} \times (800 \text{ nm})^2 = 2 \times 10^{-6} \text{ nm}^{-1} \times 640000 \text{ nm}^2 = \underline{1.28 \text{ nm}} \text{ for } \lambda = 800 \text{ nm}.$$

In this context belongs also the **spectral resolving power**, which is defined as the following ratio: $\lambda/\Delta\lambda$. Example: find the spectral bandwidth for a spectral range from 1.0 - 2.5 μm when the spectral resolving power ($\lambda/\Delta\lambda$) of the instrument is given as 250.

$\Delta\lambda = \lambda/250 = 1 \mu\text{m}/250 = 0.004 \mu\text{m}$ or 4 nm at the lower bound of the spectral range
 $\Delta\lambda = \lambda/250 = 2.5 \mu\text{m}/250 = 0.010 \mu\text{m}$ or 10 nm at the upper bound of the spectral range.

WGS-72 (World Geodetic System 1972) an Earth-centered datum of DMA (Defense Mapping Agency of US DoD). WGS-72 was preceded by WGS-60 and WGS-66. A principal objective of WGS is to allow referencing of local geodetic systems to a single geocentric system. WGS-72 is the result of an extensive effort (extending over 3 years) to collect satellite, surface gravity, and astrogeodetic data available throughout 1972. These data were combined using a unified WGS solution (a large-scale least squares adjustment).

WGS-84 (World Geodetic System 1984).²¹⁰²⁾ WGS-84 was also developed by DMA and is an improvement and a replacement for WGS-72. Radar altimeter data from GEOSAT was used to deduce geoid heights from oceanic regions of latitude $\pm 70^\circ$. Geoid heights were also deduced from a large number of ground-based Doppler stations and ground-based laser satellite-tracking data, as well as surface gravity data.

Definition: WGS-84 is a set of parameters for determining geometric and physical geodetic relationships on a global scale. The system includes a geocentric reference ellipsoid, a coordinate system, and a gravity field model. The ellipsoid is essentially that of the International Union of Geodesy and Geophysics Geodetic Reference System 1980. The coordinate system is a realization of the conventional terrestrial system, as established by the International Earth Rotation Service.²¹⁰³⁾

Wind shear. The rate of change of the wind velocity components with distance.

Window (electromagnetic). Wavelength or frequency region in which the atmosphere is largely transparent to electromagnetic radiation (e.g. optical window, microwave window, etc.).

Window operation. Processing of the (radiation) values of pixels within a predefined window, mostly limited to one spectral band - also called a 'filter.' Examples are convolution filters, variance filters, etc. . The filter output is assigned to the central pixel of the window.

Whiskbroom scanner. A line-scanning optomechanical sensor system.

World Geodetic System 1984 (WGS-84). Refers to a set of parameters established by the US Defense Mapping Agency (DMA) for determining geometric and physical geodetic relationships on a global scale. The system includes a geocentric reference ellipsoid, a coordinate system, and a gravity field model. The ellipsoid is essentially that of the International Union of Geodesy and Geophysics (IUGG) 'Geodetic Reference System 1980.' The coordinate system is a realization of the conventional terrestrial system, as established by the International Earth Rotation Service.

Zenith angle. The angular distance of any celestial object from a given observer's zenith, measured along the great circle of the celestial sphere from zenith to object.

Zodiacal light. A faint glow that extends away from the sun in the ecliptic plane of the sky, visible to the naked eye in the western sky shortly after sunset or in the eastern sky shortly before sunrise. Its spectrum indicates it to be sunlight scattered by interplanetary dust. The zodiacal light contributes about a third of the total light in the sky on a moonless night.

Appendix B Acronyms and Abbreviations

Units of Measure and some Physical Constants

A	ampere - unit of electric current [named after André M. Ampère (1775-1836), French physicist]
Ah	ampere hour
Å	angstrom - unit of length (used in particular for the short wavelength spectrum); $1\text{Å} = 10^{-10}\text{ m}$ [named after Anders Jonas Ångström (1814-1874), Swedish physicist and astronomer]
amu	atomic mass unit ($1.6605402 \cdot 10^{-27}\text{ kg}$)
are	unit of area ($1\text{ are} = 100\text{ m}^2$)
arcmin	arcminute [$1' = (1/60)^\circ$]
arcsec	arcsecond [$1'' = (1/60)'$]
au	astronomical unit - unit of length, namely the mean Earth/sun distance [$= 1.495978706 \cdot 10^{13}\text{ cm}$, which is the semimajor axis of the Earth's orbit around the sun (or about 150 million km)]
bar	pressure, ($1\text{ bar} = 10^5\text{ Nm}^{-2}$)
c	speed of light in vacuum ($299,792,458\text{ m/s}$)
cd	candela (unit of luminous intensity). The candela is the luminous intensity, in a given direction, of a source that emits monochromatic radiation of frequency $540 \times 10^{12}\text{ Hz}$ and that has a radiant intensity in that direction of $1/683\text{ watt per steradian}$.
cm	centimeter (unit of length) $1\text{ cm} = 10^{-2}\text{ m}$
C	coulomb - unit of electrical charge; $1\text{ C} = 1\text{ As}$ [named after Charles-Augustin Coulomb (1736-1806), French physicist. The coulomb is the quantity of electricity transported in 1 second by a current of 1 ampere.
°C	degree Celsius [named after Anders Celsius (1701-1744), Swedish astronomer]
dB	decibel - a unit for expressing the signal strength [named after Alexander Graham Bell (1847-1922), Scottish-born American inventor]
dm	decimeter (length) $1\text{ dm} = 10^{-1}\text{ m}$
E	Eötvös ($1\text{ E} = 10^{-9}\text{ s}^{-2}$). The linear gradient of gravity is defined in units of Eötvös, named in honor of the Hungarian physicist Roland Eötvös (1848-1919)
eV	electron volt ($1.60217733 \cdot 10^{-19}\text{ J}$). A unit of energy, equal to the energy an electron (or proton) would gain when accelerated by 1 volt.
F	farad - a unit of capacitance [named after Michael Faraday (1791-1867), English physicist and chemist]. The farad is the capacitance of a capacitor between the plates of which there appears a difference potential of 1 volt when it is charged by a quantity of electricity equal to 1 coulomb.
f	focal length
f/d	focal-length-to-diameter ratio
GHz	Gigahertz (10^9 Hz)
gal	unit of acceleration (used in particular in gravity measurements): $1\text{ gal} = 10^{-2}\text{ m s}^{-2} = 1\text{ cm s}^{-2}$; $1\text{ mgal} = 10^{-5}\text{ m s}^{-2}$ [named after Galilei Galileo (1564-1642), Italian mathematician, astronomer and physicist]
gauss	unit of magnetic induction [named after Carl Friedrich Gauss (1777-1855), German mathematician]
H	henry - unit of magnetic inductance; $1\text{ H} = 1\text{ Wb/A}$ or 1 Vs/A [named after Joseph Henry, a nineteenth-century US physicist]
Hz	hertz - a measure of frequency; $1\text{ Hz} = 1/\text{s}$ [named after Heinrich Hertz (1857-1894), German physicist]
h	hecto (10^2)
h (or hr)	hour

h	Planck's constant = $6.6260755 \times 10^{-34}$ Js (joule second)
ha	hectare ($1 \text{ ha} = 10^4 \text{ m}^2$)
hPa	hectopascal (international standard of pressure, $1 \text{ hPa} = 100 \text{ Pa}$)
Isp	specific impulse with a unit Ns/kg. The numerical value of the specific impulse also corresponds to the effective exhaust velocity (m/s) of the gas exiting the thruster in a vacuum. See also Glossary.
J	joule - unit of work or energy; $1 \text{ J} = 1 \text{ Nm} = 1 \text{ Ws}$ [named after James Prescott Joule (1818-1889), British physicist]
K	degree Kelvin [named after Sir William Thomson (Lord Kelvin, 1824-1907), Scottish engineer, physicist and mathematician]. The degree Kelvin is the unit of temperature determined by the Carnot cycle with the triple-point temperature of water defined as 273.15 K (corresponds exactly to 0°C).
k	kilo (10^3)
kbit/s	kilobit per second (10^3 bit/s)
keV	kiloelectron volt (10^3 eV)
kg	kilogram (10^3 g)
kg/m^3	density
kHz	kilohertz (10^3 Hz)
km	kilometer (10^3 m)
krad	kilorad (see rad below)
kW	kilowatt (10^3 watt)
kWe	kilowatt electric (used to distinguish electrical power from thermal power)
L	liter (volume) $1\text{l} = 1 \text{ dm}^3$ [the symbol for liter is capitalized (when alone by itself) to avoid confusion with the number 1]
lm	lumen (cd sr) luminous flux. The lumen is the luminous flux emitted in a solid angle of 1 steradian by a uniform point source having an intensity of 1 candela.
lx	lux (lm/m^2) illumination
M	Mega (10^6)
Mbit/s	Megabit per second ($10^6 \text{ bit per second}$)
MeV	Megaelectron volt (10^6 eV)
MHz	Megahertz (10^6 hertz)
m	meter
m	milli (10^{-3})
m^2	area (square meter)
m^3	volume (cubic meter)
mb (mbar)	millibar
min	minute
mg	milligram (10^{-3} g)
mgal	milligal (10^{-3} gal)
mJ	millijoule (10^{-3} J)
ml	milliliter (10^{-3} l)
mm	millimeter (unit of length) $1 \text{ mm} = 10^{-3} \text{ m}$
mN	millinewton
mrad	milliradian ²¹⁰⁴⁾
ms	millisecond
m/s	meter per second (velocity)
μ	micro (10^{-6})
μm	micrometer (10^{-6} m)
μrad	microradian
μs	microsecond (10^{-6} second)
N	newton - unit of force; $1\text{N} = 1 \text{ kgm/s}^2$ [named after Sir Isaac Newton (1643-1727), English natural philosopher and mathematician]

²¹⁰⁴⁾ An example is given to better visualize the plane angle of a milliradian. The apparent sun disk angle as seen from Earth is $32^\circ 26''$ (max, or about **30.7 mrad**), and $31^\circ 31''$ (min).

Nm	newton meter (work or energy)
n	nano (10^{-9})
nm	nanometer (10^{-9} m)
nm	nautical miles [1 nm = 1852 m (international)]
nT	nanotesla (10^{-9} tesla) unit of magnetic flux density
Ω	ohm - unit of electrical resistance; $1 \Omega = 1 \text{ V/A}$ [named after Georg Simon Ohm (1789-1854), German physicist]
Pa	pascal - unit of pressure; $1 \text{ Pa} = 1 \text{ N/m}^2$ [named after Blaise Pascal (1623-1662), French mathematician and physicist]
p	pico (10^{-12})
pC	picocoulomb (10^{-12} coulomb)
pT	picotesla (10^{-12} tesla)
ppb	parts per billion (10^{-9})
ppbv	parts per billion, by volume
ppm	parts per million (10^{-6})
ppmv	parts per million, volume
pps	pulses per second
ppt	parts per trillion (10^{-12})
pptv	parts per trillion (10^{-12}), by volume
R_E	Earth radius = 6378.140 km (mean equatorial radius)
rad	radian - a unit of plane angular measurement equal to the angle at the center of a circle subtended by an arc equal in length to the radius
rad/s	radian per second (angular velocity)
rad	In the context of radiation shielding, the term “rad” is also used for energy accumulated in matter (dosimetry for the energy absorbed per unit mass of material, usually by ionization processes). A rad is the amount of particle radiation that deposits 10^{-2} J/kg of target material. Besides the “rad” is the “Gray.” $1 \text{ rad} = 1/100 \text{ Gray}$. Note: A Gray is the radiation absorbed dose unit of SI (Système Internationale). $1 \text{ Gray} = 1 \text{ J/kg}$ (=100 rad). Or $10 \text{ Gray} = 1000 \text{ rad} = 1 \text{ krad}$. ²¹⁰⁵⁾
rms	root mean square
rpm	revolutions per minute
rps	revolutions per second
S	siemens - unit of electrical conductance; $1 \text{ S} = 1 \text{ A/V}$ [named after Werner von Siemens (1816-1892), German electrical engineer]
s	second
sr	steradian - a unit of measure of solid angles expressed as the solid angle subtended at the center of a sphere by the portion of the surface whose area is equal to the square of the radius of the sphere
T	Tera (10^{12})
TB	TeraByte (10^{12} Byte)
THz	Terahertz (10^{12} hertz)
tesla (T)	unit of magnetic flux density. $1 \text{ T} = 1 \text{ Wb/m}^2$ which corresponds to 10^4 gauss [named after Nikola Tesla (1856-1943), Croatian-born American inventor]
V	volt - unit of electrical potential [named after Alessandro Volta (1745-1827), Italian physicist]
W	watt - unit of power; $1 \text{ W} = 1 \text{ J/s}$ [named after James Watt (1736-1819), a Scottish mechanical engineer and inventor]
Wb	weber - unit of magnetic flux [named after Ernst Weber (1901-), Austrian-born US engineer]
Wh	watt hour (work or energy)
Ws	watt second (work or energy)

²¹⁰⁵⁾ Typical CMOS devices can tolerate 1-10 krad/year. Dose rates for a silicon target are usually stated in g/cm^2 or in thickness of aluminum shielding for a given orbit. For a sun-synchronous orbit, about 0.8 g/cm^2 (or 4 mm silicon thickness) is needed for a 1-year lifetime, and about 3 g/cm^2 (13 mm silicon) for a 10 year lifetime.

General conventions of unit representations:

The symbol “m” is used with various meanings depending on its position and occurrence in a unit. In single-digit instances, the symbol m stands simply for meter. This is also the case in double symbol instances, when m is in last position, like in Nm (newtonmeter), nm (nanometer), or mm (millimeter). When m is used in double-digit symbols in first place, like mm (millimeter), ml (milliliter), ms (millisecond), mN (millinewton), etc., then the first small “m” is always used in a diminutive sense referring to “milli” (10^{-3}).

The term small “k” stands for kilo (10^3) as in km (kilometer), kg (kilogram), kW (kilowatt), or kbit (kilobit). The capital letter “K,” on the other hand, has the meaning of Kelvin, referring to a degree temperature on the absolute temperature scale.

The designations M (Mega), G (Giga), T (Tera), or μ (micro), n(nano), p (pico), etc., in combinations with other units, follow the same logic as outlined above and in Table 568.

Quantity	Unit name	Unit symbol
Length	meter	m
Mass	kilogram	kg
Time	second	s
Electric current	ampere	A
Thermodynamic temperature	kelvin	K
Luminous intensity	candela	cd
Amount of substance	mole	mol

Table 567: Symbols for the seven basic units in the SI system

The basic SI units come in all sizes. Since the SI system is built upon the base 10, the different sizes are base 10 multiples of the basic units as illustrated in Table 568.

Prefix	Symbol	Multiplication factor	Examples
Exa	E	$10^{18} = 1,000,000,000,000,000,000$	
Peta	P	$10^{15} = 1,000,000,000,000,000$	
Tera	T	$10^{12} = 1,000,000,000,000$	TByte
Giga	G	$10^9 = 1,000,000,000$	GHz, GByte,
Mega	M	$10^6 = 1,000,000$	MHz, Mbit/s,
kilo	k	$10^3 = 1,000$	km (kilometer), kg (kilogram),
hecto	h	$10^2 = 100$	hl (hectoliter), ha (hectare)
deca	da	$10^1 = 10$	
		$10^0 = 1$	
deci	d	$10^{-1} = 0.1$	dg (decigram), dl (deciliter)
centi	c	$10^{-2} = 0.01$	cm (centimeter), cl (centiliter)
milli	m	$10^{-3} = 0.001$	mm (millimeter), ml (milliliter)
micro	μ	$10^{-6} = 0.000001$	μm (micrometer), μg (microgram)
nano	n	$10^{-9} = 0.000000001$	nm (nanometer), ns (nanosecond)
pico	p	$10^{-12} = 0.000000000001$	ps (picosecond), pf (picofarad)
femto	f	$10^{-15} = 0.000000000000001$	fs (femtosecond)
atto	a	$10^{-18} = 0.000000000000000001$	

Table 568: Commonly used prefixes of SI multiples and submultiples

Quantity	Unit name	Unit symbol (derivation)
Force	newton	N (kgms^{-2})
Energy	joule	J (Nm) or (Ws) or ($\text{kgm}^2\text{s}^{-2}$)
Energy	kilowatt hour	kWh ($3.6 \cdot 10^6$ J)
Energy	electron volt	eV ($1.6 \cdot 10^{-19}$ J)
Power	watt	W (Js^{-1}) or ($\text{kgm}^2 \text{s}^{-3}$)

Quantity	Unit name	Unit symbol (derivation)
Frequency	hertz	Hz (s^{-1})
Electrical potential	volt	V (JC^{-1}) or (WA^{-1})
Electrical charge	coulomb	C (As)
Electrical resistance	ohm	Ω ($V A^{-1}$)
Electrical conductance	siemens	S ($A V^{-1}$)
Electrical capacitance	farad	F ($C V^{-1}$) or ($A s V^{-1}$)
Magnetic inductance	henry	H ($Wb A^{-1}$) or ($V s A^{-1}$)
Magnetic flux	weber	Wb (Vs)
Magnetic flux density	tesla	T ($Wb m^{-2}$)
Area	square meter	m^2
Volume	cubic meter	m^3
Volume	liter	L ($10^{-3} m^3$)
Velocity (speed)	meter per second	ms^{-1}
Temperature	degree Celsius	$^{\circ}C$
Pressure	pascal	Pa (Nm^{-2}) or ($kg m^{-1} s^{-2}$)
Pressure	standard atmosphere	atm ($1.01325 \cdot 10^5$ Pa)
Torque		Nm (newton meter)
Electric field strength		$V m^{-1}$ (volt per meter)
Magnetic field strength		$A m^{-1}$ (ampere per meter)
Plane angle (arc length)	degree arcmin (minute) arcsec (second)	$1^{\circ} = (\pi/180)$ rad $1' = (1/60)^{\circ}$ $1'' = (1/60)'$

Table 569: Derived units commonly used in science and engineering 2106) 2107)

Numbers

3DMA Three-Dimensional Microgravity Accelerometer (Shuttle payload)

A

AAAS American Association for the Advancement of Science (Washington DC)
AAE Austrian Aerospace GmbH, Vienna, Austria
AAOE Airborne Antarctic Ozone Experiment (1987)
AARGOS A340 Atmospheric Research Global Observation System (MOZAIC)
AARI Arctic and Antarctic Research Institute (St. Petersburg, Russia)
AAS American Astronomical Society
AASE Airborne Arctic Stratospheric Expedition (see campaign survey)
ABLE Atmospheric Boundary Layer Experiment (campaign)
AC Alternating Current
ACC Anthropogenic Climate Change (CLIVAR subprogram)
ACCESS Assembly Concept for Construction of Erectable Space Structure (Shuttle)
ACE Advanced Composition Explorer (NASA, APL, etc., see K.1)
ACE-1, -2 Aerosol Characterization Experiment (campaigns)
ACE Atmosphere Climate Experiment (an ESA mission, A.1)
ACEChem Atmospheric Chemistry Explorer (a proposed ESA mission as of 2001)
ACES Acoustic Containerless Experiment System (Shuttle payload)
ACORN Airborne Composition Observations in the Region of the North-Atlantic-Corridor (P.40.2)
ACRES Australian Centre for Remote Sensing (Belconnen, Australia)
ACSYS Arctic Climate System Study (WCRP program)
ACT Applied Coherent Technology, Herndon VA (commercial provider of remote sensing products, operator of satellites, etc.)

2106) "Symbols and Abbreviations for Electrical and Electronic Engineering," IEE, 1980

2107) R. A. Nelson, "Guide for Metric Practice," Physics Today, Supplement to August 1997 issue, pp. 13--14

ACTS	Advanced Communications Technology Satellite in GEO (NASA, Launch: Sept. 1993 by Shuttle Discovery). ACTS advanced considerably the use of Ka-band technology and paved the way for high-speed commercial Ka-band communications.
A/D	Analog/Digital converter
ADCP	Acoustic Doppler Current Profilers [(U. of Florida, Tokai University, Hiroshima University, Kyushu University, Japan, and CSIRO), subsurface upward-looking moorings]
ADEN	ALOS Data European Node [an ESA initiative involving a number of distributed acquisition facilities capable of receiving ALOS data (SAR and optical) for European users: a) Toulouse (France) with upgraded X-band stations, b) DLR Neustrelitz (Germany) and Libreville (Gabon), c) TSS Tromsø (Norway) and SSC Sturup (Sweden, d) ASI Ma-teira (Italy and Maspalomas (Spain)]
ADEOS	Advanced Earth Observation Satellite (NASDA, D.1, D.2)
ADM	Atmospheric Dynamics Mission (ESA Earth Explorer Core Mission)
ADPCM	Adaptive Differential Pulse Code Modulation (a lossy data compression technique)
ADS-B	Automatic Dependent Surveillance-Broadcast [an FAA system installed in aircraft (first prototypes as of 2000). When coupled with GPS, an aircraft's ADS-B unit can continuously broadcast its identification, position, altitude, direction, speed, rate of climb or descend, etc.] ADS-B is a key technology to free flight.
ADSF	Automated Directional Solidification Furnace (Shuttle payload)
ADV CGBA	Advanced Commercial Generic Bioprocessing Apparatus (Shuttle)
ADV XDT	Advanced X-Ray Detector (Shuttle payload)
AEAP	Atmospheric Effects Aircraft Program (NASA)
AEB	Agencia Espacial Brasileira - Brazilian Space Agency, Brasilia, Brazil (since 1994)
AEM-1	Applications Explorers Mission-1 (see HCMM A.18)
AEM-2	Applications Explorers Mission-2 (A.5)
AERCam/Sprint .	Autonomous Extravehicular Activity Robotic Camera Sprint [Shuttle free-flying camera, first flown on STS-87 (Nov. 19 - Dec. 5, 1997)]
AEROCE	Atmospheric/Ocean Chemistry Experiment (campaign)
Aerospace Corp. .	'The Aerospace Corporation' (since 1960), a US private nonprofit research and development center with HQs in El Segundo, CA. Aerospace operates a Federally Funded Research and Development Center (FFRDC) for the Department of Defense (DoD). The primary customer is the Space and Missile Systems Center (SMC) of the US Air Force Materiel Command. The Aerospace Corporation provides engineering services and space technology expertise to DoD space programs and other US government agencies. Other company locations are in the Washington DC area, Colorado Springs, CO, Albuquerque, NM, Sunnyvale CA, VAFB, CA, and at KSC (Kennedy Space Center), FLA.
Aerospatiale	A French aerospace conglomerate with 38,000 employees, HQ in Paris. Builder of the main stages of Ariane 4 and 5. Manufacturer of satellites and sensors. Three major divisions: Aircraft, Helicopters, and Space & Defense. Spacecraft platforms: Spacebus series.
AES	Atmospheric Environment Service (of Environment Canada)
AESA	Atmospheric Effects of Stratospheric Aircraft (NASA)
AF	US Air Force
AFB	Air Force Base (US Air Force)
AFC	Affiliated Data Center (these are institutional facilities that are affiliated with EOSDIS, in particular NOAA facilities are AFCs)
AFE	American Flight Echocardiograph (Shuttle payload)
AFGL	Air Force Geophysics Laboratory (Hanscom AFB, Bedford, MA, USA) Note: in 1998 AGFL was renamed to "Hanscom Research Site"

AFP-675 Air Force Program 675 (Shuttle payload)
 AFNOR Association française de normalization (French standards institute)
 AFOSR Air Force Office of Scientific Research (an AFRL directorate)
 AFRL Air Force Research Laboratory (USA). The nine AFRL sites are located at: Wright Laboratory, Wright-Patterson AFB, Ohio (AFRL HQs, directorates of: Air Vehicles, Propulsion, Directed Energy, and Materials & Manufacturing); Hanscom AFB, MA (Sensors directorate); Phillips Research Site, Kirtland AFB, Albuquerque, NM (Space Vehicles directorate); Rome Laboratory, Griffis AFB, Rome, NY; Edwards AFB, Edwards, CA; Brooks AFB, TX; Eglin AFB, FL; Tyndall AFB, FL; Bolling AFB (AFOSR directorate), Washington DC.
 AFSCN Air Force Satellite Control Network (USA)
 AFSK Amplitude Frequency Shift Keying (modulation technique)
 AGARD Advisory Group for Aerospace Research and Development. AGARD is a NATO agency (with HQ in Neuilly-sur Seine, France), formed in 1954, with the objective to enhance the exchange of aerospace technology within NATO.
 AGASP Arctic Gas and Aerosols Sampling Project (airborne campaign)
 AGC Antenna Gain Control
 AGGA Advanced GPS/GLONASS ASIC (ESA/ESTEC development). As of the end of 2000 the AGGA chip set is available to European industry, it is manufactured by ATMEL of Nantes, France. It is used in GRAS, in the LAGRANGE GNSS receiver of Laben SpA, Italy, and in the RIMS stations of the EGNOS program.
 AGILE Astro-rivelatore Gamma ad Immagini LEggero (Gamma-ray Astronomical Low-Mass Detecor), an approved ASI mission with a planned launch in 2003
 AGL Above Ground Level (usually the altitude of aircraft)
 AGU American Geophysical Union (a society with over 35,000 members in over 115 countries. The objective is to advance progress in the Earth, atmospheric, oceanic, hydrologic, and space and planetary sciences.)
 AIAA American Institute of Astronautics and Aeronautics (Reston, VA)
 AIDJEX Arctic Ice Dynamics Joint Experiment (campaign)
 Airbus Industrie . A consortium of European aerospace companies, founded in 1970. (partners are: Aerospatiale of France, DASA Airbus of Germany, British Aerospace, and Spain's CASA). Italy's Alenia, Fokker of the Netherlands, and Belairbus in Belgium are associate members who participate in selected programs. Some 32,000 people work directly for Airbus Industrie within the partner companies. Airbus Industrie is headquartered near Toulouse, France. Builder of civil aircraft (Airbus).
 AIRS Autonomous Information Reception Station (see Meteor-3M series)
 AIP American Institute of Physics
 AIP Astrophysikalisches Institut Potsdam (Germany)
 AKR Auroral Kilometric Radiation (ionospheric phenomenon)
 ALACE Autonomous Lagrangian Circulation Explorer (free-floating ocean buoys designed to seek a pre-programmed depth; they drift with the ocean currents of that depth, and pop up periodically to report their position to a satellite), see also PALACE
 ALE/GAGE Atmospheric Lifetime Experiment/Global Atmospheric Gas Experiment (campaign)
 Alenia Spazio ... Alenia Aerospazio S.p.A. is a company of the Finmeccanica IRI group, an Italian consortium in aerospace, defense, energy, transportation and automation markets. Partner in many space programs (2500 employees), builder of COSMO-SkyMed. Subsidiaries: Laben S.p.A. (Laboratori Elettronici Nucleari) in Vimodrone (Milano, Italy) since 1958; SSI (Space Software Italia S.p.A. in Taranto, Italy; QSW (Quadrics Supercomputer World Ltd.) in Rome, Italy; HCSA (Hellenic Company

	for Space Applications S.A.) in Paradisos Amarousiou, Italy; EuroSky-Way in Rome, Italy
ALEXIS	Array of Low Energy X-Ray Imaging Sensors (LANL, K.3)
ALISSA	l'Atmosphere par Lidar Sur SALiout (the French sensor was at first proposed by CNES for a Salyut flight)
ALMAZ	ALMAZ = 'rough diamond' (Earth observation series, Russia), D.4
ALOHA	One of several communication access methods
ALOHA	Airborne Lidar and Observations of the Hawaiian Airglow (campaign)
ALOS	Advanced Land Observing Satellite (D.3)
ALPEX	Alpine Experiment (campaign)
AM	Amplitude Modulation (modulation technique of the main carrier)
AM	Ante Meridiem (US time notation designating morning hours, to distinguish from PM)
AMBIACE	Amazon Biogeochemistry and Atmospheric Chemistry Experiment (campaign)
AMEX	Australian Monsoon Experiment (campaign)
AMM	Antarctic Mapping Mission (Radarsat)
AMOS	Air Force Maui Optical Station (Shuttle experiment). AMOS is located at the summit of Haleakala, on the island of Maui, Hawaii. The Air Force experiment is using the Shuttle orbiter as a calibration target for a ground-based experiment (research for electro-optical sensors)
AMPTE	Active Magnetosphere Particle Tracer Explorers (cooperative mission of US/ NASA, Germany and UK, K.4)
AMS	Alpha Magnetic Spectrometer (Shuttle payload) AMS was first flown on STS-91 (June 2 - 12, 1998). It is an anti-matter demonstration, an experiment with international cooperation from: USA, China, Finland, Germany Italy, and Switzerland
AMS	American Meteorological Society
AMSAT	The Radio Amateur Satellite Corporation (worldwide groups of Amateur Radio Operators (volunteers, normally organized by country), building, launching and communicating with each other through non-commercial amateur satellites, since 1969, also the name of satellites)
AMTEC	Alkali Metal Thermal-to-Electric Converter (Shuttle payload)
ANL	Argonne National Laboratory (Argonne, IL, USA, a DOE facility, operated by the University of Chicago)
ANSI	American National Standards Institute
ANSTO	Australian Nuclear Science and Technology Organization
Antrix Corp.	Bangalore, India (the commercial marketing arm of ISRO, Antrix is the distributor of IRS data, etc.)
AO	Announcement of Opportunity (usually for a sensor on a particular mission)
AOCS	Attitude and Orbit Control System
AOET	Atomic Oxygen Exposure Tray (Shuttle D2 mission)
AOS	Acousto-Optical Spectrometer
AOTF	Acousto-Optic Tunable Filter (an imaging dispersion technique)
APARE	Asia/North Pacific Regional Study (campaign)
APCF	Advanced Protein Crystallization Facility (Shuttle, see also PCF)
APCG	Advanced Protein Crystal Growth (Shuttle, see also PCG)
APD	Avalanche Photodiode (detector type)
APDA	Arctic Precipitation Data Archive
APE	Airborne Polar Experiment (campaign)
APE	Auroral Photography Experiment (Shuttle payload)
APEX	Active Plasma Experiment (Interkosmos, K.5)
APFO	Aerial Photography Field Office (Salt Lake City, UT, USA)
APL	Applied Physics Laboratory, since 1942, a facility of Johns Hopkins University (JHU), in Laurel, MD, USA
APM	Ascent Particle Monitor (Shuttle experiment)

APRS	Automatic Position Reporting System (a protocol used by the Amateur Radio community)
APS	Active Pixel Sensor
APSC	Asia Pacific Space Center
APT	Automatic Picture Transmission (one type of NOAA downlink transmission; APT transmits data from two channels of the AVHRR at a reduced resolution of 4 km in the VHF frequency band (at 137.50 and 137.62 MHz)).
APV	Autonomously Piloted Vehicle (Condor)
AR	Anthrorack (Shuttle D2 mission)
ARAT	Avion de Recherche Atmosphérique et de Télédétection (Atmospheric Research and Remote Sensing Aircraft), ARAT is jointly operated by INSU-CNRS, CNES, DMN (French National Weather Center), and IGN (Institut Géographique National). The aircraft is IGN property. ARAT is a Fokker 27 MK pressurized twin turboprop aircraft (service altitude = 5800 m, cruising speed = 350 km/h, flight endurance = 5 hr; on-board computer systems: HP1000 A900, recordings on high-capacity digital video cassette, two Exabyte 2.5 GByte recorders) .
ARC	Ames Research Center (NASA facility at Moffett Field, CA, and at the Dryden Flight Research Facility in Edwards, CA, USA)
ARC	Aggregation of Red Blood Cells (Shuttle experiment)
Archimedes I, II .	Coordinated European airborne campaigns in the North Sea region (start in 1983, Archimedes IIa took place in April 1988)
ARCS	Austrian Research Center Seibersdorf (since 1956, with sites at Seibersdorf, Leoben, Ranshofen, Vienna, Graz, Dornbirn, Wiener-Neustadt, and Budapest)
ARCSS	Arctic Center of System Science (at NSIDC of U. of Colorado, Boulder, CO, USA)
ARESE	ARM Enhanced Shortwave Experiment (campaign)
ARGO	“Array for Geostrophic Oceanography,” a global array of buoys [an international ocean program, part of GCOS/GOOS and CLIVAR - it consists of an array of 3000 free-drifting (Lagrangian) profiling floats that measure the temperature and salinity of the upper 2000 m of the ocean; start of deployment in 2000].
ARGOS	Argos (CNES System) is a data collection and location system with a space segment and a ground segment. ARGOS is operational on NOAA polar-orbiting S/C. G.15.4, C.1
ARGOS	Advanced Research and Global Observation Satellite (DoD, M.1)
ARIANESPACE	A commercial launch service provider of Europe with HQ in France (since 1980, first commercial operator of launchers in the world). Twelve European countries participate in the Ariane program.
ARIES	Australian Resource Information and Environment Satellite
ARISTOTELES .	Applications and Research Involving Space Techniques Observing The Earth's Field from Low Earth Orbiting Satellite (planned but cancelled ESA Mission)
ARM	Atmospheric Radiation Measurement (campaign program of DOE)
ARMCAS	Arctic Radiation Measurements in Column Atmosphere-Surface System (campaign)
ARNS	Aeronautical Radionavigation Service
ARTEMIS	Advanced Relay and Technology Mission Satellite (ESA)
ARPA	Advanced Research Project Agency (US)
ARQ	Automatic-Repeat Request
ASA	Austrian Space Agency (Vienna, since 1972)
ASAP	Adaptive Sensor Array Processing (MIT/LL)
ASAP	Advanced Sensors Application Program (US Navy)
ASAP	Airborne Science and Application Program (USGS, NASA)

ASAP	Ariane Structure for Auxiliary Payloads (ASAP provides launch opportunities for microsatellites on a commercial basis, the ASAP-5 ring structure can accommodate up to 8 microsatellites with a volume restriction of 60 cm x 60 cm x 80 cm)
ASCOT	Atmospheric Studies in Complex Terrain (campaign)
ASCS	Agricultural Stabilization and Conservation Service (USA)
ASDAR	Aircraft to Satellite Data Relay (wind observations are reported from commercial aircraft at cruising altitude via meteorological satellite communication links at 7 minute intervals)
ASE	Automatic Air-Sampling Equipment, see P.40.4
ASEM	Assembly of Station by EVA Methods (Shuttle demonstration)
ASES	American Solar Energy Society
ASF	Alaska SAR Facility in Fairbanks, Alaska (DAAC of NASA EOS Program. ASF is located at the Geophysical Institute of the University of Alaska at Fairbanks. Position: 65°N, 148°W. ASF is in effect a US-PAF for ERS-1/2 data as well as for JERS-1 and RADARSAT data.)
ASHOE	Airborne Southern Hemisphere Ozone Experiment (campaign)
ASI	Agenzia Spaziale Italiana (formerly PSN). ASI is the Italian Space Agency, Rome (since 1988)
ASI/CGS	ASI/Centro di Geodesia "Guiseppe Colombo" in Matera, Italy, for Space Geodesy, Remote Sensing and Space Robotics. CGS hosts the I-PAF (Italian Processing and Archiving Facility), a multimission facility for archiving, processing and distributing remote sensing data.
ASI	Alcatel Space Industries, France, since 1998 (ASI represents the merger of four space hardware development divisions from Alcatel, Dassault, Thomson and Aerospatiale)
ASIC	Application Specific Integrated Circuit
ASIM	Application Specific Microinstrument
ASP	Attitude Sensor Package (Shuttle payload of ESA)
ASPRS	American Society for Photogrammetry and Remote Sensing (Bethesda, MD, since 1934)
ASRI	Asher Space Research Institute (of Technion Israel Institute of Technology, Haifa, since 1986)
ASRI	Australian Space Research Institute, Elizabeth, SA
ASTEX	Atlantic Stratocumulus Transition Experiment (airborne campaign at the Azores in 1992)
ASTP	Apollo-Soyuz Test Project (1975)
ASTRE	Accéléromètre Spatial Triaxial Electrostatique [an ESA accelerometer built by ONERA and part of ESA's MMA (Microgravity Measurement Assembly) flown on Shuttle flights STS-83 and STS-94]
Astrium	Astrium is the name of a new European space company, a daughter of EADS, formally created in 2000. Astrium is a merger of Aerospatiale Matra of Paris, France, DASA of Munich Germany, and Marconi Electronic Systems of Stanmore, UK. German Astrium facilities are at Bremen, Ottobrunn, Friedrichshafen, Lampoldhausen, Rostock and Trauen. The French/British MMS (Matra Marconi Space) facilities are located at Portsmouth and Stevenhage, UK, and at Toulouse and Vélizy, France.
ASTRO-SPAS	Astronomy Platform - Shuttle Pallet Satellite
ASU	Arizona State University (Tempe, AZ)
ATEx	Advanced Tether Experiment (NRL)
ATEX	Atlantic Tropospheric Experiment (campaign)
ATI	Along-Track Interferometry
ATLAS	Atmospheric Laboratory for Application and Science (NASA program, payload series on Shuttle), J.2
ATLAS	Autonomous Temperature Line Acquisition System (NOAA/PMEL mooring system measuring surface wind, air temperature, SST, ten sub-

	surface temperatures and two subsurface pressures; all data are monitored by ARGOS)
ATLID	Atmospheric Lidar (Sensor), an ESA backscatter lidar
ATN	Advanced TIROS-N Series (NOAA, launched from 1983 on)
ATS	Application Technology Satellite (NASA GEO satellite series prior to GOES)
ATSB	Astronautic Technology SB, Kuala Lumpur, Malaysia
ATTAS	Advanced Technology Testing Aircraft System (VFW-614 of DLR)
ATV	Roton Atmospheric Test Vehicle (of Rotary Rocket Company, Redwood City, CA). Roton ATV is a fully reusable, single-stage-to-orbit, commercial launch vehicle. Roton is powered by a rotary engine burning liquid oxygen and jet fuel. ATV made its first successful flight on July 23, 1999.
ATV	Automated Transfer Vehicle (ESA cargo resupply vehicle for ISS to be launched by Ariane-5, payloads of up to 7,500 kg can be delivered)
AU	Astronomical Unit, Sun-Earth distance = 1.496×10^8 km (average)
AURA	Association of Universities for Research in Astronomy [Washington DC, since 1957, AURA/STSI (Space Telescope Science Institute) is the operator of the Hubble Space Telescope for NASA]
AVHRR	Advanced Very-High Resolution Radiometer (NOAA Sensor, AVHRR/3 on NOAA-K,L,M,N is to be renamed in VIRSR for NOAA-O,P,Q)
AVISO	Archivage Validation and Interprétation des données des Satellites Océanographiques [Archiving, Validation and Interpretation of Satellites oceanographic data (CNES data center for GEOSAT, Topex/Poseidon, ERS-1/2, ENVISAT, Jason-1, etc.)]
AWCS	Automated Wafer Cartridge System (Shuttle payload)
AWG	American Wire Gauge (the higher the number the thinner the wire)
AWI	Alfred Wegener Institut for Polar and Marine Research, Bremerhaven (since 1980) and Potsdam since 1992 (Germany)
AWS	Automated Weather Station
AXAF	Advanced X-ray Astrophysics Facility, a NASA satellite mission in a high elliptical Earth orbit, deployed by Shuttle STS-93; in the spring of 1999 AXAF has been renamed to “Chandra X-ray Observatory” in honor of the late India-American Nobel Laureate Subrahmanyan Chandrasekhar
AZBS	Avionik Zentrum Braunschweig (Germany)

B

BA	Baroreflex (Shuttle payload on D2 mission)
BAC	Block Adaptive Quantization (a SAR raw data compression method)
BADC	British Atmospheric Data Center (at RAL, Chilton, UK)
BAEX	Baltic Aerosol Experiment (campaign)
BAHC	Biospheric Aspects of the Hydrological Cycle (IGBP core project since 1994)
BALTEX	Baltic Sea Experiment (campaign)
BAMS	Bulletin of the American Meteorological Society (a periodical)
BAS	British Antarctic Survey (Cambridge, UK)
BATC	Ball Aerospace and Technologies Corporation (Aerospace Systems Division in Boulder, CO, and Telecommunication Products Division in Broomfield, CO) formerly: Ball Brothers Research Corporation, since 1956, [manufacturer of satellites such as: Seasat, SIR-C, COBE (Cosmic Background Explorer), CGRO (Compton Gamma Ray Observatory), ERBS, CRRES, GFO-1; and builder of instruments: CZCS, GHRS (Goddard High Resolution Spectrograph), STIS (Space Telescope Imaging Spectrograph), and NICMOS (Near-Infrared Camera and Multi-Object Spectrometer), all on HST, etc.]

BASE	Beaufort and Arctic Storm Experiment (campaign)
BATERISTA ...	Biosphere-Atmosphere Transfer and Ecological Research, In situ Studies in Amazonia (campaign)
BATGE	Biosphere-Atmosphere Trace Gas Exchange in the Tropics (IGBP/IGAC campaign)
BATS	Bermuda Atlantic Time-Series Study (campaign)
BB	Biolabor (Shuttle D2 mission)
BBXRT	Broad Band X-Ray Telescope (part of ASTRO-1 observatory, Shuttle)
BCP	Ball (or BATC) Commercial Platform (BCP 2000 series bus, BCP 4000 series, BCP 5000, etc.)
BCRS	Netherlands Remote Sensing Board (Delft, The Netherlands)
BCSC	Boeing Commercial Space Co. (a subsidiary of the Boeing Co, chartered to commercialize space technologies)
BDPU	Bubble, Drop and Particle Unit (Shuttle experiment)
BDS	Bioreactor Demonstration System (Shuttle payload)
BEST	Bilan Energétique du Système Tropical (Tropical System Energy Budget), a proposed CNES mission
BGR	Bundesanstalt für Geowissenschaften und Rohstoffe (Hannover, Germany)
BIB	Blocked Impurity Band (detector type)
BIBEX	Biomass Burning Experiment (program of IGBP/IGAC)
BIMDA	Bioserve/Instrumentation Technology Associates Materials Dispersion Apparatus (Shuttle payload)
BiCMOS	Bipolar Complementary Metal-Oxide Semiconductor
BIL	Band Interleaved by Line (image organization)
BILTEN	TUBITAK-METU BILTEN - Information Technologies and Research Institute of the Scientific and Technical Council of Turkey [located on the campus of the Middle East Technical University (METU), Ankara, Turkey]
BIO3D	Biochemistry of 3-D Tissue Engineering (Shuttle Payload)
BIP	Band Interleaved by Pixel (image organization)
BIPM	Bureau International des Poids et Mesures (Paris)
BIRA	Belgisch Instituut voor Ruimte Aeronomie (Brussels, Belgian Institute of Space Aeronomy)
BLAST	Battlefield Laser Acquisition Sensor Test (Shuttle experiment)
BLM	Bureau of Land Management (USA)
BMBF	Bundesministerium für Bildung, Wissenschaft, Forschung und Technologie (German Ministry of Education, Science, Research and Technology, the successor to BMFT, since 1994)
BMDO	Ballistic Missile Defense Organization [US, Division within DoD, formerly SDIO (Strategic Defense Initiative Organization)]
BMFT	Bundesministerium für Forschung und Technologie (German Ministry of Research and Technology, prior to 1994)
BMO	British Meteorological Office (same as UKMO, HQs in Bracknell, Remote Sensing Instrumentation branch in Farnborough)
BMRC	Bureau of Meteorology Research Centre (Melbourne, Australia)
BMV	Bundesministerium für Verkehr (German Ministry of Transportation)
BMVg	Bundesministerium für Verteidigung (German Ministry of Defense)
BNL	Brookhaven National Laboratory (Upton, NY, USA)
BNSC	British National Space Centre (London, UK) since 1985
BOC	Binary Offset Coding (modulation technique)
Boeing Co.	Seattle, WA, USA. A conglomerate (over 200,000 employees) of Boeing + Rockwell International (purchase of Rockwell's aerospace and defense business in Dec. 1996) + McDonnell Douglas Corp. (merger with Boeing in Aug. 1997). Boeing is also a large manufacturer of telecommunication satellites. In October 2000, The Boeing Company acquired three units within Hughes Electronics Corporation: Hughes

Space and Communications Company, Hughes Electron Dynamics, and Spectrolab, Inc., in addition to Hughes Electronics' interest in HRL (Hughes Research Laboratory). The four are now part of Boeing's newest subsidiary, Boeing Satellite Systems, Inc.

BOREAS	Boreal Ecosystem-Atmosphere Study (campaign)
BOST	Belgian Office of Science and Technology
BPDF	Bidirectional Polarization Distribution Function
BPOT	Bioluminescence Potential
BPSK	Bi-Phase Shift Keying (modulation technique)
BRDF	Bidirectional Reflectance and Distribution Function
BREMSAT	University of Bremen Satellite (Shuttle payload)
BRIC	Biological Research in Canister (Shuttle experiment)
BrO	Bromine monoxide
BSH	Bundesamt für Seeschifffahrt und Hydrographie (Hamburg, Germany)
BSI	British Standards Institution
BSPO	Belgian Science Policy Office
BSRN	Baseline Surface Radiation Network (WCRP/GEWEX)
BSTC	Biotechnology Specimen Temperature Controller (Shuttle)

C

C/A	Coarse Acquisition (a GPS and GLONASS code)
CAAC	Civil Aviation Association of China
CAFE	Central Australian Fronts Experiment (campaign)
CAM	Centre d'Aviation Météorologique (France)
CAMAREX	Carbon in the Amazon River Experiment (campaign)
CAMEX	Convection and Atmospheric Moisture Experiment (airborne campaign conducted at NASA Wallops Flight Facility, Wallops Island, VA)
CAN	Controller Area Network (used in embedded systems)
CANEX	Canadian Experiments (Shuttle payload)
CAO	Central Aerological Observatory (Moscow)
CAPE	Convection and Precipitation Electrification Experiment (campaign)
CAPL	Capillary Pumped Loop (Shuttle experiment of Hitchhiker payload, see also 'CPL')
CARIBIC	Civil Aircraft for Remote-Sensing and In-Situ-Measurements in Troposphere and Lower Stratosphere Based on the Instrumentation Container Concept (P40.3)
CART	Cloud and Radiation Testbed [field measurement component of the DOE ARM program; the three CART sites are: SGP (Southern Great Plains) near Billings in northern Oklahoma, TWP (Tropical Western Pacific on Manus Island, Papua, New Guinea), and NSA (North Slope of Alaska)]
CAPTEX	Cross-Appalachian Tracer Experiment (campaign)
CAS	Chinese Academy of Sciences (Beijing, China, since 1949)
CAS/CSSAR	CAS/Center for Space Science and Applied Research, Beijing, China
CAS/IRSA	CAS/Institute for Remote Sensing Applications, Beijing, China
CAS/SITP	CAS/Shanghai Institute of Technical Physics, Shanghai, China
CASA	Construcciones Aeronauticas S.A. (Madrid, Spain). In July 1999 CASA merged with DASA (DaimlerChrysler Aerospace AG)
CASC	China Aerospace Science & Technology Corporation (Beijing, since 1993, also referred to as CAC). CASC, as a large state-owned enterprise, exerts primary control over the national space program on a day-to-day basis (handling of internal matters). CASC specializes in developing, building and supplying launch vehicles, satellites, various types of strategic and tactical missiles as well as satellite ground application systems and providing commercial launch services. Over 130 Chinese organizations are subordinate to CASC, including five large academies [CALT (Chinese Academy of Launch-Vehicle

	Technology), CAST (Chinese Academy of Space Technology), SAST (Shanghai Academy of Space-Flight Technology), CASET (Chinese Academy of Space Electronic Technology), and the Academy of Space Chemical Propulsion Technology]
CASI	Canadian Aeronautics and Space Institute
CASP	Canadian Atlantic Storms Program (campaign)
CAST	Center for Aerospace Technology (Weber State University, Ogden, Utah)
CAST	Chinese Academy of Space Technology (Beijing, China, since 1968)
CATSAT	Cooperative Astrophysical and Technology Satellite (part of STEDI program, see N.17.3)
CBE	Chemical Beam Epitaxy (a growth technique)
CBERS	China/Brazil - Earth Resources Satellite, D.7. The satellite is also referred to as Ziyuan-1, meaning 'resource' in Chinese.
CCAFS	Cape Canaveral Air Force Station (Cape Canaveral, FL, USA)
CCD	Charge-Coupled Device (solid-state detector type)
CCE	Charge Composition Explorer (S/C of AMPTE mission, K.4.3)
CCIR	Comité Consultatif International des Radiocommunications (International Consultative Committee for Radio Communications, an organ of ITU). As of 1990 CCIR was renamed to ITU-R.
CCITT	Comité Consultatif International Téléphonique et Télégraphique (one of three bodies for the definition of OSI. CCITT is a permanent organ of ITU). As of 1990 CCITT was renamed to ITU-T (ITU-Telecommunications)
CCM-A	Cell Culture Module-A (Shuttle experiment)
CCN	Cloud Condensation Nuclei
CCPD	Charge-Coupled Photo Detector
CCRS	Canada Center for Remote Sensing (Ottawa, Ontario; established in 1972, part of 'Department of Energy, Mines and Resources,' Canada)
CCSDS	Consultative Committee for Space Data Systems
CD	Compact Disk (introduction in 1982)
CDA	Command and Data Acquisition (NOAA Antenna, downlink concept)
CDDIS	Crustal Dynamics Data Information System (database at GSFC)
CDGPS	Carrier-phase Differential GPS (a relative position measurement technique)
CDMA	Code Division Multiple Access (a communication access scheme)
CDP	Crustal Dynamics Program (NASA)
CdZnTe	Cadmium Zinc Telluride (a detector material - also referred to as CZT)
CD-ROM	Compact Disk - Read Only Memory (storage capacity up to 650 MByte)
CD-R/W	Compact Disk - Read/Write
CDTI	Center for Technological and Industrial Development, Madrid, Spain
CDWL	Coherent-detection Doppler Wind Lidar
CEA	Commissariat à l'Energie Atomique
CEAREX	Coordinated Eastern Arctic Experiment (campaign)
CEBAS	Closed Equilibrated Biological Aquatic System (Shuttle payload)
CEC	Commission of the European Communities (Brussels, Belgium)
CEES	Committee on Earth and Environmental Sciences (US interagency committee)
CEMAGREF ...	Centre d'Etude du Machinisme Agricole du Genie Rural et des Eaux et Forests (France)
CEOS	Committee on Earth Observation Satellites
CEPEX	Central Equatorial Pacific Experiment (campaign)
CEPT	European Conference of Postal and Telecommunications Administrations (Montreux, Switzerland, since 1959). CEPT comprises 43 European countries and is charged with representing Europe on such items as spectrum issues, etc.

CERFACS	Centre Européen de Recherche et de Formation Avancée en Calcul Scientifique (Toulouse, France, since 1987) European Center for Research and Advanced Training in Scientific Computation
CERGA	Centre d'Etudes et des Recherches en Geodynamique et Astrometrie (in Grasse, France)
CERISE	Caracterisation de l'Environnement Radioelectrique par un Instrument Spatial Embarque, (French S/C), D.40.11
CERN	Centre Européen de Recherche Nucléaire (Geneva, Switzerland)
CES	Committee on Earth Studies - a standing committee of the Space Studies Board within the National Research Council (NRC), USA
CESAR	Cooperacion Española-Argentina (satellite of INTA and CONAE)
CESBIO	Centre d'Etudes Spatiales de la Biosphère (Toulouse, France)
CESR	Centre d'Etude Spatiale des Rayonnements (Toulouse, France, part of CNRS)
CETA	Crew and Equipment Translation Aids (Shuttle experiment)
CETP	Centre d'etude des Environnements Terrestre et Planetaire (Velizy/Saint-Maur, France, CNRS Lab)
CEU	Commission of the European Union (successor of previous CEC)
CEV	Centre d'Essais en Vol (French Test Flight Center)
CfAO	Center for Adaptive Optics, UCSC (University of California at Santa Cruz)
CFCs	Chlorofluorocarbons
CFC-11	CCl_3F , trichlorofluoromethane, Freon-11
CFC-12	CCl_2F_2 , dichlorodifluoromethane, Freon-12
CFES	Continuous Flow Electrophoresis System (Shuttle payload)
CFRP	Carbon Fiber Reinforced Plastic (also: CFRM for Material)
CGBA	Commercial Generic Bioprocessing Apparatus (Shuttle experiment)
CGWIC	China Great Wall Industry Corporation (Beijing, since 1980), provider of Long March launch services to the world market
CGMS	Coordination Group for Meteorological Satellites [since 1972; active CGMS members are: EUMETSAT (Europe), JMA (Japan), China, Russia, NOAA (USA), WMO]. The global network of meteorological satellites constitutes a major portion of the space-based GOS (Global Observing System) of WWW (World Weather Watch).
CGP	Shuttle payload consisting of: [CSE (Cryo System Experiment), GP (Glow Phenomenon)]
CGWIC	China Great Wall Industry Corporation (launch service provider)
CH_3Cl	Methyl chloride
CH_4	Methane
CHAMP	Challenging Minisatellite Payload (E.1)
CHAMP	Comet Halley Active Monitoring Program (Shuttle experiment)
CHASE	Coronal Helium Abundance Spacelab Experiment (Spacelab-2)
CHEOPS	CHEmistry of Ozone in the Polar Stratosphere (airborne campaign)
CHORUS	Chemistry of Ozone Reduction in the Lower Stratosphere (first Strato-2C mission)
CHROMEX	Chromosomes and Plant Cell Division (Shuttle experiment)
CHRPT	Chinese High Resolution Picture Transmission (downlink mode)
CID	Charge-Injection Device (a charge-transfer detection technology)
CID	Collision-Induced Dissociation (a measurement technique in the atmospheric sciences for studies of ion-molecule reactions, etc.)
CIDESON	Centro de Investigacion y Desarrollo de los Recursos Naturales de Sonora (Hermosillo, Mexico)
CIEMAT	Centro de Investigaciones Energéticas y Medioambientales (Environmental and Energetic Research Center), Spain
CIESIN	Consortium for International Earth Science Information Network (a private nonprofit corporation in Ann Arbor, Michigan (University Center). CIESIN serves scientific, policy-making, educational, and

public access data and information needs. CIESIN developed and is operating SEDAC (Socio-Economic Data and Applications Center) as part of one of nine data centers of EOSDIS.

CIGNET	Cooperative International GPS Network of IAG (International Association of Geodesy), H.4.3.6
CIGS	Copper Indium Gallium Diselenide (solar arrays based on thin film technology)
CIMS	Chemical Ionization Mass Spectrometry (a measurement technique frequently used for atmospheric measurements)
CIMSS	Cooperative Institute for Meteorological Satellite Studies (University of Wisconsin, Madison)
CINDE	Convection Initiation and Downburst Experiment (campaign)
CIR	Color Infrared (video images)
CIRA	Centro Italiano Ricerche Aerospaziali (Italian Aerospace Research Center) since 1984, Capua, Italy
CIRAC	Canadian Institute for Research in Atmospheric Chemistry
CIRES	Cooperative Institute for Research in Environmental Sciences (University of Boulder, and at NOAA, Boulder, CO, USA)
CIS	Commonwealth of Independent States (part of former Soviet Union or USSR)
CIT	California Institute of Technology (Pasadena, CA)
CIT	Computerized Ionospheric Tomography
CITE	Chemical Instrumentation Test and Evaluation (campaign)
CIV	Critical Ionization Velocity (Shuttle experiment)
CIVEX	Cloud Instruments Validation Experiment (campaign)
CLARA	Cloud And Radiation (campaign)
CLASS	Cross-chain LORAN Atmospheric Sounding System (NCAR ground-based sounding stations)
CLEOPATRA ...	Cloud Experiment Oberpfaffenhofen and Transports (campaign)
CLIVAR	Climate Variability and Predictability (WCRP campaign program)
CLIVAR-ACC ..	CLIVAR - Anthropogenic Climate Change
CLIVAR-DecCen	CLIVAR - Decadal-to-Centennial time-scales
CLIVAR-GOALS	CLIVAR - Global Ocean-Atmosphere-Land System
CLOUDS	Cloud and Radiation Monitoring Satellite (a proposed ESA mission as of 2001, A.7)
CLOUDS	Cloud Logic to Optimize Use of Defense Systems (Shuttle payload)
CLUSTER	ESA/NASA Solar-Terrestrial Mission (K.7)
CIO	Chlorine monoxide
CIONO ₂	(CIONO ₃) Chlorine nitrate
CLS	Collecte, Localisation, Satellites (with HQ in Toulouse, France) CLS was set up in 1986 to market the Argos (data collection) system.
C-MAN	Coastal-Marine Automated Network [NOAA/NWS/NDBC moored buoy network (over 100 buoys) with hourly reports via GOES DCS]
CMA	China Meteorological Administration, Beijing (government agency)
CMA/NSMC	CMA/National Satellite Meteorological Center, Beijing, China
CMC	Canadian Meteorological Centre
CME	Coronal Mass Ejection (of the sun)
CMESS-95	Cooperative Multiscale Experiment Spring/Summer 1995 (campaign)
CMIX	Commercial Materials Dispersion Apparatus Instrument Technology Associates Experiments (Shuttle experiment)
CMOS	Complementary Metal-Oxide Semiconductor (solid-state microprocessor technology)
CMS	Centre de Météorologie Spatiale (Lannion, France)
CMT	CdHgTe (detector type)
CN	Condensation Nuclei
CNCR	Characterization of Neurospora Circadian Rhythms (Shuttle payload)

CNES	Centre National D'Etudes Spatiales (Space Agency of France, Paris, Toulouse, Evry, and Kourou, since 1962). Employment (1999) of 2500 scientists and engineers; of these, about 1700 employees are at Toulouse. CNES/HQ is in Paris with about 250 employees.
CNES/AVISO . . .	CNES/Archiving, Validation and Interpretation of Satellites oceanographic data (CNES data center for GEOSAT, Topex/Poseidon, ERS-1/2, ENVISAT, Jason-1, etc.)
CNET	Centre National d'Etudes des Télécommunications (France Télécom)
CNIE	Comision Nacional de Investigaciones Espaciales (former Space Agency of Argentina)
CNR	Consiglio Nazionale delle Ricerche (National Research Council of Italy, Rome). CNR is a government agency which promotes and coordinates institutional research in the interests of Italy. CNR was founded in 1923 and reorganized in 1945 and 1979. CNR funds/maintains 157 institutes, 117 study centers, and 16 research groups throughout Italy. Research is supported in the natural and human sciences. In 1980 PSN (National Space Program) was created within CNR. Some space projects supported by CNR are: Italsat, TSS (Tethered Satellite System), Iris (propulsion system for the transfer of useful loads from the Space Shuttle's "hold" to a higher orbit), Lageos-2, and Sax (X-ray astronomy). CNR maintains a number of cooperations with various space agencies. In 1988 ASI (Agenzia Spaziale Italiana) was founded which succeeded CNR in relations concerning matters of planning and administrative nature. Nevertheless, CNR continues to follow specific aspects of research within the context of its own bodies.
CNR/DCAS	CNR / Direzione Centrale Attività Scientifiche (Rome, Italy)
CNR/FISBAT . . .	CNR / Istituto per lo Studio dei Fenomeni Fisici e Chimici della Bassa ed Alta Atmosfera (Institute of Physics and Chemistry of the Lower and Upper Atmosphere, Bologna, Italy)
CNR/IFA	CNR / Istituto di Fisica dell' Atmosfera (Institute for the Physics of the Atmosphere, Frascati, Italy)
CNR/IFAM	CNR / Istituto di Fisica Atomica e Molecolare (Pisa, Italy)
CNR/IFCTR	CNR / Istituto di Fisica Cosmica e Tecnologie Relative (Milano)
CNR/IFSI	CNR / Istituto di Fisica dello Spazio Interplanetario (Frascati, Italy)
CNR/IROE	CNR / Istituto di Ricerca sulle Onde Elettromagnetiche (Florence, Italy)
CNR/IMGA	CNR / Istituto per lo Studio delle Metodologie Geofisiche Ambientali (Bologna, Italy)
CNR/ITRE	CNR / Istituto di Tecnologie e Studi della Radiazioni Extraterrestri (Bologna, Italy)
CNR/LARA	CNR / Laboratorio Aereo per Ricerche Ambientali (Laboratory for Airborne Environmental Studies, Rome, Italy)
CNR/PSN	Consiglio Nazionale delle Ricerche / Piano Spaziale Nazionale (Italy)
CNRM	Centre National des Recherches Meteorologiques (France)
CNRS	Centre National de la Recherche Scientifique (National Research Center of France). CNRS is a government-funded basic-research organization which employs about 26,000 people, including more than 11,000 research scientists. The agency maintains facilities throughout France. There are over 1500 CNRS laboratories active in all fields of science. Most CNRS laboratories rely for their research on partnerships with French universities. There are also many CNRS cooperations and exchanges with other research organizations on a national and international level as well as with French industry. Only a few facilities (dealing mostly with the sciences of the universe, such as: oceanography, geophysics, climatology, hydrology, volcanology, seismology, astronomy, astrophysics, etc.) are listed below.
CNRS/CESR . . .	CNRS/Centre d'Etude Spatiale des Rayonnements (Toulouse, France)

CNRS/CERGA	CNRS/Centre d'Etudes et des Recherches en Geodynamique et Astrometrie (Grasse, France)
CNRS/CETP	CNRS/Centre d'Etude des Environnements Terrestre et Planétaires, (sites at: Vélizy, Issy-les-Moulineaux, and Saint-Maur des Fossés, France)
CNRS/IAS	CNRS/Institut d'Astrophysique Spatiale (Orsay, France)
CNRS/INSU	CNRS/Institut National des Sciences de l'Univers (Paris, France)
CNRS/LAS	CNRS/Laboratoire d'Astronomie Spatiale (Marseille, France)
CNRS/LMD	CNRS/Laboratoire de Météorologie Dynamique (Palaiseau, France)
CNRS/LOA	CNRS/Laboratoire d'Optique Atmosphérique (University of Lille, France)
CNRS/LPCA	CNRS/Laboratoire de Physique et Chimie de l'Atmosphère (University of Strasbourg, France)
CNRS/LPCE	CNRS/Laboratoire de Physique et de Chimie de l'Environnement (Orleans-la-Source, France)
CNRS/SA	CNRS/Service d'Aeronomie (Verrières-le-Buisson, France)
CNRSC	China National Remote Sensing Center (since 1981)
CNSA	China National Space Administration (Beijing, since 1993). The principal role of CNSA is to serve as China's policy organization and interface with other national space agencies.
CNS/ATM	Communication, Navigation and Surveillance/Air Traffic Management)
CNTS	Centre National des Techniques Spatiales (Algiers, Algeria)
CO	Carbon monoxide
CO ₂	Carbon dioxide
COARE	Coupled Ocean Atmosphere Response Experiment (campaign, see TOGA/COARE)
COAST	Coastal Oxidant Assessment for Southeast Texas (campaign)
CODAG	Cosmic Dust Aggregation (Shuttle payload)
CODAR	Coastal Ocean Dynamic Application Radar (a ground-based, over-the-horizon radar which reflects off of the ionosphere to measure sea surface roughness and currents)
CODE	Coastal Ocean Dynamics Experiment (campaign)
COF	Columbus Orbital Facility (ESA module on ISS)
COHMEX	Cooperative Huntsville Meteorological Experiment (campaign)
COMETS	Communications and Broadcasting Engineering Test Satellite (prototype data relay satellite of Japan)
CONAE	Comisión Nacional de Actividades Espaciales, Buenos Aires, Argentina (National Commission on Space Activities, since 1992) - Space Agency of Argentina
CONCAP	Consortium for Materials Development in Space Complex Autonomous Payload (Shuttle experiment)
CONUS	Continental United States ('lower 48 states')
COPE	Coastal Ocean Probing Experiment (campaign)
COPS-91	Cooperative Oklahoma Profiler Study-1991 (campaign)
CORONAS	Complex of Orbital Observations of the Activity of the Sun (Satellite of the Russian Space Agency, K.8)
COSMIC	Constellation Observing System for Meteorology, Ionosphere and Climate (A.24)
COSMOS	The term 'Cosmos' or 'Kosmos' is used in Russia to designate any of a series of unmanned satellites that were launched starting in 1962 with Cosmos-1 (the counting in 1988 was up to 1800, in 1993 it is around 2200). The Cosmos satellite series has been used for a wide variety of purposes, including scientific research, Earth observation, experimental/technological payloads, preoperational meteorological satellites, navigation satellites, etc. There are also many satellites with military payloads under the Cosmos designation.

	‘Cosmos’ is also the name of a Russian launch vehicle (first launch in 1964, from 1970-’87 there were 371 successful flights of the Cosmos launcher). The Cosmos launch vehicle remains in service (1996).
COSPAR	Committee on Space Research (of ICSU, since 1958). COSPAR is an interdisciplinary scientific organization concerned with international progress in all areas of scientific research carried out with space vehicles, rockets, and balloons.
COSPAS	Space System for the Search of Distressed Vessels (Russia’s equipment flown on polar-orbiting S/C).
COSSA	CSIRO Office of Space Science and Applications (since 1984, Canberra, Australia)
COTES	Conventional Terrestrial Reference System (an IERS program for the specifications of positions on or near the Earth’s surface) ²¹⁰⁸⁾
COTS	Commercial-Off-The-Shelf (products)
CPCG	Commercial Protein Crystal Growth (Shuttle experiment)
CPFSK	Continuous Phase Frequency Shift Keying (a modulation method)
CPL	Capillary Pumped Loop Experiment (Shuttle)
CPMA	Code Position Multiple Access (communication access concept)
CPR	Cloud Profiling Radar (GEWEX)
CPRA	Control of the Reception Pattern multi-element Antenna
CRA	Centro Ricerche Aerospaziali (University of Rome, Italy)
C-RAM	Chalcogenide - Random Access Memory
CRC	Communication Research Center (an institute of Industry Canada, located at Shirleys Bay, west of Ottawa)
CRCSS	Cooperative Research Center for Satellite Systems (Canberra, Australia, the new Australian space agency, as of Jan. 1, 1998 - it is also referred to as simply “CRC”). CRCSS, under the Cooperative Research Centres Program of the Commonwealth of Australia, is a union of 12 Australian organizations, including government, university and industry. Some of the participants are: CSIRO, University of South Australia, Queensland University of Technology, University of Newcastle, University of Technology, Sydney, Auspace Ltd. of Mitchell, ACT [Note: since 1990, Auspace has been a subsidiary of MMS (Matra Marconi Space) of France]
CREAM	Cosmic Ray Effects and Activation Monitor (Shuttle payload)
CREST	Center for Research in Earth and Space Technology (North York, Ontario, Canada). Formerly known as ISTS (Institute of Space and Terrestrial Science)
CRI	Crown Research Institute (New Zealand)
CRISP	Center for Remote Imaging, Sensing and Processing (since 1992, National University of Singapore, Singapore)
CRL	Communications Research Laboratory, Tokyo, a division of the Ministry of Posts and Telecommunications (MPT) of Japan. Note: the former name of CRL (until 1987) was RRL (Radio Research Laboratories)
CRO	Chemical Release Observation (Shuttle experiment)
CRP	Cloud Radiation Program
CRPE	Centre de Recherches en Physique de l’Environnement Terrestre et Planetaire, at the following sites: Vélizy, Issy-les Moulineaux, and Saint-Maur-des-Fossés, France (Lab was part of CNRS and of CNET, starting in January 1994 CRPE was reorganized and renamed CETP, there is no more dependence on CNET)
CRPSM	Centro di Ricerca Progetto San Marco (San Marco ground receiving station and processing/archiving facilities located at Malindi, Kenya), CRPSM is owned and operated by the University of Rome, Italy

²¹⁰⁸⁾ See : “The International Earth Rotation Service,” in ‘The Interdisciplinary Role of Space Geodesy,’ Springer Verlag, 1989, pp. 229-232

CRREL	Cold Regions Research and Engineering Laboratory (US Army research facility in Hanover, NH, USA)
CRRES	Combined Release and Radiation Effects Satellite (A.11)
CRSS	Commercial Remote Sensing System (B.6); the S/C was renamed to IKONOS
CRSS	Canadian Remote Sensing Society (since 1973); CRSS is part of CASI (Canadian Aeronautics and Space Institute)
CRT	Cathode Ray Tube
CRTS	Centre Royal Teledetection Spatiales, Rabat, Morocco
CRV	Crew Return Vehicle (or X-38 CRV of NASA, used for ISS evacuation in case of an emergency)
CRYOFD	Cryogenic Flexible Diode (Shuttle payload)
CRYOHP	Cryogenic Heat Pipe Experiment (Shuttle payload)
CRYOTSU	Cryogenic Thermal Storage Unit (Shuttle payload)
CRYSYS	Use of the Cryospheric System to Monitor Global Change in Canada (campaign program)
CSA	Canadian Space Agency (since 1989; CSA HQs and control center at Saint-Hubert, Québec)
CSCE	Commercial Space Center for Engineering (established under contract with NASA/JSC, located on the Texas A&M University campus; CSCE supports industry development of palletized commercial payloads on external platforms on ISS)
CSE	Consortium for Superconducting Electronics (USA) involving Bell Labs, IBM, MIT, MIT/LL, etc.
CSEM	Centre Suisse d'Electronique et de Microtechnique (or: Swiss Center for Electronics and Microtechnology), Neuchatel, Switzerland
CSER	Center for Satellite Engineering Research (University of Surrey, UK)
CSGC	Colorado Space Grant Consortium - a NASA-funded institution which supports student-designed satellites
CSIC	Consejo Superior de Investigaciones Cientificas (Spanish Research Council, Madrid)
CSIR	Council for Scientific and Industrial Research, Pretoria, South Africa. CSIR is Africa's largest scientific and technological research, development and implementation organization.
CSIRO	Commonwealth Science and Industrial Research Organization (Canberra, Australia)
CSMA/CD	Carrier Sense Multiple Access / Collision Detection (commercially known under Ethernet)
CSMT	Center for Space Microelectronics Technology (NASA/JPL facility, since 1987)
CSOC	Consolidated Space Operations Contract (NASA/Lockheed Martin contract for Shuttle operations, etc.). The objective is to achieve a low-risk, commercially-based space operations program for Shuttle.
CSR	Centro de Sensores Remote (Italy)
CSSR	Chinese Society of Space Research
CST	CORE Software Technology, Pasadena, CA [developer of the world's first commercial on-line geo-spatial (image, cartographic, & demographic) indexing and distribution system]
CSTG	Commission on International Coordination of Space Techniques for Geodesy and Geodynamics (since 1979), (Commission VIII of the International Association of Geodesy)
CSU	Colorado State University, Fort Collins, CO
CTA	Canadian Target Assembly (Shuttle payload)
CTA	Centro Tecnico Aeroespacial (Sao José dos Campos, S.P., Brazil)
CTA	CTA Space Systems, McLean, VA, (since 1979) manufacturer of small satellite systems (Clark, EarlyBird, REX, etc.) and instruments; CTAst (CTA Space and Telecommunications) is the parent company

of CTA Space Systems. Note: CTA Space Systems was acquired by OSC of Dulles, VA, in Aug. 1997

CTD	Conductivity-Temperature-Depth profilers (a buoy type used in a number of campaigns like NORSEX, TOGA/COARE, etc.)
CTIV	Processing Center for VEGETATION Imagery (operated by Vito in Mol, Belgium, VEGETATION is a SPOT-4, 5 instrument
CTP	Cloud Top Pressure
CUE	Collaborative Ukrainian Experiment (Shuttle experiment)
CUZK	Czech office for Surveying, Mapping and Cadastre
CVF	Circular Variable Filter (filter technology)
CVTE	Chemical Vapor Transport Experiment (Shuttle payload)
CVX	Critical Viscosity of Xenon (Shuttle payload)
CW	Continuous Wave
CZT	Cadmium Zinc Telluride (a detector material - also referred to as CdZnTe)

D

DAAC	Distributed Active Archive Center (NASA EOSDIS Program)
DAB	Digital Audio Broadcasting
DARA	Deutsche Agentur für Raumfahrtangelegenheiten, Bonn (German space agency (from 1989 to Sept. 30, 1997, DARA was integrated into DLR effective Oct. 1, 1997)
DARPA	Defense Advanced Research Projects Agency (US DoD agency, since 1958, DARPA started as ARPA with an early focus on space research). Technological innovations such as the Transit navigation system, Internet (in 1969 ARPANET started which become later Internet), stealth technology, and many activities in the space program were sponsored by DARPA.
DASA	DaimlerChrysler Aerospace AG, Munich (HQ), Germany (with 45,000 employees). Prior to Nov. 1998, DASA stood for 'Daimler-Benz Aerospace AG.' Prior to January 1995 the meaning of the acronym DASA was 'Deutsche Aerospace AG.' DASA/DSS (Dornier Satellitensysteme GmbH) is a DASA business unit responsible for all satellite-related activities with facilities in Friedrichshafen and Ottobrunn. DASA (founded in 1989) is a conglomerate of the previous companies: Dornier, MBB (Messerschmitt-Bölkow-Blohm), MTU (Motoren- und Turbinen-Union), and TST (Telefunken Systemtechnik). - In addition, DASA is a partner in many alliances such as: Airbus, Ariane, Eurocopter, etc. Today, the three independent business entities of DASA are: DASA/Airbus, DASA/DSS, and DASA/MTU. - As of 2000, DASA is called Astrium GmbH (see Astrium)
DAT	Digital Audio Tape (a high-volume data recording technique, helical scan tape storage)
DATA-CHASER	Distribution and Automation Technology Advancement - Colorado Hitchhiker and Student Experiment of Solar Radiation (Shuttle)
DBMS	Database Management System
DBS	Direct Broadcasting Satellite
DBSI	Direct Broadcasting Satellite Industries Inc. of Mill Valley, CA
DC	Direct Current
DCRS	Danish Center for Remote Sensing (at EMI of TUD, Lyngby, Denmark)
DCRS	Digital Cassette Recorder System
DCP	Data Collection Platform (ground segment platform for environmental data measurement, Meteosat, GOES, GMS)
DCPI	Data Collection Platform Interrogation (GOES)
DCS	Data Collection System (NOAA- GOES series, Meteosat series, GMS series, geostationary satellites).

DCT	Discrete Cosine Transformation (compression technique)
DCW	Digital Chart of the World (a vector map database by DMA, Fairfax, VA, USA)
DEBITS	Deposition of Biogeochemically Important Trace Species
DECAFE	Dynamics and Chemistry of the Atmosphere in Equatorial Forest (campaign)
DEE	Dexterous End Effector (Shuttle)
DEM	Digital Elevation Model (also referred to as DTM = Digital Terrain Model)
DEOS	Delft Institute for Earth-Oriented Space Research [at Delft University of Technology (DUT), Delft, The Netherlands]
DERA	Defence Evaluation and Research Agency [Farnborough, UK, an agency of MoD (Ministry of Defense)]. DERA was established in April 1995 from elements of the former RAE (Royal Aerospace Establishment).
DESPA	Département de Recherche Spatiale de L'Oservatoire de Paris/Meudon (France)
DFD	Deutsches Fernerkundungsdatenzentrum (German Remote Sensing Data Center, DLR, Oberpfaffenhofen)
DFG	Deutsche Forschungsgemeinschaft (German National Research Council)
DFN	Deutsches Forschungsnetz
DFVLR	Deutsche Forschungs- und Versuchsanstalt für Luft- und Raumfahrt (predecessor name of DLR from 1969 until 1989). History: In 1969 (April 1) a merger of the following German research facilities occurred, resulting in DFVLR with HQ in Köln-Porz: AVA (Aerodynamische Versuchsanstalt, founded 1907 in Göttingen), DFL (Deutsche Versuchsanstalt für Luftfahrt, founded 1936 in Braunschweig), DVL (Deutsche Versuchsanstalt für Luftfahrt, founded 1912 in Berlin-Adlershof, after WW-II in Mühlheim-Ruhr, since the 1960s in Köln-Porz). FFO (Flugfunkforschungsinstitut Oberpfaffenhofen), founded in 1937, was integrated into DVL (Köln-Porz) in 1965. FFM (Flugwissenschaftliche Versuchsanstalt München) joined DVL in 1963.
DGASP	Dye 3 Gas and Aerosol Sampling Program (IGBP/IGAC program)
DGFI	Deutsches Geodätisches Forschungsinstitut (Munich, Germany)
DGGTN	Direction General de Geografica del Territorio Nacional (Mexico)
DGLR	Deutsche Gesellschaft für Luft- und Raumfahrt - Lilienthal-Oberth e. V., Bonn
DGON	Deutsche Gesellschaft für Ortung und Navigation (Düsseldorf, Germany - German Institute of Navigation)
DGPF	Deutsche Gesellschaft für Photogrammetrie und Fernerkundung
DGPS	Differential GPS, H.4.4
DHI	Deutsches Hydrographisches Institut (Hamburg, Germany)
DIAL	Differential Absorption Lidar (lidar technique)
DIN	Deutsches Institut für Normung (German Institute for Standardization)
Discoverer II	A US (military) technology demonstration program of DARPA, USAF and NRO, started in 1998, with the objective to develop a high-resolution interferometric SAR system (IFSAR) for surveillance and reconnaissance
DISCOS	Database and Information System Characterizing Objects in Space (ESA/ESOC database for space debris and meteoroids, since 1990)
DLR	Deutsches Zentrum für Luft- und Raumfahrt e.V. (German Aerospace Center, with HQ in Köln; DLR is also the German Space Agency). On Oct. 1, 1997 DARA was re-integrated into DLR. Prior to Oct.1.1997 the meaning of DLR was: Deutsche Versuchsanstalt für Luft- und Raumfahrt e.V.

DLR/DFD	DLR/Deutsches Fernerkundungsdatenzentrum (German Remote Sensing Data Center), Oberpfaffenhofen and Neustrelitz
DLR/FB	DLR/Flugbereitschaft (aircraft operations; FB provides the services of flying sensors for other institutes of DLR)
DLR/GSOC	DLR/German Space Operations Center, Oberpfaffenhofen
DLR/IOE	DLR/Institut für Optoelektronik (Institute of Optoelectronics), Oberpfaffenhofen
DLR/IPA	DLR/Institut Physik der Atmosphäre (Institute of Atmospheric Physics), Oberpfaffenhofen
DLR/IRF	DLR/Institut für Hochfrequenztechnik (Institute of Radio Frequency Technology, Oberpfaffenhofen)
DLR/IRM	DLR/ Institut für Robotik und Mechatronik (Institute of Robotics and Mechatronics), Oberpfaffenhofen
DLR/ISST	DLR/Institut für Weltraumsensorik (Institute of Space Sensor Technology and Planetary Exploration, Berlin-Adlershof). There is also the abbreviation: DLR/IWS
DLR/MUSC	DLR/Microgravity User Support Center (Cologne, Germany)
DMA	Defense Mapping Agency (Fairfax, VA, USA, mapping, charting & geodetic products & services to the military, since 1972 - since 1996 DMA is an integral part of NIMA)
DMC	Disaster Monitoring Constellation (a 5 S/C constellation under construction by SSTL, UK, planned launch in 2002)
DMI	Danmarks Meteorologiske Institut (Danish Meteorological Institute, founded in 1872) Copenhagen, Denmark
DMN	Direction de la Météorologie National (France)
DMOS	Diffusive Mixing of Organic Solutions (Shuttle payload)
DMS	Dimethylsulphide
DMSP	Defense Meteorological Satellite Program (USA), G.1
Dnepr	Russian/Ukrainian launch vehicle for satellites. As part of a nuclear disarmament agreement, former Soviet SS-18 ICBMs (Intercontinental Ballistic Missiles), were renamed to Dnepr. They are either being used for commercial launches, or destroyed by Dec. 31, 2007
DOAS	Differential Optical Absorption Spectroscopy
DOC	Department of Commerce (USA)
DoD	Department of Defense (USA)
DOE	Department of Energy (USA). Some major laboratories of DOE are: ANL (Argonne National Laboratory), Argonne IL BNL (Brookhaven National Laboratory), Upton, NY FNAL (Fermi National Accelerator Laboratory), Batavia, IL LANL (Los Alamos National Laboratory), Los Alamos, NM LBL (Lawrence Berkeley Laboratory), Berkeley, CA LLNL (Lawrence Livermore National Laboratory), Livermore, CA ORNL (Oak Ridge National Laboratory), Oak Ridge, TN (since 1948) PNL (Pacific Northwest Laboratory), Richland, WA SLAC (Stanford Linear Accelerator Center), Stanford, CA SNL (Sandia National Laboratory), Albuquerque, NM and Livermore, CA
DODGE	Department of Defense Gravity Experiment (M.4)
DOM	Dissolved Organic Matter
DORIS	Determination Orbite Radiopositionnement Integres Satellite (CNES one-way tracking system for the measurement of precision orbits); another name convention is: Doppler Orbitography and Radiopositioning Integrated by Satellite, E.21.1
DoT	Department of Transportation (USA)
DPCM	Differential Pulse Code Mudulation (compression technique)
DRA	Defence Research Agency [Malvern, Farnborough, etc., UK, with over 6000 employees; DRA was established in 1991, it is the successor orga-

nization of RAE (Royal Aerospace Establishment), ARE (Admiralty Research Establishment), RARDE (Royal Armament Research & Development Establishment), and RSRE (Royal Signal and Radar Establishment)]. As of April 1995 DRA was regrouped again and integrated as a division into DERA (Defense Evaluation and Research Agency). Another DERA reorganization in April 1997 dissolved DRA altogether.

DRAM	Dynamic Random Access Method
Draper Lab	Charles Stark Draper Laboratory Inc. of Cambridge, MA. An MIT lab founded in the 1930s; an independent non-profit research lab since 1973. Focus on GN&C (Guidance, Navigation & Control) technologies.
DRB	Defense Research Board, Canada
DREO	Defense Research Establishment, Ottawa, Canada
DRI	Desert Research Institute (of the University of Nevada)
DRS	Data Relay Satellite (ESA system to relay information from the European space plane)
DRTS	Data Relay Technology Satellite (Japan, Ka-band transmission)
DSB	Double Sideband
DSN	Deep Space Network (NASA/JPL)
DSP	Defense Support Program (USA, DoD S/C series in GEO using infrared sensors to detect missile plumes against the Earth's background, to detect and report missile launches, space launches, and nuclear detonations) DSP S/C operate since the 1970s.
DSP	Digital Signal Processing (computer, technology)
DSRI	Danish Space Research Institute (Lyngby, Copenhagen, Denmark)
DSS	Dornier Satellitensysteme GmbH (of DASA, Germany)
DSS	Delft Sensor Systems (provider of optoelectronic instruments). DSS has been created by the integration of OIP (Optronic Instruments & Products), located in Oudenaarde, Belgium - and DIEO (Delft Instruments Electro-Optics, located in the Netherlands
DSSP	Danish Small Satellite Program
DSSS	Direct Sequence Spread Spectrum (communication technique)
DTE	Digital Terrain Elevation
DTM	Digital Terrain Model (also referred to as DEM = Digital Elevation Model)
DTU	Technical University of Denmark, Lyngby
DUT	Delft University of Technology (Delft, The Netherlands)
DVD	Digital Versatile Disk [some standard DVD formats are: DVD-5 (4.7 GByte storage capacity, one layer per disk), DVD-9 (8.5 GByte, two layers per disk on one side, one layer is semi-permeable), DVD-10 (9.4 GByte, one layer per side and disk), DVD-18 (17 GByte, two layers per side and disk, one layer per side is semi-permeable)]
DWD	Deutscher Wetterdienst [German Weather Service, with seven forecast centers in Offenbach (HQ), Hamburg, Potsdam, Leipzig, Essen, Stuttgart, and Munich]. DWD employs over 3000 people in over 150 localities throughout Germany.
DWL	Doppler Wind Lidar (a active laser instrument based either on coherent heterodyne receiver technology or on incoherent direct receiver technology)
DYCOMS	Dynamics and Chemistry of Marine Stratocumulus Experiment (campaign)

E

EA	Environment Agency (of Japan)
EADS	European Aeronautic, Defense and Space Company (a holding company of DASA and a French pool group with Lagardere as the major

partner). Merger announcement of DASA (Germany) and Aerospa-
 tiale Matra (France) in Oct. 1999 - the merger was realized July 10, 2000
 with DASA, Aerospa-
 tiale Matra, and CASA of Spain. The following
 units are part of EADS: Airbus, Ariane, Astrium (75%), Dassault, Eu-
 rocopter, Eurofighter, and Rocket Systems.

EarlyBird	Commercial imaging satellite (B.4.1)
EARSEC	European Airborne Remote Sensing Capabilities [program since 1990 between CEC (JRC in Ispra, Italy) and ESA]
EARSeL	European Association of Remote Sensing Laboratories (since 1976)
EarthCARE	Earth Clouds Aerosol and Radiation Explorer (a proposed ESA core mission)
EarthKAM	Earth Knowledge Acquired by Middle school students (a NASA educa- tion program) The camera program started in 1996 as KidSat on Shuttle.
EARTHNET ...	ESA Program since 1977. Earthnet refers to an ESA organization re- sponsible for the ground segment of Earth Observation. Functions: ac- quisition, archiving and distribution of Earth science data.
EarthWatch Inc. .	A US Earth observation company in Longmont, CO. EarthWatch was formed in January 1995 and is a joint venture of Ball Aerospace and WorldView Imaging Corporation (builder of EarlyBird and Quick- Bird)
Earth Watch	ESA program [these are the operational (or pre-operational) service- oriented missions addressing specific application areas of Europe]. The Earth Watch Initiative started in 2001 with the goal to secure for Eu- rope an independent sustainable capability in operational Earth ob- servation
EASE	Experimental Assembly of Structures in Extravehicular Activity (Shuttle)
EASOE	European Arctic Stratospheric Ozone Experiment (campaign)
EBCCD	Electron-bombarded CCD array
EC	European Commission (since 1995: CEU (Commission of the Euro- pean Union)
ECD	Electron Capture Detector
ECLIPS	Experimental Cloud Lidar Pilot Study (campaign)
ECMWF	European Centre for Medium-Range Weather Forecasts (located in Reading, UK, founded in 1973). ECMWF is an international organiza- tion supported by the following European states: Austria, Belgium, Denmark, Finland, France, Germany, Greece, Ireland, Italy, Nether- lands, Norway, Portugal, Spain, Sweden, Switzerland, Turkey, United Kingdom. ECMWF has working arrangements with WMO, EUMET- SAT and ACMAD (African Centre for Meteorological Applications for Development).
ECS	EOSDIS Core System (USA)
EDAC	Earth Data Analysis Center (NASA contractor center at the University of New Mexico, Albuquerque, NM, since 1964)
EDAC	Error Detection and Correction (information processing term)
EDC	EROS Data Center of the US Geological Survey (Sioux Falls, SD, DAAC of NASA EOS Program for Land Processes)
EDI	Electronic Data Interchange, (Format Specification according to ANSI Standard X.12; (an existing but non-ISO Protocol)
EDIFACT	Electronic Data Interchange for Administration, Commerce, and Transport
EDO	Extended Duration Orbiter (Shuttle)
EEA	European Environment Agency (since 1990, located in Copenhagen since 1993, Denmark)
EECF	Earthnet ERS-1 Central Facility (ESA facility at ESRIN, Italy)
EELV	Extended Envelope Launch Vehicle (US Air Force launcher)

EEP	Earth Explorer Program (ESA)
EEV	English Electric Valve, Chelmsford, UK (manufacturer of detectors)
EEVT	Electrophoresis Equipment Verification Test (Shuttle)
EFEDA	European Field Experiment in Desertification-threatened Areas (campaign)
e.g.	abbreviation (Latin: <i>exempli gratia</i>) for example
EGNOS	European Geostationary Navigation Overlay System (planned ESA complementary system to GPS and GLONASS to provide Europe with GPS/GLONASS service availability, continuity and signal integrity)
EGS	European Geophysical Society
EGS	Experimental Geodetic Satellite of NASDA, (Ajisai, E.3)
EHF	Extremely High Frequency (30 - 300 GHz band)
EHIC	Energetic Heavy Ion Composition Experiment
EIRP	Effective Isotropic Radiated Power
EISAC	European Imaging Spectrometry Aircraft Campaign (1989-90)
EISCAT	European Incoherent Scatter Radar
EIT	Electro-bombardment Ion Thruster (electric proplulsion system of MMS, France)
EIT	Electromagnetically Induced Transparency
ELAC	European Lidar Airborne Campaign
ELDO	European Launcher Development Organization (since 1962) ELDO is, along with ESRO, a predecessor organization of ESA
ELDP	European Lake Drilling Project (campaign under PANASH)
ELF	Extremely Low Frequency (30 - 3000 Hz)
ELINT	Electronic Intelligence (used in the context of DoD missions)
ELITE	European LITE (campaign) LITE = Lidar In-space Technology Experiment (Shuttle payload)
ELOISE	European Land-Ocean Interaction Studies (campaign)
El-Op	El-Op Electro-Optics Industries of Rehovot, Israel (as of 2000 El-Op is part of Elbit Systems Ltd. of Haifa, Israel)
ELRAD	Earth-Limb Radiance Experiment (Shuttle payload)
ELT-121.5	Emergency Locator Transmitter (see COSPAS-S&RSAT, I.6)
EMAC	European Multi-Sensor Airborne Campaign (in the framework of ESA/JRC collaboration)
EMBRAER	Empresa Brasileira de Astronautica SA (aircraft and space payload manufacturer, Saõ José dos Campos, SP, Brazil)
EMEX	Equatorial Mesoscale Experiment (campaign)
EMF	Electromotive Force
EMP	Electromagnetic Pulse
EMSL	Environmental Monitoring Systems Laboratory (Las Vegas, NV, EPA facility)
ENA	Energetic Neutral Atoms [neutral atoms or molecules created by charge exchange between energetic ions (such as the Earth's radiation belts) and a cold neutral gas (such as the Earth's exosphere)]
ENEA	Ente per le Nuove tecnologie l'Energia e l'Ambiente (Rome, Italy)
ENSO	El Niño Southern Oscillation
ENVISAT	Environmental Satellite (ESA, see D.9)
EO	Earth Observation
EO-1	Earth Observing-1 (NASA S/C)
EOCAP	NASA's Earth Observations Commercial Applications Program, since 1987 (NASA's intent is to commercialize remote sensing technology originally developed to support scientific exploration)
EOL	End of Life
EOPP	Earth Observation Preparatory Programme (of ESA)
EORF	Environment Measurements by the Real-Time Radiation Monitor (Shuttle payload)
EOS	Earth Observing System (NASA), D.11

EOS	European Optical Society
EOSAT	Earth Observation Satellite Company (Commercial distributor of Landsat imaging data, located in Lanham, MD, since 1985, EOSAT is a joint venture of Lockheed Martin and Hughes Aircraft). Space Imaging Inc. (since 1994) of Thornton, CO of LM and E-Systems, acquired EOSAT in 1995. The new company was subsequently renamed into: Space Imaging EOSAT [distributor of IKONOS imagery, ERS-1/2, JERS and Radarsat data (USA), global distributor of IRS-1C/D imagery]. Since 1998 the company name is: Space Imaging. The owners of Space Imaging are: LM, E-Systems (of Raytheon Co, Lexington, MA), Mitsubishi, Vander Horst (Singapore), Halla Heavy Industries (Korea).
EOSDIS	EOS Data and Information System
EP	Electric Propulsion (of spacecraft)
EPA	Environmental Protection Agency (USA, since 1970)
EPIRB	Emergency Position Indicating Radio Beacon (on COSPAS and S&RSAT payloads)
EPOCS	Equatorial Pacific Ocean Climate Studies (campaign)
EPOCS	European Committee on Ocean and Polar Sciences
EPOP	European Polar Platform (old name, now POEM)
EPOS	European Proximity Operations Sensor (ESA test of GPS Tensor receivers and an optical rendezvous sensor for Shuttle-Mir docking maneuvers on STS-84 and STS-86)
Equator-S	Solar Terrestrial Mission (K.9)
ER-2	Extended Range U-2 (US research aircraft of NASA/ARC)
ERA	European Robotic Arm (of ESA on ISS)
ERB	Earth Radiation Budget
ERBS	Earth Radiation Budget Satellite (NASA), A.13
ERICA	Experiment on Rapidly Intensifying Cyclones over the Atlantic (campaign)
ERIM	Environmental Research Institute of Michigan (HQ in Ann Arbor, MI). ERIM is a nonprofit contract research organization in the field of remote sensing. In May 1997, ERIM was transformed into a profit-seeking company and changed its name to "ERIM International." History: The Willow Run Laboratories were founded in 1947. In 1973 the Willow Run Laboratories team separated from the University of Michigan and became ERIM. - In 2000 ERIM International Inc. became part of Veridian Systems, the new company is called: Veridian ERIM International
EROS	Earth Resources Observation Systems (Data Center of USGS in Sioux Falls, SD, archive for Landsat and other data)
EROS	Earth Remote Observation System (B.5)
ERS-1,2	European Remote Sensing Satellite (ESA program), D.13 and D.14
ERS	Earth Resource Satellite
ERSDAC	Earth Remote Sensing Data Analysis Center (Tokyo, Japan)
ERTS-1	Earth Resources Technology Satellite (NASA satellite, in 1975 ERTS-1 was renamed to Landsat-1 and the entire ERTS program was renamed to Landsat)
ESA	European Space Agency (since 1975), ESA-HQ in Paris (ESA member states are: Austria, Belgium, Denmark, Finland, France, Germany, Ireland, Italy, Netherlands, Norway, Spain, Sweden, Switzerland, and the United Kingdom; Canada is a cooperating country)
ESA/ESTEC	ESA/European Space Research and Technology Centre (ESA facility in Noordwijk, Netherlands)
ESA/ESOC	ESA/European Space Operation Centre (ESA facility in Darmstadt, Germany)
ESA/ESRIN	ESA/European Space Research Institute (ESA facility, Frascati, Italy)

ESA-IRS	ESA - Information Retrieval Service (online database at ESRIN)
ESAC	Earth Sciences Advisory Committee (ESA)
ESA/PB-EO	ESA/Programme Board - Earth Observation
ESCAP	(UN) Economic and Social Commission for Asia and the Pacific, Bangkok, Thailand
ESCAPE	Experiment of the Sun for Complementing the ATLAS Payload and for Education (Shuttle Payload)
ESE	Earth Science Enterprise [NASA program with the previous designation of MTPE (Mission to Planet Earth)]
ESEM	Evaluation of Space Environment Effects on Materials (Shuttle payload of NASA/LaRC) ESEM experiments are focused on cosmic dust collection
ESF	European Science Foundation (Strasbourg, France)
ESDIS	Earth Science Data and Information System (NASA/GSFC)
ESIC	Earth Science Information Center (USGS operates a network of ESICs to distribute Earth science data and related products)
ESIS	European Space Information System (ESA data system)
ESOC	European Space Operation Centre [ESA facility in Darmstadt, Germany, since Sept. 1967; formerly ESDAC (European Space Data Center) under ESRO]
ESRIN	European Space Research Institute (ESA facility in Frascati, Italy)
ESRO	European Space Research Organization (founded in 1962 by ten European countries; predecessor organization of ESA)
ESSA	Environmental Science and Services Administration (this was a predecessor organization of NOAA)
ESSP	Earth System Science Pathfinder (small-scale, low-cost, and quick-turnaround NASA missions like QuikTOMS, VCL, GRACE, SORCE, ESSP-3 (formerly PICASSO-CENA), CLOUDSAT, VOLCAM, etc.)
ESTEC	European Space Research and Technology Centre (ESA facility in Noordwijk, Netherlands)
ETALON	Russian passive satellite series for geodetic measurements, E.4
ETHZ	Eidgenössische Technische Hochschule, Zürich (Swiss Federal Institute of Technology, Zürich)
ETHZ/IGP	ETHZ/Institute of Geodesy and Photogrammetry
ETL	Electrotechnical Laboratorium (of MITI, Japan)
ETS	Engineering Test Satellite (NASDA technology series, Japan)
ETSI	European Telecommunications Standards Institute (since 1988)
EU	European Union (formerly EC = European Community)
EUCREX	European Cloud and Radiation Experiment (campaign)
EUMETSAT	European Organization for the Exploitation of Meteorological Satellites (Darmstadt, Germany, since 1986 – operation of the Meteosat and the future MetOp systems). EUMETSAT member states are: Austria, Belgium, Denmark, Finland, France, Greece, Germany, Ireland, Italy, Netherlands, Norway, Portugal, Spain, Sweden, Switzerland, Turkey, and the United Kingdom.
EurasSpace	EurasSpace GmbH, Munich; Euro-Asian Space venture between DASA of Germany and CASC (Chinese Aerospace Corp. of Beijing); builders of telecommunication satellites (Sinosat-1, etc.)
EURIMAGE	European Consortium for Satellite Image Dissemination (Rome, Italy - a commercial data distributor. The consortium is made up by the following companies: SSC, MATRA, NRSC and Dornier)
EURECA	European Retrievable Carrier (platform deployed and retrieved on Shuttle) J.5
EURISY	European Association for ISY (one of two ISY organizers in Europe, see SAFISY)
Eurockot	Eurockot Launch Services GmbH, Bremen, Germany. A joint venture company between Russia's Khrunichev and Germany's DASA. The

launcher is the Rockot vehicle, built by KhSC (Khrunichev State Research and Production Space Center), Moscow. Rockot is a modified version of Russia's SS-19 missile. The first launch demonstration of a Rockot vehicle occurred on May 16, 2000 from Plesetsk with Simsat-1 and -2, two dummy payloads.

EUROLAS European Laser Stations (ground network of SLR stations)
 EUROPTO A joint venture between EOS (European Optical Society) and SPIE (Society of Photo-Optical Instrumentation Engineering)
 Eurospace The association of European space industry, Paris, since 1961
 Eutelsat European Telecommunications Satellite Organization
 EUV Extreme Ultra Violet (spectral range), see also: XUV
 EXOS Exospheric Observations, ISAS program (K.10)
 EXPRESSO Experiment for Regional Sources and Sinks of Oxidants (campaign)

F

FAA Federal Aviation Administration (regulatory agency for all civil aviation in the Department of Transportation, USA)
 FACH Fuerza Aerea de Chile (Chilenian Air Force)
 FAGS Federation of Astronomical and Geophysical Services
 FAISAT Final Analysis Inc. Satellite (C.2)
 FAO Food and Agriculture Organization (of the UN)
 FARE Fluid Acquisition and Resupply Experiment (Shuttle)
 FASat-Alfa Fuerza Aerea Satellite - Alfa (D.40.12)
 FASINEX Frontal Air-Sea Interaction Experiment (campaign)
 FAST Fast Auroral Snapshot Explorer (GSFC mission, K.21.2)
 FAST Fore-Aft Scan Technique (radar)
 FASTEX Fronts & Atlantic Storm Track Experiment (campaign)
 FATE FIRST ATSR Tropical Experiment (campaign)
 FBG Functional Cargo Block (first element of ISS also referred to as Zarya)
 FCC Federal Communications Commission (Washington, DC, USA)
 FDDI Fiber Distributed Data Interface
 FDMA Frequency Division Multiple Access (access scheme)
 FDP Fluorescent Dye Particles (a tracer technique in lidar observations)
 FEA Fluid Experiment Apparatus (Shuttle)
 FEC Forward Error Correction (transmission protocol technique)
 FEED Field Effect Electric Propulsion
 Feng-Yun (FY) .. Chinese meteorological satellite series, G.3
 FFT Fast Fourier Transform
 FET Field-Effect Transistor (JFET = Junction Field-Effect Transistor)
 FFSK Fast Frequency Shift Keying (modulation technique)
 FGAN Forschungsgesellschaft für Angewandte Naturwissenschaften (German Defense Research Laboratory, Wachtberg, Germany)
 FGGE First GARP Global Experiment (campaign)
 FhG Fraunhofer Gesellschaft (in honor of Joseph von Fraunhofer, 1787 - 1826), a leading organization of applied research in Germany (HQ in Munich). FhG operates 47 research institutes in Germany with about 8500 employees. About 2/3 of FhG research is through contracts for industry and government. There are also FhG institutes in USA and Asia. Only a few institutes are listed here:
 FhG/IAF Fraunhofer Gesellschaft/Institut für Angewandte Festkörperphysik (development of detectors), Freiburg, Germany
 FhG/IFU Fraunhofer Gesellschaft/Institut für Atmosphären und Umweltforschung (Institute of Atmospheric and Environmental Research), Garmisch-Partenkirchen, Germany
 FhG/IOF Fraunhofer Gesellschaft/Institut für Angewandte Optik und Feinmechanik (Institute of Applied Optics and Precision Engineering), Jena, Germany

FhG/IPM	Fraunhofer Gesellschaft/Institut für Physikalische Meßtechnik (Institute of Physical Measurement Techniques), Freiburg, Germany
FHT	Frequency Hopping Telemetry (a communication access method)
FIRAS	P. N. Lebedev Physical Institute of the Russian Academy of Sciences (RAS), Moscow. FIRAS was established in 1967 as part of IKI. Since 1991 it is named AKTs FIRAS (radio astronomy)
FID	Flame Ionization Detector
FIFE	First ISLSCP Field Experiment (campaign)
FILE	Feature Identification and Location Experiment (part of OSTA-1 payload on Shuttle STS-2 in Nov. 1981)
FIMR	Finnish Institute of Marine Research (Helsinki, Finland)
FINDS	Foundation of the International Non-Governmental Development of Space (USA, created in 1997)
FIR	Far infrared: from about 10 - 1000 μm (note: 1000 μm = 1 mm)
FIRE	First ISCCP Regional Experiment (campaign)
FIRESCAN	Fire Research Campaign Asia-North (IGBP-IGAC-BIBEX campaign)
FIREScheme . .	Fire Information Systems Research in the Socio-Culture, History and Ecology, of the Mediterranean Environment (campaign)
FLINN	Fiducial Laboratories for an International Network (a global network supporting Crustal Dynamics Test Sites)
FLIR	Forward Looking Infrared (sensor)
FM	Frequency Modulation (modulation technique of the main carrier)
FMC	Forward Motion Compensation
FM/CW	Frequency Modulation/Continuous Wave (a radar measurement technique to obtain range information - a sequence of FM/CW echoes contains both, range and Doppler information)
FMI	Finnish Meteorological Institute (Helsinki, Finland)
FMS	Flight Management System (avionics)
FOA	Försvarets Forskningsanstalt (National Defense Research Establishment, Department of Information Technology, Linköping, Sweden)
FOG	Fiber-Optic Gyroscope (an angular rate gyro)
FÖMI	Hungarian Remote Sensing Center, Budapest, Hungary
FOO	Flight of Opportunity
FOR	Field of Regard (total with of a ground imaging surface that is within the pointing potential of a sensor. Note: the FOV (or swath width) is always contained in the FOR)
FORTE	Fast On-Orbit Recording of Transient Events (LANL, A.16)
FOV	Field of View
FPA	Focal Plane Array (also: Focal Plane Assembly - detector assembly of an imager instrument)
FPGA	Field Programmable Gate Array
FRAM	Ferroelectric Random Access Memory (a chip technology)
FREJA	Swedish Solar-Terrestrial Mission (K.11)
FSK	Frequency Shift Keying (modulation technique)
FTAM	File Transfer Access and Management (OSI File Transfer Method)
FTFPV	Flexible Thin-Film Photovoltaic (technology)
FTIR	Fourier Transform Infrared (radiometer or spectrometer)
FTS	Fourier Transform Spectrometer
FUV	Far Ultraviolet (spectral region 90 - 125 nm)
FWG	Forschungsanstalt der Bundeswehr für Wasserschall und Geophysik (Kiel, Germany)
FWHM	Full-Width-Half-Maximum (of distribution curve)
FZJ	Forschungszentrum Jülich (Germany, old name was KfA)
FZK	Forschungszentrum Karlsruhe (Germany, old name was KfK)
FZK/IMK	FZK (Forschungszentrum Karlsruhe)/Institut für Meteorologie und Klimaforschung (Institute of Meteorology and Climate Research)

G

Ga	Gallium (detector material)
GaAs	Gallium Arsenide (a material used for solar panels, for detectors, and for fast computer chips)
GaIn	Galileo Industries SA, located in Brussels, Belgium (a joint venture of Astrium, Alenia Spazio, and Alcatel Space, founded May 25, 2000)
GaInP ₂	Gallium Indium Phosphide (solar cell type)
GaN	Gallium Nitride (used in GaN photoconductive detectors)
GAC	Global Area Coverage (the term is used for AVHRR data of NOAA)
GAF	Gesellschaft für Angewandte Fernerkundung, Munich (since 1985, German commercial distributor of Earth observation data, such as Re-surs data, Landsat data, IRS-1C/D data (via EOSAT), representative of EURIMAGE and SPOT-IMAGE in Germany, distributor for SOVIN-FORMSPUTNIK data, Radarsat data distributor for Germany, etc.
GABLE	Global Atmospheric Backscatter Lidar Experiment (campaign)
GADACS	GPS Attitude Determination and Control Experiment (a GSFC GPS instrument package on Shuttle SPARTAN)
GADFLY	GPS Attitude Determination Flyer (experiment on Lewis S/C)
GAIM	Global Analysis, Interpretation and Modeling (IGBP project)
GALE	Genesis of Atlantic Lows Experiment (airborne campaign in 1986)
Galileo Industries	Galileo Industries SA is a European joint venture of the following companies(to define and build the Galileo System): Alenia Spazio of Rome, Alcatel Space of Paris, Astrium Ltd. of Stevenage, UK, and As-trium GmbH of Friedrichshafen, Germany.
GAME	GEWEX-related Asian Monsoon Experiment (campaign)
GAMES	Gravity and Magnetic Earth Surveyor (a NASA/GSFC mission)
GANDER	Global Altimeter Network Designed to Evaluate Risk (an SSTL, UK constellation planned to be launched in 2002) + + + +
GANE	GPS Attitude Navigation Experiment (NASA Shuttle payload)
GARP	Global Atmospheric Research Program (of WMO, since 1968)
GAS	Get-Away Special (Shuttle canisters)
GATE	GARP Atlantic Tropical Experiment (campaign)
GAUSS	Galaktische Ultraweitwinkel Schmidt System, Shuttle payload (Galac-tic super wide angle Schmidt system)
GAW	Global Atmosphere Watch (WMO)
GBA	GAS Bridge Assembly (Shuttle payload)
GBRN	Global Baseline Radiation Network (WCRP)
GC	Gas Chromatograph
GCIP	GEWEX Continental-Scale International Project
GCM	General Circulation Model (atmospheric and climate research)
GCMD	Global Change Master Directory (at NASA/GSFC since 1989)
GCOM	Global Change Observation Mission (NASDA)
GCOS	Global Climate Observing System (of WMO, IOC, UNEP, and ICSU)
GCOS/JSTC	GCOS/Joint Scientific and Technical Committee (Geneva, Switzer-land)
GCP	Glow Cryoph Payload (DoD Shuttle payload)
GCTE	Global Change and Terrestrial Ecosystem (IGBP core program)
GE	General Electric Co., Fairchild, CT, USA
Ge	Germanium (detector material)
GeGa	Germanium Gallium (detector)
GEIA	Global Emissions Inventory Activity (IGBP/IGAC focus 6 activity)
GEMINI	NASA program of the 1960s
GEMINUS	Galileo European Multimodal Integrated Navigation User Service
GEMS	Global Environment Monitoring System (of UNEP)
GENESIS	Galileo European Network of Experts to Support the European Com-mission

GEO	Geostationary Earth Orbit (or geosynchronous orbit with zero inclination, the altitude is about 35,786 km)
GeoLITE	Geosynchronous Lightweight Technology Experiment (NRO funded communications satellite)
GEO-IK	Russian S/C for solid Earth research, E.5
GEOKhl RAN ..	Vernadskiy Institute for Geochemistry and Analytical Chemistry of RAN, Moscow; since 1947, participation in programs: Luna, Venera, Salyut, MIR, Vega, Phobos, Voyager, Magellan, Mars Observer
GEOMAR	Research Center for Marine Geosciences (U. of Kiel, Germany)
GEOS	Geostationary Satellite (ESA experimental program) E.6
GEOS	Geodetic Earth Orbiting Satellite, E.7.1, E.7.2
GEOS-3	Geodynamics Experimental Ocean Satellite, E.7.3 (GEOS-3 is the first radar altimeter mission, end of mission in 1978)
GEOS&R	Geostationary Search and Rescue (system)
GEOSAT	US Navy satellite (altimeter mission), E.8
GEOTAIL	Japanese (ISAS) mission to study the structure and dynamics of the geomagnetic tail (part of ISTP), K.13
GEOWARN	Global Emergency Observation Warning and Relief Network (in planning phase by NASA/MSFC, etc.)
GER	Geophysical & Environmental Research Corp. (Millbrook, NY, USA)
GEWEX	Global Energy and Water Cycle Experiment (WMO program)
GFLOPS	Billion Floating Point Operations per Second (10^9 - a measure of computer processing power)
GFO-1	Geosat Follow-On (Satellite), E.9
GFU	Geophysical Institute of the Academy of Sciences of the Czech Republic, Prague
GFZ	GeoForschungsZentrum (Potsdam, Germany, since 1992)
GGs	Global Geospace Science (US program within ISTP with two spacecraft: Wind and Polar)
GGSE	Gravity Gradient Stabilization Experiment. A technology satellite series (GGSE-1 to GGSE-5) launched by the US military (NRL of DoD) from Vandenberg AFB aboard Thor Agena-D rockets. GGSE-1 (39 kg mass): launch Jan. 11, 1964 into a 900 km altitude orbit with an inclination of 69.9°; GGSE-2 and GGSE-3 (each S/C of 4 kg mass): launch March 9, 1965; GGSE-4 and -5 (each S/C of 4 kg mass): launch May 31, 1967
GGTS-1	Gravity Gradient Test Satellite-1 (of the USAF was launched June 16, 1966 from Cape Canaveral)
GHCC	Global Hydrology and Climate Center (at NASA/MSFC, Huntsville)
GHCD	Growth Hormone Crystal Distribution (Shuttle experiment)
GIAC	GPS Interagency Advisory Council
GIF	Graphics Interchange Format of Compuserve (8-bit color format, used in HTML, etc.)
GIM	Global Integration and Modeling (IGBP/IGAC focus 6 activity)
GIMEX	Greenland Ice Margin Experiment (campaign)
GIPME	Global Investigation of Pollution in the Marine Environment
GIS	Geographic Information System (an archive in particular for forestry data)
GISP	Greenland Ice Sheet Project
GISS	Goddard Institute for Space Studies (New York, NY, since 1961 - a NASA/GSFC facility at Columbia University)
GKNPT Khrunichev	Moscow; Leading company in the development, production, testing, and operation of launch vehicles and spacecraft, utilization of Proton. Participation in programs: Venera, Mars, Luna, Kosmos, Phobos, Vega, Gorizont, Salyut, MIR, Almaz, Energia-Buran, Zond, etc.
GKSS	Gesellschaft für Kernenergieverwertung in Schiffbau und Schifffahrt (Geesthacht, Germany)

GLAS	Geoscience Laser Altimeter System (previously GLRS)
GLIS	Global Land Information System (an online land data directory guide, a public information system operated by USGS at EROS Data Center)
Glavkosmos	Russian space organization agency with the objective to develop the commercial side of space activities (created in 1985)
GLO	Glow Experiment (Shuttle payload)
GLOBE	Global Backscatter Experiment (campaign)
GLOBSAT	Proposed Earth Observation Satellite by the French Earth Science Community.
GLOCARB	Global Tropospheric Carbon Dioxide Network (IGBP/IGAC program)
GLOCHEM	Global Atmospheric Chemistry Survey (IGBP/IGAC program)
GLOMR	Global Low Orbiting Message Relay (DARPA S/C flown on STS-61A)
GLONASS	Global Orbiting and Navigation Satellite System (USSR), H.3
GLONET	Global Tropospheric Ozone Network (IGBP/IGAC program)
GLOSS	Global Sea Level Observing System (of IOC)
GLRS	Geoscience Laser Ranging System (EOS Sensor), renamed in 1992 GLAS = Geoscience Laser Altimeter System
GMES	Global Monitoring for Environment and Security (European initiative)
GMS	Geostationary Meteorological Satellite, Operational Program of JMA (Japan Meteorological Agency), F.3
GMSK	Gaussian Minimum Shift Keying (modulation technique)
GN&C	Guidance Navigation and Control
GNSS	Global Navigation Satellite System (a future civil satellite navigation system)
GOALS	Global Ocean-Atmosphere-Land System (CLIVAR subprogram)
GOBEX	Gotland Basin Experiment (campaign)
GOCE	Gravity Field and Steady-State Ocean Circulation Experiment (core mission in ESA's Earth Explorer Program)
GOES	Geostationary Operational Environmental Satellite (NOAA Series), F.4
GOFS	Global Ocean Flux Study (program)
GOMS	Geostationary Operational Environmental Satellite (Russian geostationary meteorological satellite series (at longitude 76 deg. East), F.5
GOOS	Global Ocean Observing System [a joint program of the Intergovernmental Oceanographic Organization, WMO (World Meteorological Organization), UNEP (United Nations Environmental Program), and the International Council for Science]. GOOS integrates real-time in-situ and satellite observations with numerical model to form model-based information products for a variety of applications.
GORC	Global Ocean Carbon Research Program
GORS	General Organization of Remote Sensing (since 1986, Damascus, Syria), Space Agency of Syria
GOS	Global Observing System (WWW)
GOSAMR-1	Gelatin of Sols: Applied Microgravity Research-1 (Shuttle experiment)
GOSIP	Government Open System Interconnection Profile (US Government Standard, GOSIP is a subset of OSI)
GOSNIAS	State Research Institute of Aviation Systems (Moscow, Russia)
GP-B	Gravity Probe-B Relativity Mission (E.12)
GPCC	Global Precipitation Climatology Center, (since 1988, located at the German Weather Service (DWD) in Offenbach, Germany, collection of raingauge-measured monthly precipitation data, worldwide)
GPCP	Global Precipitation Climatology Project (by ICSU and WMO)
GPS	Global Positioning System, H.4
GPS DTO	GPS Development Test Objective (Shuttle payload)
GRACE	Gravity Recovery and Climate Experiment

GRAS	Ground Regional Augmentation Ssystem (within the framework of EG-NOS)
GRDC	Global Runoff Data Center (Bundesanstalt für Gewässerkunde - Federal Institute of Hydrology, Koblenz, Germany)
GRGS	Groupe de Recherches de Géodésie Spatiale (Grasse and Toulouse, France)
GRID	(UNEP) Global Resources Information Database (at EDC) for the purpose of analyzing environmental data
GRIP	Greenland Icecore Project
GRSS	Geoscience and Remote Sensing Society
GSC	Geological Survey of Canada
GSD	Ground-Sampling Distance (spatial resolution).
GSFC	Goddard Space Flight Center in Greenbelt, MD (DAAC of NASA EOS Program)
GSI	Geological Survey Institute (Japan)
GSLV	Geosynchronous Satellite Launch Vehicle (a three-stage ISRO launcher, since 1999, of PSLV heritage)
GSM	Global System for Mobiles (digital cellular standard of ETSI)
GSOC	German Space Operations Center (DLR facility in Oberpfaffenhofen)
GSTDN	Ground-Station Tracking and Data Network (old NASA network)
G/T	(receiver) Gain / (noise) Temperature
GTCP	Global Tropospheric Chemistry Program (NSF program)
GTE	Global Tropospheric Experiment (a NASA program)
GTE/CITE	Global Tropospheric Experiment/Chemical Instrumentation Test and Evaluation (campaigns)
GTO	Geosynchronous Transfer Orbit
GTOS	Global Terrestrial Observing System (WMO, UNESCO, IOC, FAO, ICSU)
GTS	Global Telecommunications System (of the World Meteorological Organization (WMO))
GULFEX	Gulf Experiment (campaign)

H

H ₂ O	Water
H ₂ O ₂	Hydrogen peroxide
HALE	High Altitude Long Endurance (campaign)
HAPEX	Hydrologic and Atmospheric Pilot Experiment (campaign)
HaRP	Hawaiian Rainbow Project (campaign)
HBr	Hydrogen bromide
HBT	Heflex Bioengineering Test (Shuttle)
HCMM	Heat Capacity Mapping Mission (NASA sensor), A.18
HCHO	(CH ₂ O) Formaldehyde
HCl	Hydrogen chloride
HCT	HgCdTe (detector type, see also MCT)
HDDT	High Density Digital Tape
HDP	Human Dimensions Programme (of ISSC)
HDT	High Density Tape
HDLC	High-Level Data Link Control (bit-oriented protocol)
HEB	Hot Electron Bolometer (receiver type used in microwave spectrometers, etc.)
HELCOM	Helsinki Commission (since 1974, an intergovernmental organization of all countries surrounding the Baltic Sea to protect the Baltic Sea)
HELIOS-1	A European military reconnaissance satellite program (Earth observation) sponsored by France (78.9%), Italy (14.1%) and Spain (7%). Helios-1A was launched July 7, 1995. Helios-1B was launched Dec. 3, 1999 on an Ariane 4 vehicle from Kourou. Both satellites were built by MMS

of Toulouse. Helios-1B, nearly an identical twin of Helios-1A, has a launch mass of 2544 kg (design life of 5 years, power = 2.2 kW). The Helios S/C bus is almost identical to the SPOT-4 platform. Attitude is measured by star sensors and two-axis gyros, actuators are reaction wheels and magnetic torquers. Both S/C are in a sun-synchronous orbit (altitude = 680 km, inclination = 98°, period = 98 minutes), 180° apart to optimize coverage. The optical imaging system is referred to as EPV (Ensemble de Prise de Vues), built by Alcatel Space, it uses CCD line array detectors and provides a spatial resolution of about 1 m. On-board storage is provided by two digital tape recorders for each S/C, each with a capacity of 120 Gbit. Helios-1B has in addition a solid state memory of 9 Gbit. All imagery is encrypted and downlinked in X-band at 50 Mbit/s (TT&C encrypted in S-band at 2 kbit/s). CNES provides S/C operations from Toulouse. The Helios ground segment comprises three user centers at Creil (Italy), Madrid (Spain), and CPFH (Main Helios Center France). Imagery is received at ground stations of the three partner countries [Maspalomas (Spain), Colmar (France), and Lecce (Italy)].²¹⁰⁹⁾

- HELSTF High Energy Laser Systems Test Facility [a US DoD national test facility at WSMR (White Sands Missile Range), NM, supporting laser research, development, test and evaluation. HELSTF was established in 1985 as a tri-service test and evaluation facility for all high energy laser work. MIRACL (Mid-Infrared Advanced Chemical Laser) is located at WSMR]
- HEMT High Electron Mobility Transistor (receiver type for microwave spectrometers)
- HEO Highly Elliptical Orbit
- HERCULES Hand-held, Earth-oriented, Real-time, Cooperative, User-friendly, Location-targeting and Environmental System (Shuttle experiment)
- HES Hitchhiker Ejection System. HES provides a capability to eject a payload from a GAS (Get Away Special) canister on Shuttle.
- HESS High-Latitude Ecosystems as Sources and Sinks of Trace Gases (IGBP/IGAC)
- HETE High Energy Transient Experiment (MIT payload, built by AeroAstro of Herndon, VA)
- HF High Frequency (3 - 30 MHz band)
- HF Hydrogen fluoride
- HgCdTe Mercury Cadmium Telluride (mercadtelluride, a detector material) also referred to as MCT and HCT
- HgI₂ Mercury Iodine (a detector material)
- HGF Hermann von Helmholtz-Gemeinschaft Deutscher Forschungszentren, Bonn (named after Hermann von Helmholtz, 1821 - 1894). Sixteen German research centers are members of HGF, an association with the objective to coordinate and foster interdisciplinary research, to share expensive technical equipment of their infrastructure, to cooperate on long-term system solutions, and to transfer new technology for industrial applications. All HGF centers are government-funded, they employ a total of about 23,000 persons with a budget of 3.6 billion DM in 1996. The following institutions are members of HGF:
 AWI (Alfred-Wegener-Institut für Polar- und Meeresforschung, since 1980, Bremerhaven and Potsdam)
 DESY (Deutsches Elektronen Synchrotron, Hamburg, since 1959)
 DKFZ (Deutsches Krebsforschungszentrum, Heidelberg, since 1964)
 DLR (Deutsche Forschungsanstalt für Luft- und Raumfahrt)
 FZK (Forschungszentrum Karlsruhe)
 GBF (Gesellschaft für Biotechnologische Forschung, Braunschweig)

	GFZ (GeoForschungsZentrum Potsdam, since 1992)
	GKSS (Gesellschaft für Kernergieverwertung in Schiffbau und Schifffahrt, Geesthacht)
	GMD (Gesellschaft für Mathematik und Datenverarbeitung, since 1968, German National Research Center of Information Technology, St. Augustin, and Darmstadt)
	GSF (Forschungszentrum für Umwelt und Gesundheit, Neuherberg)
	GSI (Gesellschaft für Schwerionenforschung, Darmstadt)
	HMI (Hahn-Meitner-Institut, Berlin)
	IPP (Max-Planck-Institut für Plasmaphysik, Garching)
	KFA (Forschungszentrum Jülich)
	MDC (Max-Delbrück-Zentrum für Molekulare Medizin, Berlin)
	UFZ (Umweltforschungszentrum Leipzig-Halle)
HH	Hichthiker (a Shuttle flight carrier system offered by NASA for small payloads, offering the provision of extended functional features) HH-S stands for 'sidewall mounting,' HH-C stands for 'cross bay mounting'
HH	Horizontal transmit - Horizontal receive polarization
HIP	Heterojunction Internal Photoemission (detector technology)
HNO ₃	Nitric acid
HO _x (HO _x)	Odd hydrogen (OH, HO ₂ , H ₂ O ₂)
HOCl	Hypochlorous acid
HOLOP	Holographic Optics Laboratory (Shuttle D2 mission)
HOST	HST Orbital Systems Test Platform (Shuttle payload)
HPCG	Hand-held Protein Crystal Growth (Shuttle payload)
HPP	Heat Pipe Performance (Shuttle experiment)
HPT	Heterojunction Phototransistor (optoelectronic component which combines both optical detection and electrical gain in a single element)
HPTE	High Precision Tracking Experiment (Shuttle payload)
HRPT	High Resolution Picture Transmission (NOAA broadcast technique in S-band at frequencies of 1698.0 and 1707.0 MHz; data from all AVHRR channels (plus TOVS and SEM) is provided at full 1.1 km resolution)
HRS GS-A	High Resolution Shuttle Glow Spectroscopy (Shuttle payload)
HRTS	High Resolution Telescope and Spectrograph (Shuttle, Spacelab-2 sr, a 30 cm, f/15 Gregorian telescope, spectrograph in UV range 1170-1700 Å, and a spectroheliograph observing at 1550 Å)
HSC	Hughes Space & Communications Company (since 1961), an operating unit of Hughes Electronics Corporation, Los Angeles, CA. HSC is a manufacturer (world leader) of communication satellites (over 40% of market share). Provider of several standard platforms like HS 376 for spin-stabilized satellites, the HS 601 series is body-stabilized; in 1995 HSC introduced the body-stabilized HS 702 platform. Manufacturer of Syncom (first communications satellite, launch 1963), ATS-1 (first GEO weather satellite, launch in 1966), Pioneer (Venus Probe, 1978), Galileo (Jupiter Probe, launch 1989). Military satellite builder. - In January 2000, the HSC along with subsidiaries Hughes Electron Dynamics and Spectrolab were sold to the Boeing Company. They were reorganized into a business unit called "Boeing Satellite Systems."
HSCT	High-Speed Civil Transport (USA)
HST	Hubble Space Telescope (Shuttle launch)
HSRP	High-Speed Research Program (NASA)
HTML	HyperText Markup Language
HTS	High-(T _c) Temperature Superconductivity, refers to material temperature T _c levels above those of liquid helium [the technology is employed in sensor design, thin-film applications, MRI (Magnetic Resonance Imaging), wireless communication filters, and ultra-fast computer chips]

HTSQUID	High-(Tc) Temperature SQUID (Superconducting Quantum Interference Device)
HTTP	HyperText Transfer Protocol
Hughes	Hughes Electronics Corporation, a worldwide operating company with HQ in Los Angeles, CA (a wholly owned subsidiary of General Motors Corporation founded in 1985). The conglomerate consists of: Hughes Aircraft Company, Hughes Telecommunications & Space (largest manufacturer in the world of telecommunication satellites), Hughes Network Systems, DIRECTV Inc., and Delco Electronics Corporation. HSC is part of Hughes Telecommunications & Space. In 2000, Hughes Electronics Corporation sold its satellite manufacturing business to Boeing Company.
Hughes (HAC)	..	Hughes Aircraft Company, (since 1932, founded by Howard Hughes), part of Hughes Electronics Corporation, with HQ in Arlington, VA, a technology company with three major operating units: Information Systems (Reston, VA), Sensor & Communications Systems, and Weapons Systems. SBRC (as of 1996 SBRS, builder of Landsat instruments, MSS, TM, monolithic infrared focal plane arrays, etc.) is part of Sensor & Communications Systems
HUT	Helsinki University of Technology (Helsinki, Finland)
HUT	Hopkins Ultraviolet Telescope (part of Shuttle ASTRO observatory)
HV	Horizontal transmit - Vertical receive polarization
HYDROMET	..	Committee for Hydrometeorology (USSR/CIS agency in the field of Meteorology)
HypSEO	HyperSpectral Earth Observer (an ASI mission in preparation, planned flight in 2003)
HWRP	Hydrology and Water Resources Programme (WMO)

I

IAA	International Academy of Astronautics (Paris, France)
IAE	Inflatable Antenna Experiment (Shuttle)
IADC	Inter-Agency Space Debris Coordination Committee
IAF	International Astronautical Federation (Paris)
IAFE	Institute of Astronomy and Space Physics (Argentina)
IAG	International Association of Geodesy
IAHS	International Association of Hydrological Sciences
IAI	Israel Aircraft Industries (government-owned company, of Lod, Israel)
IAI/MBT	IAI/Mifal Beth. MBT stands for the Hebrew translation of MIFAL BETH (or its abbreviation of MABAT) which means 'the second plant,' since it was the second plant established by IAI in the 1960s. The Hebrew name of MABAT remained with the corresponding English acronym of MBT.
IAIN	International Association of Institutes of Navigation (since 1975)
IAMAP	International Association of Meteorology and Atmospheric Physics
IAMAS	International Association of Meteorology and Atmospheric Sciences
IAP	Institute of Atmospheric Physics, Moscow
IAPSO	International Association for the Physical Sciences of the Oceans (one of seven associations of IUGG, which in turn is a union of ICSU)
IAS	Institut d'Astrophysique Spatiale (Verrières-le-Buisson, France, lab is part of CNRS)
IASC	International Arctic Science Committee (Arctic Centre, University of Lapland, Finland)
IASIS	Interbranch Association Sovinformsputnik (commercial distributor of imagery from Russian defense satellites, Moscow)
IAU	International Astronomical Union
IBAMA	Instituto Brasileiro do Meio Ambientes Dos Recursos Naturais Renovaveis (Brazil)

IBC	Impurity Band Conduction (detector technology)
IBFRA	International Boreal Forest Research Association (since 1991)
IBFRA-SRF	IBFRA - Stand Replacement Fire (working group)
IBSE	Initial Blood Storage Experiment (Shuttle payload)
IBSFC	International Baltic Sea Fishery Commission
IBSS	Infrared Background Signature Survey (satellite of the USAF deployed on STS-39) IBSS was retrieved by the Shuttle on May 2, 1991.
ICA	International Cartographic Association
ICAE	International Conference on Atmospheric Electricity
ICAO	International Civil Aviation Organization
ICAT	Incubator-Cell Attachment Test (Shuttle)
ICBC	IMAX Cargo Bay Camera (Shuttle), a 65 mm color motion picture camera
ICBM	Intercontinental Ballistic Missile. Russia offers commercially four types of converted ICBMs for satellite launches. The types "Rockot" and "Strela" are based on the SS-19 Stiletto missile; "Dnepr" is based on the SS-18 Satan missile; "Start" is a converted SS-20 missile. The Rockot launch vehicle Rockot is a joint venture of Eurockot Launch Services GmbH, Bremen, Germany and of KhSC (Khrunichev State Research and Production Space Center), Moscow. ISC Kosmotras of Moscow markets the Dnepr vehicle. The Start (Start-1) vehicle is marketed by Puscovie Usługi of Moscow.
ICC	Instrument Control Center (EOSDIS Facility)
ICC	Integrated Cargo Carrier (Shuttle payload, first flown on STS-96). ICC is an unpressurized flat bed pallet and keel yoke assembly. Constructed of aluminum, it is 2.5 m long, 4.5 m wide and 25 cm thick and has the capability to carry cargo (up to about 1350 kg) on both faces of the pallet, both atop and below. The ICC is used by astronauts throughout the construction of the Space Station as it transports hardware from locations on the station's exterior to work sites on the truss assemblies.
ICE	International Cirrus Experiment (campaign)
ICE	International Cometary Explorer (renamed ISEE-3 mission), K.18.2
ICES	International Council for the Exploration of the Sea
ICET	International Center for Earth Tides
ICIC	Intercalibrations/Intercomparisons (IGBP/IGAC focus 7 activity)
ICSU	International Council of Scientific Unions (HQs in Paris, France. ICSU is a non-governmental body created in 1931 to promote international science and its applications. It has a membership of international organizations (Scientific Unions), national science academies and research councils, and Scientific Associates. Some committees of ICSU are: IGBP, SCOPE, SCAR, COSPAR, etc.)
ICWG-EO	International Coordination Working Group for Earth Observation
IDA	Institute of Defense Analysis (since 1957, a DoD nonprofit corporation)
IDEAL	International Decade of of East African Lakes (campaign)
IDHT	Instrument Data Handling and Transmission (ERS-1 S-band antenna)
IDN	International Directory Network (CEOS-defined for databases, former designation 'PID')
ie	abbreviation (Latin: id est) that is
IECM	Induced Environment Contamination Monitor (Shuttle)
IEE	Institution of Electrical Engineers (London, UK)
IEEE	Institute of Electrical and Electronics Engineers (USA)
IEF	Isoelectric Focusing (Shuttle payload)
IEH	International EUV Hitchhiker (Shuttle payload)
IEICE	Institute of Electronics, Information and Communication Engineers, Tokyo, Japan
IELV	Intermediate Expendable Launch Vehicle (EOS program)

IEOS	International Earth Observing System (Committee dealing with the policies, principles of data exchange, etc.; partner agencies are: CSA (Canada), ESA (Europe), NASA (USA), and STA (Japan). Delegations from agencies with operational environmental monitoring satellites: NASDA, MITI, JMA (Japan), EUMETSAT (Europe), NOAA (USA), AES (Canada). Typical IEOS missions are: ENVISAT (ESA), EOS/AM-1 (NASA), NOAA-N (NOAA), ADEOS (NASDA), and TRMM (NASA/NASDA).
IERS	International Earth Rotation Service (Central Bureau in Paris, since 1988)
IERS	International Earth Reference System
I/F	Interface
IF	Intermediate Frequency
IFAG	Institut für Angewandte Geodäsie [Institute of Applied Geodesy - a federal agency under the jurisdiction of the German Ministry of the Interior (BMI) with research in the fields of geodesy, cartography and photogrammetry]. IFAG maintains a central office in Frankfurt/Main and branch offices in Leipzig, Potsdam, and Berlin. Note: In the late 1990s, IFAG was renamed to BKG (Bundesamt für Kartographie und Geodäsie).
IFARS	Institute for Applied Remote Sensing (Wedel, Germany)
IFE	Isoelectric Focusing Experiment (Shuttle payload)
IFEOS	International Forum on Earth Observations Using Space Station Elements (since 1986)
IFOV	Instantaneous Field of View
IFREMER	Institut Francais de Recherche pour L'Exploration de la Mer (French Ocean Agency in Brest, France). IFREMER/CERSAT is a processing and archiving facility for satellite data and is part of the "Département d'Océanographie Spatiale" at IFREMER.
IFSAR	Interferometric SAR (measurement technique using two antennas, sometimes also referred to as 'InSAR')
IFTI	Ioffe Physical Technical Institute (St. Petersburg)
IGAC	International Global Atmosphere Chemistry (IGBP core program)
IGAP	International Global Programme on Atmospheric Particles
IGARSS	International Geoscience and Remote Sensing Symposium - since 1981, sponsored by GRSS (Geoscience and Remote Sensing Society)
IGBP	International Geosphere-Biosphere Programme of ICSU (IGBP is closely linked, directly or through ICSU, to other international organizations involved in global change research, including: GCOS, IOC, IPCC, ISSC, SCOPE, UNEP, WCRP, WMO. Over 50 countries have national IGBP committees and supporting bodies. The IGBP Secretariat is in Stockholm, Sweden)
IGEB	Interagency GPS Executive Board [IGEB (Presidential Decision Directive as of March 1996) offers some formal civil agency participation in the GPS program. It is jointly chaired by the DoD and DoT, with oversight and management of the dual use component of the GPS]
IGEX	International GLONASS Experiment, a campaign under the auspices of IAG (International Association of Geodesy)
IGFOV	Instantaneous Geometric Field of View
IGN	Institut Géographique National (French National Geographic Institute, Paris)
IGOS	Integrated Global Observing Strategy (for synergetic effects)
IGRF	International Geomagnetic Reference Field
IGS	International GPS Service for Geodynamics (since 1993)
IGSO	Inclined Geosynchronous Orbit
IGU	International Geographical Union

IGY	International Geophysical Year [created in 1952 by the ICSU plenary meeting; the first IGY was planned for 1957/58 (a year of expected maximum solar activity), it coincided also with the start of the space age, the launch Sputnik-1 on Oct. 4, 1957]
IHP	International Hydrology Programme (UNESCO)
IHO	International Hydrographic Organization
IIP	International Ice Patrol
IJSSE	International Journal of Small Satellite Engineering (electronic journal on internet, edited at the University of Surrey, UK)
IKF	Institut für Kosmosforschung, Berlin-Adlershof, in former East Germany. Note: as of Jan. 1992 the IKF was renamed 'Institute of Space Sensor Technology (ISST),' it is part of DLR)
IKI RAN	Space Research Institute (of the Russian Academy of Sciences, RAN (or RAS, depending on the alphabet), Moscow, Russia; extraterrestrial physics and remote sensing, since 1965)
IKI-BAN	Space Research Institute, Bulgarian Academy of Sciences (Sofia, Bulgaria)
ILS	Instrument Landing System
ILS	International Launch Services [a joint commercial venture between Lockheed Martin Corp. (USA), Khrunichev Space Center (KhSC) and RKK Energia (Russia), offering of Atlas and Proton launch systems. The first ILS launch occurred in Sept. 1996 (Inmarsat-3 from Baikonur); since April 15, 1993 all commercial contracts, involving the Proton launch vehicle, are handled by ILS.
IMAGES	International Marine Global Change Study (IGBP project)
IMAU	Institute for Marine and Atmospheric Research Utrecht (University of Utrecht, The Netherlands)
IMAX	Image Maximum (a large screen motion picture camera/format used by the NASA/Smithsonian project to document significant space activities)
IMEC	Inter-university MicroElectronics Center, Leuven, Belgium. IMEC is a Flemish government initiative to bundle all microelectronics-related efforts of the three scientific universities into one independent non-profit super-lab.
IMET	Improved Meteorological Instrumentation (WHOI buoy type)
IMEX	Inner Magnetosphere Explorer, a mission of UMM (University of Minnesota at Minneapolis)
IMF	Interplanetary Magnetic Field
IMK	Institute für Meteorologie und Klimaforschung (Institute for Meteorology and Climate Research - a cooperative institute of the Nuclear Research Center Karlsruhe (KfK) and of the University of Karlsruhe, Germany)
IML	International Microgravity Laboratory (Shuttle payload)
IMO	International Maritime Organization
IMP	International Monitoring Platform, K.16
IMS	Information Management System at GSFC (The top-level function of EOS DAACs)
IMTA	Instituto Mexicano de Tecnológica del Agua (Cuernavaca, Mexico)
IMU	Inertial Measurement Unit (navigation instrument on aircraft)
INCA	Indian National Cartographic Association
INDEX	Indian Ocean Experiment (campaign)
INDEX	Innovative Technology Demonstration Experiment (of ISAS, Japan)
INDOEX	Indian Ocean Experiment (campaign)
INDREX	Indonesian Radar Experiment (campaign)
INFN	Istituto Nazionale Fisica Nucleare (Italian National Institute of Nuclear Physics), Rome, Italy
ING	Istituto Nazionale di Geofisica (Rome Italy)

InAs	Indium Arsenide (detector type for IR spectrum)
InGaAs	Indium Gallium Arsenide (a detector type for IR spectrum)
InGaP/GaAs	Indium Gallium Phosphorus/Gallium Arsenide (solar cell type)
INM	Instituto Nacional de Meteorologica (Spanish Weather Service)
Inmarsat	International Maritime Satellite Organization (London, UK)
InP	Indium Phosphide (solar cell type)
INPE	Instituto de Pesquisas Espaciais (National Institute of Space Research, Sao José dos Campos, S.P., Brazil, since 1971)
INQUA	International Union for Quaternary Research (of ICSU)
INR	Image Navigation and Registration (GOES Second Generation S/C)
INRA	Institut National de la Recherche Agronomique (Grignon and Montfavet, France)
In-RIMT	Indian Resources Information and Management Technologies Pvt. Ltd, Hyderabad, India
INS	Inertial Navigation System (for aircraft navigation)
INS	Institute of Nuclear Physics, (New Zealand)
INSA	Ingenieria y Servicios Aeroespaciales, Madrid, Spain (Fuego mission coordinator)
INSAT	Indian National Satellite (series, employed for meteorology and communication), F6
IN-STEP	In-Space Technology Experiments Program (NASA)
INSU	Institut National des Sciences de l'Univers (Paris, part of CNRS)
InSb	Indium antimonide (detector type material for infrared region)
INTA	Instituto Nacional de Técnica Aeroespacial (Space Agency of Spain)
Intelsat	International Telecommunications Satellite Organization (Washington, DC)
INTERBALL	IKI mission program (solar-terrestrial interaction) within ISTEP, K.17
Intercosmos	USSR/CIS space program for collaborative science projects among its nine members and with other nations. Intercosmos was created in 1967 inviting the former Soviet-affiliated countries (like, East-Germany, Hungary, Bulgaria, Poland, etc.) to participate in the Soviet space program with their own national contributions (one area of participation was in remote sensing, building sensors for specific missions, dissemination and scientific interpretation of data, etc.). Activities in international manned space flight missions were also under the label of Intercosmos. Satellites in the Intercosmos program are named 'Intercosmos-n', like Intercosmos-19 (launched Feb. 27, 1979).
IOC	Initial Operating Capability (GPS, GLONASS,)
IOC	Intergovernmental Oceanographic Commission (of UNESCO)
IOCM	Interim Operational Contamination Monitor (Shuttle payload)
ION	Institute of Navigation (Washington, DC, since 1945)
IOP	Intensive Observation Period (within a campaign)
IOS	Institute for Ocean Sciences (Sydney, British Columbia, Canada)
IOW	Institut für Ostseeforschung Warnemünde (Institute for Baltic Sea Research, Warnemünde, Germany)
IPCC	Inter-Governmental Panel for Climate Change (set up by WMO and UNEP in 1988)
IPG	Institute of Applied Geophysics (Moscow, Russia)
IPG-Paris	Institut de Physique du Globe de Paris
IPMP	Investigations into Polymer Membrane Processing (Shuttle experiment)
IPO	Integrated Program Office (Silver Spring, MD), consisting of a team made up of NOAA, NASA and DoD representatives for the development of the NPOESS spacecraft series
IPOMS	International Polar-Orbiting Meteorological Satellite
IPS	Instrument Pointing System (Spacelab-2, built by ESA, structure for mounting telescopes)

IPS	Ion Propulsion System
IRCFE	Infrared Communications Flight Experiment (Shuttle)
IR&D	Independent Research & Development (company internal funding)
IRD	Institut de Recherche pour le Développement (Paris, France, successor organization to ORSTOM)
IRE RAN	Institute of Radioengineering and Electronics (of the Russian Academy of Sciences, RAN, in Moscow; founded in 1953, IRE is involved in remote sensing, etc., also providing general management services)
IRF	Swedish Institute of Space Physics [(Institutet för rymdfysik), a governmental research institute with the following divisions: IRF-K (Kiruna), IRF-Umea (Umea) with a Laboratory of Mechanical Waves and a Space Physics Group at Umea University, IRF-U (Uppsalla), IRF-STL (Solar Terrestrial Physics) Lund Division]
IR-IE	Infrared Imaging Experiment (Shuttle payload)
IRIS	International Radio Interferometric Surveying (Subcommittee of the International Association of Geodesy)
IRIS	Italian Research Interim Stage (upper stage used in conjunction with NASA's Shuttle to place payloads up to 900 kg into geo-transfer orbit)
IRLS	Interrogation, Recording and Location Subsystem (French-US Eole experiment flown on Nimbus-3 in 1969)
IRM	Ion Release Module (S/C of the AMPTE mission, K.4.1)
IRMB	Institut Royal de Météorologie Belgique (Royal Meteorological Institute of Belgium, Brussels) also referred to as KMI/IRM
IROE - CNR	Istituto Ricerca Onde Elettromagnetiche - Consiglio Nazionale delle Ricerche (Florence, Italy)
IRS	Information Retrieval System (ESA data system)
IRS	Indian Remote Sensing Satellites (ISRO), D.17 (IRS-1A, 1B, 1C, 1D, 1E, etc.)
IRS	Inertial Reference System
IRS	Institut für Raumflugsysteme (University of Stuttgart, Germany)
IRSA	Institute for Remote Sensing Applications (of JRC, Ispra, Italy. In 1996 IRSA was renamed to SAI = Space Applications Institute)
IRSA	Institute for Remote Sensing Applications, since 1980 (Beijing, Chinese Academy of Sciences)
IRSC	Iranian Remote Secing Center, Tehran, Iran (funded by the Ministry of Posts and Telecommunications)
IRT	Infrared Telescope (Spacelab-2 instrument, a 15 cm f/4 Herschelien telescope)
IRU	Inertial Reference Unit
ISA	Institute of Space Aeronomy (Brussels, Belgium)
ISA	Israel Space Agency (since 1983 -within the framework of the Ministry of Science and Technology)
ISAC	Intelsat Solar Array Coupon (Shuttle experiment)
ISAC	ISRO Satellite Center (Bangalore, India)
ISAIAH	Israeli Space Agency Investigation about Hornets (Shuttle experiment)
ISAL	Investigation of STS Atmospheric Luminosities (Shuttle)
ISAS	Institute for Space and Astronomical Science (University of Tokyo, Japan)
ISCCP	International Satellite Cloud Climatology Project (by ICSU & WMO)
ISDE (RNII KP)	Institute of Space Device Engineering, Moscow; a leading Russian company in the design and development of sensors; participation in programs: Venera, Vega, Phobos, Luna, Mars, Prognoz, Granat, Re-surs, Okean, Glonass, etc.
ISDE	International Symposium on Digital Earth
ISDN	Integrated Services Digital Network
ISEE	International Sun Earth Explorer (3 S/C mission), K.18

ISIR	Infrared Spectral Imaging Radiometer (Shuttle payload)
ISIS	Intelligent Satellite-Data Information System (a DLR/DFD archival system and service)
ISLR	Integrated Side Lobe Ratio
ISLSCP	International Satellite Land-Surface Climatology Project (by ICSU and WMO)
ISN	Institute of Satellite Navigation at the University of Leeds, UK
ISO	International Standards Organization (one of three bodies responsible for the definition of OSI)
ISOPS	International Space Conference of Pacific-Basin Societies
ISRO	Indian Space Research Organization (HQ at Bangalore, since 1969)
ISRO/IISU	ISRO Intertial Systems Unit
ISRO/ISAC	ISRO Satellite Center (Bangalore, India)
ISRO/ISTRAC	..	ISRO Telemetry, Tracking and Command Network
ISRO/LPSC	ISRO Liquid Propulsion Systems Center
ISRO/MCF	ISRO INSAT Master Control Facility
ISRO/SAC	ISRO Space Applications Center (Ahmedabad, India)
ISRO/SHAR	ISRO Sriharikota Range (ISRO launch site, East Coast of India)
ISRO/VSSC	ISRO Vikaram Sarabhai Space Center (launch vehicle development)
ISPRS	International Society for Photogrammetry and Remote Sensing
ISPR	International Standard Payload Rack (adopted by the ISS program), each ISPR provides 1.6 m ³ of space, the rack has a mass of 104 kg and can accommodate up to 700 kg of payload mass
ISS	International Space Station
ISSC	International Social Science Council (UN)
ISSI	International Space Science Institute, Bern, Switzerland
IST	Instrument Support Terminal (EOSDIS Facility)
ISTP	International Solar-Terrestrial Physics Program [involves a total of 12 satellites provided by ESA (SOHO, CLUSTER), NASA [GGS (POLAR, WIND), IMP-8, FAST], IKI (Interball, ECOS-A), ISAS (Geotail)]
ISTRAC	ISRO Telemetry and Command Center (Bangalore, India)
ISTS	Institute for Space and Terrestrial Science (North York, Ontario, Canada) Note: A name change to CREST (Center for Research in Earth and Space Technology) took place on Sept. 24, 1997
ISTS	Institute of Space and Astronautical Science (Tokyo, Japan)
ISY	International Space Year (1992)
ITAR	International Traffic in Arms Regulation (US regulations related to the export of satellite and rocket technology)
ITCZ	Inter Tropical Convergence Zone
ITEX	Island Thunderstorm Experiment (campaign)
ITIR ²¹¹⁰⁾	Intermediate Thermal Infrared Radiation (EOS sensor); ITIR was renamed in 1990 ASTER = Advanced Spaceborne Thermal Emission and Reflection Radiometer
ITO	Indium Tin Oxide (a light sensitive sensor type)
ITOS	Improved TIROS Operational System (NOAA S/C)
ITRF	International Terrestrial Reference Frame (established by IERS)
ITT A/CD	ITT (international Telephone and Telegraph Corporation) Aerospace/Communications Division (Fort Wayne, IN), builder of remote sensing instruments (AVHRR, HIRS, GOES-series instruments, etc.). The parent company is ITT Industries Inc., headquartered in New York, NY.
ITU	International Telecommunication Union (since 1865 founded as International Telegraphy Union, since 1934 as ITU, since 1947 ITU is a UN agency to cover standards for a wide range of telecommunication ser-

	vices, including frequency allocations standards for fax, ISDN, JPEG, MPEG, ATM, etc., Geneva, Switzerland)
ITU-R	ITU-Radiocommunication standardization sector (formerly known as CCIR - responsible for managing efficient use of the radio-frequency spectrum)
ITU-T	ITU-Telecommunication standardization sector (formerly CCITT)
IUGG	International Union of Geodesy and Geophysics (a union of ICSU)
IVHM	Integrated Vehicle Health Monitoring (Shuttle payload, technology demonstration)
IVHS	Intelligent Vehicle/Highway Systems
IWF	Institut für Weltraumforschung, Graz, Austria
IZMIRAN	Institute of Terrestrial Magnetism, Ionosphere and Radiowave Propagation (of Russian Academy of Sciences, Troitsk, Moscow region)

J

JAMSTEC	Japan Marine Science and Technology Center (Tokyo)
JAROS	Japan Resources Observation System Organization
JAFIC	Japan Fisheries Information Center
JCAB	Japanese Civil Aviation Bureau (JCAB is an agency/organization within the Japanese Ministry of Transport)
JEA	Japan Environmental Agency
JEM	Japanese Experiment Module (Japan's pressurized module directly attached to the Space Station Freedom)
JEM-EF	JEM-External Facility
JEOS	Japanese Earth Observation System
JERS	Japanese Earth Resources Satellite, D.18
JFET	Junction Field-Effect Transistor
JGOFS	Joint Global Ocean Flux Study (IGBP program)
JGR	Journal of Geophysical Research (a publication of AGU)
JGPSC	Japan GPS Council (over 80 manufacturers, major users, research institutes, etc.)
JHU	Johns Hopkins University (Baltimore, MD, USA)
JHU/APL	JHU/Applied Physics Laboratory, Laurel, MD, USA, since 1942; APL is a major space research institute (staff of 2700) and the designer and builder of satellites (Transit series, ACE, AMPTE/CCE, MSX, NEAR, TIMED, etc.), instruments, S/C engineering, technical innovations, etc.
JMA	Japan Meteorological Agency (JMA is an agency/organization within the Japanese Ministry of Transport)
JODC	Japan Oceanographic Data Center
JOWIP	Joint Canada-US Ocean Wave Investigation Project (campaign)
JPEG	Joint Photographic Experts Group (a compressed image format standard, 24-bit color; note: JPEG is a lossy compression technique based on DCT)
JPEG-LS	JPEG lossless - use of a 2-D edge-detection predictor. JPEG-LS is the new (1998/9) lossless/near-lossless compression standard for continuous-tone images, ISO-14495-1/ITU-T.87. The standard is based on the LOCO-I algorithm (Low Complexity LOSSless Compression for Images) developed at Hewlett-Packard Laboratories.
JPL	Jet Propulsion Laboratory, Pasadena, CA, since 1944 (DAAC of NASA EOS Program). JPL is the only NASA center that is managed by a university, namely the California Institute of Technology
JPO	Joint Program Office (GPS)
JPOP	Japanese Polar Platform
JRC	Joint Research Centre (umbrella agency of CEU coordinating eight research institutes at five sites (Geel, Belgium; Karlsruhe, Germany; Petten, Netherlands; Ispra, Italy; Seville, Spain). IRMM (Institute for Ref-

erence Materials and Measurements) is located in Geel; ITU (Institute of Transuranium Elements) is in Karlsruhe; IAM (Institute of Advanced Materials) is in Petten; IPS (Institute for Prospective Technological Studies) in Seville. The following institutes are located in Ispra: ISIS (Institute for Systems, Informatics and Safety), EI (Environment Institute), SAI (Space Applications Institute), IHCP (Institute for Health and Consumer Protection). - The JRC Program Directorate is located in Brussels.

JSC	Johnson Space Center (Houston, TX, USA)
JSC	Joint Scientific Committee (of WCRP)
JST	Japan Science and Technology Corporation (Tokyo, a Japanese government corporation promoting new technologies and basic research)
JUSREX	Joint US/Russian Internal Wave Remote Sensing Experiment (campaign)
JWGA	Joint Working Group ATMOS

K

KACST	King Abdulaziz City for Science and Technology (Riyadh, Saudi Arabia, since 1977), home of SRISA (Space Research Institute of Saudi Arabia)
KAIST	Korean Advanced Institute of Science and Technology (Seoul, Korea, since 1981)
KAIST/SaTReC .	KAIST/ Satellite Technology Research Center (Taejon, Korea, since 1989, SaTReC is a university based research center)
KARI	Korea Aerospace Research Institute (Taejon, Korea, since 1989)
KAO	Kuiper Airborne Observatory (C-141 aircraft of NASA/ARC)
KAPEX	Cape of Good Hope Experiments (campaign)
KARI	Korea Aerospace Research Institute, Taejon, Korea
KACST	King Abdulaziz City for Science & Technology, Riyadh, Saudi Arabia
KEOC	Korean Earth Observation Center, Seoul, Korea
KfA	Kernforschungsanlage Jülich (Nuclear Research Center, Jülich, Germany)
KfK	Kernforschungszentrum Karlsruhe (Nuclear Research Center, Karlsruhe, Germany; KfK was renamed to FZK (Forschungszentrum Karlsruhe as of 1995)
KFKI	Hungarian Research Institute for Particle and Nuclear Physics
KH	Keyhole (a code name designating a DoD reconnaissance satellite series as well as the principal camera system of the S/C)
KhSC	Khrunichev State Research and Production Space Center, Moscow
KidSat	A NASA-sponsored program (start in 1995, the first Shuttle flight of Kidsat was on STS-76 in March 1996) to encourage the student and educator community in space technology involvement, to bring space exploration into the classrooms. Activities may encounter interpretation of remotely-sensed images, the development of imaging instruments as well as their on-orbit operation. Further Shuttle flights of KidSat on STS-81 (Jan. 12-22, 1997) and on STS-86 (Sept. 25 - Oct. 6, 1997). Access to the program is via Internet. KidSat observation missions are carried out on Space Shuttle flights and on the future Space Station.
KITSAT	Korea Institute of Technology Satellite (D.19, D.40.6, D.40.10,)
KNMI	Koninklijk Nederlands Meteorologisch Instituut (Royal Netherlands Meteorological Institute) De Bilt, Netherlands
KOMPSAT	Korea Multi-Purpose Satellite, D.20
KSC	Kennedy Space Center (NASA facility at Cape Canaveral, FL, USA)
KTH	Kungl Tekniska Högskolan (Royal Institute of Technology) Stockholm, Sweden

L

L3	Latitude/Longitude Locator (Shuttle experiment)
LAAS	Local Area Augmentation System (GPS). LAAS is FAA's ground-based augmentation system for local area DGPS.
LABEN S.p.A. ..	Laboratori Elettronici Nucleari, of Vimodrone (Milano, Italy), Lab of Alenia Spazio (a Finmeccanica company). LABEN was founded in 1958, it produces electronic systems, transducers, LAGRANGE (LABEN GNSS Receiver for Advanced Navigation), etc.
LAC	Local Area Coverage (NOAA downlink mode)
Lacrosse/Vega ...	A DoD/NRO radar imaging satellite reconnaissance program. Lacrosse-1 was launched Dec. 2, 1988 by Shuttle (STS-27) and went into a 57° orbit with an altitude of 680 km. Lacrosse-2 was launched from VAFB on March 8, 1991. Lacrosse-3 was launched from VAFB on Oct. 24, 1997. Lacrosse-4 was launched from VAFB on May 22, 1999.
LADAR	Laser Detection and Ranging
LAEFF	Laboratorio de Astrofisica Espacial Fisica Fundamental (Villafranca, Spain, Laboratory for Space Astrophysics and Theoretical Physics, since 1990)
LAGEOS-I,II ...	Laser Geodynamics Satellite (NASA/ASI), E.15
LAMBADA	Large-scale Atmospheric Moisture Balance of Amazonia using Data Assimilation (campaign)
LAN	Local Area Network
LandSat	Land (Remote Sensing) Satellite, US EO program, D.21
LANL	Los Alamos National Laboratory (Los Alamos NM, DOE facility, operated by the University of California). Builder of satellites (ALEXIS, FORTE, MTI, etc) and instruments for space research (solar wind, lightning detection). Los Alamos played (and plays) a key role in monitoring treaty compliance with satellite sensors (detecting atmospheric nuclear tests).
LAPAN	Lembaga Penerbangan dan Antariksa Nasional (Indonesian National Institute of Aeronautics and Space, Jakarta)
LAP-B	Link Access Protocol (for B Channels)
LaRC	Langley Research Center (Hampton VA, DAAC of NASA EOS Program)
LASP	Laboratory for Atmospheric and Space Physics at the University of Colorado, Boulder, CO
LASER	Light Amplification by Stimulated Emission of Radiation
LASSO	Laser Synchronization from (Geo)Stationary Orbit (ESA, Meteosat)
LAT	Laboratoire d'Astrophysique de Toulouse (France)
Lavochkin	Lavochkina Scientific Production Association, Khimky, Russia
LBH	Lyman-Birge-Hopfield (spectral bands in the 140-180 nm range)
LCD	Liquid Crystal Display (a device acting as a valve through which polarized light passes unless blocked by the application of a low voltage)
LDCE	Limited Duration Space Environment Candidate Materials Exposure (Shuttle experiment)
LDCM	Landsat Data Continuity Mission (of NASA, an LDCM launch is considered for the 2005/6 time frame)
LDEF	Long Duration Exposure Facility, NASA S/C, J.8
LDEO	Lamont-Doherty Earth Observatory (Columbia University, New York, NY, USA, since 1949)
LDR	Linear Depolarization Ratio
LEADEx	Arctic Leads Experiment (campaign)
LED	Light-Emitting Diode (a semiconductor device which becomes luminescent on application of a low voltage)
LEDA	Landsat On-Line Earthnet Data Availability (ESA database file)
LEED	Low-Energy Electron Diffraction

LEGOS	Laboratoire d'Études en Géophysique et Océanographie Spatiale (Toulouse, France, affiliated with CNES, CNRS and the Université Paul Sabatier in Toulouse; research in geophysics, oceanography and glaciology)
LEO	Low Earth Orbit (usually for all satellite orbits up to 1000 or 2000 km altitude; in contrast to geostationary (GEO) orbits at altitudes of about 36000 km)
LEOP	Launch and Early Orbit Phase
LeRC	NASA Lewis Research Center (Cleveland, OH, USA). Note: On March 1, 1999, LeRC was renamed to NASA's John H. Glenn Research Center (GRC) at Lewis Field, OH.
LERTS	Laboratoire d'Etudes et de Recherches en Télédétection Spatiale (Toulouse, France, belongs to CNES/CNRS, renamed to CÉSPIO as of 1995)
LES	Lincoln (Laboratory) Experimental Satellite. A DoD microsatellite series (up to LES-4) and minisatellite series (LES-5 to LES-9) designed and built at MIT/LL (test of communication technologies). Launch of LES-1 on Feb. 11, 1965; launch of LES-9 on March 15, 1976
LETI	Laboratoire d'Electronique de Technologie et d'Instrumentation (at Grenoble, France)
LEWEX	Labrador Extreme Wave Experiment (campaign)
LF	Low Frequency (30 - 300 kHz band)
LFC	Large Format Camera, J.9
LFAH	Light Weight Flexible Solar Array Hinge (Shuttle payload)
LHCP	Left Hand Circular Polarization
LHP	Loop Heat Pipe (Shuttle Experiment)
LH Systems	LH Systems LLC, with company HQ in San Diego, CA (airborne cameras). In 1997, Leica AG of Heerbrugg (photogrammetry and aerial camera systems), Switzerland, formed a joint venture with BAE SYSTEMS, Inc. of San Diego, CA, and with Helava Associates Inc. a subsidiary of GDE Systems. The new company is called "LH Systems LLC" in San Diego and LH Systems GmbH in Heerbrugg, Switzerland
Li-Ion (or LI) ...	Lithium-Ion (battery type)
LIDAR	Light Detection and Ranging
LIF	Laser-Induced Fluorescence (active remote sensing method)
LIGA	Lithographie, Galvanoformung und Abformung (lithography, electroplating and moulding)
LIGO	Laser Interferometric Gravitational-wave Observatory
LIMEX	Labrador Ice Margin Experiment (campaign)
LISA	Laser Interferometer Space Antenna (a three S/C mission of NASA, ESA, etc., proposed for 2005 and beyond). The objective is to study low-frequency gravitational waves from galactic and extra-galactic binary systems. The three S/C are separated some 5,000,000 km apart, forming an equilateral triangle (a giant interferometer).
LISS	Linear Imaging Self-Scanning Sensor (ISRO sensor series)
LITE	Lidar In-space Technology Experiment, Shuttle mission, J.10
LLNL	Lawrence Livermore National Laboratory (Livermore, CA, a DOE lab managed by the University of California)
LLV1 (or 2)	Lockheed Launch Vehicle 1 (or 2)
LM	Lockheed Martin Corporation, HQ at Bethesda, MD. The world's largest space company resulted in 1995 as a merger of the former Lockheed Missiles and Space Co. with the former Martin Marietta Astronautics and Martin Marietta Astro Space (which itself is based on former GE Astro Space). The new LM structure has five sectors, each with operating units and subsidiaries. The sectors are: Aeronautics, Electronics, Energy, Information & Services, and Space & Strategic Missiles. LMMS (see below), LM Astronautics (Denver, CO), LM Telecommu-

nications (Sunnyvale, CA) are units of the Space & Strategic Missiles sector. Total LM employment is about 170,000.

LMD	Laboratoire de Météorologie Dynamique, Palaiseau (Lab of CNRS)
LMI	Lockheed Martin Intersputnik, a joint venture company (since 1997) of Lockheed Martin Corporation and the Intersputnik International Organization of Space Communications
LMLV	Lockheed Martin Launch Vehicle [after its first successful flight, Aug. 23, 1997 (Lewis S/C), LMLV was renamed to Athena the Greek goddess of wisdom)]
LMMS	Lockheed Martin Missile & Space Company (HQ at Sunnyvale, CA). LMMS is a major builder of satellites and sensors for civil (TIROS, AM-1, ISS, HST, Gravity Probe-B, Wind, Polar, Landsat-7, TRACE, etc.) and military (DMSP, GPS, etc.) US space programs as well as for commercial Earth observation programs (CRSS, etc.). LMMS has a workforce of about 19,000 employees and maintains facilities at the following locations: Huntsville, AL; Cape Canaveral, FL; Kings Bay, GA; East Windsor, NJ; Valley Forge, PA; Charleston, SC; Magna, UT; Bangor, WA; and Sunnyvale, Santa Cruz, Palo Alto and VAFB, all in CA. LMMS is also the manufacturer of the following standard platform series (communication satellite buses): S3000, S4000, S5000, S7000, and A2100; and the manufacturer of Motorola's Iridium system.
LMS	Life and Microgravity Spacelab (Shuttle mission)
LNA	Low Noise Amplifier
LNETI	Laboratorio Nacional de Engenharia e Tecnologia Industrial (PoSAT consortium, Portugal)
LO	Local Oscillator
LOA	Laboratoire d'Optique Atmosphérique, (of CNRS, at the University of Sciences and Technology, Lille, France)
LOICZ	Land-Ocean Interactions in the Coastal Zone (core program of IGBP)
LORAN	Long Range Aid to Navigation (a radionavigation system as well as an instrument name). LORAN-C operates on 100 kHz and is a maritime and aeronautical radionavigation system.
LOS	Loss of Signal
LOS	Line of Sight
LOTREX	Landoberflächen-Traversen Experiment (campaign)
LOWS	Lake Ontario Winter Storms (campaign)
LOWTRAN	LOW-resolution TRANsmittance a computer code (model of USAF Geophysics Laboratory), see Glossary.
LPCE	Laboratoire de Physique et de Chimie de l'Environnement (CNRS), Orleans, France
LPCM	Laboratoire de Physique et Chimie Marines (CNRS), Villefranche-sur-mer, France
LRPT	Low Resolution Picture Transmission (NOAA downlink technique in S-band)
LS	Landsat Satellite Series of NOAA
LSPIM	Land Surface Processes and Interactions Mission (in ESA's Earth Explorer Program), see SPECTRA
LST	Land Surface Temperature
LTAN	Local Time Ascending Node (orbit parameter)
LTER	Long-Term Ecological Research (NFS program that started in 1981, there are 19 major sites within LTER spread throughout the US)
LTS	Low Temperature Superconductivity (refers to conductor material levels at liquid helium temperatures, $T_c = 4$ K)
LUCC	Land-Use/Cover Change (IGBP program)
LUT	Local User Terminal (NOAA concept for S&R reception)
LWIR	Long-Wavelength Infrared (6-14 μm) same range as TIR

M

MAB	Man and Biosphere Programme (UNESCO, since 1989)
MABL	Marine Atmospheric Boundary Layer
MAC	Multiphase Atmospheric Chemistry (IGBP/IGAC program)
MACE	Middeck Active Control Experiment (of NASA and AFRL on Shuttle). MACE and MACE-II (AFRL) are designed to to investigate modeling and control issues (high precision pointing and vibration control)
MAC-Europe ...	Multisensor Airborne Campaign - Europe
MACSI	Microwave Airborne Campaign over Snow and Ice (campaign)
MAESA	Measurement for Assessing the Effects of Stratospheric Aircraft (cam- paign)
MAESTRO	Multiple Airborne Experiments Towards Radar Observations (cam- paign)
MAGE	Marine Aerosol and Gas Experiment (campaign)
Magnolia/MFE ..	(MFE = Magnetic Field Experiment) A joint French/US program (proposal status) for long-term (>5 years) monitoring of the Earth's magnetic field and its temporal variations (objectives: main field mod- el, secular variations, core motion determination, electrical conductiv- ity of the mantle)
MAGS	Mackenzie River GEWEX Study (campaign)
MAHLOVS	Middle and High-Latitude Oceanic Variability Study
MAMA	Multi-Anode Michrochannel Array (detector type)
MAP	Mesoscale Alpine Programme (campaign)
MAP	Microwave Anisotropy Probe (NASA S/C mission within the MIDEX program, measurement of the full sky cosmic microwave radiation)
MAPS	Measurement of Air Pollution from Space Radiometer (Shuttle OSTA-1 experiment during STS-2 in Nov. 1981, and STS-59), J.11
MASER	Microwave Amplification by Stimulated Emission of Radiation
MAST	Military Application of Ship Tracks (Shuttle)
MAST	Monterey Area Ship Tracks (campaign)
MAST	Marine Science and Technology (campaign)
MASTEX	Mediterranean Aircraft-Ship Transmission Experiment (campaign)
MAUS	Material Science Autonomous Payload (Shuttle D2 mission)
MBA	Microbolometer Array (detector type)
MBARI	Monterey Bay Aquarium Research Institute, Monterey, CA
MBB	Messerschmitt Bölkow & Blohm (Munich, Germany, since 1989 MBB was integrated into the DASA conglomerate)
MBE	Molecular Beam Epitaxy [a technique (developed by Bell Labs in 1968) to grow perfect crystals, atom by atom, over areas vast on an atomic scale. Applications: the production of photodiode arrays, quantum wells, heterojunction structures, etc.]
MCC	Mission Control Center
MCHIP/s	CHIP stands for Yes/No sequences in data transmissions. One MCHIP/s = 1 million information sequences/s
MCP	Meteorological Communications Package (Meteosat). MCP permits direct data access to the operational meteorological instruments in full resolution during a pass. MCP allows in addition the transmission of global data sets for central ground stations.
MCP	Microchannel Plate (detector)
MCSA	MIR Cooperative Solar Array (installation on MIR by STS-74 crew)
MCT	Mercury Cadmium Telluride (detector material, HgCdTe, also referred to as HCT detector)
MCTEX	Marine-Continental Thunderstorm Experiment (campaign)
MDA	MacDonald Dettwiler Associates Ltd, Richmond, BC, Canada (MDA is a developer of SAR processors, builder and operator of Radarsat-2)
MDL	Multi-use Data Link (GOES Second Generation S/C)
MDT	Mean Down Time

MEDALUS	Mediterranean Desertification and Land Use (campaign)
MEDEA	Material Science Experiment Double Rack for Experiment Modules and Apparatus (Shuttle experiment)
MEDS	Marine Environmental Data Service (Ottawa, Ontario, Canada)
MEEP	MIR Environmental Effects Payload (Shuttle payload)
MEG	Magneto-Encephalography (medical X-ray imagery)
MEI	Moscow State Aviation Institute (Department of Spacecraft Electric Propulsion and Power Plants)
MELCO	Mitsubishi Electric Company, Tokyo, Japan
MELEO	Materials Exposure in Low Earth Orbit (Shuttle experiment)
MELV	Medium Expendable Launch Vehicle (EOS program)
MEMS	Micro-Electromechanical System (sensor technology), also Shuttle payload
MEO	Medium Earth Orbit (altitude range of about 5000 - 25000 km)
MFD	Manipulator Flight Demonstration (Shuttle payload, JEM flight demo)
Megha-Tropiques	A CNES/ISRO minisatellite EO mission considered for launch in 2005. Note: Megha is the Hindi word for clouds.
MEPhI	Moscow Engineering Physics Institute
MERIT	Measure Earth Rotation and Intercompare the Techniques (an International Earth Rotation Service Program)
Meteo-France . . .	Meteorological agency of France (Toulouse, Brest, etc.)
METEOR	Russian meteorological satellite family, G.4 - G.8
METEOSAT	European meteorological satellite series of EUMETSAT, F.7
METOC	Meteorology & Oceanography [a US Navy program considering everything from weather observation (instruments), operations of the system, GIS services, to oceanography applications and the combination of both functions]
MetOp	EUMETSAT Meteorological Operational satellite series, G.2.1
MeV	Mega-electron volt
MF	Medium Frequency (300 - 3000 kHz band)
MFLOPS	Million Floating Point Operations per Second (a measure of computer power)
MGBX	Microgravity Glovebox Facility (Shuttle payload)
MGM	Mechanics of Granular Materials (Shuttle payload)
MHS	Message Handling System (MOTIS is the ISO definition of MHS)
MHT	Matra Hautes Technologies, France, (MHT's parent company is the Ladardere Groupe; Matra Marconi Space (MMS) is a unit of MHT)
Microlab	OSC satellite renamed to OrbView-1, B.8.1
MIDEX	Medium-class Explorers (NASA program). A series of cost and schedule-capped programs, led by a PI and funded by NASA.
MIGITS	Miniature Integrated GPS/INS Tactical System (a family of GPS-related receiver systems of Boeing Co.)
MILOX	Mid-Latitude Ecosystems and Photochemical Oxidants (IGBP/IGAC)
MIL-STD-1553B	A spacecraft communications bus standard. The structure of the bus consists of a single bus controller connected to remote terminals (up to 31 max can be used).
MILSTAR	Military Strategic and Tactical Relay (heritage of STP). MILSTAR is a series of advanced US military (DoD) communication satellites. The first two Block 1 spacecraft, launched in 1995, will eventually be replaced by the Block 2 Milstar 3 through 6, which are scheduled for launch beginning in 1999.
Minotaur	An OSC (Dulles, VA) launch vehicle. The Minotaur is a four-stage vehicle with the first and second stages being Minuteman-II stages; the two upper stages come from OSC's Pegasus launcher. OSC's Minotaur is also known as the "Orbital/Suborbital Program Space Launch Vehicle." The US Air Force developed the Orbital/Suborbital Program as

a way to cheaply launch small military payloads. OSC integrates the Minotaur launch vehicles and conducts launch operations under an Air Force contract.

MIR	Russian Space Station, L3
MIRAS	MIR Infrared Spectrometer (note: this is a modified GRILLE sensor by ISA on the Shuttle ATLAS-1 mission)
MIRSL	Microwave Remote Sensing Laboratory (U. of Massachusetts at Amherst, MA)
MIRP	Manipulated Information Rate Processor (NOAA S/C subsystem)
MIS-1, -B	Microcapsules in Space-1 (Shuttle experiment)
MIST	Microbursts and Severe Thunderstorms (campaign)
MISU	Meteorological Institute of Stockholm University (Stockholm, Sweden)
MIT	Massachusetts Institute of Technology (Cambridge, MA)
MIT/ERL	MIT/Earth Resources Laboratory (Cambridge, MA, since 1982)
MIT/LL	MIT/Lincoln Laboratory (Lexington, MA, since 1951)
MITA	Microsatellite Italiano a Tecnologia Avanza (Italian Advanced Microsatellite platform), ASI standard platform
MITI	Ministry of International Trade and Industry (Japan)
MIZ	Marginal Ice Zone
MIZEX	Marginal Ice Zone Experiment (campaign)
MLE	Mesoscale Lightning Experiment (Shuttle payload)
MLML	Marine Light-Mixed Layers (campaign program and a moored site)
MLOPEX	Mauna Loa Observatory Photochemistry Experiment (campaign)
MLR	Monodisperse Latex Reactor (Shuttle experiment)
MLS	Microwave Landing System (cancelled by FAA in 1994)
MLTI	Mesosphere and Lower-Thermosphere/Ionosphere (altitude from about 60 to 180 km)
MMA	Microgravity Measurement Assembly (ESA payload on Shuttle)
MMIC	Microwave Monolithic Integrated Circuit (also: Millimeter-wave Monolithic Integrated Circuit)
MMS	Magnetospheric Multi-Scale (planned mission of NASA)
MMS	Matra Marconi Space [of France (HQ at Velizy, and major assembly plant at Toulouse) and UK (Bristol, Portsmouth, Stevenage)]. MMS was formed in 1990 by Matra Espace of France (Lagadere) and Marconi Space Systems (GEC) of UK (since 1994). MMS employs 5,000 people, 2300 in France and 2700 in the UK. MMS covers science (SOHO, Giotto, Hipparcos), Earth observation (Spot series, ERS, Polar Platform for Envisat, Metop), communications (builder of the Eurostar and Leostar platforms) launch vehicles, military reconnaissance S/C (Helios), etc. MMS is also an EO instrument builder (HRV on Spot series, ASAR, GOMOS, AASTR, SEVIRI, etc.) - As of 2000 MMS is called Astrium SAS in France and Astrium Ltd. in the UK (see Astrium)
MMW	Millimeter Wave (spectral range of 1mm to 10 mm)
MOBILHY	Modélisation du Bilan Hydrique (HAPEX campaign)
MOBLAS	Mobile Laser System (USA)
MOCE	Marine Optical Characterization Experiment (campaign)
MoD	Ministry of Defence (London, UK)
MODE	Middeck 0-Gravity Dynamics Experiment (Shuttle payload)
MO Disk	Magneto-Optical Disk
MODTRAN	Moderate-resolution LOWTRAN (see glossary under LOWTRAN)
MOEM	Micro Optoelectronic-Mechanical (device)
MOMS	Modular Optoelectronic Multispectral Scanner (Shuttle payload of 1983 and 84), J.12 and J.13
MONEX	Monsoon Experiment (campaign)

MOP	Meteosat Operational Programme (European series of weather satellites from EUMETSAT)
MOS	Marine Observation Satellite (NASDA Satellite, MOS-1 Launch: 1987, MOS-1b launch: Feb. 1989), D.23
MOS	Metal-Oxide Semiconductor (solid-state technology); CMOS = Complementary MOS
MOSFET	Field-Effect Transistor (FET) using MOS technology
MOSES	Molecules in Outer Space and Earth Stratosphere (Swedish Mission, renamed ODIN), A.20
MOVPE	Metalorganic Vapor Phase Epitaxy (a growth technique)
MOZAIC	Measurement of Ozone by Airbus In-Service Aircraft, P.40.1
M2P2	Mini-Magnetospheric Plasma Propulsion (a new propulsion system/technique, funded by NASA. The technology creates an electromagnetic bubble around a S/C and lets the solar wind push the S/C) ²¹¹¹⁾
MPAe	Max-Planck-Institut für Aeronomie (Katlenburg-Lindau, Germany)
MPE	Max-Planck-Institut für Extraterrestrik (Garching, Germany)
MPEG	Motion Pictures Experts Group [compression/decompression standard for data, MPEG-1 is a video coding standard for small images on internet (since 1993), MPEG-2 is a standard for high-quality video images (since 1996)]
MPEI	Moscow Power Engineering Institute, builder of EO instruments like radiometers [also known as SRB/MPEI (Special Research Bureau of MPEI)]
MPG	Max-Planck-Gesellschaft zur Förderung der Wissenschaften e.V. (Germany). MPG is the single largest government-funded research organization in Germany. MPG is the successor of the Kaiser-Wilhelm-Gesellschaft founded in 1911. MPG maintains 68 research centers (and extensions), referred to as MPIs (Max Planck Institutes), throughout Germany. The organization employs about 11,000 people, including some 3000 scientists. In addition to its workforce MPG hosts a large number of (more than 5000 mostly on a yearly basis) research fellows, doctoral candidates, and guest scientists from other institutions. Basic research in the natural and human sciences is emphasized in all MPIs. Major fields of research are: physics, chemistry, biology, physical chemistry, astronomy, mathematics, computer science, and medicine.
MPI	Max-Planck-Institut (generic)
MPIA	Max Planck Institut für Astronomie (Heidelberg, Germany)
MPICH	Max-Planck-Institut für Chemie (Mainz, Germany)
MPIfM	Max-Planck-Institut für Meteorologie (Hamburg, Germany)
MPIK	Max-Planck-Institut für Kernphysik (Heidelberg, Germany)
MPNE	Microgravity Plant Nutrient Experiment (Shuttle payload)
MPSE	Morelos Payload Specialist Experiments (Shuttle payload)
MPT	Ministry of Posts and Telecommunication (Tokyo, Japan)
MRF	Meteorological Research Flight (UK)
MRI	Magnetic Resonance Imaging
MS	Multispectral (data)
MSAS	Multi-Transport Satellite Augmentation System (GNSS-1 element of Japan)
MSFC	Marshall Space Flight Center (Huntsville, AL, DAAC of NASA EOS Program; Note: MSFC/DAAC closed as of March 31, 1997 due to reduced NASA budgets)
MSK	Minimum Shift Keying
MSL	Material Science Laboratory (Shuttle payload)
MSS	Mobile Servicing System [a robotics system consisting of the elements: SSRMS (Space Station Remote Manipulator System), SPDM (Special Purpose Dextrous Manipulator), and MBS (Remote Mobile Server

	Base System), all systems are built by Canada, that will be used to assemble and maintain the ISS (International Space Station)]
MSSL	Mullard Space Science Laboratory (University College London, UK)
MSTI	Miniature Sensor Technology Integration (a Phillips Laboratory technology demonstration program, Kirtland AFB, Albuquerque, NM)
MSU-E	Multispectral Scanner - Electronic Scanning
MSU-K	Multispectral Scanner - Circular Scanning
MSU-M	Multispectral Scanner - Low Resolution
MSU-S	Multispectral Scanner-Moderate Resolution
MSU-SK	Multispectral Scanner-Moderate Resolution,Conical Scanning
MSW	Medium and Short Wave (spectrum)
MSX	Midcourse Space Experiment (DoD mission, M.14, Note: MSX experiments are also performed from several Shuttle missions in conjunction with the MSX spacecraft)
MTBF	Mean Time Between Failure
MTF	Modulation Transfer Function
MTI	Moving Target Indication
MTPE	Mission To Planet Earth [US program, see D.12, Note: As of January 1998 MTPE was renamed by NASA to “Earth Science Enterprise” (ESE)]
MW	Microwave (spectral region with wavelengths from 1mm to 1 m)
MWIR	Mid-Wavelength Infrared (about 3 - 5 μm)
MWR	Microwave Radiometer

N

N ₂ O	Nitrous oxide
N ₂ O ₅	Nitrogen pentoxide
N/A	Not Applicable (Not Available)
NABE	North Atlantic Bloom Experiment (campaign within JGOFS)
NAC	Narrow-Angle Camera
NACA	National Advisory Committee on Aeronautics (USA, 1915-1958, predecessor organization of NASA)
NADC	Naval Air Development Center (Warminster, PA, USA)
NAE	National Aeronautical Establishment of NRC (National Research Council, Canada)
NAL	National Aerospace Laboratory, Japan
NAPP	National Aerial Photography Program (of USGS). NAPP was initiated in 1987 with the objective to acquire and archive aerial photography (using either color or black-and-white film) on a five-year cycle at a scale of 1:40,000. NAPP is a program jointly funded by federal agencies and states that choose to participate. Data are available through the EROS Data Center in Sioux Falls, SD, USA
NARE	North Atlantic Regional Experiment (campaign)
NARSS	National Authority for Remote Sensing and Space Sciences, (Cairo, Egypt)
NAS	National Academy of Sciences (USA)
NAS	National Airspace System (FAA, USA)
NASA	National Aeronautics and Space Administration (USA, since 1958)
NASA/ARC	NASA/Ames Research Center (Moffett Field, CA, since 1939)
NASA/DFRC ...	NASA/Dryden Flight Research Center (Edwards AFB, CA, since 1946)
NASA/GSFC ...	NASA/Goddard Space Flight Center (Greenbelt, MD, since 1959)
NASA/HQ	NASA/Headquarters (Washington, DC)
NASA/JPL	NASA/Jet Propulsion Laboratory (Pasadena, CA, since Dec. 3, 1958)
NASA/JSC	NASA/Johnson Space Center (Houston, TX, since 1961)
NASA/KSC	NASA/Kennedy Space Center (Cap Canaveral, FL, since 1967)

NASA/LaRC NASA/Langley Research Center (Hampton, VA, since 1917)
 NASA/LeRC NASA/Lewis Research Center (Cleveland, OH, since 1941). Note:
 LeRC was renamed to John H. Glenn Research Center (NASA/GRC)
 on March 1, 1999
 NASA/GRC NASA/John H. Glenn Research Center
 NASA/MSFC ... NASA/Marshall Space Flight Center (Huntsville, AL, since 1960)
 NASA/SSC NASA/Stennis Space Center (Pearl River, MS). Testing of rockets and
 engines (Shuttle); colocation of US Navy facilities, Naval Oceano-
 graphic Office, Naval Research Laboratory, National Data Buoy Cen-
 ter (NDBC, a NOAA/NWS facility), etc.
 NASDA National Space Development Agency (of Japan, since 1969)
 NASDA/EOC ... NASDA/Earth Observation Center (Tokyo, Japan, since 1978)
 NASDA/EOPD . NASDA/Earth Observation Planning Department
 NASDA/EORC . NASDA/Earth Observation Research Center (Tokyo)
 NASDA/EOSD .. NASDA/Earth Observation Satellite Department
 NATAC North Atlantic Chemistry Experiment (campaign)
 NAVCEN Navigation Center (US Coast Guard, Alexandria, VA - NAVCEN is re-
 sponsible for gathering system status information on GPS, DGPS,
 Omega, and Loran-C)
 NAVSOC Naval Satellite Operations Center (US Navy, NAVSOC HQ is at Point
 Mugu, CA, since 1962. NAVSOC facilities stretch across the USA)
 NAVSTAR-GPS . Navigation System with Time and Ranging - Global Positioning System
 (Precision real-time position determination system of the US Air Force,
 H.4)
 NAWC Navy Air Warfare Center (Point Mugu, CA)
 NaSBE Sodium Sulfur Battery Experiment (Shuttle payload)
 NBIOME Northern Biosphere Observation and Modelling Experiment (cam-
 paign)
 NBS National Bureau of Standards (USA, since 1901, predecessor of NIST)
 Nb:AlOx:Nb Niobium:Aluminum Oxide:Niobium (tunnel junction material)
 Nd:YAG A neodymium-doped yttrium aluminum garnet crystal (solid-state) la-
 ser
 NCAR National Center for Atmospheric Research (Boulder CO, NCAR is
 managed and operated by the University Corporation for Atmospheric
 Research (UCAR) under the sponsorship of the National Science
 Foundation (NSF), NCAR has two laboratory sites in Boulder: Mesa
 Laboratory since 1966, Foothills Laboratory since 1992)
 NCAR/ATD NCAR / Atmospheric Technology Division
 NCAR/ACD NCAR / Atmospheric Chemistry Division
 NCAR/RAF NCAR / Research Aviation Facility
 NCAR/MMM ... NCAR / Mesoscale & Microscale Meteorology Division
 NCAR/CGD NCAR / Climate and Global Dynamics Division
 NCAR/HAO NCAR / High Altitude Observatory
 NCC National Climatic Center (USA)
 NCDC National Climatic Data Center (of NOAA/NESDIS, Asheville, NC)
 NCDS NASA Climate Data Center (at GSFC, Science data archive for atmo-
 spheric chemistry and climate (ERBE, etc.)
 NDBC National Data Buoy Center [a NOAA/NWS facility at Stennis Space
 Center (SSC), MS, since 1982; between 1970-1982 NDBO (NOAA Da-
 ta Buoy Center) was the predecessor of NDBC at SSC]
 NDIR Non-Dispersive Infrared (Spectrometer)
 NDOC National Oceanographic Data Center (USA)
 NDSC Network for the Detection of Stratospheric Change
 NDTP North Dakota Thunderstorm Project (campaign)
 NDVI Normalized Difference Vegetation Index
 NEAT Near Earth Asteroid Tracking (NASA/JPL ground-based program to
 track NEO asteroids)

NEC	Nippon Electric Company, Tokyo, Japan
NEDRES	National Environmental Data Referential Service (NOAA service)
NEIS	National Earthquake Information Service (USGS, Denver, CO)
NEAR	Near Earth Asteroid Rendezvous S/C (of NASA with a launch Feb. 17, 1996, the mission is managed and operated by JHU/APL). As of March 2000, NASA renamed the satellite to “NEAR Shoemaker” in honor of Eugene M. Shoemaker, a geologist.
NEAR	Noise Equivalent Delta (or Differential) Radiance (system sensitivity)
NEAT	Noise Equivalent Delta (or Differential) Temperature (system sensitivity), also referred to as NEDT
NEFD	Noise-Equivalent Flux Density (see Glossary)
NEMO	Navy EarthMap Observer (D.25)
NEMS	Nano-Electromechanical System (sensor technology)
NEO	Near Earth Object
NEP	Noise-Equivalent Power
NER	Noise Equivalent Radiance
NERC	Natural Environment Research Council (Swindon, UK)
NERSC	Nansen Environmental and Remote Sensing Centre (Bergen, Norway), formerly known as NRSC, a non-profit research institute affiliated with the University of Bergen.
NESR	Noise-Equivalent Spectral Radiance (see Glossary)
NESDIS	National Environmental Satellite Data and Information Service (NOAA centers at Suitland, MD, and Boulder, CO)
NEWS	NOAA Earth Watch Service (information system)
NEXRAD	Next-Generation Weather Radar (a US ground-based system with the name of WSR-88D (Weather Surveillance Radar-1988 Doppler))
NFOV	Narrow Field of View (sensor)
NGDC	National Geophysical Data Center (NOAA facility at Boulder, CO, since 1965)
NGST	Next Generation Space Telescope [NASA satellite (an infrared observatory positioned at L2) with a planned launch in 2009 to replace HST (Hubble Space Telescope)]
NH ₃	Ammonia
NH ₄	Ammonium (ammonia radical)
NiCd	Nickel Cadmium (battery)
NiH ₂	Nickel Hydrogen (battery)
NiMH	Nickel Metal Hydride (battery)
NNMRS	National Natural Resources Management System [an agency of DOS (Department of Space), India]
NO	Nitric oxide
NO ₂	Nitrogen dioxide
NO ₃	Nitrate radical
NO _x (NO _x)	Nitrogen oxides (NO, NO ₂ , NO ₃)
NO _y (NO _y)	Total active nitrogen
NOHRSC	National Operational Hydrologic Remote Sensing Center (of NOAA/ NWS at Chanhassen, MN, USA)
NIAC	NASA Institute for Advanced Concepts
NICMOS	Near-Infrared Camera and Multi-Object Spectrometer (Hubble sensor, built by Ball Aerospace)
NIES	National Institute of Environmental Studies, Tsukuba, Japan
NIH-R	National Institute of Health (Shuttle experiment)
NIIEEM	Scientific and Research Institute of Electromechanics, Istra (Moscow Region), Russia; NIIEEM was founded in 1960 by VNIIEEM. In 1992 the institute NIIEEM became an independent entity. Development of LEO meteorological satellites.
NIIR	State Radio Scientific Research Institute, Moscow; developer/builder of communication equipment in the widest sense, participation in pro-

	grams: Orbita, Ekran, Ekran-M, Moskva, Gorizont, Gals, Express, Interkosmos, Intersputnik, Apollo-Soyuz, Vega, Phobos, etc.
NILU	Norwegian Institute for Air Research (Lillestrom, Norway)
NIMA	National Imagery and Mapping Agency (Arlington, VA, a US government agency established in Oct. 1996). NIMA incorporates the Defence Mapping Agency (DMA), the Central Imagery Office, and the Defense Dissemination Office as well as CIA's Photographic Interpretation Center. NIMA is also the principal buyer of commercial imagery for all DoD organizations.
NIMBUS	NASA EO missions series, M.17
NIMS	Navy Ionospheric Monitoring System (H.6)
NIPR	Nippon Institute for Polar Research, Japan
NIR	Near Infrared (spectrum, from 0.75 to about 1.3 μm)
NIST	National Institute of Standards and Technology (USA, an agency of DOC, formerly National Bureau of Standards, since 1901)
NIVR	Nederlands Instituut voor Vliegtuigontwikkeling en Ruimtevaart (Netherlands Institute for Air and Space Development, Delft, The Netherlands, since 1946)
NKAU	National Space Agency of Ukraine (since 1992), also referred to as NSAU
NLO	Nonlinear Optics (NLO is widely used in solid-state laser technology)
NLR	Nationaal Lucht- en Ruimtevaartlaboratorium (National Aerospace Laboratory, Amsterdam and Noordoostpolder, Netherlands) since 1961. NLR is of NLL (Nationaal Luchtvaart Laboratorium) heritage which was founded in 1937.
NMC	National Meteorological Center (USA)
NMHC	Non-methane hydrocarbons
NMOS	N-channel MOS (Metal-Oxide Semiconductor)
NMP	New Millennium Program (NASA/JPL)
NNSS	Navy Navigation Satellite System (USA, also known as the 'Transit' system, was the world's first satellite navigation system, H.6)
NOAA	National Oceanic and Atmospheric Administration (NOAA is an agency of the US Department of Commerce, established in 1970 (predecessor ESSA), it has the following major divisions: NOS (National Ocean Service), NWS (National Weather Service), NMFS (National Marine Fisheries Service), NESDIS (National Environmental Satellite, Data and Information Service), OAR (Office of Oceanic and Atmospheric Research), and ONCO (Office of NOAA Corps Operations).
NOAA/AL	NOAA/Aeronomy Laboratory (Boulder CO)
NOAA/AOML ..	NOAA/Atlantic Oceanographic and Meteorological Laboratory, Miami, FL. The HRD (Hurricane Research Division) is part of AOML.
NOAA/ARL	NOAA/Air Resources Laboratory, Silver Spring, MD. Note: ARL consists of the HQ-Division in Silver Spring, MD, the ATTD in Oak Ridge TN, the ASMD (Atmospheric Sciences Modeling Division) in Research Triangle Park, NC, the FRD (Field Research Division) in Idaho Falls, ID, and the SRRB (Solar Radiation Research Branch) in Boulder, CO.
NOAA/AOC	NOAA/Aircraft Operations Center, MacDill AFB, Tampa, FL. Note: AOC was created in 1983 [initially known as OAO (Office of Aircraft Operations)] to manage NOAA aircraft, personnel, budget and facilities in support of NOAA aircraft programs. AOC is under ONCO.
NOAA/ATDD ..	NOAA/Atmospheric Turbulence and Diffusion Division, Oak Ridge, TN
NOAA/CDC	NOAA/Climate Diagnostics Center (Boulder, CO)
NOAA/CMDL ..	NOAA/Climate Monitoring and Diagnostics Laboratory, Boulder CO.

NOAA/ERL NOAA/Environmental Research Laboratories, headquartered in Silver Spring, MD. (under OOAR). All NOAA laboratories are run through OOAR/ERL, these are: AL, AOML, ARL, CDML, ETL, FSL, GFDL, GLERL, NSSL, PMEL, SEL, CDC, and the Joint Institutes.

NOAA/ETL NOAA/ Environmental Technology Laboratory, Boulder, CO, (formerly WPL = Wave Propagation Laboratory)

NOAA/FSL NOAA/Forecast Systems Laboratory (Boulder, CO)

NOAA/GFDL . . . NOAA/Geophysical Fluid Dynamics Laboratory, Princeton, NJ.

NOAA/GLERL . NOAA/Great Lakes Environmental Research Laboratory, Ann Arbor, MI.

NOAA/NSSL . . . NOAA/National Severe Storms Laboratory, Norman, OK.

NOAA-NESDIS . NOAA/National Environmental Satellite Data and Information Service, Suitland, MD. - NESDIS functions are: Satellite Operations, Satellite Data Processing and Distribution, Research and Applications, Systems Development, National Climatic Data Center (NCDC), National Oceanic Data Center (NODC), National Geophysical Data Center (NGDC).

NOAA/NCDC . . NOAA-NESDIS/National Climatic Data Center, Asheville, NC.

NOAA/NDBC . . NOAA-National Data Buoy Center (a NOAA/NWS facility at Stennis Space Center, MS)

NOAA/NGDC . . NOAA-NESDIS/National Geophysical Data Center, Boulder, CO

NOAA/NODC . . NOAA-NESDIS/National Oceanographic Data Center (Silver Spring MD)

NOAA/NOS NOAA/National Ocean Service - NOS functions are: coast and geodetic survey, ocean resources conservation and assessment, ocean and coastal resources management, ocean and earth sciences.

NOAA/NSIDC . . NOAA/National Snow and Ice Data Center, Boulder, CO (NSIDC is located at the University of Colorado at Boulder)

NOAA/NWS NOAA/National Weather Service - NWS functions are: meteorology, hydrology, systems operations, systems development, national meteorological center, national data buoy center

NOAA/OAO NOAA/Office of Aircraft Operations, Miami, FL (old designation)

NOAA/OOAR . . NOAA/Office of Oceanic and Atmospheric Research - OOAR functions: oceanic research program, environmental research laboratories.

NOAA/PMEL . . . NOAA/Pacific Marine Environmental Laboratory (Seattle, WA, since 1973)

NOAA/SEC NOAA/Space Environment Center (Boulder, CO)

NOAA/SEL NOAA/Space Environment Laboratory (Boulder, CO), Note: NOAA/SEL changed its name to NOAA/SEC in 1997

NODS NASA Ocean Data System (located at JPL; Measurements in the archive are related to altimetry, scatterometry, and microwave radiometry. NODS archives and distributes data products for TOPEX/Poseidon)

NOPEX Northern-Hemisphere Climate Processes Land-surface Experiment (campaign)

NOPP National Oceanographic Partnership Program (USA, since 1997, NOPP has a mandate from Congress). The objective is to foster cooperation and partnerships among federal agencies, academia, industry and other members of the oceanographic scientific community.

NORCSEX Norwegian Continental Shelf Experiment (campaign)

NORDA Northern Oceans Research and Development Activities (Canada)

NORSEX Norwegian Remote Sensing Experiment (campaign)

NOSC Naval Ocean Systems Center (San Diego, CA)

NOSL Night/Day Optical Survey of Lightning (Shuttle experiment)

NOSS Naval Ocean Surveillance Satellite, also referred to as "Whitecloud," "White Cloud" or "Classic Wizzard" (a US Navy S/C series, sponsored

by NRO, and launched from VAFB, CA on Atlas vehicles). ²¹¹²) NOSS is a wide area ocean surveillance system used to determine the location of radio and radar transmissions, using triangulation. - Each NOSS launch placed a cluster of one primary satellite and three smaller sub-satellites (that trail along at distances of several hundred m apart in a triangle formation) into low polar orbit. This satellite array can determine the location of radio and radars transmitters, using triangulation, and the identity of naval units, by analysis of the operating frequencies and transmission patterns. NOSS used the ELINT technique called TDOA (time difference of arrival), rather than true interferometry. NOSS-1 launch April 30, 1976 (1100 km altitude, inclination = 63.5°), NOSS-2 launch Dec. 8, 1977, NOSS-3 launch March 3, 1980, NOSS-4 launch Feb .9, 1983, NOSS-8 launch May 15, 1987 (also referred to as USA-22), NOSS-9 launch Sept. 5, 1988 (also known as USA-32). - Second generation NOSS satellites were launched starting in 1990. There are three groups of the 2nd generation NOSS satellites each having three satellites in close proximity to one another. The first NOSS-2-1 triplet was launched on June 8, 1990 on a Titan-IV vehicle from Cape Canaveral; the second NOSS-2-2 triplet was launched on Nov. 8, 1991; and the third triplet of NOSS-2-3 was launched May 12, 1996 from VAFB.

NOWES	Northern Wetlands Study (campaign)
NO _x	Nitrogen oxides
NO _y	Total reactive nitrogen
NPL	National Physical Laboratory (Teddington, Middlesex, UK; NPL is an agency of the Department of Trade and Industry)
NPO	Naulshno Proizvodstvennoye Obiedijenie (Scientific/Research Production Association, Russia)
NPO AP	NPO for Automation and Instrument Engineering, Moscow; since 1947; participation in the following programs: Venera, Mars, Luna, Soyuz, Proton, Zenit, Energia-Buran; builder of on-board guidance and navigation systems
NPO Geofizika	..	Moscow; since 1908, a major enterprise for the development of automatic and visual opto-electronic instruments; participation in national programs: Vostok, Salyut, Soyuz, MIR, Energia-Buran, etc.
NPO Machinostroyenia		Russian company, Reutov, Moscow Region, builder/integrator of S/C (ALMAZ series), participation in programs: Kosmos, Proton, Polyot, Salyut, etc.
NPO Planeta	Scientific and Research Center on Space Hydrometeorology (Moscow, since 1974), operators of satellites (Meteor, Okean, Resurs, GOMS series) along with corresponding ground segments, providers of services to the user community in the areas of meteorology/climate, oceanography, Earth resources, and ecological monitoring. From an organizational point of view, NPO Planeta is an agency positioned under RO-SHYDROMET, the 'Committee for Hydrometeorology and Environmental Monitoring'
NPO PM	Research and Production Association of Applied Mechanics (Prikladnoi Mekaniki), Krasnoyarsk (a closed city until 1991) Siberia. NPO PM was founded in 1959, since 1977 it is builder/integrator of communication satellites (Gorizont, Express, Molniya-1, -2, -3, Raduga-1, Ekran, Ekran-M, Luch, Radio, etc.), navigation satellites (GLONASS, Tsikada), and geodetic satellites (GEO-IK, Etalon); advanced programs (Express-M, Gonets, Arkos, Mayak, Gals)
NPO Vega	Russian space/defense industry consortium, Moscow, designers and builders of SAR instruments, etc., operators of airborne instruments

²¹¹²) A. Andronov, "The US Navy's "White Cloud" Spaceborne ELINT System," in Zarubezhnoye Voennoye Obzreniye (Foreign Military Review), ISSN 0134-921X, No. 7, 1993, pp. 57-60, translated by Allen Thomson

NPO Yuzhnoye . .	Design Office Yuzhnoye, in Dnepropetrovsk, Ukraine (builder of OKEAN S/C series)
NPOESS	National Polar-orbiting Operational Environmental Satellite System (merged POES and DMSP series, with launches projected for 2008 and beyond)
NPOP	NASA Polar Platform
NPP	NPOESS Preparatory Project
NPS	Naval Postgraduate School (Monterey, CA)
NRC	National Research Council (Washington, DC, USA)
NRC (NRCAN) .	Natural Resources Canada (Ottawa, Canada)
NRCS	Normalized Radar Cross-Section (an aspect of ocean surface reflectivity, also referred to as σ^0)
NRCT	National Research Council of Thailand
NRL	Naval Research Laboratory (Washington, DC). NRL is the US Navy's corporate research and development laboratory, created in 1923 with over 4000 personnel (among them 1500 scientists) in the 1990s. NRL maintains 15 research sites throughout the US. The three main NRL sites are at: Washington DC, NRL/SSC (Stennis Space Center in Bay St. Louis, MS), and NRL/MRY (Monterey, CA).
NRL/NCST	NRL/Naval Center for Space Technology
NRL/RSD	NRL/Remote Sensing Division
NRLM	National Research Laboratory of Meteorology (Japan)
NRO	National Reconnaissance Office (agency of DoD, Chantilly, VA, USA). NRO sponsors and operates US reconnaissance S/C (Corona series, etc.). The primary user of the imagery is NIMA.
NROSS	Navy Remote Ocean Sensing System (satellite)
NRSA	National Remote Sensing Agency (since 1975, Balanagar, Hyderabad, India)
NRSC	National Remote Sensing Centre (UK, this agency was privatized in 1989, commercial sale of remote sensing data, operator of UK-PAF for ESA)
NRSCC	National Remote Sensing Center of China (Beijing)
NRZ	Non-Return to Zero (communication signal parameter)
NSBF	National Scientific Balloon Facility (NASA-owned facility in Fort Sumner, NM)
NSC	Norwegian Space Centre (Oslo, Norway)
NSERC	Natural Sciences and Engineering Research Council (Canada)
NSF	National Science Foundation (Arlington, VA, USA; since 1950; NSF is an independent government agency responsible for promoting science and engineering). About 20,000 programs per year are supported by NSF.
NSI	NASA Science Internet - an international dual protocol (TCP/IP and DECnet) network (successor to SPAN)
NSIDC	National Snow and Ice Data Center (Boulder, CO, NOAA facility at University of Colorado, established in 1982). NSIDC is co-located with WDC-A (World Data Center A for Glaciology). NSIDC is also a DAAC site of the EOS Program. NSIDC has extensive holdings of cryospheric and polar ocean surface-flux data and routinely produces sea ice maps from SSM/I sensor.
NSMC	National Satellite Meteorological Center [since 1971, NSMC is the research and operational facility of CMA (China Meteorological Administration)]. NSMC has ground stations in Beijing, Guangzhou, and Urumqi.
NSPO	National Space Program Office (Hsin-Chu City, Taiwan)
NSSDC	National Space Science Data Center (at NASA/GSFC)
NSSL	National Severe Storms Laboratory (Norman, OK)
NSTAR	NASA Solar Electric Power (SEP) Technology Application Readiness

NSW	New South Wales (Australia)
NTIS	National Technical Information Service (USA)
NTS	Navigation Technology Satellite (DoD/NRL program of the 1970s also referred to as Timation which predated the GPS program)
NTSC	National Television Standards Committee (US TV display standard which is also adopted by a number of other countries. This is a 525-line video signal with a 3.58 MHz chroma subcarrier at 60 Hz)
NTT	Nippon Telegraph and Telephone Corporation (Japan)
NWP	Numerical Weather Prediction
NWS	National Weather Service (USA)

O

O ₂	Molecular oxygen
O ₃	Ozone
O _x (O _x)	Odd oxygen (O+O ₃)
OACT	Office of Advanced Concepts and Technology (NASA, formerly OAST)
OAI	Ohio Aerospace Institute, Cleveland, OH [consortium of nine Ohio universities, NASA/GRC (Lewis Field in Cleveland), AFRL (Dayton), and private industry]
OARE	Orbital Acceleration Research Experiment (Shuttle payload)
OACES	Ocean-Atmosphere Carbon Exchange Study (campaign)
OASIS-1	Orbiter Autonomous Supporting Instrumentation System (Shuttle payload)
OASIS	On-Line Data Access and Service Information System (Catalog system at NOAA-NCDC)
OAST	Office of Application and Space Technology (NASA, Shuttle payloads are also designated by this name - OAST-1, OAST-2, etc.)
OBC	On-Board Computer
OBS	Observatoire Paris-Mendon (France)
OCE	Ocean Color Experiment (Shuttle payload)
OCEAN	Ocean Color Environment Archive Network (ESA Program)
OCIO	(ClO ₂) Chlorine dioxide
OCOS	Ocean Climate Observing Study (campaign)
OCTW	Optical Communications Through Windows (Shuttle experiment)
ODERACS	Orbital Debris Radar Calibration System (Shuttle payload)
ODIN	Proposed Swedish astronomy and aeronomy mission (A.20, in Norse mythology Odin (also called Woden or Wotan) is one of the principal gods)
OECD	Organization for Economic Cooperation and Development
OEDIPUS	Observations of Electric-field Distributions in the Ionosphere Plasma - a Unique Strategy (Canadian sounding rocket missions from Andoya, Norway and Poker Flats, Alaska)
OES	Office of Earth Science (NASA/HQ, since 1998, formerly Office of Mission to Planet Earth (OMTPE))
OEX	Orbiter Experiments (Shuttle)
OGLOW	Sun Orbiter Glow (Shuttle experiment)
OH	Hydroxyl radical
OHB-System	Orbital- und Hydrotechnologie Bremen System GmbH (since 1958, originally known as: Otto Hydraulik Bremen). A mid-sized aerospace and telecommunication company, located in Bremen, Germany - with a number of company participants and subsidiaries in Germany and Italy. OHB-System is part of the Fuchs Gruppe (since 1981). Satellites built by the Fuchs Gruppe are: BremSat, SAFIR-1, -2, ABRIXAS, DIAMANT, MITA. Note: The company CARLO GAVAZZI SPACE S.p.A, Milan, Italy was taken over by the Fuchs Gruppe in 1996; OHB-Teledata was founded in 1996.

OICETS	Optical Interorbit Communications and Engineering Test Satellite (of NASDA, Japan)
OIP	Optronic Instruments & Products [OIP is trading under the trade name 'Delft Sensor Systems' (DSS)], located in Oudenaarde, Belgium
OKEAN	Ukrainian/Russian satellite series, D.26
OMNI	Operating Missions as Nodes on the Internet. OMNI is the first end-to-end demonstration of operating NASA missions as nodes on IP.
ONERA	Office National d'Etudes et de Recherches Aérospatiales - The French Aeronautics and Space Research Center (Chatillon, Meudon, Palaiseau, Avrieux, Mauzac, Toulouse, Lille, France) ONERA reports to the French Ministry of Defense. CERT (Centre d'Etudes et de Recherches de Toulouse) is a center of ONERA. It carries out research for and with the aeronautics, space and defense industries.
ONR	Office of Naval Research (HQ in Arlington, VA). ONR coordinates the science and technology programs of the US Navy and Marine Corps. NRL is a technical department of ONR.
OPO	Optical Parametric Oscillator (laser type)
O-QPN	Offset Quadriphase Pseudo-Noise
ORFEUS	Orbiting Retrievable Far and Extreme Ultraviolet Spectrograph (German/US Shuttle payload)
OREGIN	Organization of European GNSS Equipment and Services Industry (an industry association to support development of Galileo equipment and services)
ORI	Ocean Research Institute (University of Tokyo, Japan)
ORNL	ORNL (Oak Ridge National Laboratory), Oak Ridge, TN (of DOE)
Ørsted	Danish research satellite, E.18
ORSTOM	Office de la Recherche Scientifique et Technique Outre-Mer (Paris, Montpellier, Orleans, etc., France) also: L'Institut français de recherche scientifique pour le développement en coopération (French scientific research institute for development in cooperation). In 1998 ORSTOM was renamed to IRD (Institut de Recherche pour le Développement)
OSA	Optical Society of America
OSDPD	Office of Satellite Data Processing and Distribution (of NOAA)
OSC	Orbital Sciences Corporation (Dulles, VA, USA, since 1982, builder of small satellites and instruments, owner/operator of commercial launch services for small payloads, Pegasus vehicle, etc.). ORBCOMM, ORB-IMAGE and Magellan (GPS receivers) are affiliates of OSC, so are CTA Space Systems (McLean, VA) and MacDonald Dettwiler Associates Ltd (MDA, Vancouver, BC).
OSI	Open System Interconnect (a standard for open communication)
OSKAR	Orbiting Satellite Carrying Amateur Radio (initially a satellite series of a USA-based group of amateur radio enthusiasts; OSKAR-1 was launched Dec. 12. 1961; in 1969 AMSAT was founded to give amateur radio satellites an international base)
OSS	NASA's Office of Space Science (Shuttle payloads, etc.)
OSSS	One Stop Satellite Solutions (Ogden, UT, since 1996, a spin-off commercial company of CAST at Weber State University). OSSS built MPA (Multi-Payload Adapter) for JAWSAT. OSSS is also the US contact/partner for the Dnepr launch vehicle of ISC Kosmotras of Moscow.
OSTC	Federal Office for Scientific, Technical, and Cultural Affairs of Belgium [also referred to as SSTC (Services Fédéraux des Affaires Scientifiques, Techniques et Culturelles, Belgium)]
OSTA	Office of Space and Terrestrial Applications, NASA (a designation that was also given to the early Shuttle payloads)
OSVS	Orbiter Space Vision System (Shuttle payload)
OTTER	Oregon Transect Ecosystem Research (campaign)

OWWS Operational Windshear Warning System (NCAR)

P

PACSAT A Protocol suite first developed by SSTL. PACSAT uses packet radio techniques in the microsatellite system to transmit its data over the satellite RF link. Several layers of protocol are implemented in the PACSAT suite, at the lower level HDLC (High-Level Data Link Control) and X.25 provide the functions of packet multiplexing, error detection and ARQ (Automatic-Repeat Request) error correction. PACSAT is a point-to-multipoint protocol (broadcast); small ground terminals in the satellite footprint receive/send the data. The PACSAT protocol suite is also supporting data communications within the radio amateur community.

PAF Processing and Archiving Facility (ESA facilities for the ERS-1 mission in Europe: D-PAF at DLR/DFD, Oberpfaffenhofen, Germany; F-PAF at CERSAT, Brest, France; I-PAF at ASI Matera, Italy; UK-PAF at RAE, Farnborough, UK)

PAGES Past Global Changes (IGBP core program)

PAL Phase Alternation Line (German TV display standard). PAL has 625 scan lines per frame at 50 Hz.

PALACE Profiling ALACE (Autonomous Lagrangian Circulation Explorer) of NOAA/AOML. PALACE is a later version of ALACE, first deployed in 1997. PALACE buoys have the added capability of data storage. They carry a sensor package providing measurements of various parameters such as conductivity and temperature. In the late 1990s, hundreds of PALACE floats in the Atlantic Ocean are reporting to data collection satellites on subsurface currents as well as profiles of salinity and temperature.

PALE Paleoclimates for Arctic Lakes and Estuaries (campaign)

PAM Portable Automated Mesonet (weather stations of NCAR)

PAMS Passive Aerodynamically-Stabilized Magnetically-Damped Satellite (Shuttle payload)

PAN Panchromatic (data)

PAN Peroxyacetylnitrate

PANASH Paleoclimates of the Northern and Southern Hemispheres (IGBP/PAGES program under focus 1)

PANSAT Petite Amateur Naval Satellite (S/C of Naval Postgraduate School, Monterey, CA, ejected from Shuttle)

PARE Physiological and Anatomical Rodent Experiment (Shuttle experiment)

PARLIQ Phase Partitioning in Liquids (Shuttle experiment)

PAS PanAmSat Corporation of Greenwich, CT (a daughter of Hughes Electronics Corporation of Los Angeles, CA. PanAmSat is the world leader of commercial satellite-based communications services, launch of first satellite (Galaxy-1) in 1983, launch of PAS-1 in 1988)

PASC Polar Atmospheric and Snow Chemistry (IGBP/IGAC project)

PASDE Photogrammetric Appendage Structural Dynamics Experiment (Shuttle)

PBL Planetary Boundary Layer

PbS Lead Sulfide (detector material)

PbSi Lead Silicon (detector material)

PC Photoconductive (detector)

PCG Protein Crystal Growth (Shuttle experiment)

PCG/STES Protein Crystal Growth / Single-Locker Thermal Enclosure System (Shuttle experiment)

PCM Pulse Code Modulation

PD Photodiode (detector)

PDA	Photodiode Array (detector)
PDP	Plasma Diagnostics Package (Spacelab-2 sensor, studies of the interaction between the Earth's magnetic field and charged particles in the ionosphere)
PE&RS	Photogrammetric Engineering & Remote Sensing (ASPRS journal)
PEACAMPOT ..	Perturbation by East Asia Continental Air Mass to Pacific Oceanic Troposphere (campaign)
PEM-West	Pacific Exploratory Mission - West (campaign)
PEP	Pole-Equator-Pole (transect of PANASH campaign)
PGIM	Plant Growth Investigations in Microgravity (Shuttle experiment)
PHCF	Pituitary-Growth Hormone Cell Function (Shuttle experiment)
PHOTON	Russian solar-terrestrial mission (K.8.1)
PL	Phillips Laboratory of USAF (PL is headquartered at Kirtland Air Force Base, Albuquerque, NM, and has locations at Hanscom AFB, Bedford, MA, and Edwards AFB, CA)
PI	Principal Investigator
PID	Prototype International Directory (CEOS-defined Directory Interchange Format (DIF)); CEOS members operating an archive with PID capability are: CCRS, DLR/DFD, ESA/ESRIN, NASA, NASDA, NOAA, RAE, etc. . Hence, standardized archival access is possible (see: IDN).
PIDC	Precision Instrument Development Center (of the National Science Council, Taiwan), Hsinchu, Taiwan ROC
PIK	Potsdam Institut für Klimaforschung (Potsdam Institute for Climate Impaxct Research, Potsdam, Germany)
PILOT	Portable Inflight Landing Operations Trainer (Shuttle experiment)
PILPS	Project for Intercomparison of Landsurface Parameterization Schemes (WCRP/GEWEX project)
PIN	Positive Insulator Negative (diode)
PIPOR	Program for International Polar Ocean Research
PIXEL	Picture Element
PLB	Personal Locator Beacon (COSPAS and S&RSAT)
PLL	Phase Locked Loop (communication technique to enable integration of voice and data)
PLO	Phase Locked Oscillator
PM	Phase Modulation (modulation technique of the main carrier)
PM	Polymer Morphology (Shuttle experiment)
PM	Post Meridiem (refers to the afternoon time designations in the US; a time of 5 PM is equivalent of 17:00 hours in international notation)
PMA	Pressurized Mating Adapter (Shuttle)
PMAP	Paleoenvironment Multiproxy Analysis and Mapping Project (see PANASH campaign)
PMG	Plasma Motor Generator (Q.36.5)
PMOD/WRC ...	Physikalisch-Meteorologisches Observatorium Davos, World Radiation Center (Switzerland)
PMS	Particle Measuring Systems Inc. (of Boulder CO)
PMT	Photomultiplier Tube (detector)
PMV&D	(Plume Model Validation and Development (campaign)
PN	Pseudo Noise (code)
PNEDC	Programme National d'Etude de la Dynamique du Climat (France)
PNL	Pacific Northwest Laboratory (Richland, WA, USA) of DOE, operated by Batelle Memorial Institute
PNR	Pseudo Noise Number (a GPS series designation)
PNRA	Italian National Programme for Antarctic Research
PRN	Pseudo Random Noise
POCC	Payload Operations and Control Center
POEM-1	Polar-Orbit Earth-Observation Mission (planned ESA Series) D.9

POES	Polar-orbiting Operational Environmental Satellites (NOAA series of operational polar orbiting satellites), G.13
POGO	Polar-Orbiting Geophysical Observatory
POL	Prowdman Oceanographic Laboratories (UK)
POLAR	NASA/GSFC Solar-Terrestrial Mission (K.19)
POLARIS	Photochemistry of Ozone Loss in the Arctic Region in Summer (campaign)
POLINAT	Pollution from Aircraft Emissions in the North Atlantic Flight Corridor (campaign)
PoSAT	Portuguese Satellite (D.40.9)
PPARC	Particle Physics and Astronomy Research Council, UK
PPE	Phase Positioning Experiments (Shuttle payload)
PPF	Polar Platform (ESA Columbus program, PPF is utilized for POEM payloads)
PPS	Precise Positioning Service (GPS)
PRARE	Precision Rate and Range-Rate Equipment, H.7.2
PRF	Pulse Repetition Frequency
PRIMA	Piattaforma Riconfigurabile Italiana Multi-Applicativa (Reconfigurable Italian Platform for Multiple Applications), ASI platform for a total S/C mass of 300-1000 kg
PRIRODA	Research module of the Space Station MIR (D.28)
PRN	Pseudo Random Noise
PROBE	Prototype Radiation Observation Experiment (campaign)
ProSEDS	Propulsive Small Expandable Deployer System (tether experiment)
PROTEUS	Plateforme Reconfigurable pour l'Observation, les Telecommunications et les Usages Scientifiques (French minisatellite bus for a S/C mass less than 500 kg)
PROTEUS	Profile Telemetry of Upper Ocean Currents [a NOAA/PMEL mooring system, a taut-wire surface mooring with a toroidal float similar to ATLAS]
PSI	Paul Scherrer Institute, Villigen, Switzerland (database of space environmental data)
PSC	Polar Stratospheric Clouds
PSE	Physiological Systems Experiment (Shuttle)
PSE	Polar Sunrise Experiment (campaign)
PSK	Phase Shift Keying (a modulation technique)
PSLR	Peak Side Lobe Ratio
PSLV	Polar Satellite Launch Vehicle (ISRO launch vehicle)
PSN	Piano Spaziale Nazionale (previous name of Italy's Space agency , now ASI)
PSRC	Polish Space Research Center, Warsaw, Poland
PtSi	Platinum-silicide (detector material)
PTT	Platform Transmitter Terminal (data collection platform for ARGOS system)
PTT	Public (Postal) Telephone and Telegraph (utility company). Refers to operating agencies directly or indirectly controlled by governments in charge of telecommunication services in most countries of the world.
PTTI	Precise Time and Time Interval
PV	Photovoltaic (detector)
PVTOS	Physical Vapor Transport of Organic Solids (Shuttle experiment)
PWV	Precipitable Water Vapor (atmosphere)
PYREX	Pyrenean Experiment (campaign)

Q

QinetiQ	New name of DERA (Defence Evaluation and Research Agency), Farnborough, UK, pronounced as "kin-et-tik" (as of July 2, 2001)
QMW	Queen Mary and Westfield College (London, UK)

QPN	Quadra Pseudo Noise (modulation technique)
QPSK	Quadra-Phase Shift Keying (4-PSK is a modulation technique and a data transmission standard). Soon 8-PSK and higher modulations for such applications as DBS (Digital Broadcast System) will be used.
QuickBird	Commercial imaging satellite (B.4.2)
QUT	Queensland University of Technology, Australia
QWIP	Quantum Well Infrared Photodetector (for applications in the range from 6 - 25 μm)

R

RADAR	Radio Detection and Ranging
RADARSAT	A Canadian (CSA/CCRS) EO mission with a SAR instrument (D.29)
RADCAL	Radar Calibration Satellite (A microsatellite of USAF, launch June 25, 1993 from VAFB. It provides space-based radar cross-sectional area calibration for more than 70 radars operating in the C-band, and carries two GPS receivers with the aim to demonstrate GPS based attitude determination.)
RADFET	Radiation-sensitive Field Effect Transistor
RAE	Royal Aerospace Establishment [Farnborough, UK, (in the early 1990s RAE was renamed into 'DRA' - Defense Research Establishment)]
RAIM	Receiver Autonomous Integrity Monitoring (a GPS and GLONASS technology - RAIM requires a minimum of five visible satellites for fault detection and six satellites for fault detection and exclusion)
Rosaviakosmos ..	Russian Aviation and Space Agency (RSA), Moscow. The name of Rosaviakosmos was adopted by decree (No 1186) on Oct. 25, 1999. The previous name was RKA (Russian Space Agency) which in turn was created Feb. 25, 1992.
RAL	Rutherford Appleton Laboratory (Chilton, Oxon, UK)
RAM	Random Access Memory
RAN (RAS)	Russian Academy of Sciences
RASS	Radio-Acoustic Sounding System (a ground-based system of wind and temperature vertical profiles is used in meteorology and atmospheric research).
RBDS	Radio Broadcast Data System
RCVR	Receiver
R&D	Research & Development
RDL	Research and Development Laboratories, Culver City, CA
REBAL	Radiation and Energy Balance for Imagery and Electromagnetic Propagation (campaign)
REFLEX	Radiation and Eddy Flux Experiment (campaign)
REFLEX	Return Flux Experiment (Shuttle SPARTAN payload)
REM	Release/Engage Mechanism (Shuttle, used for Spartan flights)
RENE	Rehearsal ERS-1 Validation Northern Europe (campaign)
RESTEC	Remote Sensing Technology Center, Tokyo, Japan (since 1975)
Resource21	Commercial imaging satellite (under development by Resource21)
Resurs	Russian satellite series for resource monitoring, D.31, D.32
RF (R/F)	Radio Frequency (of active sensors, also data transmission link, etc.)
RFI	Radio Frequency Interference
RGB	Red, Green, Blue (color code)
RHCP	Right Hand Circular Polarization
RICE	Regional Interactions of Climate and Ecosystems (IGBP/IGAC program)
RIN	Royal Institute of Navigation (UK)
RIRT (RIRV) ...	Russian Institute of Radionavigation and Time, St. Petersburg, since 1957 (before 1993 the institute was called: Leningrad Scientific and Research Electrotechnical Institute); participation in programs: Tsikada, Glonass, Cospas-S&RSAT

RIS	Resonance Ionization Spectroscopy (a laser technique)
RISDE	Russian Institute of Space Device Engineering
RIT-10	Radio-frequency Ion Thruster (electric propulsion system of DASA)
RIT	Royal Institute of Technology, Sweden
RITS	Radiatively Important Trace Species (campaign)
RKA (RSA)	Russian Space Agency, Moscow, since Feb. 25, 1992 (by decree issued by the President of the Russian Federation). RKA has centralized control of Russia's civilian space program, including all manned and unmanned nonmilitary space flights. - On Oct. 25, 1999, RKA changed its name officially to " Rosaviakosmos " (Russian Aviation and Space Agency). -- The prime contractor used by Rosaviakosmos is RKK Energiya, which owns and operates the Mission Control Center in Kaliningrad and operates the Mir space station.
RKK Energia ...	Rocket Space Corporation, Kaliningrad, Moscow region (also referred to as RSC, since 1946); responsibility for all Russian manned space projects; builders of launch vehicles (Proton) and of S/C (i.e. MIR space station), payloads, sensors, etc.
RLG	Ring Laser Gyroscope (an angular rate gyro)
RLSBO	Radiolokazionnaja Sistema Bokowo Obzora (side view radar system)
RME	Radiation Monitoring Experiment (Shuttle payload)
RMS	Remote Manipulator System (robot arm of Shuttle)
RMS	Royal Meteorological Service (UK)
RNII KP (ISDE)	Russian Institute of Space Device Engineering, Moscow; a leading company in the design and development of sensors; participation in programs: Venera, Vega, Phobos, Luna, Mars, Prognoz, Granat, Ressurs, Okean, Glonass, etc.
ROCSat	Republic of China Satellite (Taiwan)
ROIC	Readout Integrated Circuit (silicon device for readout of infrared detector photodiodes)
ROM	Read Only Memory
ROMPS	Robot Operated Materials Processing System (Shuttle payload)
ROSHYDROMET	Committee for Hydrometeorology and Environmental Monitoring (Russian Government Agency, similar in functions and services to EU-METSAT and NOAA)
ROTEX	Robotic Experiment (Shuttle experiment)
RSCC	Russian Satellite Communication Company (Moscow)
RSI	Radarsat International Ltd. (Richmond, BC, Canada, established in 1989 by a consortium of Canadian aerospace companies and Lockheed Martin of USA, RSI is the distributor of Radarsat data)
RSIF	Rain-Sea Interaction Facility (at NASA/GSFC/WFF, established in 1993; RSIF provides a controlled environment for studies of a) microwave scattering from rain-generated features, and b) physical processes at the air-water interface and in the adjacent boundary layers)
RSRE	Royal Signals and Radar Establishment (Great Malvern, Worcestershire, UK)
RTCA	Radio Technical Commission for Aeronautics (Washington, DC)
RTCM SC-104 ..	Radio Technical Commission for Maritime Services [the RTCM Special Committee 104 established the worldwide standard for meter-level differential GNSS (Global Navigation Satellite System) broadcasts]
RTG	Radioisotope Thermoelectric Generator (a nuclear propulsion system first flown on Transit-4A, also on Ulysses K.28). Deep space missions in particular depend on RTG propulsion
RTK	Real-Time Kinematic (a DGPS technique)
R/V (or RV)	Research Vessel
RVSN	Russian Strategic Missile Force (agency responsible for launching most of Russia's military satellites)
RWS	Rijkswaterstaat (Rijswijk, Netherlands)

S

S/A	Signal to Ambiguity ratio
SA	Selective Availability (GPS)
SAA	South Atlantic Anomaly
SAAMD/WBSAAMD	Stand Alone Acceleration Measurement Device/Wide Band Stand Alone Acceleration Measurement Device (Shuttle payload)
SAAMEX	Surface & Atmospheric Airborne Microwave Experiment (campaign)
SABLE	South Atlantic Backscatter Lidar Experiment (campaign)
SAC/CSIR	Satellite Application Center [of CSIR (Council for Scientific and Industrial Research), South Africa]. The SAC ground receiving station (Landsat, Spot, NOAA/POES series, ERS series, Radarsat, etc.) is located at Hartebeesthoek south-west of Pretoria, South Africa. Initial SAC tracking services started in 1961.
SAFARI	Southern African Fire-Atmosphere Research Initiative (campaign)
SAFER	Simplified Aid for EVA Rescue (Shuttle system)
SAFIR	Satellite for Information Relay, C.5
SAFISY	Space Agency Forum for the International Space Year in Europe (in 1992)
SAGA	Soviet-American Gases and Aerosols Experiment (campaign)
SAGE	Stratospheric Aerosol and Gas Experiment (NASA mission, G.8)
SAI	Space Applications Institute (of JRC, Ispra, Italy)
SAI	Spectrum Astro Inc. of Gilbert, AZ
SAIC	Science Applications International Corporation (HQs in San Diego, CA, since 1969, with over 35,000 employees worldwide)
SAIR	Synthetic Aperture Interferometric Radiometer
SALRO	Saudi Arabian Laser Ranging Observatory, located some 45 km north-west of Riyadh, Saudi Arabia (tracking of SLR systems)
SALSA	Semi-Arid Land-Surface-Atmospheric Program (campaign). The SALSA program is a multi-agency, multi-national global-change research effort that seeks to evaluate the consequences of natural and human-induced changes in semi-arid environments.
SALT	Savannas on the Long Term (IGBP program of France)
SALT	Strategic Arms Limitation Treaty (cold war agreement)
SAM	Shuttle Activation Monitor (Shuttle experiment)
SAMIR	Satellite Microwave Radiometer (ISRO sensor on Bhaskara S/C)
SAMPEX	Solar Anomalous and Magnetospheric Explorer (GSFC mission, K.21.1)
SAMS	Space Acceleration Measurement Systems (Shuttle experiment)
SAMSO	Space and Missile System Organization (USAF in El Segundo, CA)
SAN MARCO ..	Cooperative Italian/NASA mission (A.25)
SAO	Smithsonian Astrophysical Laboratory (Cambridge, MA, USA)
SAR	Synthetic Aperture Radar (a high-rate imaging technique)
SAREX-2	Shuttle Amateur Radio Experiment (Shuttle payload)
SAREX-92	South American Radar Experiment (ESA airborne campaign)
S&R	Search and Rescue (Emergency System on NOAA S/C)
S&RSAT	Search and Rescue Satellite Aided Tracking System (Canada/France/NOAA). I.6
SAS-1	Small Astronomy Satellite-1 (DoD S/C, launched Dec. 12, 1970)
SAS	Synthetic Aperture Sonar
SAS&R	Satellite Aided Search & Rescue (INSAT-2 system)
SASS	Subsonic Assessment (program, NASA)
SaTReC	Satellite Technology Research Center (Taejon, Korea, since 1992, SaTReC is a university based research center of KAIST) SaTReC performs KITSAT operations, etc.

SatReCi	SaTReC Initiative (SaTReCi Co. Ltd was established in January, 2000 by former SaTReC engineers, Taejon, Korea)
SATO	Space Adaptation Tests and Observations (Shuttle experiment)
SAXON-FPN	Synthetic Aperture Radar and X-band Ocean Nonlinearities - Forschungsplatform Nordsee (campaign)
Sb	Antimonide (detector type material)
SBAS	Satellite Based Augmentation System (element of GNSS)
SBIR	Small Business Innovation Research (a NASA-sponsored program)
SBIRS	Space Based Infrared System (a US DoD 10-year development program that was approved in Oct. 1996 to include HEO/GEO and LEO satellite constellations along with a corresponding ground segment. The SBIRS mission is to develop, deploy, and to operate space-based surveillance systems for missile warning, missile defense, battlespace characterization, and technical intelligence). The SBIRS program office is at SMC, Los Angeles AFB, CA.
SBRC	Santa Barbara Research Center (of Hughes Aircraft Company in Goleta, CA - The name (SBRC) was valid until 1996; the facility was renamed to SBRS)
SBRS	Santa Barbara Remote Sensing (of Hughes Aircraft Company in Goleta, CA, since 1996). Note: in Dec. 1997 Raytheon merged with the defense operations of Hughes Electronics. The merger outcome was the "Raytheon Systems Company" with HQ in Washington DC, consisting of the following units: Raytheon Electronic Systems, Raytheon E-Systems, Raytheon TI Systems and Hughes Aircraft Company. SBRS instruments include: multispectral imagers (MSS and TM), radiometers, spectrometers, polarimeters, and sounders.
S/C	Spacecraft
SCAPE	Shenandoah Cloud and Photochemistry Experiment (campaign)
SCAR	Smoke/Sulfates Clouds and Radiation (campaign)
SCAR	Scientific Committee on Antarctic Research (of ICSU)
SCARLET	Solar Concentrator Array with Refractive Linear Element Technology (a patented solar cell technology of AEC-Able Engineering Co., Goleta, CA, sponsored by BMDO and NASA/LeRC)
SCATHA	Spacecraft Charging at High Altitude (satellite of the USAF)
SCATT	(Wind) Scatterometer (ESA)
SCCCAMP	South Central Coast Cooperative Aerometric Monitoring Program (campaign)
SCD	Swept Charge Detector
SCD-1	Satélite de Coleta de Dados (Data Collection Satellite of Brazil), C.6
SCE	Superconducting Electronics
SCISAT/ACE	Science Satellite/Atmospheric Chemistry Experiment, A.26
SCIGN	Southern California Integrated GPS Network
SCMS	Small Cumulus Microphysics Study (campaign)
SCOPE	San Clemente Ocean Probing Experiment (campaign)
SCOPE	Scientific Committee on Problems of the Environment (ICSU)
SCPS	Space Communications Protocol Standard (A standardization initiative by NASA, DoD, DERA and others with the objective to complement and expand the current CCSDS standards) Although the CCSDS packetised standards provide the underpinning for the automated, error-free exchange of data between space and ground stations, it is limited to basic data transfer. SCPS will provide the additional capability to aggregate both telecommand and telemetry data into recognisable files and transport them end-to-end through the data networks containing space links in a reliable and secure manner.
SCRS	Saudi Center of Remote Sensing, Riyadh, Saudi Arabia
SCS	Soil Conservation Service (USA)
SCSMEX	South China Sea Monsoon Experiment (campaign)

SEACAT	type of buoy (made by Sea-Bird Electronics), temperature and conductivity sensor
SEADEx	Shoreline Environment Atmospheric Dispersion Experiment (campaign)
SEAFIRE	South-East Asia Fire Experiment (campaign)
Sea Launch	A sea-going launch system, based at Long Beach, CA. Sea Launch is a joint venture of The Boeing Commercial Space Co., Seattle, USA, KB Yuzhnoye/PO of Dnepropetrovsk, Ukraine (provider of the Zenit rocket), RSC Energia of Korolev, Russia (builder of an upper stage of the rocket), and Kvaerner Maritime A/S, Lysaker, Norway and London, UK (builder of the self-propelled launch platform and the Sea Launch command and assembly ship). The Sea Launch venture was announced in June 1994. The first launch of a demonstration satellite with a Zenit-3SL rocket took place March 27, 1999 from the floating Sea Launch platform, positioned at the equator. Sea Launch has a capacity to put up to 5000 kg of launch mass into a geostationary transfer orbit (GTO).
Seasat	NASA/JPL EO mission (D.35)
SEASOAR	Towed profiling CTD and ADCP system (TOGA/COARE campaign)
SeaStar	An ORBIMAGE mission with the SeaWiFS sensor (B.8.2). In 1997 OSC renamed the SeaStar mission to Orbview-2)
SeaWiFS	Sea Wide Field Sensor (this sensor is considered the CZCS successor)
SECAM	Sequential Color and Memory [European (French) video standard]. SECAM has an image format of 4:3, operating with 625 lines per picture frame at 50 Hz and 6 MHz video bandwidth with a total of 8 MHz video channel width.
SECDDED	Single Error Correction - Double Error Detection
SEDAC	Socio-Economic Data and Applications Center (DAAC at CIESIN)
SEDIS	SeaWiFS European Data Information System (ESA/ESRIN)
SEDS	Students for the Exploration and Development of Space (since 1980, international student organization)
SEE	Société des Electriciens et des Electroniciens
SEE	Space Environments and Effects program since 1995 [NASA (US government, industry and university participants), also international participation]
SEEDS	Seeds in Space Experiment (Shuttle payload)
SEH	Solar Extreme Ultraviolet Hitchhiker (Shuttle payload)
SEI	Space Electronics Inc., San Diego, CA
SEL	Space Environment Laboratory (NOAA, Boulder CO, real-time processing of all SEM package data, space environment forecasts)
SEL	Surface-Emitting Laser (a conventional diode laser with a horizontal cavity, beams are emitted in the direction parallel to the wafer plane)
SELODE	Solar Exposure to Laser Ordnance Device (Shuttle experiment on SPARTAN)
SEM	Space Environment Monitor (NOAA Sensor package on GOES and POES series; Note: the GOES series SEM package arrangement differs considerably from the POES series SEM package)
SEM	Space Experiment Module (Shuttle structure for small experiments)
SEMAPHORE	Structure des Echanges Mer-Atmosphere, Proprietes des Heterogenites Oceaniques (French airborne campaign)
SERC	Science and Engineering Research Council (UK, the Mullard Space Science Laboratory of SERC)
SERON	South Eastern (US) Regional Oxidant Network (field program to study atmospheric chemistry, July-August 1991)
SES	Saab-Ericsson Space, Sweden
SES	Societe Europeenne des Satellites (Luxembourg, owner and operator of the ASTRA satellite series)

SESAME	Second European Stratospheric Arctic and Midlatitude Experiment (campaign)
SESAME	Severe Environmental Storms and Mesoscale Experiment (campaign)
SESO	Société Européenne de Systèmes Optiques, (Aix en Provence, France)
SET	Single Electron Transistor
SETAS	Space Environments and Technology Archive System (NASA/LaRC)
SEU	Single Event Upset
S&F	Store-and-Forward (a non-real-time communication technique)
SFDU	Standard Format Data Unit (a CCSDS format concept)
SGG	Satellite Gravity Gradiometry
SGGM	Superconducting Gravity Gradiometer Mission, NASA (SGGM was cancelled by NASA in the 1990s due to budget constraints)
SGLS	Space-to-Ground Link System (satellite communications)
SGS 85	Soviet Geodetic System 1985
SGS	Svalbard Ground Station, located (78° N, 20° E) on the Norwegian Svalbard archipelago (Spitzbergen is the largest island of the Svalbard archipelago) near the town of Longyearbyen, is owned by the Norwegian Space Center (Norsk Romsenter), Oslo, Norway, and operated by the Tromsø Satellite Station. The high latitude makes SGS (just 960 km from the North Pole) a very sought-after link for polar-orbiting satellites. In 1999, NASA built its own receiving station (two 11m antennas in X- and S-band) right next to SGS (part of Lockheed's Consolidated Space Operations Contract) to receive data from Earth observing satellites (Landsat-7, Terra, etc.). - SGS can provide S/C contact for all orbits of polar orbiting satellites having altitudes above 500 km.
SHAR	Sriharikota Range (ISRO launch site, India)
SHARE	Space-Station Heat Pipe Advanced Radiator Experiment (Shuttle)
SHEBA	Surface Heat Budget in the Arctic (campaign)
SHELS	Shuttle Hitchhiker Experiment Launch System
SHF	Super High Frequency (3 - 30 GHz band)
SHOM	Service Hydrographique et Océanographique de la Marine (French Naval Hydrographic and Oceanographic Service) since 1971, with HQ in Brest, France. SHOM is a public service and a defense support agency - providing science and technical services (data acquisition, bathymetry, cartography, geophysics, oceanography).
SHOOT	Super Fluid Helium On Orbit Transfer (Shuttle experiment)
SHS	Spatial Heterodyne Spectroscopy
Si	Silicon (detector material)
SiAs	Arsenic-doped silicon detectors
SiGa	Silicon gallium (detector)
SI	Système International d'Units (International System of Units)
SiC	Silicon carbide (example: SiC-type ceramic mirrors and structures are components in opto-mechanical systems)
SICH	Owl (in Ukrainian, see SICH-1 under OKEAN)
SIL	Space Innovations Limited, Newbury, Berks, UK [founded in 1983, since 1998 a subsidiary of SpaceDev Inc., San Diego, CA; SSTL (Surrey) purchased SIL in 2000]
SIM	Space Interferometry Mission (NASA)
SIMMS	Seasonal Sea Ice Monitoring and Modeling Site (campaign)
SIMPLEX	Shuttle Ionospheric Modification with Pulsed Local Exhaust (Shuttle payload)
SIO	Scripps Institution of Oceanography (part of UC at San Diego, La Jolla, CA)
SIPT	Société Internationale de Photogrammétrie et de Télédétection
SIR	Shuttle Imaging Radar (SIR-A with Payload A; SIR-B with Payload B, etc.), see J.19 - J.21
SIRTF	Space InfraRed Telescope Facility (NASA)

SIS	Superconductor-Insulator-Superconductor (tunnel junctions, also a microwave spectrometer receiver type)
SITe	Scientific Imaging Technologies Inc. (US company in Beaverton, OR, CCD imaging products)
SITP	Shanghai Institute of Technical Physics (of the Academy of Sciences of China), founded in 1958. Development of optical and infrared sensors since 1964 as well as radiometers.
SIZEX	Seasonal Ice Zone Experiment (campaign)
SJ	Shi Jian (meaning “experiment” or “experimental”). A spin-stabilized scientific minisatellite series of CAST, China; launch of SJ-1 on March 3, 1971; SJ-2 (2A and 2B) launch Sept. 19, 1981, S/C mass = 257 kg for each S/C (note: three satellites were launched by a single launch vehicle); SJ-4 launch on Feb. 8, 1994 (orbit: 210 km x 36125 km, inclination = 28.6°), S/C mass = 396 kg; SJ-5 launch on May 10, 1999
SKYLAB	Sky Laboratory, NASA Space Station of the 1970s (L.5)
SL	Spacelab - a modular general purpose laboratory. An integral element of NASA's Space Shuttle Program provided by ESA (build by MBB/ERNO). Spacelab itself comprised several elements that could be mixed-and-matched to suit mission requirements. A typical launch mass of a Spacelab was in the order of about 10 tons. SL-1 totalled a PM (Pressurized Module) mass of 8,145 kg plus a Pallet mass of 3,386 kg (including 1392 kg of payload mass). Spacelab is the first European manned space project. A total of 22 missions were flown with Spacelab starting with STS-9 (Nov. 28, 1983) until STS-90 (April 17, 1998). The Spacelab program provided numerous investigators from many countries an opportunity, to fly their instruments. Experiments conducted were generally in the fields of Earth observation, astronomy, atmospheric physics, life sciences, and material sciences under microgravity conditions.
SLA	Shuttle Laser Altimeter (Shuttle payload)
SLAR	Side-Looking Airborne Radar (an active sensor with Real Aperture Radar technology)
SLC	Satellite Launch Center (complex)
SloshSat-FLEVO	A small satellite of the Netherlands to study fluid dynamics in low gravity with FLEVO (Facility for Liquid Experimentation and Verification in Orbit). Shuttle payload
SLR	Satellite Laser Ranging (a network of ground stations providing services of laser range measurements)
SLS	Space Life Sciences (Shuttle payload)
SLS	Strained Layer Superlattice (infrared detector type)
SMART	Small Missions for Advanced Research in Technology (ESA Horizons 2000 mission)
SMC	Space and Missile Systems Center, part of Air Force Materiel Command, with HQs located at Los Angeles AFB, El Segundo, CA (since 1954). SMC has operating sites throughout the USA, including the operating location detachment at NASA's Johnson Space Center, Houston, Texas; Detachment 2 at Onizuka Air Station in Sunnyvale, CA; and Detachment 9 at Vandenberg Air Force Base, CA. SMC is also the parent center of the host unit at Kirtland Air Force Base, Albuquerque, NM. SMC's work force totals over 9,500 employees. Some major programs of SMC are GPS/NAVSTAR, DMSP, SBIRS, etc.
SMC/TE	Space and Missile Systems Center / Test & Evaluation Directorate. A tri-service (Army, Navy, Air Force) S/C division with locations at Kirtland AFB, Albuquerque, NM; Falcon AFB, Colorado Springs, CO; VAFB, Vandenberg, CA; Los Angeles AFB, El Segundo, CA; and at NASA/JSC, Houston TX. SMC/TE was established in 1992.

SMC/TEL	Space and Missile Systems Center / Space and Missile Test Evaluation Directorate. The Air Force serves as the executive agent for the Space Test Program (STP).
SMC/TEO	SMC / Orbital Telemetry, Tracking and Commanding Operations Division
SME	Solar Mesosphere Explorer (NASA, K.20)
SMEX	Small Explorer Program (NASA/GSFC program since 1988 supporting disciplines in astrophysics, space physics and upper atmospheric science; SMEX missions are SAMPEX, FAST, SWAS, TOMS, etc.)
SMHI	Sveriges Meteorologiska och Hydrologiska Institut (Swedish Meteorological and Hydrological Institute), Norrköping
SMM	Solar Maximum Mission (NASA, K.22)
SMOS	Soil Moisture and Ocean Salinity (ESA mission, D.36)
SMS	Synchronous Meteorological Satellite (designation of the first US weather satellites (1974); this series was later renamed GOES (NOAA))
SMTP	Simple Mail Transfer Protocol
SNAP	Surrey Nanosatellite Applications Program (D.40.16)
SNCMP	Service National des Champs Magnetique Pulses (Toulouse, France)
SNL	Sandia National Laboratories (Albuquerque, NM - since 1945, and Livermore CA, USA; SNL is part of DOE and operated by AT&T since 1949). Since Oct. 1, 1993, SNL is managed by Martin Marietta Corp., now Lockheed Martin. Part of SNL is now part of LANL.
SNOE	Student Nitric Oxide Explorer (N.17.1)
SNR	Signal-to-Noise Ratio
SNSB	Swedish National Space Board (RYDSTYRELSEN), Solna Sweden
SO ₂	Sulphur dioxide
SO ₄	Sulphur radical
SOCC	Satellite Operations and Control Center (NOAA)
SOCEX	Southern Ocean Cloud Experiment (campaign)
SODAR	Sound Detection and Ranging (system)
SODERN	Societe Anonyme d'Etudes et Realisations Nucleaires (French instrument company)
SOFIA	Stratospheric Observatory For Infrared Astronomy (P.188). A cooperative NASA and DLR astronomy observatory. A Boeing 747-SP aircraft, a modified airliner, is the platform of SOFIA. Flights start in late 2002, long-term observations for up to 20 years are planned. The telescope of SOFIA, provided by DLR, has an effective diameter of 2.5 m. The mass of the telescope is 18,000 kg.
SOFIA	Surface of the Ocean, Fluxes and Interaction with the Atmosphere (campaign)
SOHO	Solar and Heliospheric Observatory (see K.23)
SOI	Silicon-On-Insulator (thin film technology). In SOI devices the electronic active layers are fabricated on the insulator layer, while in conventional bulk devices the active layers are fabricated on the silicon layer. SOI is the technology of choice for radiation-critical applications (immunity to single-event latch-up from high-energy particles).
SOLAR-A	ISAS Solar-Terrestrial Mission, K.24
SOLSE/LORE	Shuttle Ozone Limb Sounding Experiment/Limb Ozone Retrieval Experiment (Shuttle payload)
SONEX	SASS Ozone and NO _x Experiment (NASA campaign in planning)
SOP	Special Observation Period (in campaigns)
SOP	Standard of Practice (referring to those technologies which are mainstream and in common use)
SORCE	Solar Radiation and Climate Experiment, A.27
SOS	Southern Oxidants Study (campaign)
SOUP	Solar Optical Universal Polarimeter (Spacelab-2 sensor)

SpaceDev	SpaceDev Inc. is a commercial company with HQ in Poway (San Diego), CA, offering fixed-price (deep-space) missions.
SPACEHAB	A concept for commercially sponsored and procured payloads and services on Shuttle. SPACEHAB Inc., of Vienna, VA, has a NASA contract leasing Shuttle space on a commercial basis in the so-called 'Commercial Middeck Augmentation Module' (CMAM), a pressurized research lab owned by SPACEHAB® (an extension of the Shuttle orbiter mid-deck in the Shuttle cargo bay). SPACEHAB in turn sells its services, providing the needed support for commercial development of space payloads as well as physical and operational integration, and all services (training, etc.) for these payloads. Once in flight, SPACEHAB payloads are crew-tended on request. The SPACEHAB contract was awarded in Nov. 1990, the first SPACEHAB flight took place on STS-57 in June 1993. - SPACEHAB-1, -2 identifies also a series of Shuttle payloads.
SPACELAB	Space Laboratory on NASA Shuttle missions (J.22 - J.23)
Space Imaging . .	Space Imaging Inc. (since 1994) of Thornton, CO, acquired EOSAT in 1995 [distributor of IKONOS imagery, ERS-1/2, JERS and Radarsat data (USA), global distributor of IRS-1C/D imagery]. The owners of Space Imaging are: LM, E-Systems (of Raytheon), Mitsubishi, Vander Horst (Singapore), Halla Heavy Industries (Korea).
SPADE	Stratospheric Photochemistry, Aerosols and Dynamics Experiment (campaign)
SPDM	Special Purpose Dextrous Manipulator
SPAN	Space Physics Analysis Network (based on the DECnet protocol). [The US - SPAN (NASA) service was discontinued at the end of 1990; the E-SPAN (ESA) service will be continued]. SPAN permits user access to data archives. The successor of SPAN in the US is NSI (NASA Science Internet), a dual protocol (TCP/IP and DECnet) network.
SPARC	Stratospheric Processes and their Role in Climate (WCRP project, successor to STIB)
SPARTAN	Shuttle Pointed Autonomous Research Tool for Astronomy (Shuttle). SPARTAN is a small free-flying vehicle (about 1 x 1.25 x 1.5 m) for a variety of experiments (managed by OAST)
SPAS	Shuttle Pallet Satellite (a Shuttle retrievable free-flyer platform for payloads, SPAS was built by MBB), SPAS-1 on STS-7 in 1983, ASTRO-SPAS is a direct successor of SPAS, ASTRO-SPAS-1 on STS-51 in Sept. 1993
SPECTRA	Surface Processes and Ecosystems Changes through Response Analysis (a proposed ESA Core Mission), in 2001 SPECTRA is the new name and successor of PRISM (Processes Research by an Imaging Space Mission), an instrument, and LSPIM (Land Surface Processes and Interactions Mission)
SPECTRE	Spectral Radiance Experiment (campaign)
SPICE	Sensors Performance in Cloud Experiment (campaign)
SPIE	Society of Photo-Optical Instrumentation Engineering (international)
SPIE	Shuttle Plume Impingement Experiment
SPIFEX	Shuttle Plume Impingement Flight Experiment
SPIN-2	Space Information-2 Meter. SPIN-2 is a joint venture (company) of Interbranch Association SOVINFORMSPUTNIK (Moscow, Russia), Aerial Images, Inc. (Raleigh, NC), and Central Trading Systems, Inc., (Huntington Bay, NY). The objective is to market high-resolution panchromatic imagery data (2 m) of past Russian missions (Resurs-F series). See KFA-1000 camera system under RESURS-F (the camera is also known by the name KVR-1000).
SPORT	Small Payload Orbit Transfer (an AeroAstro concept)
SPOT	Système Pour l'Observation de la Terre (French Earth Observing Satellite), (D.37)
SPOT-IMAGE . .	Spot data distributor (Toulouse, France, and Reston, VA, USA)

SPRE	SPARTAN Packet Radio Experiment (an amateur radio experiment on Shuttle SPARTAN)
SPS	Standard Positioning Service (GPS)
SPST	Single Pole Single Throw (Switch)
SPT	Stationary Plasma Thruster (method of electric on-orbit propulsion)
SQUID	Superconducting Quantum Interference Device (detector type, most sensitive device for magnetic field detection in particular with superconducting technology)
SQPSK	Staggered Quadrature Phase Shift Keying (modulation type)
SRAM	Static Random Access Method
SRB	Surface Radiation Budget (GEWEX project)
SRC	Space Regatta Consortium (Konsorsium Kosmicheskaya regata) since 1990, the association is based on the premises of RSC Energia
SRI	Stanford Research Institute (original designation, founded in 1946), now: 'SRI International' at Menlo Park, CA. The institute separated from the University for legal reasons, - SRI International is a nonprofit organization funded by contract research. About 2700 employees.
SRI	Système de Référence Inertielle
SRL	Space Radar Laboratory (Shuttle missions of SIR-C/X-SAR payloads)
SRON	Space Research Organisation Netherlands (Stiching Ruimteonderzoek Nederland, Utrecht, Groningen - the Netherlands), since 1983, builder of scientific instruments (HXIS, SCIAMACHY, HIFI, etc.)
SRSC	Siberian Remote Sensing Center, Novosibirsk, Russia
SRTC	Savannah River Technology Center (DOE facility in Aiken, SC, USA)
SRTM	Shuttle Radar Topography Mission, J.25
SS/CPMA	Spread Spectrum/Code Position Multiple Access (communication concept)
SSB	Single Sideband
SSBUV	Shuttle Solar Backscatter Ultraviolet (Shuttle Experiment)
SSC	Swedish Space Corporation (Solna, Sweden; a government-owned limited corporation under the Ministry of Industry, established in 1972)
SSC	Stennis Space Center (a NASA center in Bay St. Louis, MS)
SSCE	Solid Surface Combustion Experiment (Shuttle payload)
SSDL	Space Systems Development Laboratory, since 1994 (at the Department of Aeronautics and Astronautics of Stanford University, Stanford, CA)
SSEOP	Space Shuttle Earth Observation Project
SSH	Sea Surface Height (measured by satellite altimetry)
SSI	Spaceport Systems International, operators of the commercial California Spaceport at Vandenberg, CA
SSIP	Shuttle Student Involvement Program
SS/L	Space Systems/Loral, Palo Alto, CA (major US builder of communication satellites, consortium leader of Globalstar series, sensors, etc.)
SSMA	Spread Spectrum Multiple Access (communication transmission technique) Spread-spectrum modulation is emerging as the technology of choice to provide secure, interference-tolerant transmission.
SSM/I	Special Sensor Microwave/Image (US Department of Defense, US Air Force Sensor)
SSN	Space Surveillance Network (of the US Space Command, Colorado Springs, CO)
SSP	Sub-Satellite Point
SSPA	Solid-State Power Amplifier
SSPM	Solid-State Photomultiplier (detector type)
SSPP	Shuttle Small Payloads Project
SSRMS	Space Shuttle Remote Manipulator Arm (since 1981, also referred to as Canadarm), built by Spar Aerospace of Canada
SSS	Sea Surface Salinity

SST	Space Solar Telescope (planned Chinese satellite mission in LEO with a 1 m diameter telescope using a 2048 x 1024 CCD detector array)
SST	Satellite-to-Satellite Tracking (a technique employed with two or more S/C in various orbits for determining the Earth's gravity field)
SST	Sea Surface Temperature (a physical parameter derived from radiometer data)
SSTI	Small Spacecraft Technology Initiative (a NASA program started in 94)
SSTL	Surrey Satellite Technology Ltd (University of Surrey, UK). SSTL is a commercial company whose principal shareholder is the University of Surrey. SSTL was set up in 1985 to provide a commercial outlet for the University's S/C engineering research.
SSU	Stratospheric Sounding Unit (UK sensor on NOAA S/C)
STA	Science and Technology Agency (of Japan)
STA	Space Transportation Association [Washington DC, In March 1998, a NASA study on space tourism was released ("General Space Travel and Tourism"). In response to the report's findings, STA has created a new "Space Travel und Tourism Division" (under DOC coordination) to promote public and private space travel]
STABLE	Suppression of Transient Accelerations By Levitation Evaluation (Shuttle payload)
STADAN	Space Tracking and Data Acquisitions Network (NASA/GSFC)
STALO	Stable Local Oscillator
STARE	Southern Tropical Atlantic Regional Experiment (campaign)
Starlette	CNES 'Solid Earth' mission, a passive satellite for geodetic studies with SLR observations (E.19)
STARLink	Satellite Telemetry and Return Link (ER-2 telemetry link, see P.80)
STAR-LITE	Spectrograph/Telescope for Astronomical Research (Shuttle payload)
START	System for Analysis, Research and Training (WCRP, IGBP, HDP)
State Center Priroda	Moscow; Scientific and production enterprise for Earth remote sensing, commercial distributor of imagery; participation in programs: Resurs-F1, -F2, Salyut, MIR
STC	Sensitive Time Control (SAR antenna parameter)
STC	Star Tracker Camera
STCUI-RAS	Scientific Technological Center of Unique Instruments - Russian Academy of Sciences (Moscow)
STDN	Standard Tracking and Data Network (NASA)
STEDI	Student Explorer Demonstration Initiative (N.17)
Stella	CNES experiment on-board Spot-3 for gravity field studies of the Earth (E.20)
STEP	Satellite Test of the Equivalence Principle, an ESA/NASA program proposal (1989). A MiniSTEP mission resulted due to economic constraints.
STEP	Science and Technology for Environmental Protection (CEC program)
STEP	Solar-Terrestrial Energy Program (International Program)
STEP	Space Test Experiment Platform (a minisatellite bus of TRW Inc. for the DoD STP program)
STEP	Stratosphere Troposphere Exchange Project (campaign)
STERAO	Stratosphere-Troposphere Experiments: Radiation, Aerosols, and Ozone (campaign)
STEREO	Solar-Terrestrial Relations Observatory, K.26
STEX	Sensor Technology Experiment (Shuttle)
STEX	Space Technology Experiment (USA, NRO satellite launched Oct. 3, 1998)
STIB	Stratosphere Troposphere Interactions and the Biosphere (Program)
STIS	Space Telescope Imaging Spectrograph (new Hubble sensor since Feb. 1997)
STJ	Superconducting Tunnel Junction

STL-1	Space Tissue Loss-1 (Shuttle experiment)
STOIC	Stratospheric Ozone Intercomparison Campaign
STORM-FEST ..	Stormscale Operational and Research Meteorology - Fronts Experiment Systems Test (campaign)
STP	Space Test Program [of DoD, the USAF manages STP, since 1965; As of 2001, STP has flown more than 420 experiments on more than 130 missions (STEP, POAM-III on SPOT-4, FORTE, REX-II, ARGOS are some current missions of STP)]
STP	Solar Terrestrial Probes (NASA program with such missions as TIMED, SOLAR-B, STEREO, MMS)
STP-1	Space Test Payload-1 (Shuttle)
STRAT	Stratospheric Tracers of Atmospheric Transport (campaign)
STREAM	Stratosphere and Troposphere Experiments by Aircraft Measurements (campaign)
STS	Space Transport System (Shuttle)
STSI	Space Telescope Science Institute (Washington DC, see AURA)
STSP	Solar Terrestrial Science Program (ESA). STSP comprises the SOHO and CLUSTER missions
SUCCESS	Subsonic aircraft: Contrail and Clouds Effects Special Study (campaign)
SUMMiT	Sandia Ultra-planar Multi-level MEMS Technology (a MEMS fabrication process developed at Sandia National Laboratories, Albuquerque, NM)
SUNY	State University of New York (Albany, Binghamton, Brockport, Buffalo, Stony Brook, etc.)
SUPARCO	Space and Upper Atmosphere Research Commission (Pakistan)
SURFSAT-1	Summer Undergraduate Research Fellowship Satellite (NASA/JPL)
SUVE	Solar Ultraviolet Experiment (Shuttle experiment)
SVAT	Soil-Vegetation-Atmosphere Transfer (models)
SVFE	Shuttle Vibration Forces Experiment (Shuttle payload on STS-90 and STS-96)
SVGA	Super Video Graphics Adapter
SVHS	Super Video Home System (a tape recorder system)
SVI	Spectral Vegetation Index
SVN	Satellite Vehicle NAVSTAR (a GPS series numbering system)
SVS	Space Vision System (Shuttle camera system for ISS assembly)
SWADE	Surface Wave Dynamics Experiment (campaign)
SWAS	Submillimeter Wave Astronomy Satellite (NASA/GSFC)
SWIR	Short Wave Infrared (spectrum, from about 1.3 μm to 3 μm)
SwRI	Southwest Research Institute (San Antonio, Texas, an independent, nonprofit, applied research and development organization with more than 2,700 employees)
SWUIS	Southwest Ultraviolet Imaging System (Shuttle payload)

T

TACAN	Tactical Air Communication and Navigation System (a navigation aid, primary Shuttle navigation device for landing, TACAN navigation is provided for Shuttle within 300 miles of the landing site)
TAMEX	Taiwan Area Mesoscale Experiment (campaign)
TANS	Trimble Advanced Navigation Sensor ('TANS Vector' is a solid state GPS attitude-determination and position-location system)
TAO	Tropical Atmospheric Ocean (TOGA campaign)
TAS	Technology Applications and Science (Shuttle payload)
TAS	Thallium Arsenic Selenide (Ti_3AsSe_3)
TBD	To be defined (or: To be determined)
TCIPO	TOGA/COARE International Project Office (at UCAR, Boulder, CO)

TCP/IP	Transmission Control Protocol/Interchange Protocol. TCP/IP represents a communication framework for other protocols such as: email, FTP, HTTP, SSH (Secure Shell), voice over IP, other multimedia protocols, teleoperation of remote systems. Note: the TCP/IP represents two layers of protocol: the TCP part and the lower level IP part. IP deals with how the data gets routed around the network. TCP deals with making sure that all the packets arrive and are in the correct order. TCP implies a two-way connection and a higher level of communications overhead to assure that all the packets arrive and are in the correct order.
TCS	Thomson-CSF Semiconducteurs Spécifiques, Orsay, France
TCS	Trajectory Control Sensor (Shuttle payload)
T&DR	Tracking and Data Relay (NOAA)
TDI	Time Delay Integration (a cumulative exposure concept for CCD imaging)
TDL	Tunable Diode Laser (spectrometer; TDLs are suited for detection of trace gases by optical absorption)
TDLAS	Tunable Diode Laser Absorption Spectrometer
TDMA	Time Division Multiple Access
TDRSS	Tracking and Data Relay Satellite System (NASA)
TEA	Transverse Excitation Atmospheric (pressure) laser
TEAMS	Technology Experiments Advancing Missions in Space (Shuttle)
TEC	Thermoelectric Cooler
TEC	Total Electron Content (of ionosphere)
Technion	Israel Institute of Technology, Haifa, Israel
TEMISAT	Telespazio Micro Satellite (see C.7)
TeO ₂	Tellurium dioxide
TerraServer	A joint venture of Aerial Images Inc., Raleigh, NC; Microsoft Corp., Redmond, WA; Compaq Computer Corp., Houston, TX; and Eastman Kodak Co., Rochester, NY. TerraServer is a commercial service of spaceborne and airborne imagery provision via internet. The imagery offered comes from a variety of sources (commercial and institutional).
TERRIERS	Tomographic Experiment using Radioactive Recombinative Ionospheric EUV (STEDI mission, N.17.2)
TERS	Tropical Earth Resources Satellite [a joint program conceived by the Netherlands (NIVR) and Indonesia (LAPAN) in 1985, the program got stalled after phase A because of a lack of funds]
TERSS	Tasmanian Earth Resources Satellite Station (Hobart, Australia)
TES	Thermal Energy Storage (Shuttle payload)
TES	Transition-Edge Sensor (calorimeter)
TFOV	Total Field of View
TGDF	Turbulent Gas-Jet Diffusion Flames (Shuttle Experiment)
TIFF	Tagged Image File Format (a raster format in pixel representation used for scanned images)
TIMED	Thermosphere, Ionosphere, Mesosphere Energetics and Dynamics (A.28)
TIP	TIROS (or Telemetry) Information Processor (on-board POES S/C, also a downlink data stream of NOAA S/C)
TIPPs	Trans-Ionospheric Pulse Pairs (These strange signals, observed on ALEXIS, are the most intense radio sources from Earth which can be much stronger than typical lightning)
TIR	Thermal Infrared (spectrum, from 6 μ m to about 14 μ m)
TIROS	Television and Infrared Observation Satellite (US Environmental/Meteorological Remote Sensing Program; TIROS 1-10 = 1st generation, ESSA 1-9 = 2nd generation, ITOS (TIROS-M) = 3rd generation,)
TIROS-N	TIROS-NOAA (4th generation TIROS satellite series, starting with NOAA-6, -7, -8, etc.)

TKSC	Tsukuba Space Center, located Tsukuba Science City, Japan (since 1972)
TLD	Thermoluminescent Dosimeter (Shuttle payload)
TLM	Telemetry
TMA	Three Mirror Anastigmatic (telescope off-axis design method). Note: the term ‘anastigmatic’ refers to lenses that are able to form approximately point images of target (object) points.
TMIBD	Thermocapillary Migration and Interaction of Bubbles and Droplets (Spacelab experiment)
TMIP	TeleMedicine Instrumentation Pack (Shuttle payload)
TMSAT	Thai MicroSatellite, was renamed to Thai-Phutt (D.40.15)
TNO/FEL	Netherlands Organization for Applied Scientific Research/Physics and Electronics Laboratory (The Hague and Delft, The Netherlands)
TNSC	Tanegashima Space Center (NASDA’s launch site at Tanegashima Island, Japan, located at 30.4° N, 131.0° E)
TOA	Top-of-Atmosphere
TOF	Time-of-Flight (measurement)
TOGA	Tropical Oceans and Global Atmosphere Experiment (Program)
TOGA/COARE .	Tropical Oceans and Global Atmosphere Experiment / Coupled Ocean Atmosphere Response Experiment
TOGA/TAO	TOGA/Tropical Atmosphere-Ocean (array of wind and upper ocean thermistor chain moorings in the Tropical Pacific)
TOGA/WOCE . .	TOGA/World Ocean Circulation Experiment
TOMS	NASA missions (A.29)
TOPEX/Poseidon	Topography Experiment for Ocean Circulation (NASA/CNES EO Mission), E.21
TOS	TIROS Operational System (NOAA)
TOVS	TIROS Operational Vertical Sounder (NOAA, a three instrument system consisting of : HIRS-2; SSU; and the MSU)
TPCE	Tank Pressure Control Equipment (Shuttle payload)
TPF	Two Phase Flow (Shuttle payload)
TPFLEX	Two-Phase Fluid Loop Experiment (Shuttle payload)
TPFO	TOPEX/POSEIDON Follow-On (mission, was renamed to Jason)
TRACE-A	Transport and Atmospheric Chemistry near the Equator - Atlantic (campaign)
TRAGEX	Trace Gas Exchange: Mid-Latitude Terrestrial Ecosystems and Atmosphere (IGBP/IGAC program)
TRANSHAB	An inflatable system NASA is considering for use on the ISS starting in 2004
TREE	Tropical Rain-Forest Ecology Experiment (campaign)
TREES	Tropical Ecosystem Environment Observation by Satellites (Joint CEC, JRC and ESA program)
TRIAD	Transit-Improved DISCOS (US Navy S/C built by APL) H.6
TRMM	Tropical Rainfall Measuring Mission (NASA-NASDA Mission), A.31
TRSC	Thailand Remote Sensing Center, Bangkok
TRW	Thompson, Ramo and Wooldridge [TRW Space & Electronics Group is located at Redondo Beach, CA]. Manufacturer of communication satellites (TDRS, Odyssey series), military spacecraft (STEP, AXAF, etc.), and remote sensing satellites (Lewis, EOS/PM-1, TOMS/EP, KOMPSAT-1, ROCSat-1, etc.)
TSI	Total Solar Irradiance
TSIM	Total Solar Irradiance Mission
TsNIIMASH	Central Research and Scientific Institute of Machine Building, Korolev (Moscow Region), Russia (there is also the spelling of TzNIIMASH)
TsSKB-Progress .	the Russian acronym for “Central Specialized Design Bureau Progress,” Samara, builder of Resurs-F (and Resurs-RK) satellite series
TSS-1R	Tethered Satellite System (ASI payload on Shuttle)

TT&C	Telemetry, Tracking & Command (Data for S/C Operations)
TTFM	Two-Tone Frequency Modulation (a measurement technique for trace gases)
TTL	Transistor-Transistor Logic (semiconductor technology of the 1960s and 1970s - the microprocessor revolution began in 1973)
TUB	Technical University of Berlin, Germany
TUBSAT	Technical University of Berlin Satellite (N.21)
TUD	Technical University of Denmark (Lyngby, Denmark)
TUFI	Toughened Uni-Piece Fibrous Insulation (Shuttle payload)
TVA	Tennessee Valley Authority (USA)
TWTA	Traveling Wave Tube Amplifier (communication, amplification of a microwave frequency)

U

UAH	University of Alabama in Huntsville, AL
UARP	Upper Atmospheric Research Program (NASA)
UARS	Upper Atmosphere Research Satellite (NASA satellite, launch: Sept. 1991) A.32
UAV	Unmanned Aerial Vehicle (PERSEUS, CONDOR, etc.)
UC	University of California [a nine campus university across the state, UCLA (Los Angeles), UCB (Berkeley), UCSD (San Diego), UCSB (Santa Barbara), UCI (Irvine), UCR (Riverside), UCSC (Santa Cruz), UCD (Davis), etc.]
UCAR	University Corporation for Atmospheric Research (Boulder, CO, UCAR is sponsored by NSF - there are over 60 member institutions in UCAR)
UCB	University of California, Berkeley
UCCS	University of Colorado at Colorado Springs
UCLA	University of California, Los Angeles
UDP/IP	User Datagram Protocol/Internet Protocol. Note: UDP/IP does not need any handshaking to transfer data. TCP/IP requires bi-directional handshaking prior to data transfer.
UHB	User Home Base
UHF	Ultra High Frequency (300 - 3000 MHz band)
UIT	Ultraviolet Imaging Telescope (part of ASTRO-1 payload on Shuttle)
UIT	Union Internationale des Télécommunications
UKAEA	United Kingdom Atomic Energy Authority
UKDoE	United Kingdom Department of the Environment
UKMO	United Kingdom Meteorological Office (same as BMO, HQs and Hadley Centre for Climate Prediction & Research are located in Bracknell, Remote Sensing Instrumentation branch in Farnborough)
UKS	United Kingdom Subsatellite (S/C of the AMPTE mission, K.4.2)
ULIRGs	Ultra-Luminous IR Galaxies
UMTS	Universal Mobile Telecommunications System (standard)
UNAM	Universidad Nacional Autónoma de México, Mexico City
UNAM-CE	Universidad Nacional Autónoma de México - Centro de Ecología, Mexico
UNAM-IG	Universidad Nacional Autónoma de México - Instituto de Geología
UNAVCO	University Navstar Consortium (a US Earth sciences community initiative to foster GPS applications in particular in the area of surveying)
UNCED	United Nations Conference on Environment & Development
UNDP	United Nations Development Programme
UNAVCO	University NAVSTAR Consortium (USA)
UNCOPUOS ...	UN Committee on the Peaceful Uses of Outer Space
UNEP	United Nations Environmental Programme (since 1972)
UNEP/GRID ...	UNEP Global Resource Information Database

UNESCO	United Nations Educational Scientific and Cultural Organization (based in Paris, France)
UN-ESCAP	UN-Economic and Social Commission for Asia and the Pacific, Bangkok, Thailand
UnESS	University Earth System Science (a NASA initiative with the objective to involve the student community in Earth science projects)
UNEX	University-class Explorer [(mission) - A NASA program supporting university-designed/developed missions. The UNEX program is designed to provide frequent flight opportunities for highly focused and relatively inexpensive science missions whose total cost to NASA is limited to \$13 million. The program is managed by NASA/GSFC.]
UNH	University of New Hampshire, Durham, NH
UNISPACE	United Nations Conference on the Exploration of the Committee on the Peaceful Uses of Outer Space (UNISPACE-III took place in Vienna, Austria (July 19-30, 1999 - the first two UNISPACE conferences were held in 1968 and 1982)
UNOLS	University National Oceanographic Laboratory System (USA)
UNS	Universal Navigation System
UNOOSA	United Nations Office for Outer Space Affairs
UoSAT	University of Surrey Satellite (UK, D.40)
UPC	Universidad Politecnica de Barcelona (Spain)
UQPSK	Unbalanced Quadrature Phase-Shift Keying (technique)
URE	User Range Error (of GPS position service)
URL	Uniform Resource Locator (WWW) for ‘file:’, ‘http:’, ‘news:’, and ‘telnet:’
URSI	Union Radio Scientifique Internationale (International Union of Radio Science)
USA	United States of America
USA	United Space Alliance LLC [of Houston, TX, a joint venture of Rockwell International (now The Boeing Company) and Lockheed Martin] - USA is the NASA prime contractor for all Space Shuttle operations/management at MSFC and at KSC, since Oct. 1996)
USACE	US Army Corps of Engineers
USAF	US Air Force
USAFA	United States Air Force Academy (Colorado Springs, CO)
USAFB	US Air Force Base
USAF/PL	USAF/Phillips Laboratory, Kirtland AFB, Albuquerque, NM [part of AFRL (Air Force Research Laboratory), note: in 1998 the Phillips Laboratory was renamed: “Phillips Research Site”]
USAF/RL	USAF/Rome Laboratory, Griffis AFB, Rome, NY [part of AFRL]
USAF/SMC	USAF/Space & Missile Systems Center (see SMC/TE)
USCG	US Coast Guard
USCON-CICTUS	Universidad de Sonora - Centro de Investigaciones Cientificas y Tecnologicas de la Universidad de Sonora, Hermosillo, Mexico
USDA	US Department of Agriculture
USDA/ARS	USDA/Agricultural Research Service (Beltsville, MD and Tucson, AZ)
USEPA	US Environmental Protection Agency
USES	Universal Source Encoder for Space (a NASA developed chipset)
USFS	US Forest Service
USFWS	US Fish and Wildlife Service
USGCRP	US Global Change Research Program (since 1990). USGCRP sponsors global change research in a large number of institutions (over 300).
USGS	United States Geological Survey (the science and technology agency of the Department of the Interior, DOI; USGS was established in 1879). The mission of USGS is to provide geologic, topographic, and hydrographic information to contribute to the management of the Nation’s natural resources.

USML	US Microgravity Laboratory (Shuttle payload)
USMP	US Microgravity Payload (Shuttle payload)
USRA	Universities Space Research Association, Columbia, MD [a nonprofit corporation organized in 1969 by NAS (National Academy of Sciences) at the request of NASA; as of 1995 there are 78 member universities]
USS	Unique Support Structure (Shuttle)
USSR	Union of Soviet Socialist Republics (former)
USU/SDL	Utah State University / Space Dynamics Laboratory (Logan, UT, Bedford, MA, and Albuquerque, NM). SDL is a non-profit organization owned by USU.
USWRP	US Weather Research Program
UTA	University of Texas at Austin
UTA/CSR	UTA/Center for Space Research (since 1981)
UTC	Universal Time Coordinated
UTM	Universal Transverse Mercator (coordinate reference system for large-scale maps)
UV	Ultra Violet (spectral range from 0.01 - 0.38 μm)
UVCS	Ultraviolet Coronal Spectrometer (a SAO instrument flown on the SPARTAN-201 series)
UVPI	Ultraviolet Plume Instrument (Shuttle experiment)
UVSTAR	Ultraviolet Spectrograph Telescope for Astronomical Research (Shuttle payload)
UWB	Ultra Wideband (involves multi-octave frequency coverage of a sensor such as a radar system for the purpose of ground penetration)

V

VAFB	Vandenberg Air Force Base, Vandenberg, CA
VCL	Vegetation Canopy Lidar Mission, D.39
VCO	Voltage Controlled Oscillator
VCR	Video Cassette Recorder (also: Video Color Recorder)
VCS	Voice Command System (Shuttle)
VCSEL	Vertical Cavity Surface-Emitting Laser (type of semiconductor diode laser; the cavity is perpendicular to the wafer plane, thus the optical beam is guided in the vertical direction)
VDA	VHF Collection System Antenna (NOAA)
VDC	Volt Direct Current
VENTEX	Venting Experiment (campaign)
VFT-1	Visual Function Tester-1 (Shuttle experiment)
VH	Vertical transmit - Horizontal receive polarization
VHF	Very High Frequency (30 - 300 MHz band)
VHS	Video Home System
VI	Vegetation Index
Viking	Swedish satellite mission for the study of the Earth's magnetosphere, K.29
VIR	Visible Infrared (spectrum)
VIS	Visible (spectrum 0.4 - 0.7 μm)
VITA	Volunteers in Technical Assistance (a humanitarian organization in Arlington, VA, USA, providing communication services on a global scale)
VITO	Vlaamse instelling voor technologisch onderzoek (Flemish institute for technological research), located in northern Belgium. One of its centers is the image processing/archiving center of the VEGETATION instrument on SPOT.
VLBI	Very Long Baseline Interferometry
VLDS	Very Large Data Store
VLF	Very Low Frequency (frequency band of 10 - 30 kHz)
VLS	Veiculo Lancador de Satellites (Brazil's launch vehicle)
VLSI	Very Large Scale Integration (solid-state technology)

VLWIR	Very Long Wavelength Infrared (14-30 μm)
VME	Versatile Multi-bus Extension (computer)
VNIEM	All-Russian Scientific and Research Institute of Electromechanics (Moscow; S/C builder/integrator, Meteor series, Okean series, Resurs series, GOMS, etc. also referred to as: NPP VNIEM). Background: the enterprise was funded in 1941, in 1944 it was named "Science and Research Institute #627" or NII-627. In 1953, NII-627 was renamed to VNIEM. In the early 1960s, VNIEM began to develop meteorological spacecraft, using an innovative electromechanical stabilization system. - In Nov. 1992, the Istra Branch of VNIEM separated to become an independent enterprise, NII of Electromechanics (NIIEM). Since May 1998, VNIEM reports to the Russian Space Agency (RKA).
VNIR	Visible Near Infrared (spectral range 0.4 - 1.3 μm)
VOC	Volatile Organic (carbon) Compounds
VORTEX	Verification of the Origins of Rotation in Tornadoes Experiment (campaign)
VORTEX	Vortex Ring Transit Experiment (G-93R Shuttle payload on STS-88)
VOXEL	Volume Element
VPN	Virtual Private Network
VRA	VHF Realtime Antenna (NOAA)
VRAM	Video RAM
VRTE	Vented Tank Resupply Experiment (Shuttle payload)
VSAT	Very Small Aperture Terminal (small ground antenna for satellite communication)
VSWR	Voltage Standing Wave Ratio
VT	Virtual Terminal
VTT	Technical Research Center of Finland, (Espoo, Helsinki, Finland)
VV	Vertical transmit - Vertical receive polarization

W

WAAS	Wide Area Augmentation System (FAA). WAAS is the US space-based augmentation system that provides DGPS service over a very large geographical area (USA) by using a satellite broadcast of separate corrections for GPS clock, orbital data and ionospheric delay.
WAC	Wide-Angle Camera
WADGPS	Wide Area Differential GPS
WAIS	West Antarctic Ice Sheet Project (campaign)
WARC	World Administrative Radio Conference (of ITU)
WATS	Water-Vapor and Wind in Atmospheric Troposphere and Stratosphere (a proposed ESA mission as of 2001)
WAU	Wageningen Agricultural University, The Netherlands
WBVTR	Wideband Video Tape Recorder (on Landsat-1 to -3 series)
WCASP	World Climate Applications and Services Programme (WMO)
WCC	World Climate Conference (WCC-1 in 1979, WCC-2 in 1990)
WCDMP	World Climate Data and Monitoring Programme (WMO)
WCIRP	World Climate Impact Assessment and Response Strategies Programme (UNEP)
WCP	World Climate Program (WMO is the lead agency of WCP)
WCRP	World Climate Research Programme (since 1980, jointly sponsored by WMO, ICSU, and IOC)
WDC	World Data Center
WDCGG	World Data Center for Greenhouse Gases (of WMO)
WDM	Wavelength Division Multiplexing (optical high-rate transmission technology)
WEFAX	Weather Facsimile (NOAA broadcast service of GOES S/C; transmission of environmental data in WEFAX format to ground stations)
WENPEX	Western North Pacific Cloud-Radiation Experiment (campaign)

WESTEX	West Coast Ship Tracks Experiment (campaign)
WEU	Western European Union (with HQ in Brussels; WEU has 10 member states: Belgium, France, Germany, Greece, Italy, Luxembourg, Netherlands, Portugal, Spain, and UK)
WFF	Wallops Flight Facility (of NASA/GSFC, founded in 1945 by NACA)
WFOV	Wide Field of View (of a sensor)
WGS-84	World Geodetic System - 1984 (DoD reference ellipsoid for GPS, etc. GPS positions are computed in WGS-84, the system has been adopted internationally as the single worldwide datum for marine navigation)
WHRC	Woods Hole Research Center (Woods Hole, MA, USA)
WHOI	Woods Hole Oceanographic Institution, (Woods Hole, MA, USA - a marine science non-profit research facility founded in 1930)
WIND	NASA/GSFC Solar-Terrestrial Mission (K.30)
WINDEX	Window Experiment (Shuttle)
WINDOS	Western Indian Ocean Study (campaign)
WISP	Winter Icing and Storms Project (campaign)
WL	Werkstofflabor (materials laboratory on Shuttle D2 mission)
WLC	White Light Coronagraph (instrument flown on SPARTAN-201 series)
WMO	World Meteorological Organization (an agency of the United Nations, located in Geneva, Switzerland, since 1951). Major science and technical programs of WMO are: WWW (World Weather Watch), WCRP (World Climate Research Program), GAW (Global Atmosphere Watch), HWRP (Hydrology and Water Resources Program), GCOS (Global Climate Observing System), GOOS (Global Ocean Observing System)
WMSCC	World Meteorological Service Computing Center
WOCE	World Ocean Circulation Experiment (Program)
WPLTN	Western Pacific Laser Tracking Network (a ground network for SLR in the Pacific region) WPTLN coordinates the activities of SLR stations in China, Japan, Australia, and Eastern Russia.
WRC	World Radiocommunication Conference (of ITU, Geneva, Switzerland, see also WARC)
WRMC	World Radiation Monitoring Center (Zürich, Switzerland)
WRS	Worldwide Reference System (a global indexing scheme of the Landsat program which is based on nominal scene centers defined by path and row coordinates)
WSF	Wake Shield Facility (Shuttle payload, a retrievable platform)
WSMC	Western Space and Missile Center (of USAF at Vandenberg, CA)
WSTF	White Sands Test Facility (White Sands, NM), a facility of NASA/JSC
WUPPE	Wisconsin Ultraviolet Photo Polarimeter Experiment (part of ASTRO-1 payload on Shuttle)
WV	Water Vapor (in the 5.7 - 7.1 μm water vapor absorption band)
WWW	World Weather Watch (WMO Program)
WWW	World Wide Web (a wide-area client/server architecture for exchanging hypermedia across the Internet network). WWW offers platform independence and the use of different communication protocols, such as: FTP (File Transfer Protocol), HTTP (HyperText Transfer Protocol), and SMTP (Simple Mail Transfer Protocol).

X

XeCl	Xenon Chloride laser
XIPS	Xenon Ion Propulsion System (on platform HS702 of Hughes Space and Communications Company, Los Angeles, CA)
XML	eXtensible Markup Language (a document markup language for the creation of hierarchical information structures)
XMM	X-Ray Multi-Mirror Mission (of ESA). Note: XMM was officially re-named to "XMM–Newton" in Feb. 2000

XPD X-ray Photoelectron Detection
 XRT X-Ray Telescope (Spacelab-2 sensor, energy detection 2.5-25 keV)
 XSS Experimental Spacecraft System (US AFRL minisatellite series)
 XTI Cross-Track Interferometry
 XTR Transmitter
 XUV Extreme Ultra Violet (same as EUV, i.e. 1 - 130 nm spectral range)

Y

YAG Yttrium Aluminum Garnet (a type of solid-state crystal laser)
 YBCO Yttrium-Barium-Copper-Oxide ($\text{YBa}_2\text{Cu}_3\text{O}_7$)
 YBLCO Yttrium-Barium-Lanthanum-Copper-Oxide
 YLF Yttrium Lithium Fluoride (a laser type)
 YUZHNOYE ... Research and Production Association, Dnepropetrovsk, Ukraine
 (there is also the spelling of YUZHNOE - builders of two launch vehicles: Zenit and Cyclone; builders of OKEAN series satellites)

Z

ZAMG Zentralanstalt für Meteorologie und Geodynamik, with HQs at Vienna, Austria, since 1851 (Austrian Institute for Meteorology and Geodynamics)
 ZARM Zentrum für angewandte Raumfahrttechnologie und Mikrogravitation (Center of Applied Space Technology and Microgravity - since 1985), an institute of the University of Bremen, Germany
 ZUP Flight Control Center, Kaliningrad, Russia (TT&C function for MIR station along with RKK Energia)

Appendix C Index of Sensors

Numbers

3D-Electron Analyzer, 875

3D-Ion Analyzer, 875

3D-Plasma Analyzer, 897

A

AA3500 = Airborne Bispectral Scanner (ABS), 1612

AADS1220 = Dual Channel Terrain Surveillance Scanner, 1611

AADS1221 = Maritime Surveillance Scanner, 1611

AADS1230 = Dual Channel Quantitative Infrared Scanner, 1611

AADS1250 = Eleven Channel Analog Multispectral System, 1612

AADS1260 = Daedalus Multispectral Scanner (predecessor of ATM), 1609

AADS1268 = ATM (Airborne Thematic Mapper), 1609

AADS1278 = ATMX (ATM extended), 1609

AADS1280 = Daedalus Multispectral Scanner, 1609

AAHIS = Advanced Airborne Hyperspectral Imaging Spectrometer, 23, 1513

AAMAS (Aircraft-borne Automatic Mass Spectrometer), 1514, 1913, 1914

AARGOS (A340 Atmospheric Research Global Observation System), 1571

AAS = Airborne ASTER Simulator, 23, 1666

AATSR = Advanced Along Track Scanning Radiometer, 358, 370

ABI (Advanced Baseline Imager), 627

ABLE (Airborne Lidar Experiment), 1550

AC = Actinometric instrument (radiation budget sensor), 700

AC = Radiation Budget Sensor, 693

AC-ITMS (Air Concentrator-Ion Trap Mass Spectrometer), 1542

ACAP = Airborne Counter of Aerosol Particles, 1553

Accelerometer Testbed, 1160

ACCESS (Advanced Cosmic-Ray Composition Experiment for Space Station), 985

ACCESS (All Composite Experiment Spacecraft Structure), 1136

ACE-FTS (ACE-Fourier Transform Spectrometer), 236

ACES (Atomic Clock Ensemble in Space), 986

ACH = Aircraft Condensation Hygrometer, 1553

ACRIM = Active Cavity Radiometer Irradiance Monitor, 118, 119, 167, 262, 822, 953

ACS (Advanced Composite Structure), 1048

ADACS (Attitude Determination and Control Subsystem), 228

ADAM (Advanced Data Acquisition and Messaging System), 435, 1043

ADC = Airborne Digital Camera, 1619

ADOLAR = Airborne Doppler Lidar, 1623

ADS = Analyzer of Dynamic Spectra, 929

ADTS (Advanced Detection Technology Sensor), 1729

AEPI = Atmospheric Emissions Photometric Imaging Experiment, 823

AERCam (Autonomous EVA Robotic Camera), 144

Aerosol Experiment, 1518, 1625

AES = Airborne Emission Spectrometer, 53, 1520, 1907

AFA-41/10 (Aerial Foto Apparatus), 1824

AFA-41/20 = Aerial Foto Apparatus, 1774

AFF (Autonomous Formation Flying), 91

AGEMA Thermal Imager, 1540

AHS = Airborne Hyperspectral Scanner, 23, 1618

AHSTRA (Airborne Heterodyne Spectrometer THz Astronomy), 1520

AIMR = Airborne Imaging Microwave Radiometer, 1521

AIMS-1000 (Airborne Imaging Mapping and Surveillance System), 1522

AirCam, 1522

AIRDAS = Airborne Disaster Assessment System, 1523

AIRES (Airborne InfraRed Echelle Spectrometer), 1806

Airglow Instrument (SME), 944

AIRS (Atmospheric Infrared Sounder), 376, 387

AIRSAR = Airborne SAR, 31, 1525, 1864, 1880, 1884, 1890, 1894, 1908

AIS = Airborne Imaging Spectrometer, 23, 1529

AISA = Airborne Imaging Spectrometer for different Applications, 23, 1529, 1892

AKR-2 = Analyzer of Kilometric Radiation, 930

AKS = Aerial Krypton Sampler, 1542

ALADIN (Atmospheric Laser Doppler Instrument), 171

ALADIN = Atmospheric Laser and Doppler Instrument, 1255

ALAE = Atmospheric Lyman-Alpha Emissions, 823

ALAS = Airborne Laser Altimeter System, 1531

ALCOR (ARPA, Lincoln Laboratory, C-band, Observables Radar), 30

ALEX = Aerosol Lidar Experiment, 1621, 1865, 1882

ALEXIS = Array of Low Energy X-Ray Imaging Sensors, 870

ALF = Airborne Laser Fluorosensor, 1532

ALI (Advanced Land Imager), 17, 21, 26, 91, 1026

ALIAS = Aircraft Laser Infrared Absorption Spectrometer, 1534, 1850, 1907

ALIAS-I on ER-2 Aircraft, 1534, 1895

ALIAS-II on Perseus Aircraft, 1534, 1763

ALISSA = l'Atmosphere par Lidar Sur SAliout, 482, 1000, 1255

ALPHA-1, -2 (Airborne Lidar Plume and Haze Analyzer), 1809

ALPHA-3 = Ion Trap Experiment, 928, 929

ALPS = Airborne Laser Polarization Sensor, 1535

ALSE (Apollo Lunar Sounder Experiment), 29

Altimeter, further considerations, 358, 405, 572, 602, 1917

ALTM = Airborne Laser Terrain Mapping, 1536

AMAP (Airborne Microwave Altimeter Platform), 1576

AMAS = Advanced Millimeter-Wave Atmospheric Sounder, 1309

AMEI-2 = Energy-Mass Analyzer, 929

AMI = Active Microwave Instrument, 30, 400, 1877, 1881, 1892, 1897, 1903, 1917
further considerations, 407

AMI-SCAT = Active MW Instrument - Scatterometer (ERS-1), 401

AMIE (Asteroid Moon micro-Imager Experiment), 1108

AMMR = Airborne Multichannel Microwave Radiometer, 1537, 1917

AMMS = Airborne Microwave Moisture Sounder, 1537, 1917

AMPR = Advanced Microwave Precipitation Radiometer, 1537, 1854, 1855, 1917

AMPS (Airborne Multisensor Pod System), 1538

AMR = Airborne Microwave Radiometer, 1692

AMS (Alpha Magnetic Spectrometer), 986

AMS = Airborne Multispectral Scanner, 1541, 1597, 1614

AMSOS (Airborne Millimeter & Sub-millimeter-wave Observing System), 1543

AMSR = Advanced Microwave Scanning Radiometer, 336

AMSR-E (Advanced Microwave Scanning Radiometer-EOS), 389

AMSS (Advanced MultiSpectral Scanner), 1693

AMSS MK-II (Airborne Multi-Spectral Scanner), 23, 1544

AMSU (Advanced Microwave Sounding Unit), 388, 750

AMSU-A = Advanced Microwave Sounding Unit - A, 388, 681, 750

AMSU-B = Advanced Microwave Sounding Unit - B, 751, 1869

ANAPURNA = Energy and Pitch Distribution Experiment, 867

AOCI = Airborne Ocean Color Imager Spectrometer, 1609, 1613, 1614

AOE (Atomic Oxygen Experiment), 1112

AOE-2 (Atomic Oxygen Experiment-2), 1116

AOL = Airborne Oceanographic Lidar, 1545

AOS (Acousto-Optical Spectrometer), 1817

AP (Auroral Photometer), 1172

APDOR-95 (Airborne Polarimetric Doppler Radar), 1545, 1920

APE (Airborne Polar Experiment), 1546

APEX (Alpha, Proton and Electronics Experiment), 210

APT (Automatic Picture Transmission), 725, 728, 1077, 1078

ARAEX (Autonomous Remote Agent Experiment), 1023

ARES = Airborne Remote Earth Sensing, 23, 1559

ARGOS = Remote Data Collection System, 681, 736, 747, 754

ARGOS/ADCS (Advanced Data Collection System), 681, 688

ARGUS (Two-Channel Atmospheric Tracer Instrument), 1561, 1763

ARIAS (Airborne Remote-Sensing & In-Situ Aerosol Measuring System), 1548

ARISS (Amateur Radio on the International Space Station), 986

ARL (Airborne Raman Lidar), 1563, 1918

ARMAR = Airborne Rain Mapping Radar, 1564, 1917

ARP (ATV Rendezvous Pre-development), 787

ARP (ATV Rendezvous Predevelopment), 819

ASAR = Advanced SAR (ESA sensor), 358, 363, 1765

ASAS = Advanced Solid-State Array Spectrometer, 23, 1566

ASAS = Advanced Solid-State Array Spectroradiometer, 1565, 1853, 1854, 1869, 1894

ASC (Advanced Stellar Compass), 504, 555, 558, 588, 599, 880, 1095, 1099, 1105, 1121

ASCAT = Advanced Wind Scatterometer, 681

ASCE (Advanced Solar Cell Experiment), 1048

ASDL (NOAA Aircraft Satellite Data Link), 1753

ASPOC = Active S/C Potential Control, 886

ASSI = Airglow Solar Spectrometer Instrument, 233

AST20 (Autonomous Star Tracker 20), 1100

ASTER (Advanced Spaceborne Thermal Emission and Reflection Radiometer), 17, 378

ASTER simulator, 1666, 1667

ASTRAIA = Analyse Stereoscopique par Radar Aeroporte sur Electra, 1635

ASTRE (Accéléromètre Spatial Triaxial Electrostatique), 128

ASUR (Airborne Submillimeter SIS Radiometer), 1817

ASUSat Imager, 1141

ATHOS (Airborne Tropospheric Hydrogen Oxide Sensor), 1566, 1918

ATLAS = Airborne Terrestrial Applications Scanner, 1568

ATLAS = Airborne Tunable Laser Absorption Spectrometer, 1567, 1850, 1895, 1907, 1913

ATLID = Atmospheric Lidar, 1255, 1621

ATM = Airborne Thematic Mapper, 1609

ATMOS = Atmospheric Trace Molecule Spectrometer, 395, 821, 854

ATMOS = Atmospheric Trace Molecule Spectroscopy, 1296, 1298, 1727
 Atmospheric Drag, 175
 ATMS (Advanced Technology Microwave Sounder), 707
 ATOMS (Atmospheric Tomography Experiment), 457
 ATOS (Arcjet Thruster on OSCAR Satellite), 97, 1282
 ATSR = Along Track Scanning Radiometer and Microwave Sounder, 403, 407, 1246, 1848, 1857, 1869, 1870, 1877, 1917
 ATSS = Airborne Terrain Survey System, 1576
 ATV = Visible and UV Auroral TV, 904
 AutoNav (Autonomous navigation), 1021
 AVCH-2T = HF-Field Analyzer, 877
 AVCS (Advanced Vidicon Camera System), 727, 728, 729, 730, 731, 737, 1077
 AVHRR = Advanced Very-High Resolution Radiometer, **741**
 further consideration, 734, 735, 737, 1310
 further mention, 383, 1676, 1847, 1848, 1851, 1853, 1855, 1857, 1860, 1864, 1869, 1870, 1874, 1877, 1879, 1881, 1882, 1888, 1890, 1891, 1892, 1894, 1896, 1901, 1904, 1906, 1910, 1917
 AVHRR/3 = Advanced Very High Resolution Radiometer, 681, **748**
 AVIRIS = Airborne Visible/Infrared Imaging Spectrometer, 23, **1578**, 1848, 1853, 1854, 1864, 1869, 1870, 1884, 1894, 1901, 1902
 AVNIR = Advanced Visible and Near-Infrared Radiometer, 330, 342
 AVNIR-2 (Advanced Visible and Near-Infrared Radiometer - 2, 342
 AVS (Autonomous Vision System), 1121
 AWI Sensors, 1581
 AWiFS (Advanced Wide Field Sensor), 17, 427
 AWSR = Airborne Water Substance Radiometer, 1582

AXBT (Air Expendable Bathythermograph), 1755

AXIS (X-ray, proton and electron spectrometer), 261

B

B-Flux (Boundary-Layer Flux System), 1582, 1853, 1907

Balkan-1 = Lidar on MIR Station, 1000

BBHIR (Broad Bandpass Hemispheric Infrared Radiometer), 1779

BBHSR (Broad Bandpass Hemispheric Solar Radiometer), 1779

BCS = Bent-Crystal Spectrometer, 954

BCS = Bragg Crystal Spectrometer, 961

BEPT (Bradford Engineering Pressure Transducer), 1120

BERIR (Broadband Earth Radiation Imaging Radiometer), 188

BGIS 2000 (Ball Global Imaging System 2000), 17, 278

BGSR (microGPS - Bit Grabber Space Receiver), 1173

BHRC 60 (Ball High Resolution Camera 60), 278

BIMS (Bennett Ion-Mass Spectrometer), 179

Blackbeard, 871

BlackJack (GPS Flight Receiver), 46, 139, 231, 504, 507, 556, 588, 590, 592, 858, 1044

BLISS (Balloon-borne Laser In-Situ Sensor), 1534

BRE (Battery Recharge Experiment), 1112

BUUV = Backscatter Ultraviolet Spectrometer, 47, 182, 737, 1081

C

C/X-SAR = C-Band and X-Band SAR (CCRS), 31, 1605, 1853, 1856, 1885, 1905, 1915

C-band Radar Transponder, 571, 572

C-P = Coronagraph - Polarimeter, 953

C-RADAR (C-band Radar Instrument), 30, 861

- C-SCAT (C-band Scatterometer), 1603, 1915
- C-STAR (Conically-Scanning Two-Look Airborne Radiometer), 1604
- CACTUS (Capteur Accélérométrique Capacitif Triaxial Ultra Sensible), 128
- CAE (Charge Alleviation Experiment), 1112
- CAESAR = CCD Airborne Experimental Scanner for Applications in Remote Sensing, 1585, 1885
- CAI = Electron Isotopes Investigation, 925
- CALS = Cloud and Aerosol Lidar System, 1586, 1847, 1848, 1850, 1856, 1870, 1886, 1901, 1902, 1917, 1919
- Camera (Photographic Camera System), 1734
- Camera Assembly, 1188
- Cameras
- Photographic Systems
 - ESC -Electronic Still Camera (Shuttle), 854
 - Hasselblad 500 ELX (Shuttle), 855
 - Hasselblad 500-EL (MIR), 998
 - KAP-350 (Kvant 2 on MIR), 998
 - KATE-140 (Salyut), 1002
 - KFA-1000 (Resurs-F), 494
 - KFA-200 (Resurs-F), 493
 - LFC = Large Format Camera, 833
 - Linhof Aero Technika (Shuttle), 855
 - Metric Camera (Spacelab-1), 853
 - MK-4 (Resurs-F), 494
 - MKF-6 (Salyut), 1001, 1688
 - MKF-6MA (on Kvant 2 of MIR), 1000
 - Nikon F3, F4 (Shuttle), 855
 - Rolleiflex 6008 (Shuttle), 855
 - S190A (Skylab), 1002
 - S190B (Skylab), 1003
 - S191 (Skylab), 1003
 - TV Cameras
 - Atlas (on Kvant 2 of MIR), 1000
 - EIS (PoSAT-1), 537
 - KL-103W (Color camera on Kvant2 of MIR), 1000
 - MR-2000M (Meteor-3), 696
 - MR-900B (Meteor-3), 696
 - TV camera (Priroda), 482
- CAMMICE = Charge and Mass Magnetospheric Ion Composition Experiment, 938
- CAMPR = CRL Airborne Multiparameter Precipitation Radar, 1694
- CAMS = Calibrated Airborne Multispectral Scanner, 1587
- CAR = Cloud Absorption Radiometer, 1587, 1850, 1870, 1901
- CARABAS = Coherent All Radio BAnd Sensing, 31, 76, 1589, 1852
- CARIBIC (Civil Aircraft for Remote-Sensing and In-Situ-Measurements in Troposphere and Lower Stratosphere Based on the Instrumentation Container Concept), 1572
- CASI = Compact Airborne Spectrographic Imager, 23, 1541, 1592
- CASIMIR (Caltech Submillimeter Interstellar Medium Investigations Receiver), 1805
- CASIR (Clouds and Aerosol Shortwave Imaging Radiometer), 185
- CASSAR = Chinese Academy of Sciences SAR, 31, 1598, 1908
- Cast Eyes, 1594
- CBE = Controlled Beam Experiment, 900
- CBEMG (Confined Boiling Experiment under Microgravity), 211
- CCD Camera, 638
- CCR (Carbon Carbon Radiator), 1030
- CCS (CCD Camera System), 410
- CDE (Compact Dosimeter Experiment), 347
- CDL = Cloud Detection Lidar, 1626, 1764
- CDMS (Cosmic Debris and Micrometeoroid Sensor), 1117
- CDS = Coronal Diagnostic Spectrometer, 956
- CEASE (Compact Environmental Anomaly Sensor Experiment), 1117, 1137
- CEDEX (Cosmic Ray Energy Deposition Experiment), 552
- CEIS = CCD Earth Imaging System, 431, 536
- CELIAS = Charge, Element and Isotope Analysis, 958

CEP (Cylindrical Electrostatic Probe), 176

CEPAC = COSTEP/ERNE Particle Analyzer, 958

CERES (Clouds and the Earth's Radiant Energy System), 119, 257, 380, 1217, 1903

CERES = Clouds and the Earth's Radiant Energy System, 1309

CERTO (Coherent Radio Topography Experiment), 1013, 1094

CERTO/PLUS (Coherent EM Radio Tomography & Profiling the Limb with UV Sensors), 1119

CESS (Coarse Earth-Sun Sensor), 292, 556, 561, 587

CHADOCC (Circuit Hydraulique a Ammoniaque Diphasique en Orbite a Pompe Capillaire et Centrifuge), 211

CHASE = Coronal Helium Abundance Spacelab Experiment, 1297, 1407

CHAWS-LD (Charging Hazards and Wake Studies - Long Duration experiment), 1150

CHE = Cosmic Ray & Solar flare Isotopes Investigation, 925

CHEM = Charge-Energy-Mass Spectrometer, 875

Chemiluminescent Sensors
FOZAN, 1554
NCARNOX, 1745
NO/NOy Instrument, 1673
OS-AP-M, 1573
UMMCI, 1824

CHIPS (Cosmic Hot Interstellar Plasma Spectrometer), 1144

CHOPPY = Chopped Pyrgeometer, 1599, 1843, 1857

CHRIS (Compact High Resolution Imaging Spectrometer), 1096

CHRISS = Compact High Resolution Imaging Spectrograph Sensor, 23, 1513, 1600

CID (Cold Ion Detector), 1113

CIOP (CLOUDS Integrated Optical Payload), 185

CIRIR (Clouds InfraRed Imaging Radiometer), 187

CIRRIS (Cryogenic Infrared Radiance Instrumentation for Shuttle), 824

CIS = Chinese Imaging Spectrometer, 23, 1596

CIS = Cluster Ion Spectrometer, 885

CIV (Critical Ionization Velocity), 1009

CIWSIR (Cloud Ice and Water-vapor Sub-mm Imaging Radiometer), 189

CLAES = Cryogenic Limb Array Etalon Spectrometer, 259

CLAPMIR (Cloud Liquid-water And Precipitation Microwave Imaging Radiometer), 190

CIO/BrO Instrument, 1671, 1763, 1850, 1895

CIONO2 Instrument, 1673, 1763

CLS (Cloud Lidar System), 1586, 1856

CLS (Color Line Scanner), 1581

CLT (Cross Link Transceiver), 91

CMIS (Conical-scanning Microwave Imager/Sounder), 197, 716

CMOS Video Camera, 546

CNC = Condensation Nucleus Counter, 1601

CO2 Instrument, 1673, 1763, 1913

CODIF = Composition and Distribution Functions analyzer, 885

COHU 5560 Low Light Camera, 1541

COIS (Coastal Ocean Imaging Spectrometer), 17, 21, 22, 25, 465, 1072

Collector Arrays, 911

Color Video Camera, 1192

Complex ASPI = Analysis of Plasma Spectra Instabilities, 929

COPAS = Condensation Particle Detection System, 1555

COR1 (Coronagraph1 Imager), 967

COR2 (Coronagraph2 Imager), 967

CORALL = Wide-Range 3-D Ion Spectrometer, 929

COSPAS = Space System for the Search of Distressed Vessels, 811

COSPIN = Cosmic-ray and Solar Particle Investigation, 975

CPC (Condensation Particle Counter), 1574

CPE (Communications Payload/Experiment), 1043

CPE (Cosmic Particle Experiment), 534

CPE = Charged Particle Experiment, 599

CPI = Comprehensive Plasma Investigation, 915

CPL (Capillary Pumped Loop), 210

CPLM (Column of Liquid Bridge in Microgravity), 1054

CPME = Charged Particle Measurement Experiment, 925

CPR (Cloud Profiling Radar), 193

CPV (Common Pressure Vessel type battery), 1047

CQCM (Cryogenically-cooled Quartz Crystal Microbalance), 1064

CRE = Cosmic Ray Experiment, 535, 538, 553

CREDO (Cosmic Radiation Environment and Dosimetry Experiment), 534

CREDO-II (Cosmic Radiation Environment and Dosimetry Experiment), 1114

CRESPO (Coral Reef Ecosystem Spectro-Photometric Observatory), 986

CrIS (Cross-Track Infrared Sounder), 710, 717

CRIS = Cosmic Ray Isotope Spectrometer, 864

CRISTA = Cryogenic Infrared Spectrometer and Telescopes for the Atmosphere, 816

CRL Radar/Radiometer, 1602

CRL-SAR (Communications Research Laboratory - SAR), 1766

CSD (Commercial Semiconductor Device), 1046

CSE (Cryo System Experiment), 61, 1238

CSS (Closed-Source Neutral Mass Spectrometer), 178

CTS (Chirp-Transform Spectrometer), 1817

CUBIC (Cosmic Unresolved X-Ray Background Instrument using CCDs), 942

CVI = Counterflow Virtual Impactor, 1555, 1605, 1843, 1888, 1914

CVSE (Cryocooler Vibration Suppression Experiment), 1114

CZCS = Coastal Zone Color Scanner, 383, 1086

further mention, 737, 1860

D

D2P (Delay/Doppler Phase-monopulse Radar), 562, 1608

DAIS-16115 (Digital Airborne Imaging Spectrometer), 23, 1666, 1669

DAIS-2815 (Digital Airborne Imaging Spectrometer), 23, 1667

DAIS-3715 (Digital Airborne Imaging Spectrometer), 23, 1670

DAIS-7915 (Digital Airborne Imaging Spectrometer), 23, 1668, 1892

DANI = Potential and Soft Particle Analyzer, 876

DAOCS (Drag, Attitude and Orbit Control System), 1067

DARMS (Digital Aerial Right-of-Way Monitoring System), 1620

DBI = Drag Balance Instrument, 233

DCIXS (Demonstration of a Compact Imaging Xray Spectrometer), 1107

DCS (Data Collection System), 1648, 1683

DCS = Data Collection System, 31, 311, 339, 352, 444, 613, 616, 625, 634, 635, 736, 737, 754

DDM (Deep Dose Monitor), 1117

DEBIE (DEBris In-orbit Evaluator), 1099

Deimos, 1620, 1866, 1892

Delta-2D = Scanning Microwave Radiometer, 475

Delta-K Spectrometer, 1689

DEP-2E = Electric Field Instrument, 876

DEP-2R = AC Field Analyzer, 876

Device 174 K = IR Spectrometer, 469, 697

DGS = Directional Gamma-ray Spectrometer, 1177

DIARAD (Differential Absolute Radiometer), 119, 959

DIDM (Digital Ion Drift Meter), 559

DIFOS = Solar Flux Optical Photometer, 891, 893

Digital Camera, 1165

DINA (Detector of Ions and Neutral Atoms), 1157

DIOGENESS = Diagnostic of Energy Sources and Sinks in Flares, 890, 893

DLTV = Day Light Television, 1542

DME = Soft Electron Detector, 867

DMSV (Digital Multi-Spectral Video), 1624

DO-SAR (Dornier SAR), 31, 1628

DOAS (Differential Optical Absorption Spectroscopy), 1518, 1624

DOAS-UV Czerny-Turner spectrograph, 1625

DOAS-VIS spectrograph, 1625

DOK-2A = Electron and Proton Experiment, 928

DOK-2X = Electron and Proton Experiment, 929

DOK-A-S = Silicon Detector Spectrometer, 869, 878

Doppler System GEOS-3, 572

DORIS = Doppler Orbitography and Radiopositioning Integrated by Satellite, One-Way Tracking System, 358, 519, 523, 592, 603

DPA (Deflection Plate Analyzer), 1153

DPA = Digital Photogrammetric Assembly, 1629

DPL = Doppler Shift Measurement, 900

DRA-SAR (Defense Research Agency SAR), 31, 1631

DSPE (Digital Signal Processing Experiment), 552

DSPE = Digital Signal Processing Experiment, 431, 536, 538, 546

DTE = Data Transfer Experiment, 540

Dual Polarized 37 GHz Radiometer, 1632

Dual Vidicon Cameras, 1019

DUST = Dust Experiment, 976

DUTSCAT = DUT Airborne Radar Scatterometer, 1633

DWP = Digital Wave Processor, 885

E

E-SAR (Experimental SAR), 31, 1653, 1866

E-SLAR (Experimental Side-Looking Airborne Radar), 1654

EarthKAM (Earth Knowledge Acquired by Middle school students), 997

Earthwatch Imager, 456

EBM = EarlyBird Multispectra, 277

EBP = EarlyBird Panchromatic, 277

ECOC (Electrochemical Ozone Cell), 1552

ECP (Experimental Communication Payload), 500

ECSE (Encrypted CCSDS Space Experiment), 1119

EdEx = Educational Experiment, 540

EDI = Electron Drift Instrument, 885, 897

EDOP (ER-2 Doppler Radar), 1633, 1854, 1917

EFD = Electric Field Detector, 901, 915

EFF (Enhanced Formation Flying), 1032

EFI = Electric Field Experiment, 936

EFI = Electric Field Instrument, 234

EFLPI = Electric Field / Langmuir Probe Instrument, 948

EFW = Electric Fields and Waves, 883

EGG (Electrostatic Gravity Gradiometer), 129, 130, 579

EGNOS (European Geostationary Navigation Overlay Service), 1017

EGS = Echelle Grating Spectrometer, 1541

EHIC = Energetic Heavy Ion Composition, 741

EIC (Earth Imaging Camera), 347, 1190

EICS = Energetic Ion Mass Spectrometer, 203

EIS (EUV Imaging Spectrometer), 963

EIS = Earth Imaging System, 535, 537, 540, 546

EIT = Extreme UV Imaging Telescope, 957, 967

EITA (Electron-bombardment Ion Thruster Assembly), 1016, 1288

ELDORA (ELectra DOppler Radar), 1635, 1917, 1919

ELECTRON = 3-D Electron Distribution Function, 928

Electron Spectrometer (EXOS-A), 899

Electron Temperature and Density, 175

Electron Temperature Probe (Exos-C), 901

ELECTRON-5 (Charged Particle Spectrometer), 895

ELFWA = Extremely Low Frequency Wave Analyzer, 202

EMIL = Electron Measurements, In-situ and Lightweight, 879

EMIRAD = Electromagnetics Institute Radiometer, 1637, 1892

EMISAR = Electromagnetics Institute SAR, 31, 1638, 1866, 1891, 1892

EMITS (Electric Microthruster Test in Space), 1286

EMMA (Electrical and Magnetic field Monitoring of the Aurora), 881

ENAP (Energetic Neutral Atom Precipitation), 823

Energy Spectrum Analyzer (Exos-C), 901

EOC (Electro-Optical Camera), 17, 437

EOS (Opto-Electronic Scanner), 18, 1639

EPAC = Energetic Particle Composition Experiment, 976

EPACT = Energetic Particles Acceleration, Composition, and Transport, 982

EPAM = Electron, Proton, and Alpha-particle Monitor, 864

EPAS = Electron and Proton Wide-Angle Spectrometer, 202

EPDM (Electric Propulsion Demonstrator Module), 96, 1289

EPDP (Electric Propulsion Diagnostic Package), 1107

EPE = Energetic Particle Experiment, 925

EPI = Energetic Particle Instrument, 897

EPIC (Earth Polychromatic Imaging Camera), 251

EPIC = Energetic Particle and Ion Composition Experiment, 915

EPIC = Energetic Particles and Ion Composition Experiment, 202

EPS (Electric Propulsion System), 544

EPS = Energetic Particle Sensor, 620

EPV (Ensemble de Prise de Vues), 1427

ERASME = Etude Radar des Sols et des Mers, 1641

ERB = Earth Radiation Budget, 737, 1084, 1087

ERBE = Earth Radiation Budget Experiment, 205, 737, 739, 743, 1676

ERIP (Earth Remote-Sensing Imaging Package), 1183

ESA = Quadrispherical Electrostatic Electron Analyzer, 947

ESC = Electronic Still Camera (Shuttle), 854

ESEX (Electric Propulsion Space Experiment), 96, 1009, 1289

ESMR (Electrically Scanning Microwave Radiometer), 737, 1083, 1084, 1246, 1655, 1845, 1917

ESMR = Electronic Scanning Microwave Radiometer, 737

ESP = Charged Particle Detectors, 900

ESR (Enhanced Surveillance Radar), 1632

ESTAR = Electronically Steered Thinned Array Radiometer, 1656, 1722, 1917, 1919

ESUM (Extreme Solar UV Monitor), 177

ETB (Electronics TestBed), 1120

ETB (Engineering Test Bed), 1137

ETM = Enhanced Thematic Mapper (LS-6), 446

ETM+ = Enhanced Thematic Mapper Plus, 16, 21, 26, 54, 91, 158, 448

ETP (Electron Temperature Probe), 434

ETRV (Experiencia Tecnológica de un Regulador de Velocidad - Speed Regulator Technological Demonstrator), 1055

EURD (Espectrógrafo Ultravioleta extremo para la observación de la Radia-

ción Difusa - Extreme UV Spectrograph for the Study of Diffuse Radiation), 1054

EUTEF (European Technology Exposure Facility), 987

EUV (Extreme Ultraviolet Imager), 922

EUV (Extreme Ultraviolet), 816

EUV-PHOKA (EUV Photocathode Experiment), 895

EUVI (Extreme Ultraviolet Imager), 967

EUVIP (Extreme Ultraviolet Imaging Photometer), 1007

EUVS (Solar EUV Spectrometer), 177

EXES (Echelon-Cross-Echelle Spectrograph), 1805

F

F1: Electric Field Experiment (Freja), 905

F2: Magnetic Field Experiment (Freja), 905

F3C: Particles Experiment - Cold Plasma, 906

F3H: Particles Experiment - Hot Plasma, 907

F4: Waves Experiment (Freja), 907

F5: Auroral Imager (Freja), 907

F6: Electron Beam Experiment (Freja), 908

F7: Particle Correlator Experiment (Freja), 908

FAST (Frequency-modulated Absorption Spectroscopy by Tunable diode lasers), 54, 1658, 1913, 1914

FAUST = Far Ultraviolet Space Telescope, 823

FCS = Flat-Crystal Spectrometer, 954

FDS = Photometer, 869

FEEP (Field Emission Electric Propulsion), 1285

FFI (Fine Field Imager), 1800, 1801

FGM = Fluxgate Magnetometer, 883

FGM/VHM = Fluxgate Magnetometer/Vector Helium Magnetometer, 976

FGM-1 = 3-D Magnetic Field, 930

FIFILS (Field-Imaging Far-Infrared Line Spectrometer), 1803

FIMS (FUV Imaging Spectrograph), 435

FIPEX (Flux Probe Experiment), 1121

FIRS-2 (Far Infrared Spectrometer), 53, 1658

FIRSC (Far Infrared Sensor for Cirrus), 40, 1660

FIS (Fuego Imager Suite), 806

FISH (Fast In-Situ Stratospheric Hygrometer), 1661, 1914

FLASH = FOA Laser Airborne Sounder for Hydrography, 1661

FLI = Fluorescence Line Imager, 23, 1592, 1662

FLIR (Forward Looking Infrared) camera, 1542

FLITECAM (First Light Infrared Test Experiment Camera), 1807

FluxRad (Fluxmeter Radiometer), 211

FM-3K (Fluxgate Magnetometer), 196

FOCUS (Fire Detection and Analysis Sensor System), 987

FODB (Fiber Optic Data Bus), 1031

FOG (Fiber-Optic Gyro), 134

FOLPEN = Foliage Penetration VHF Impulse SAR, 31, 1663

FORCAST (Faint Object infraRed Camera for the SOFIA Telescope), 1807

FOZAN = Fast Ozone Analyzer, 1554

FPI (Focal Plane Imager), 1800, 1801

FPI = Fabry-Perot Interferometer, 204

FPR = Flat Plate Radiometer, 737

Frecopa = French Cooperative Payload, 833

FRP (Flat Plate Radiometer), 728, 729, 730, 731

FSSP-100 (Forward Scattering Spectrometer Probe), 1769

FSSP-300 (Forward Scattering Spectrometer Probe), 1549

FTHSI = Fourier Transform HyperSpectral Imager, 22, 54, 1050

FTS = Fourier Transform Spectrometer, 40, 43, 48, 52, 53, 1756

FTVHSI (Fourier Transform Visible Hyperspectral Imager), 23, 53, 1050, 1664

FUV (Far Ultraviolet Imager), 923
 FUV (Far Ultraviolet), 816
 FUVIS (Far UV Imaging Spectrograph), 845
 FWS (Filter Wedge Spectrometer), 1082
 FXM (Fast X-ray Monitor, MEPhI), 894

G

GADACS (GPS Attitude Determination and Control System), 786, 846
 GADFLY (GPS Attitude Determination Flyer), 452, 455, 787
 GAF = DC Electric Fields Investigation, 924
 GAGE (GPS At GEO Experiment), 1117
 GAS = Interstellar Neutral Gas Experiment, 976
 GASCOD = Gas Absorption Spectrometer Correlating Optical Differences, 1549
 Gemma = Spectrometer System, 998
 GEO/SAMS (Geostationary Synthetic Aperture Microwave Sounder), 42
 GEOS&R (Geostationary Search and Rescue), 157, 626, 813
 GER-63 = Airborne 63-channel Imaging Spectrometer, 1669
 GER-63 Channel Scanner, 23, 1669
 GERB (Geostationary Earth Radiation Budget), 119, 651
 GFSE (Gas Flow Sensor Experiment), 1118
 GHIS (Geostationary HIS), 1676
 GIFTS (Geosynchronous Imaging Fourier Transform Spectrometer), 10, 53, 1033
 GIMI (Global Imaging Monitor of the Ionosphere), 1011
 GISSMO (Gas Ionization Solar Spectral Monitor), 1175
 GIT-12T (GLONASS/GPS Receiver System), 196
 GLAS (Geoscience Laser Altimeter System), 412
 GLI = Global Imager, 48, 337

GLRS = Geoscience Laser Ranging System, 412
 GME = Solar and Cosmic Ray Particles Investigation, 925
 GNF = Magnetic Fields Experiment, 924
 GNS (GPS Navigation System), 242
 GOES Imager = Visible and Infrared Radiometer (NOAA), 622
 GOES SOUNDER = Infrared Sounder (NOAA), 623
 GOLF = Global Oscillations at Low Frequencies, 959
 GOLPE (GPS Occultation and Passive reflection Experiment), 140, 507
 GOME = Global Ozone Monitoring Experiment, 407, 1817, 1861
 GOME-2 (Global Ozone Monitoring Experiment-2), 685
 GOMOS = Global Ozone Monitoring by Occultation of Stars, 47, 367
 further considerations of GOMOS, 358
 GPR = Ground Penetrating Radar, 1664
 GPS Receiver, 1126
 GPS receiver, 898
 GPS Tensor, 786
 GPS/MET = GPS Meteorology, 300, 556, 592, 784
 GPSDR = GPS Demonstration Receiver, 603
 GPSOS (GPS Occultation Sensor), 719
 GRaBS (Gamma Ray Burst Spectrometer), 942
 GRAS (GNSS Receiver for Atmospheric Sounding), 46, 153, 166, 681, 686, 688, 719, 754
 GRB = Gamma-Ray Burst Experiment, 977
 GREAT (German Receiver for Astronomy at Terahertz Frequencies), 1803
 Greben = Precision Radar Altimeter (CIS), 1000
 GRILLE = Infrared Spectrometer, 853
 GRS = Gamma-Ray Spectrometer, 952, 953
 GUVI = Global Ultraviolet Imager, 245
 GWE = Gravitational Wave Experiment, 977

GXRE (Goddard X-Ray Experiment),
942

H

H₂O Instrument, 1671, 1913

H₂O-DIAL = Water Vapor Differential
Absorption Lidar, 1622, 1857, 1858,
1864

HALOE = Halogen Occultation Experi-
ment, 260, 1861

HAPI = High Altitude Plasma Instru-
ment, 203

Hasselblad 500 ELX = Shuttle EO cam-
era, 855

Hasselblad 500-EL = MIR camera, 998

HAWC (High-resolution Airborne Wide-
bandwidth Camera), 1808

Hawk Eye, 1662

HB = Heat Budget Instrument, 737

HCMR = Heat Capacity Mapping Radi-
ometer, 220

HELICON = Solar X-ray and Gamma-
ray Scintillation Spectrometer, 890,
893

HELISCAT = Helicopter Scatterometer,
1673, 1900

HENA (High-Energy Neutral-Atom
Imager), 922, 972

HEP = High Energy Particles Experi-
ment, 915

HEPAD = High Energy Proton and Al-
pha Particle Detector, 620, 735, 737,
744

HEPD (High Energy Particle Detector),
438

HEPS (Charged particle spectrometer),
261

HEPT (High Energy Particle Telescope),
433

HESSI (High Energy Solar Spectroscopic
Imager), 917

HET (High Energy Telescope), 970

HF Receiver, 1126

HI (Heliospheric Imager), 967

HI-SCALE = Heliosphere Instrument for
Spectra Composition and Anisotropy
at Low Energies, 977

HIA = Hot Ion Analyzer, 885

High-Volume Sampler with Normal Pres-
sure Impactor, 1518

HILT = Heavy Ion Large Telescope, 946

HIP (Heterojunction Internal Photoemis-
sion) Infrared Sensors, 1115

HIRAAS (High-Resolution Airglow/Au-
rora Spectroscopy), 1009

HIRAASS = High Resolution Airborne
Autotracking Sun Spectrometer, 1764,
1819

HIRDLS (High-Resolution Dynamics
Limb Sounder), 376, 391

HIROC (High Resolution Optical Cam-
era), 1133

HIRS = High Resolution Infrared Radi-
ation Sounder, 742
further consideration, 737, 1085
further mention, 383, 1676, 1846, 1864,
1905

HIRS/3 = High Resolution Infrared
Sounder, 681, 747

HIRS/4 (High Resolution Infrared Sound-
er), 748

HIS (High-Resolution Interferometer
Sounder), 53, 1033, 1674, 1850, 1854,
1855, 1870

HITS (High Resolution Ionospheric/
Thermospheric Spectrograph), 1010

HONER (Hemispherical Optimized Net-
flux Radiometer), 1627, 1764

HOPI (High-speed Occultation Photome-
ter and Imager), 1804

HPCE (High Performance Computer Ex-
periment), 1045

HPCE = Hot Plasma Composition Ex-
periment (CCE), 875

HPHET (High-Power Hall-Effect Thrust-
er), 1290

HRC (High Resolution Camera), 1100

HRCC (High Resolution CCD Camera),
17, 350

HRDI = High Resolution Doppler Imag-
er, 261

HRG (High Resolution Geometric), 17,
526

HRI (High Resolution Imager), 433, 1179
 HRIR (High-Resolution Infrared Radiometer), 737, 1077, 1078
 HRMSI = High-Resolution Multispectral Stereo Imager, 449
 HRS (High Resolution Stereoscopic), 17, 527
 HRSC (High Resolution Stereo Camera, 1829
 HRTC (High-Resolution Technological Camera), 505
 HRTS = High Resolution Telescope and Spectrograph, 1297, 1428
 HRV = High Resolution Visible (Sensor), 16, 517, 1310, 1855, 1869, 1877, 1890
 HRVIR = High Resolution Visible and Infrared (sensor), 16, 521
 HSB (Humidity Sounder for Brazil), 388
 HSC (High Sensitivity Camera), 505
 HSI (Hyper-Spectral Imager), 453
 HSRS (Hot Spot Recognition Sensor), 801
 HTSSE-II (High Temperature Superconducting Space Experiment II), 63, 1006
 HUTRAD (Helsinki University of Technology Radiometer), 1678, 1866
 HUTSCAT = Helsinki University of Technology Scatterometer, 1680
 HUTSLAR (HUT Side-Looking Airborne Radar), 1681
 HXIS = Hard X-Ray Imaging Spectrometer, 954
 HXR = Hard X-Ray spectrometer, 1177
 HXRBS = Hard X-Ray Burst Spectrometer, 953
 HXRS (Hard X-Ray Spectrometer), 462
 HXRS (Hard X-Ray Spectrometer), 942
 HXT = Hard X-Ray Telescope, 960
 HYDICE = Hyperspectral Digital Imagery Collection Experiment, 24, 1683
 HYDRA = Hot Plasma Analyzer Experiment, 937
 HYPERBOLOID = Ion Mass Analyzer, 928
 Hyperion, 1029

IALFS = Imaging Airborne Laser Fluoresensor System, 1701
 IAP (Instrument Analyseur de Plasma), 1066
 IASI = Improved Atmospheric Sounder Interferometer, 681, 684
 ICARE (Influence of Space Radiation on Advanced Components), 507
 ICE (Instrument Champ Electrique), 1066
 ICI = Ion Composition Instrument, 898
 IDICS (Image Dissector Camera System), 737, 1079, 1080
 IDM = Ion Drift Meter, 204
 IEF = Impedance and Electric Field Measurement, 900
 IES (Imaging Electron Sensor), 938
 IESP-2 = Electric Field and Intensity Experiment, 927
 IFPE = Investigations of Fluctuations of Protons and Electrons, 929
 IFSAR = Interferometric SAR, 31, 1686
 IFSARE = Interferometric SAR for digital terrain Elevation data, 31, 1650
 IIR (Imaging Infrared Radiometer), 208
 IKAR-D = MW radiometer, D=scanning (CIS), 478, 486, 1000
 IKAR-D2 = Passive Microwave Radiometer (Delta), 1774
 IKAR-P = MW scanning Radiometer - Panorama (CIS), 478, 486, 1000
 IKAR-P = Passive Trace Microwave Radiometers RP-225 and RP600, 1774
 IKAR=N = Apparatus of 5 Scanning Radiometers- Nadir (CIS), 479, 486, 1000
 IKFS-2 (Infrared Fourier Spectrometer-2), 703
 IKIRAD (IKI Radiometer), 1689
 ILAS = Improved Limb Atmospheric Spectrometer, 334
 ILAS-II = Improved Limb Atmospheric Spectrometer-II, 338
 Imaging Radars (active devices)
 AMI (ERS-1,-2), 400, 407
 ASAR (Envisat-1), 265, 272, 293, 296, 342, 358, 363, 861

PR (TRMM), 255
 RLSBO (Okean), 470, 473
 SAR (Almaz-1), 346
 SAR (Cosmos-1870), 344
 SAR (JERS-1), 428
 SAR (Radarsat), 488, 491
 SAR (Seasat), 509
 SAR (SIR-A), 848
 SAR (SIR-B), 849
 SAR (SIR-C, X-SAR), 850
 SAR Travers (Priroda module on Mir), 479, 486, 1000
 IMAPS (Interstellar Medium Profile Spectrometer), 816
 IMARC = Imaging Multifrequency Airborne Radar Complex, 31, 1822
 IMG = Interferometric Monitor for Greenhouse Gases, 333
 IMPACT (In-situ Measurements of Particles and CME Transients), 968
 IMS (Ion Mass Spectrometer), 1063
 IMS (Ionosphere Measurement Sensor), 438
 IMS-HI = Ion Mass Spectrometer - High/Medium Energy, 202
 IMS-LO = Ion Mass Spectrometer - Low Energy, 202
 IMSC (Instrument Magnetometre Search Coil), 1065
 INES (Italian Navigation Experiment), 507
 Infrared Radiometer, 944
 INGARA = Australian Airborne Imaging Radar System, 31, 1690
 IOE = Low Energy Particles Investigation, 924
 IOF = AC Electric and Magnetic Fields Experiment, 924
 ION = Ion Spectra Experiment, 927
 Ion Mass Spectrometer (EXOS-A), 899
 IONDS (Integrated Operational Nuclear Detection), 776
 Ionospheric Plasma Probes (EXOS-A), 899
 IOX (Ionospheric Occultation Experiment), 1094
 IPD (Instrument Detecteur de Plasma), 1065
 IPEI (Ionospheric Plasma and Electrodynamics Instrument), 500
 IPEX-II (Interferometry Program Experiment 2), 820
 IPIP = IRM Plasma Instrument Package, 874
 IPP (Ion Propulsion Package), 1016
 IPS (Imaging Proton Sensor), 938
 IPS (Instrument Pointing System), 1378
 IPS (Ion Propulsion System), 69, 1021, 1284
 IR = TV IR instrument, 695, 700
 IR = TV IR instrument Lastocha, 693
 IR Solar Spectrometer (EXOS-C), 901
 IR/UV (Infrared/Ultraviolet System), 1611, 1733
 IRCAM (Infrared Camera), 353
 IREX (Infrared Experiment), 431
 IRI = Infrared Imager, 1775
 IRIS (International Retrieval of Information via Satellite), 314
 IRIS = Infrared Interferometer Spectrometer, 80, 737, 1079, 1081
 IRIS = Solar Burst Spectrometer, 891, 893
 IRLS (Infrared Line Scanner), 1581
 IRLS (Interrogation, Recording, and Location System), 737, 1079, 1082
 IRMSS (Infrared Multispectral Scanner), 17, 351
 IRP = Infrared Passive, 737
 IRR = Infrared (Imaging) Radiometer (part of ATSR), 403
 IRR = Infrared Radiometer (Meteor, also known by the name of SM), 700
 IRT = Infrared Telescope, 1297
 ISAAC (Ionospheric Spectroscopy & Atmospheric Chemistry spectrograph), 1011
 ISAMS = Improved Stratospheric and Mesospheric Sounder, 260
 ISEE-1 and -2 Sensors
 ANM/AND = Electrons & Protons Instrument, 931

- BAM/PAD = Fast Plasma Experiment, 931
- FRM/FRD = Low Energy Protons & Electrons, 931
- GUM/GUD = Plasma Wave Investigation, 931
- RUM/RUD = Fluxgate Magnetometer Experiment, 932
- WIM/KED = Medium Energy Particles Experiment, 933
- ISEE-1 Sensors
- HAM = Plasma Density Experiment, 932
- HEM = VLF Wave Propagation Experiment, 932
- HOM = Low Energy Cosmic Ray Experiment, 932
- HPM = DC Electric Field Experiment, 932
- MOM = Quasi-Static Electric Field Experiment, 932
- OGM = Fast Electron Spectrometer Experiment, 933
- SHM = Ion Composition Experiment, 933
- ISEE-2 Sensors, EGD = Solar Wind Ion Experiment, 932
- ISEE-3 Sensors
- ANH = X-Rays and Electrons Instrument, 934
- BAH = Solar Wind Plasma Experiment, 934
- DFH = Low Energy Proton Experiment, 935
- HKH = High Energy Cosmic Ray Experiment, 934
- HOH = Low Energy Cosmic Ray Experiment, 935
- MEH = Cosmic Ray Electrons and Nuclei, 935
- OGH = Plasma Composition Experiment, 935
- SBH = Radio Mapping Experiment, 935
- SCH = Plasma Wave Experiment, 935
- SMH = Helium Vector Magnetometer, 935
- STH = Heavy Isotope Spectrometer Telescope, 935
- TYH = Medium Energy Cosmic Ray Experiment, 936
- ISENA = Imaging Spectrometer for Energetic Neutral Atoms, 942
- ISIR (Infrared Spectral Imaging Radiometer), 829
- ISL (Instrument Sonde de Langmuir), 1066
- ISM = Infrared Imaging Spectrometer, 1691
- ISM = Infrared Spectro-Imager, 24
- ISO = Imaging Spectrometric Observatory, 823
- ISP-2 (Izmeritel Solnechnoy Postoyanoy-2), 119, 497
- ISSC (Improved Standard Spacecraft Cryocooler), 74, 1238
- IST (Italian Star Tracker), 506
- ISTOK-1 = IR Spectroradiometric System (CIS), 480, 1001
- ISUAL (Imager of Sprite Upper Atmospheric Lightning), 124, 503
- ITPR (Infrared Temperature Profile Radiometer), 1082
- ITPR = Infrared Temperature Profile Radiometer, 737
- ITS-7D = IR Telescope Spectrometer (MIR), 1001
- IVI = Ion Velocity Instrument, 234
- ## J
- JAMI (Japanese Advanced Meteorological Imager), 115, 658
- JMR (Jason Microwave Radiometer), 592
- ## K
- K-band Dual-frequency Atmospheric Radiometer, 1689
- KAP-350 = Space Camera for Remote Sensing, 998, 1000
- KaTE (X/Ka-band TT&C Experiment), 1107
- KATE-140 = Camera System, 1002
- KBR (K-Band Ranging), 589
- KEM-1 = Magnetic and Electric Field Analyzer, 868, 877
- KF/KR (Krypton Flashlamp/Radiometer), 1064

KFA-1000 Camera System, 494, 998
 KFA-200 Camera System, 493, 494
 KGI-4S (Radiation Monitoring System), 704
 KL-103 W = Klest (Crossbill name of a bird), MIR, 1000
 Klimat = Infrared Radiometer, 697, 700
 KM-10 = Cold Plasma Measurements, 876
 KM-12 = Cold Plasma Analyzer, 868, 877
 KM-6 = Cold Plasma Analyzer, 867
 KM-7 = Cold Plasma Experiment, 928
 Kondor = DCPs data collector and transmitter, 471
 KONUS = Gamma Ray Burst Investigation, 982

L

LAC (LEISA Atmospheric Corrector), 1030
 LAC = Large Area Collector, 1695
 LAGRANGE (Laben GNSS Receiver for Advanced Navigation, Geodesy, and Experiments), 507
 LANG = Langmuir Probe, 204
 Langmuir Probe, 174, 724
 LAP = Los Alamos Plasma Experiment, 924
 LAPI = Low Altitude Plasma Instrument, 204
 LARSEN = Airborne Scanning Lidar, 1696, 1882
 LAS=Limb Scanning Spectrometer, 334, 901
 LASAL (Large Aperture Scanning Airborne Lidar), 1696, 1882
 LASCO = Large-Angle and Spectrometric Coronagraph, 957, 967
 LASE = Lidar Atmospheric Sensing Experiment, 1697, 1882, 1886, 1918
 Laser Reflector Package, 603
 Laser Tracking Reflector, 511, 569, 572
 Lasercom (Laser Communication Experiment), 58, 1136

LASSII = Low-Altitude Satellite Studies of Ionosphere Irregularities, 201
 LASSOR (Los Alamos Solid-State Optical Refrigerator), 1239
 LAWS = Laser Atmospheric Wind Sounder, 43, 1255
 LCDE (Laser Communications Demonstration Equipment), 989
 LCE (Laser Communication Equipment), 58
 LCE (Linear Concentrator Experiment), 1118
 LDE (Lightning Detection Experiment), 60
 LEAF = Laser Environmental Airborne Fluorosensor, 1698
 LEANDRE (Lidar Embarqué Aerosols Nuages Dynamique Rayonnement Environment), 1699, 1865, 1867, 1896
 LEE (Low-Energy Electron Experiment), 179
 LEED (Low Energy Electron Detector), 431
 LEGRI (Low Energy Gamma Ray Imager), 1055
 Leica RC30 (Aerial Camera System), 1539, 1702, 1739
 LEISA = Linear Etalon Imaging Spectrometer Array, 453
 LENA (Low-Energy Neutral-Atom Imager), 920, 972
 LEP = Low Energy Particle Detectors, 903
 LEP = Low Energy Particles Experiment, 915
 LET (Low Energy Telescope), 970
 LFC = Large Format Camera, 833
 LFR (Lower Fuselage Radar), 1751, 1860, 1912
 LFS = Laser Fluorosensor, 1700, 1847
 LFSA (Lightweight Flexible Solar Array), 1031
 Lidar, 208
 Lidar Systems (active laser systems)
 ABLE (U. of Rome), 1550
 ALAS (NASA/GSFC), 1531
 ALEX (DLR), 1621

- LPI 80 (Low-Pressure Impactor), 1518
- LRA (Laser Corner-cube Reflector Assembly), 590
- LRA (Laser Retroreflector Array), 593
- LRIR (Long-Range Imaging Radar), 30
- LRIR = Limb Radiance Infrared Radiometer, 737, 1085
- LRR = Laser Retro Reflector, 358, 367, 403, 558, 580
- LSAR (L-band SAR instrument), 30, 296
- LSC (Line Scan Camera), 1581
- LUCE (Laser Utilizing Communications Equipment), 58, 1091
- ## M
- M-5 (Michigan-5 Imager), 1642
- M-7 (Mapper Multispectral Testbed), 1643
- M2M (Makrel-2 Modified), 1791
- MACAWS (Multi-Center Airborne Coherent Atmospheric Wind Sensor), 1706

MACE (Middeck Active Control Experiment), 1378
 MACEK (Mikroakcelerometr), 129, 597
 MADRAS (Microwave Analysis & Detection of Rain & Atmospheric Structures), 222
 MAE = Ion and Electron Investigation, 925
 MAESTRO (Measurement of Aerosol Extinction in the Stratosphere and Troposphere Retrieved by Occultation), 236
 MAG = Magnetic Field Monitor, 865
 MAG-1 = Magnetometer on DE-1, 203
 MAG-2 = Magnetometer on DE-2, 204
 Magnetometer, 571
 Magnetometer (CCE), 875
 Magnetometer (IRM), 874
 Magnetometer (UKS), 875
 Magnetometer of SEM package, 620
 Magnetometer Testbed, 1160
 MAHRSI = Middle Atmospheric High Resolution Spectrograph Investigation, 818, 820
 MAIS (Modular Airborne Imaging Spectrometer), 1597
 MAKREL-2 Lidar, 1789
 MAL (Micro-Joule Airborne Lidar), 1551
 MAM (Magnetic Field Instrument), 897
 MAMS = Multispectral Atmospheric Mapping Sensor, 1707, 1854, 1855
 MAP = Multiple-Foil Micro-Abrasion Package, 833
 MAP = Solar Plasma Faraday Cup Experiment, 925
 MAPLE-1 (Microsystem and Packaging for Low Power Electronics), 1048
 MAPS (Charged particle spectrometer), 261
 MAPS (Measurement of Air Pollution from Satellites), 835, 853, 1298
 MARA = Multimode Airborne Radar Altimeter, 1708, 1915, 1917
 MARSS (Microwave Airborne Radiometer Scanning System), 1709, 1850, 1866, 1869, 1892
 MAS (Multiwavelength Aerosol Scatterometer), 1548
 MAS = Millimeter-Wave Atmospheric Sounder, 821, 1246, 1298, 1543
 MAS = MODIS Airborne Simulator, 24, 1617, 1847, 1848, 1850, 1853, 1854, 1856, 1870, 1886, 1901, 1902, 1919
 MASP = Multiangle Aerosol Spectrometer Probe, 1710, 1843, 1850, 1895, 1918
 MAST = Mass Spectrometer Telescope, 946
 MAVIR (Multi-Angle VIS Imaging Radiometer), 188
 MAXIE = Magnetospheric Atmospheric X-Ray Imaging Experiment, 740
 MBLA (Multi-Beam Laser Altimeter), 530
 MCR = Multispectral Cloud Radiometer, 1713, 1850
 MDC (Munich Dust Counter), 1142
 MDIM (Meteoroid and Debris Impact Monitor), 1137
 MEDUSA (Miniaturized Electrostatic Dual-tophat Spherical Analyzer), 881, 1157
 MEIS (Metrological Earth Imaging System), 552
 MEIS (Multispectral Earth Imaging System), 433, 551
 MEIS = Multi-detector Electro-optical Imaging Sensor, 1714
 MEMO = Analyzer of Magnetic Waves, 927
 MENA (Medium-Energy Neutral-Atom Imager), 921, 972
 MEOSS = Monocular Electro-Optical Scanner, 417
 MEPA = Medium Energy Particle Analyzer (CCE), 875
 MEPED = Medium Energy Proton and Electron Detector, 735, 737, 744, 752
 MERES = Multifrequency Radiometer for Remote Sensing of the Sea Surface, 1715
 MERIS = Medium Resolution Imaging Spectrometer, further consideration, 358, 1309

Merlion Communications Package, 544
 MESA (Miniature Electrostatic Analyzer), 176
 MESSR = Multispectral Electronic Self-Scanning Radiometer, 459
 Metric Camera, 853
 MFCBS (Multi-Functional Composite Bus Structure), 1052
 MFE = Magnetic Field Experiment, 936
 MFI = Magnetic Field Investigation, 981
 MFI = Magnetic Fields Instrument, 949, 1044
 MGF = Magnetic Field Detector, 900, 902
 MGF = Magnetic Field Experiment, 915
 MHS = Microwave Humidity Sounder , 681, 683, 751
 MIAS (Magnetometer Instrument Assembly System), 558
 MICAS (Miniature Integrated Camera Spectrometer), 20, 1022
 Microlidar, 1623
 MicroMAPS (Micro-Measurement of Air Pollution from Satellites), 456
 Micrometeorite Impact Detector, 1192
 Microwave Radiometers (passive devices), overview on, 1246
 AMSU = Advanced MSU, 747
 ATSR = Along-Track Scanning Radiometer and MW Sounder, 403, 407
 IKAR-D = Scanning MW Radiometer, 478, 1000
 IKAR-N = MW Radiometers (5), 479, 1000
 IKAR-P = Panorama Scanning MW Radiometer, 478, 1000
 MAS = Millimeter-Wave Atmospheric Sounder, 821
 MLS = Microwave Limb Sounder, 392
 MLS = MW Limb Sounder, 260
 MSR = MW Scanning Radiometer, 459
 MSU = Microwave Sounding Unit, 743
 NEMS = Nimbus E MW Spectrometer, 737, 1083
 R-400 = Polarization Scanner MW Radiometer, 479
 RM-08 = Passive Microwave Radiometer, 470
 SMMR = Scanning Multichannel MW Radiometer, 510, 1089
 SMR = Submillimeterwave Radiometer, 223
 SSM/I = Microwave Imager Radiometer, 665
 TMI = TRMM MW Imager, 257
 TMR = Topex MW Radiometer, 602
 MIF-M = Multicomponent Investigations of Fluctuations of the Magnetic Field, 929
 MIMR = Multi-frequency Imaging Microwave Radiometer, 1773
 MIMR = Multifrequency Imaging Microwave Radiometer, 1679
 MIMS (Magnetic Ion-Mass Spectrometer), 179
 MINISCAT, 1682
 Minitrack System, 570, 571
 MIO = Miniature Imaging Optics, 880
 MIPAS = Michelson Interferometer for Passive Atmospheric Sounding, 358, 360, 1309, 1716
 MIPAS-B (MIPAS Balloon), 53, 1717, 1863
 MIPAS-B2, 53, 1718
 MIPAS-FT (Flugzeug Transall), 53, 1518, 1625, 1719
 MIPAS-LM (Laboratory Model), 1717
 MIPAS-STR (MIPAS-STRATO), 53
 MIR (Millimeter-Wave Imaging Radiometer), 1720, 1854, 1917
 MIRACO2LAS (Mid-IR Airborne CO2 Laser Spectrometer), 1720
 MIRAS (Microwave Imaging Radiometer with Aperture Synthesis), 514, 1721
 MIRIAM = MIR Infrared Atmospheric Measurements, 483
 MIROR = Michelson Interferometer with Rotating Retroreflector, 53, 1723
 MIS (Meteoroid Impact Sensor), 1180
 MISI = Modular Imaging Spectrometer Instrument, 24, 1725
 MISR (Multi-angle Imaging SpectroRadiometer), 381
 MITE (Megapixel Imaging Technology Camera System), 1726
 MIVIS = Multispectral Infrared and Visible Spectrometer, 24, 1616

MK-4 = Four-Channel Camera System, 494
 MKF = Multispectral Camera, 1001, 1688
 MKF-6 (Multi-Kanal-Fotografie-6), 13
 MKF-6MA = Multispectral Space Camera (IKF), 1000
 MkIV (Mark-IV Interferometer), 53, 1727
 MKS-M = Multichannel Spectrometer, 998, 1001
 MKS-M = Passive Multichannel Trace Radiometer, 1774
 MLE (Mesoscale Lightning Experiment), 60
 MLS = Microwave Limb Sounder, 260, 392, 1861
 MMRS = Multispectral Medium Resolution Scanner, 505
 MMS = Meteorological Measurement System, 1728, 1850, 1907, 1913
 MMW-SAR (Millimeter Wave SAR), 31, 1729
 MNCH = Search-Coil Magnetometer, 877
 MOBY = Marine Optical Buoy, 1731
 Mode-A Transponder, 1167
 Mode-L Transponder, 1167
 Model 1000 camera system, 287
 MODIS (Moderate-Resolution Imaging Spectroradiometer), 377, 383, 386
 MOMS = Modular Optoelectronic Multispectral Scanner, 836
 further consideration, 837
 MOMS-2P (Modular Optoelectronic Multispectral/Stereo Scanner - 2 Priroda), 483
 MOMSNAV (MOMS Navigation), 485
 MONITOR-3 = Solar Wind Analyzer, 929
 MOPITT (Measurement of Pollution in the Troposphere), 385
 MOS = Multispectral Optoelectronic Scanner, 421, 481
 MOS-Obsor-A = Modular Optoelectronic Scanner, 1000
 MOS-P (Modular Optoelectronic Scanner - Priroda), 481
 MOZAIC (Measurement of Ozone by Airbus In-Service Aircraft), 1570
 MP-900M TV Camera, 498
 MPID (Micro-Particle Impact Detector), 1049
 MPIR = Multispectral Pushbroom Imaging Radiometer, 1625, 1764
 further mention, 1625, 1847
 MPS (Micro-Propulsion System), 549
 MPS SEA = Energetic Particle Spectrometer, 869, 878
 MR-2000 = TV Camera System, 696, 700
 MR-900B = TV Camera System (CIS), 696, 700
 MRIR = Medium Resolution Infrared Radiometer, 737, 1078
 MRSE = Microwave Remote Sensing Experiment, 853
 MSC (Multi-Spectral Camera), 17, 439
 MSEIS (Multi-Spectral Earth Imaging System), 552
 MSGI-MKA (Spectrometer for Geoactive Measurements), 703
 MSI (Multispectral Imager), 543
 MSIS = Mass-Separating Ion Spectrometer (IRM), 874
 MSMR (Multifrequency Scanning Microwave Radiometer), 425
 MSR = Microwave Scanning Radiometer, 459, 1246
 MSRS (Multi-Spectral high Resolution System), 17, 267
 MSS = Maritime Surveillance System, 1732
 MSS = Multispectral Scanner System, 16, 443, 1310
 MSS Fragment (Multispectral Scanning System Fragment), 11, 16, 694, 695
 MSSCC (Multicolor Spin scan Cloud Camera), 114, 737
 MSU = Microwave Sounding Unit, 743, 1309
 further consideration, 737, 1246
 MSU-E = Multispectral Scanner - Electronic Scanning (CIS), 16, 18, 480, 486, 496, 694, 1000

MSU-M = Multispectral Scanner, 1774
 MSU-M = Multispectral Scanner - Low Resolution (CIS), 469, 471, 473, 695
 MSU-MR (Low Resolution Multispectral Scanner), 703
 MSU-S = Multispectral Scanner - Moderate Resolution (CIS), 471, 694
 MSU-SK = Multispectral Scanner- Moderate Resolution and Conical Scanning (CIS), 16, 473, 480, 486, 496, 694, 1000
 MSU-SR (Medium Resolution Multispectral Scanner), 703
 MSU-V = High-Resolution Multispectral Scanner, 473
 MTB (Microwave Test Bed), 1118
 MTI (Multispectral Thermal Imager), 461
 MTP = Microwave Temperature Profiler, 1735, 1763, 1850, 1907, 1913, 1918
 MTS (Microwave Temperature Sounder), 1744
 MTS (Millimeter-Wave Temperature Sounder), 1736, 1854, 1855, 1917
 MTS-AMOS (Micro Tech Sensor-Attitude and Orbit Measurement System), 1057
 MTVZA (Microwave Radiometer for Temperature Sounding of the Atmosphere), 702
 Multipolarization K- and Ka-band Polarimeters, 1690
 MUSE (Monitor of UV Solar Energy), 737, 1080, 1081
 MUSIC (Multi-Spectral Infrared Camera), 24, 1737
 MUXCAM (Multispectral Camera), 353
 MVE (Micro-Vibration Measurement Equipment), 75, 1092
 MVISR (Multichannel Visible and IR Scanning Radiometer), 689, 691
 MVS (Machine Vision System), 145, 548
 MWIR (Medium Wave Infrared Imager), 1135
 MWR (Scanning Microwave Radiometer), 1732, 1733
 MWR = Microwave Radiometer, 358, 370

MWR = Microwave Radiometer (part of ATSR), 403, 1246

N

NACE (Neutral Atmosphere Composition Experiment), 182
 NACS = Neutral Atmosphere Composition Spectrometer, 204
 NAILS = NCAR Airborne Infrared Lidar System, 1738
 NAM-5 = Radiofrequency Mass-Spectrometer, 867, 877
 NAMR (Nadir-looking Airborne Multichannel Radiometer), 1688, 1880
 NAPP (National Aerial Photography Program), 1739
 NASAR-1 (NASDA Airborne SAR-1), 31, 1740
 NASIC (NASA Aircraft - Satellite Instrument Calibrator), 1740
 NAST (NPOESS Aircraft Sounder Testbed), 1033, 1742
 NAST-I (NPOESS Aircraft Sounder Testbed - Interferometer), 1743
 NAST-M (NPOESS Aircraft Sounder Testbed - Microwave Sounder), 1744
 NATALYA-2M (Gamma-ray Spectrometer, FIRAS and MEPhI), 894
 NATE (Neutral Atmosphere Temperature Experiment), 178
 NCARNOX (NCAR NO_x Chemiluminescent Sensor), 1745, 1824
 NCLT (Nanosatellite Cross Link Transceiver), 91
 NEC-SAR (NEC Corporation SAR), 31, 1747
 NEMS = Nimbus E Microwave Spectrometer, 737, 1246
 NEOPONA (Nitrogen Oxide Emission and Photochemistry over the North Atlantic), 1571
 Neutral Mass Spectrometer, 174
 Neutral Particle Magnetic Mass Spectrometer, 175
 NewMag (Magnetometer Experiment), 1044
 NFOVR (Narrow FOV Radiometer), 1779

Nikon F3/F4 = Shuttle EO film camera, 855
 NINA (New Instrument for Nuclear Analysis), 498
 NINA-2 (New Instrument for Nuclear Analysis), 1056
 NISTAR (National Institute of Standards and Technology Advanced Radiometer), 120, 252
 NIT (Side-looking Airborne Real Aperture Radar), 1688, 1880
 NMS (Neutral Mass Spectrometer), 1063
 NNE (Neural Networks Experiment), 1115
 NO/NO_y Instrument, 1673
 NOAA P-3 Infrared Radiometers, 1754
 NOAA WP-3D Doppler Radar System, 1750, 1855, 1866
 NOAL = NOAA Ozone Airborne Lidar, 1755, 1859, 1913
 NOSL (Night-time and daytime Optical Survey of Lightning), 60
 NPW-A = Natural Plasma Wave Astronomy Mode, 899
 NS001 = Thematic Mapper Simulator, 1758, 1877, 1884, 1890, 1894
 NSCAT = NASA Scatterometer, 331, 1706, 1903
 NSCAT II = NASA Scatterometer II, 227, 338
 NSX (NRL SGLS Transponder), 1052
 NTR (Nose-mounted Doppler Turbulence-detection Radar), 1750
 NUSCAT (Airborne Ku-band Scatterometer), 1758, 1915
 NVK-ONCH (Low Frequency Wave Analyzer), 196
 NVK-ONCH = VLF Analyzer, 866, 876
 NVK-ONCH = VLF Electromagnetic Waves Experiment, 927

O

O3 Instrument, 1672, 1763, 1913
 OAP-230X = Optical Array Cloud Droplet Probe, 1769

OCE = Ocean Color Experiment, 849
 OCI (Ocean Color Imager), 500
 OCM (Ocean Color Monitor), 424
 OCS (Ocean Color Scanner), 410
 OCS = Ocean Color Scanner, 849
 OCSE (Optical Calibration Sphere Experiment), 1153
 OCTS = Ocean Color and Temperature Scanner, 330
 ODD (Orbiting Debris Device), 1122
 ODUS (Ozone Dynamics Ultraviolet Spectrometer), 48, 216
 ODW (Omega Dropwind Sonde), 1754
 OH/HO₂ Instrument, 1671, 1763, 1850, 1907
 OHIS (OrbView Hyperspectral Imaging System), 17, 307
 Empty, 17, 274
 OHRIS (OrbView High Resolution Imaging System), 17, 305, 307
 OLEX = Ozone-Aerosol Lidar Experiment, 1518, 1621, 1622, 1625
 OLME = Ozone Layer Monitoring Experiment, 47, 540
 OLS (Optical Lightning Subsystem), 60, 214
 OLS = Oceanographic Lidar System, 1760
 OLS = Operational Linescan System (DMSP), 663, 1855, 1888, 1910, 1917
 OM-2 (Ozone Meter-2), 1182
 OMI (Ozone Monitoring Instrument), 393
 OMPS (Ozone Mapping and Profiler Suite), 718
 OPALE (Optical Payload for Intersatellite Link Experiment), 58, 523, 1016
 OPERA = Onde di Plasma Et Radiazioni Aurorali, 929
 OPPEX (Optical Precision Platform Experiment), 1095
 OPS = Optical Sensor, 429
 Optical Beacon System, 569, 570
 ORA = Occultation Radiometer Instrument, 827
 Ørsted-2 (Magnetic Mapping Payload), 506

OS-AP-M (Ozone Sonde Aircraft Platform Mid-altitude), 1573
 OSA (Optical Sensor Assembly), 17, 286
 OSIRIS = Optical Spectrograph and Infrared Imaging System, 225
 OSMI (Ocean Scanning Multispectral Imager), 437
 OSS (Open-Source Neutral Mass Spectrometer), 178
 OTD = Optical Transient Detector, 299
 OVID (Optical Visible and Near-Infrared Detector), 1760, 1857, 1867
 OXFLUX (Oxygen Flux), 1142
 Ozon-M = Multichannel UV Spectrometer on MIR, 482, 999
 Ozone Analyzer, 1571

P

P-3/SAR (ERIM/Navy Sensor), 31, 1646, 1856, 1880, 1900, 1908
 P3 = Pulsed Plasma Probe, 202
 PALIS (Polarized Airborne Laser Imaging Sensor), 1536
 PALSAR (Phased Array L-band Synthetic Aperture Radar), 30, 342
 PAN = Panchromatic Camera, 16, 419
 PAN-A (Panchromatic Aft-pointing Camera), 17, 426
 PAN-F (Panchromatic Forward-pointing Camera), 17, 426
 PANCAM (Panchromatic Camera), 353
 PARCS (Primary Atomic Reference Clock in Space), 990
 PASM (Power Actuation and Switching Module), 1024
 PASS (Payload Autonomous Star Sensor), 1099
 PASTEL (Passager SPOT de Télécommunication Laser), 58, 523, 1015
 PBEX (Polymer Battery Experiment), 1094
 PBMR = Pushbroom Microwave Radiometer, 1761, 1869, 1877, 1890
 PCASP-100X = Passive Cavity Aerosol Spectrometer Probe, 1768

PCD (Potential Control Device), 898
 PCS (Parallel Computer System), 1047
 PDP (Plasma Diagnostic Package), 210
 PDP = Plasma Diagnostics Package, 1297, 1455
 PEACE = Plasma Electron and Current Analyzer, 885
 PEAS = Electron and Ion Analyzer, 876
 PEM = Particle Environment Monitor, 261
 PENGUIN (Hard X-ray Polarimeter and Neutron Detector, IFTI and MEPhI), 894
 PEPE (Plasma Experiment for Planetary Exploration), 1023
 PES (Photoelectron Spectrometer), 177
 PEST (Plasma Experiment Satellite Test), 1153
 PET (Photovoltaic Engineering Testbed), 990
 PET = Proton/Electron Telescope, 946
 PGAMS (Portable Ground-based Atmospheric Monitoring System), 1167
 PHARAO (Project d'Horloge Atomique à Refroidissement d'Atomes en Orbite), 986
 PHARS - Testbed/Prototype Phase of PHARUS, 1765
 PHARUS = PHased ARray Universal SAR, 31, 1764
 Photometer, 1148
 PI-SAR (Polarimetric and Interferometric - SAR), 1766
 PIC (Panchromatic Imaging Camera), 17, 283, 467, 1074
 PIC-2 (Panchromatic Imaging Camera-2), 17, 284
 Picosat Launcher and Payload, 1160
 PicoSat-1.1 Experiment, 1052
 PIP (Plasma In-situ Package), 435
 PIPPI = Prelude in Planetary Particle Imaging, 879
 PIXIE = Polar Ionospheric X-ray Imaging Experiment, 940
 PLASMA = 3-D Plasma and Energetic Particles Experiment, 982
 Plasma Wave Spectrometer (CCE), 875

Plasma Wave Spectrometer (UKS), 875
 PlasMag (Plasma Magnetometer), 253
 PLASTIC (PLAsma and SupraThermal Ion and Composition), 970
 PLP (Planar Langmuir Probe), 559
 PM (Proton Monitor), 1118
 PMO6-V (Physikalisch-Meteorologisches Observatorium, 6th radiometer - VIR-GO), 959
 PMR (Pressure Modulated Radiometer), 1085
 PMR = Pressure Modulated Radiometer, 737
 PMS = Portable Multichannel Spectrometer, 1769
 PMS LAS-X (Laser Aerosol Spectrometer with Passive Cavity), 1518
 PMS LPC 550 (Laser Particle Counter), 1518
 POAM-II = Polar Ozone and Aerosol Measurement), 47, 519
 POAM-III (Polar Ozone and Aerosol Measurement), 47, 524
 POLAS-128 (Polarization-sensitive Acousto-optic Spectrometer), 474
 POLDER = Airborne Instrument, 1771, 1850, 1867, 1877, 1884
 POLDER = Polarization and Directionality of the Earth's Reflectances, 332, 339, 1069
 POLRAD = Polish Radiometer, 927
 PORTOS, 1773, 1877
 Poseidon-2 (Solid-State Radar Altimeter), 591
 PPC (Pointed Proportional Counter), 422
 PPS-1350 (Propulseur Plasmique Stationnaire - or Stationary Plasma Thruster-1350), 1106
 PPT (Pulsed Plasma Thruster), 1031
 PR = Precipitation Radar, 255, 1564, 1633, 1903
 PR41/53 (UHF Receivers), 196
 PRAM = Adaptive Processing of Wave Information, 930

PRARE = Precise Range and Range Rate Equipment, 403
 further considerations, 405, 407, 699, 700
 Precipitating Electron Detector, 571
 PREMOS (Precision Monitoring of Solar variability), 120, 1071
 Pressure Gauge, 174, 175
 Priroda-5 = KFA-1000 Camera System, 998, 1000
 PRISM (Panchromatic Remote-sensing Instrument for Stereo Mapping), 17, 341
 PROMICS-3 = Ion Composition Experiment, 927
 PROMICS-3 = 3-D Ion Composition Spectrometer, 928
 PRS = Plasma Wave Spectrometer, 867
 PRS-2-C = Radiowave Spectrometer, 869, 878
 PSA (Pressure Sensor A), 181
 PSB (Pressure Sensor B), 181
 PVP = Generator of Electric Oscillations, 866
 PWI = Plasma Wave Instrument, 203, 936
 PWI = Plasma Wave Instrumentation (IRM), 874
 PWI = Plasma Waves Investigation, 915
 PWS = Plasma Wave Detectors and Sounder, 903

Q

QC40 (Quad-TMS320C40 processor), 1052
 QIMS = Quadrupole Ion Mass Spectrometer, 202
 QOMAC (Quarter-Orbit Magnetic Attitude Control), 726
 QWIP (Quantum Well Infrared Photodetector), 1119

R

R-400 = MW Radiometer (CIS), 479, 486
 R-225 = Passive Microwave Radiometer, 476

R-600 = Passive Microwave Radiometer, 476
 R-SLAR (RRL-SLAR), 1786
 R-TARAC (Real-Time Airborne Radionuclide Analyzer and Collector), 1543
 R10M = Radiation Measurement Complex, 695
 RA = Radar Altimeter, 574
 RA-1 = Radar Altimeter, 402, 1892
 RA-2 = Radar Altimeter-2 (ESA), 366
 RACE (Rubidium Atomic Clock Experiment), 991
 RACS (Rotating Antenna C-band Scatterometer), 1777, 1897
 Radar Altimeter, 407, 510, 571, 573
 Radar Altimeter (active devices)
 ALT (Topex/Poseidon), 602
 Altimeter (Seasat), 510
 GEOS-3, 571
 GEOSAT, 573
 GFO-1, 574
 RA-1 (ERS-1,-2), 402, 407
 RA-2 (Envisat), 366
 RA-2 (POEM), 358
 SSALT (Topex/Poseidon), 603
 Radar Scatterometer
 AMI-SCATT (ERS-1,-2), 401, 407
 NSCAT (ADEOS), 331
 SASS (Seasat), 511
 SeaWinds (NASA/JPL), 227, 338
 Radio Doppler System, 569, 570
 Radio Range/Rate System, 570
 Radius = Microwave Radiometer, 1778
 RAL-Sensor, 1817
 RAMS = RADIATION Measurement System, 1779, 1847, 1850, 1856, 1870, 1901, 1902, 1917
 RAMSES = Radar Aéroporté Multi-Spectral d'Etude des Signatures, 31, 1780
 RAPID = Research with Adaptive Particle Imaging Detectors, 886
 RBV = Return Beam Vidicon, 16, 443
 RDRS (Radiation Dose Rate Sensor), 1114
 RedEye (Regional Environmental Dynamics Active-aperture Infrared Imager), 55
 REFLEX (Return Flux Experiment), 845
 REIS (Complex for the Measurement of Electromagnetic Fields), 895
 REIS (RapidEye Earth Imaging System), 17, 309
 REM (Radiation Environment Monitor), 1115
 REME (Radiation Effect on Micro-Electronics), 433
 RENE, 1781
 RES-C = Solar X-Ray Spectral Polarimeter, 890, 893
 RESSAC (Radar pour l'Etude du Spectre des Surfaces par Analyse Circulaire), 1782, 1915
 REX (Radiation Experiment), 228
 RF (Radio Frequency) System, 214
 RF Ion Mass Spectrometer, 175
 RF-15 = Solar X-Ray Experiment, 929
 RFA (High Frequency Wave Analyzer), 196
 RFUV (Raman, Fluorescent and UV-DIAL Lidar), 1811
 RGA3 (Reduction Gas Analyzer), 1573
 RGR (Relative GPS Receiver), 91
 RIMS = Retarding Ion Mass Spectrometer, 203
 RIS = Retroreflector in Space, 334
 RIT-10 (Radio-frequency Ionization Thruster), 1286
 RITA (Radio-Frequency Ion Thruster Assembly), 580, 827
 RITA (Radio-frequency Ion Thruster Assembly), 1016, 1286
 RLG (Ring Laser Gyro), 133
 RLSBO = Side-Looking Real Aperture Radar, 470, 473
 RM-08 = Passive Microwave Scanning Radiometer, 470
 RMK = Reihenmeßkammer - Metric Camera, 1783, 1865, 1880
 RMK A = Reihenmeßkammer (Metric Camera), 1784
 RMK-2 = Radiation Measurement Complex, 498, 695, 697, 700

RMK-M (Radiation Measurement Control), 498
 RMS (Radiation Measurement System), 608, 632
 RMT (Radiofrequency with Magnetic field ion Thruster), 1285
 Rolleiflex 6008 = Shuttle EO film camera, 855
 RON = Ion Emitter Experiment, 928
 ROSIS = Reflective Optics System Imaging Spectrometer, 24, 1774, 1784
 ROWS = Radar Ocean Wave Spectrometer, 1785, 1915
 RPA (Retarding Potential Analyzer/Drift Meter), 177
 RPA = Retarding Potential Analyzer, 204
 RPI (Radio Plasma Imaging), 923
 RPM-0.8 WA (Radiometer/Polarimeter/Multipolarization, 0.8 cm wavelength, Waveguide, Airborne), 1690
 RPM-1.5 WA (Radiometer/Polarimeter/Multipolarization, 1.5 cm wavelength, Waveguide, Airborne), 1690
 RRA (Retro-Reflector Array), 532
 RRA (RetroReflector Array), 693
 RSI (Remote Sensing Instrument), 17, 503
 RSIS (Radio Science Investigation Series), 1107
 RT-2 (X-ray Telescope), 894
 RTVK-M (Radio and TV Complex), 473

S

S 192 = Multispectral Opto-mechanical Scanner, 1003
 S 300 = Search Coil Magnetometer, 567
 S 302 = Electrostatic Analyzers, 568
 S 303 = Combined Electrostatic and Magnetic Analyzer, 568
 S 310 = Electrostatic Analyzers, 568
 S 321 = Magnetic Deflection System, 568
 S 329 = Tracing of Electron Beam over one or more Gyration, 568
 S 331 = Fluxgate Magnetometer, 568

S&FE (Store & Forward Experiment), 347
 S&R = Search & Rescue, 737
 S&R = Search and Rescue (System), 626, 681, 738, 747
 S&RSAT (Search&Rescue Satellite Aided Tracking System), 688
 S&RSAT=Search and Rescue Satellite Payload, 811
 S-VISSR (Stretched - Visible and Infrared Spin-Scan Radiometer), 610
 S-193 = Passive Microwave Radiometer/Active Scatterometer and Radar Altimeter, 12, 572, 1003
 S-194 = Passive Microwave Radiometer, 1004
 S190A = Multispectral Photographic Camera (Skylab), 1002
 S190B = Earth Terrain Camera (Skylab), 1003
 S191 = Infrared Spectrometer (Skylab), 1003
 S193 = Passive MW Radiometer/Active Scatterometer (Skylab), 1246
 S194 = Passive Microwave Radiometer (Skylab), 1246
 SABER = Sounding of the Atmosphere using Broadband Emission Radiometry, 244
 SABL = Scanning Aerosol Backscatter Lidar, 1786
 SAFI (Solar Array Flexible Interconnect), 1052
 SAFIRE (Submillimeter And Far Infrared Experiment), 1806
 SAFIRE-A (Spectroscopy of the Atmosphere w. FIR Emission - Airborne), 53, 1547
 SAGE III (Stratospheric Aerosol and Gas Experiment III), 704
 SAGE-I = Stratospheric Aerosol and Gas Experiment, 183
 SAGE-II = Stratospheric Aerosol and Gas Experiment II, 207
 SAI = Spin-Scan Auroral Imager, 204
 SAM II = Stratospheric Aerosol Measurement II, 1088

SAMIR (Satellite Microwave Radiometer), 349, 1246

SAMMES (Space Active Modular Materials Experiment System), 1136

SAMS = Stratospheric and Mesospheric Sounder, 260, 1088
further mention, 737

Sandia SAR, 31, 1540

SAPHIR (Sondeur Atmospherique du Profil d'Humidite Intertropicale par Radiometrie), 222

SAR = Synthetic Aperture Radar, 30, 344, 346, 848
further considerations, 30, 400, 428, 479, 488, 491, 509, 849, 850

SAR Travers = Synthetic Aperture Radar, 31, 1773

SAR-10 (Synthetic Aperture Radar-10), 30, 265

SAR-2000 (Synthetic Aperture Radar-2000), 30, 272

SAS (Satellite Attitude Sensor), 1119

SAS&R = Satellite Aided Search and Rescue (Indian system), 635

SASAR = South African SAR, 31, 1787

SASS = Seasat-A Scatterometer System), 511

SBUV = Solar Backscatter Ultraviolet, 47, 822, 861, 1089, 1298
further mention, 737

SBUV/3 = Solar Backscatter Ultraviolet Radiometer, 743, 752

SBV (Space Based Visible) camera, 1063

SCA (Star Camera Assembly), 589

Scalar Magnetometer, 599

Scalar Magnetometer (Magsat), 595

ScaLARS (Scanning Laser Altitude and Reflectance Sensor), 1576

SCAMS (Scanning Microwave Spectrometer), 1085

SCAMS = Scanning Microwave Spectrometer (NOAA), 737, 1246

Scanning Radiometer, 722, 723, 724

ScaRaB (Scanner for Radiation Budget), 119, 221, 498, 698, 700

SCARLET-II (Solar Concentrator Array with Refractive Linear Element Technology), 1024

SCDE (Surface Charge Detector Experiment), 1113

SCE = Solar Corona Experiment, 978

SCIAMACHY = Scanning Imaging Absorption Spectrometer for Atmospheric Cartography, 372, 1309
further considerations of, 358

SCL (Spacecraft Command Language), 1120

SCMR (Surface Composition Mapping Radiometer), 737, 1083

SCPS (Space Communications Protocol Standards), 1120

SCR (Cosmic Ray Spectrometer), 893

SCR (Selective Chopper Radiometer), 1082, 1083

SCR (Surface Contour Radar), 1709

SCR = Selective Chopper Radiometer, 737

SCTE (Solar Cell Technology Experiment), 1115, 1118

SCTE = Solar Cell Technology Experiment, 535

SDST (Small Deep Space Transponder), 1023

SEASIS (SEDSAT Earth Atmospheric and Space Imaging System), 1166

SeaWifs = Sea-viewing Wide-Field Sensor, 302

SeaWinds = NASA Scatterometer (old name NSCAT II), 227, 338

SECOR (Sequential Collation of Range), 569, 570

SEDA (Space Environment Data Acquisition), 1046

SEDA-AP (Space Environment Data Acquisition equipment-Attached Payload), 991

SEE (Space Environmental Effects), 1115

SEE = Solar EUV Experiment, 244

SELODE (Solar Exposure to Laser Ordinance Device), 846

SEM = Space Environment Monitor, 352, 613, 619, 681, 688, 737, 744

SEM-2 (Space Environment Monitor-2), 752

SEP (Solar Energetic Particles), 969
 SEP = Spectrometer for Electron and Protons, 202
 SEPAC = Space Experiments with Particle Accelerators, 823
 SEPICA = Solar Energetic Particle Ionic Charge Analyzer, 864
 SEPT (Solar Electron Proton Telescope), 969
 SESAM (Surface Effects Sample Monitor), 816, 819
 SESS (Space Environment Sensor Suite), 719
 SETS (Shuttle Electrodynamic Tether System), 1132
 SEU (Single Event Upset), 433
 SEU (Single Event Upset)/RADMON (Radiation Monitor) Experiment, 1115
 SEVIRI (Spinning Enhanced Visible and Infrared Imager), 649
 SFSI = SWIR Full Spectrographic Imager, 24, 1791, 1792
 SGR (Space GPS Receiver), 544
 SGR-05 (Space GPS Receiver-05), 550
 SGR-5 = Fluxgate Magnetometer, 877
 SGR-7 = 3-axis Fluxgate Magnetometer, 867, 877
 SGR6 = 1-component Fluxgate Variometer, 867, 877
 SHASH = VLF Spectroanalyzer, 866
 SHC (Surrey High-resolution Camera), 543
 SHF = Passive MW Radiometer (CIS), 695
 SHOALS = Scanning Hydrographic Operational Airborne Lidar Survey, 1792
 SHOOT (Superfluid Helium On-Orbit Transfer), 61
 SI-GDR = Spectrometer/Interferometer (GDR sensor), 695
 SIGI (Space Integrated GPS/INS), 152, 787
 SII (Suprathemal Ion Instrument), 1126
 SILEX (Semiconductor Intersatellite Link Experiment), 58, 523, 1015

SILVACAM = Real-time False Color CCD Video Camera, 1794
 SIM (Spectral Irradiance Monitor), 240
 SIMS = Chemical and Isotopic Measurements of Micrometeoroids by Secondary Ion Mass Spectrometry, 833
 SIR (Scanning Infrared Radiometer), 1822
 SIR (SMART1 Infrared Spectrometer), 1108
 SIRAL (SAR Interferometer Radar Altimeter), 138, 562
 SIRS (Satellite Infrared Spectrometer), 737, 1079, 1081
 SIS = Scanning Imaging Spectrometer, 1566
 SIS = Solar Isotope Spectrometer, 864
 SIS = Star Imaging System, 537
 SIT (Suprathemal Ion Telescope), 970
 SKA-1 = 3-D Ion Distribution Measurement, 928
 SKA-2 = Spectrometric Device Complex, 929
 SKA-3 = Electron/Proton Distribution Experiment, 927
 SKDR (S/Ka-band Data Relay), 1015
 SKL = Solar Cosmic Ray Spectrometer Complex, 891
 SLAR (Side-Looking Airborne Radar, NLR), 1795, 1885
 SLAR (Side-Looking Airborne Radar), 1733
 SLRRE (Satellite Laser Ranging Retroreflector Experiment), 1184
 SM = Multichannel Spectrometer, 697, 700
 SMAG (Scientific Magnetometer), 433
 SMARD (Shape-Memory Actuated Release Device), 1049
 SMATTE (Shape Memory Alloy Thermal Tailoring Experiment), 1052
 SMEI (Solar Mass Ejection Imager), 199
 SMIFTS = Spatially Modulated Imaging FTS, 24, 53, 1796
 SMILES (Superconducting Submillimeter-wave Limb Emission Sounder), 28, 63, 992

SMIRR = Shuttle Multispectral Infrared Reflectance Radiometer, 848
 SMMR = Scanning Multichannel Microwave Radiometer, 510, 737, 1089, 1246, 1869, 1888, 1893
 further mention, 737
 SMR = Sub-Millimeter-wave Radiometer, 223
 SMS (Submillimeterwave Sensor), 1543, 1817
 SMS = Suprathermal Ion Mass Spectrometer, 904
 SMS = SWICS + STICS, 982
 SMX-1 (Sparc Microprocessor Experiment), 1119
 SMX-2 (Sparc Microprocessor Experiment-2), 1120
 SOAR (SIGI Operational Attitude Readiness), 152
 SODISM (Solar Diameter Imager and Surface Mapper), 120, 1069
 SOFIS (Solar-Occultation FTS for Inclined-orbit Satellite), 48, 216
 SOL-ACES (Solar Auto-Calibrating EUV/UV Spectrophotometers), 120, 996
 Solar Cell Diagnostic, 898
 Solar Image Radiometer (EXOS-C), 901
 Solar UV Monitor (SME), 944
 Solar Wind Concentrator, 911
 Solar-A (Solar Monitoring Observatory), 120, 994
 SOLCON = Solar Constant Sensor, 822, 827, 853, 1298
 SOLSPEC (Solar Spectral Irradiance Measurements), 120, 996
 SOLSPEC = Solar Spectrum Measurement, 822, 853, 1298
 SOLSTICE = Solar Stellar Irradiance Comparison Experiment, 238, 261, 1861
 Sony DXC-750 3-CCD Video Camera, 1539
 SOR (Starfire Optical Reflectors, 1053
 SORS = Solar Radiospectrometer, 891, 893
 SOSNA-2 = Dosimeter, 929
 SOSP = Solar Spectrum Instrument, 119, 828
 SOT (Solar Optical Telescope), 963
 SOUP = Solar Optical Universal Polarimeter, 1297, 1464
 SOVA = Solar Constant and Variability Instrument, 119, 827
 SOVAP (Solar Constant Variability, Picard), 120, 1070
 SOVIM (Solar Variability and Irradiance Monitor), 120, 994
 SOXS (Soft X-Ray Spectrometer), 942
 SPACE = Spacecraft Particle Correlator Experiment (UKS), 875
 Space Fluid Experiment Device, 1104
 SPADUS (Space Dust Experiment), 1009
 SPE-1 = High Energy Particles Experiment, 867
 SPECK (Spectrophotometer), 1147
 SPEDE (Spacecraft Potential, Electron and Dust Experiment), 1107
 SPIM (Spectrographic Imager), 1060
 SPIRIT-III (Spatial Infrared Imaging Telescope), 1058
 SPM (Solar Proton Monitor), 731, 732
 SPM (Sunphotometer), 959
 SPM = Solar Proton Monitor, 737
 SPRE (SPARTAN Packet Radio Experiment), 846
 SPRITE (Signal Processing In The Element), 51, 1214
 SPS (Space Physics Sensor), 438
 SPT (Stationary Plasma Thruster), 1106, 1289
 SPW = Stimulated Plasma Wave Experiment, 899
 SQUID (Superconducting Quantum Interference Device), 586
 SR (Scanning Radiometer), 731, 732
 SR = Scanning Radiometer, 737
 SREM (Standard Radiation Environment Monitor), 580, 1098, 1119
 SSALT = Single-Frequency Solid-State Altimeter, 603, 1917
 SSB = Gamma Tracker (DMSP), 673
 SSB/A = X-Ray Spectrometer (DMSP), 674

SSB/O = Omnidirectional Gamma Detector (DMSP), 674

SSB/S = Scanning X-Ray Detector (DMSP), 674

SSB/X-2 = Gamma Ray Particle Detector, 670

SSC = Snow Cloud Discriminator (DMSP), 674

SSCC (Spin-Scan Cloudcover Camera), 113, 737

SSD = Atmospheric Density Sensor (DMSP), 674

SSDRE = Solid-State Data Recorder Experiment, 540

SSE = Temperature Sounder (DMSP), 673

SSH = Infrared Spectrometer (DMSP), 674

SSH-2 = Infrared Temperature and Moisture Sounder, 674

SSI/E = Topside Ionospheric Plasma Monitor (DMSP), 673

SSI/ES-2 = Special Sensor Ionospheric Plasma Drift/Scintillation Monitor, 669

SSI/ES-3 = Enhanced Ionospheric Plasma Drift/Scintillation Monitor, 670

SSJ = Auroral Electron and Ion Spectrometer, 673

SSJ* = Space Radiation Dosimeter (DMSP), 674

SSJ/4 = Precipitation Electron/Proton Spectrometer, 669

SSJ/5 = Precipitation Electron/Proton Spectrometer, 669

SSL = Lightning Detector (DMSP), 673

SSM = Triaxial Fluxgate Magnetometer, 669

SSM/I = Special Sensor Microwave Imager, **665, 716**, 1246, 1853, 1855, 1869, 1870, 1874, 1877, 1881, 1882, 1891, 1892, 1903, 1906, 1917

SSM/T = Temperature Sounder (DMSP), 1246

SSM/T-1 (Special Sensor Microwave Temperature Sounder), 666

SSM/T-2 (Special Sensor Microwave Water Vapor Profiler-2), 666

SSM/T-2 = Special Sensor Microwave Water Vapor Profiler-2, 1903

SSM-Boom = Triaxial Flux Gate Magnetometer, 670

SSMIS (Special Sensor Microwave Imager Sounder), 44, 667, 716, 1557

SSNI (Data Collection System), 893

SSPSR (Small Satellite Power System Regulator), 492, 1102

SSR (Solid State data Recorder), 1047

SSTI (Satellite to Satellite Tracking Instrument), 130, 578, 580

SSTR = Sea Surface Temperature Radiometer, 1812, 1856, 1917

SSU = Stratospheric Sounding Unit, 735, 743
further consideration, 737

SSULI = Special Sensor Ultraviolet Limb Imager, 670, 1011

SSUSI = Special Sensor Ultraviolet Spectrographic Imager, 672

SSZ = Laser Threat Detector, 670

STAFF = Spatio-Temporal Analysis of Field Fluctuations, 883

STAR (Space Three-axis Accelerometer for Research mission), 557, 1066

STAR = Sea-Ice and Terrain Assessment Radar, 31, 1813

STE (Suprathermal Electron Telescope), 969

STICS = Mass Sensor and Suprathermal Ion Composition Study, 982

STR = Scanning TV Radiometer (GOMS sensor), 632

SUFR-Sp-C = Solar UV Radiometer, 891, 893

SULEICA = Suprathermal Energy Ionic Charge Analyzer (IRM), 874

SUMAS (Submillimeter Atmospheric Sounder), 1817, 1863

SUMER = Solar UV Emitted Radiation, 956

SUMO (Superconducting Microwave Oscillator), 996

Sunphotometer, 1818

SuperSTAR (Super Space Three-axis Accelerometer for Research mission), 589, 1066

SUPEX (Superconductivity Experiment), 1183

SUSIM = Solar Ultraviolet Spectral Irradiance Monitor, 1297

SUSIM = Solar Ultraviolet Spectral Irradiance Monitor, 261, 822

Svetozar-3 Lidar, 1790

SVS (Space Vision System), 144

SWAN = Solar-Wind Anisotropies, 958

SWAVES (STEREO/WAVES), 970

SWE = Solar Wind Experiment, 982

SWEA (Solar Wind Electron Analyzer), 968

SWEPAM = Solar Wind Electron, Proton, and Alpha Monitor, 864

SWICS = Solar Wind Ion Composition Spectrometer, 864

SWICS = Solar Wind Ion Composition Study, 982

SWICS = Solar Wind Ion Composition Spectrometer, 977

SWIFT (Stratospheric Wind Interferometer For Transport studies), 218, 711

SWIMS = Solar Wind Ion Mass Spectrometer, 863

SWOOPS = Solar Wind Observations Over the Poles of the Sun, 977

SXI = Solar X-Ray Imager, 620, 626

SXP (Solar X-ray Photometer), 1172

SXR = Soft X-Ray spectrometer, 1176

SXT = Soft X-Ray Telescope, 951, 960

T

T+DRE (Tracking and Data Relay Experiment), 737, 1086

TANS Vector (Trimble Advanced Navigation Sensor), 785

TBB (Triband Beacon Transmitter), 232

TCS (Trajectory Control Sensor), 152, 820

TDDR (Total Diffuse Direct Radiometer), 1779

TDE (Total Dose Effect), 433

TDE = Total Dose Experiment, 534, 535, 538

TDLHS = Tunable Diode Laser Heterodyne Spectrometer, 1757

TDR (Tail-mounted Doppler Radar), 1751, 1860, 1912

TEAMS = Time-of-Flight Energy Angle Mass Spectrograph, 948

TECHS (Thermal Electron Capped Hemisphere Spectrometer), 1126

TED = Thermal Electron Detectors, 904

TED = Total Energy Detector, 735, 737, 744, 752

Telemetry Experiment, 1166

TEREK-C = Solar X-Ray Telescope/Coronagraph (Coronas), 889, 893

TES (Tropospheric Emission Spectrometer), 395

TESS (Tomographic EUV Spectrograph System), 1173

TEXAS (Technology Experiment Augmenting Spartan), 845

TGRS = Transient Gamma Ray Spectrometer, 982

THD (Tunneling Horizon Detector), 1165

THERMO = Thermal Radiometer, 1734

THIR (Temperature-Humidity Infrared Radiometer), 737, 1081, 1084, 1086, 1090

THOMAS (THz OH Measurement Airborne Sounder), 28, 40, 1817, 1819, 1861

Three-Axis Fluxgate Magnetometer, 1019

TICCE = Timeband Capture Cell Experiment, 827

TIDE/PSI = Thermal Ion Dynamics Experiment/Plasma Source Investigation, 937

TIDI = TIMED Doppler Interferometer, 244

TIM (Total Irradiance Monitor), 238, 719

TIMAS = Toroidal Imaging Mass-Angle Spectrograph, 937

TIMS = Thermal Imaging Multispectral Scanner, 1597

TIMS = Thermal Infrared Multispectral Scanner, 1609, 1615, 1869, 1877, 1880, 1890, 1894

TIP (Tiny Ionosphere Photometer), 232

TM = Thematic Mapper, 444, 1310
further mention, 383, 1864, 1869, 1870, 1877, 1890, 1901

TMI = TRMM Microwave Imager, 257, 716, 1903

TMR= Topex Microwave Radiometer, 602, 1246, 1917

TMS = Thematic Mapper Simulator (NS001), 1707, 1758, 1864, 1869, 1894

TOMS = Total Ozone Mapping Spectrometer, 245, 246, 332, 696, 821, 1076
further considerations, 47, 697, 700, 737, 1089, 1840, 1863, 1879, 1905, 1910

TOMS-5 (Total Ozone Mapping Spectrometer), 248

TOPOSYS (Scanning Laser System), 1819

TOPSAR = Interferometric Radar Topographic Mapping Instrument, 31, 1527, 1908

Topside Ionospheric Plasma Sounder (EXOS-C), 901

TOVS = TIROS Operational Vertical Sounder, 734, 737, 1840, 1846, 1851, 1855, 1863, 1870, 1879, 1892, 1917

TPS (Total Pressure Sensor), 1064

TQCM (Temperature-controlled Quartz Crystal Microbalance), 1064

TQMS (Triple Quadrupole Mass Spectrometer), 1515

TRACE (Transition Region and Coronal Explorer), 950

Trasser-O (Polarization Spectroradiometer), 473

TRAVERS = Sideview Radar System, 30, 479, 1000

TRSR (TurboRogue Space Receiver), 46, 556, 590, 600, 1180

TRWIS = TRW Imaging Spectrometer, 1820

TSC (Terrestrial Solar Cells), 1046

TSCC (Tilt Scan CCD Camera), 1821, 1850, 1870, 1901, 1902, 1917

TSIS (Total Solar Irradiance Sensor), 120, 719

TTS = Target Tracking System, 1542

TV = TV instrument (framing technique), 695, 700

TV = TV optical instrument (MR-600A), 693

TV Camera = Priroda optical instrument, 482

TV-MA (Television-Medium Angle), 723

TV-NA (Television-Narrow Angle), 721

TV-WA (Television-Wide Angle), 721

TVS (TV System), 19

TWERLE (Tropical Wind Energy conversion and Reference Level Experiment), 80, 1086

U

UAV-AERI (UAV Atmospheric Emitted Radiance Interferometer), 53, 1628, 1764

UCB = Extreme Ultraviolet Cosmic Background Explorer, 454

UEM-2 = Electron Accelerator, 876

UF-3K = Photometer, 876

UFSIPS = Radiation Emission Experiment, 928

UHCRE = Ultra High Cosmic Ray Experiment, 833

UHF Radiometer, 346

UK-10 (Electron Bombardment Ionization Thruster), 1288

ULEIS = Ultra-low Energy Isotope Spectrometer, 864

UMMCI (University of Michigan Multichannel Chemiluminescence Instrument), 1824

UPM = Neutral Plasma Accelerator, 876

URAP = Unified Radio and Plasma-Wave Experiment, 977

USA (Unconventional Stellar Aspect), 1008

UV Auroral TV Camera (EXOS-A), 898

UV Glow Spectrophotometer (Exos-A), 899

UV Ozone Experiment (SME), 943
 UV Spectrometer (EXOS-C), 901
 UV-DIAL, 1755, 1859
 UVAI = UV Auroral Imager, 928
 UVCS (Ultraviolet Coronal Spectrometer), 844
 UVCS = UV Coronagraph Spectrometer, 957
 UVI = Ultraviolet Imager, 939
 UVISI (Ultraviolet/Visible Imaging and Spectrographic Imaging), 1060
 UVISI Imagers, 1062
 UVNO (Ultraviolet Nitric-Oxide Experiment), 180
 UVS (Ultraviolet Spectrometer), 1171
 UVSP = Ultraviolet Spectrometer and Polarimeter, 954

V

V1 = Electric Field Experiment (Viking), 978
 V2 = Magnetic Field Experiment (Viking), 979
 V3 = Hot Plasma/Energetic Particle Experiment (Viking), 979
 V4H = High-Frequency Wave Experiment (Viking), 980
 V4L = Low-Frequency Wave Experiment (Viking), 980
 V5 = Auroral Imaging Experiment (Viking), 980
 VAE (Visible Airglow Experiment), 180
 VAPS (Vertical Air Profiling System), 1754
 VAS = VISSR Atmospheric Sounder, 616, 737, 1869
 VDP = 3-D Ion Faraday Cups, 928
 Vector Magnetometer, 599
 Vector Magnetometer (Magsat), 595
 VEFI = Vector Electric Field Instrument, 204
 VEGETATION = Spot-4 sensor, 16, 522
 VGS (Video Guidance Sensor), 845
 VHRR (Very High Resolution Radiometer), 732

VHRR = Very High-Resolution Radiometer (INSAT sensor), 634
 VHRR/2 (Very High Resolution Radiometer), 637
 Video (Video Camera System), 1734
 Vidicon TV Camera, 349
 VIFIS = Variable Interference Filter Imaging Spectrometer, 24, 1825
 VIIRS (Visible/Infrared Imager and Radiometer Suite), 82, 710, 713
 VIRGO = Variability of Solar Irradiance and Gravity Oscillations, 119, 959
 VIRL = Visible and near Infrared Lidar, 1827, 1917
 VIRR = Visible and Infrared Radiometer, 511
 VIRS = Visible Infrared Scanner, 256
 VIS = Video Imaging System, 1828
 VIS = Visible Imaging System, 940
 Visible Nitrogen Experiment (SME), 944
 VISS (Vibration, Isolation, Suppression and Steering System), 1136
 VISSR = Visible Infrared Spin Scan Radiometer, 612, 616, 643
 further mention, 737
 Visual Light Spectrometer, 1192
 VLF = Very Low Frequency Wave Detectors, 899, 902
 VLF = Very-Low Frequency Generator, 865
 VLF-2 = Very-Low Frequency Generator 2, 867
 VMAG (three-axis fluxgate magnetometer), 261
 VMC (Visual Monitoring Camera), 1100
 VMI (Vegetation Monitoring Instrument), 522
 VNIRI (Visible Near Infrared Imager), 236
 VTIR = Visible and Thermal Infrared Radiometer, 459
 VTPR (Vertical Temperature Profile Radiometer), 732
 VTPR = Vertical Temperature Profile Radiometer, 737
 VTS (Visual Telemetry System), 20, 145, 1100, 1122

VUSS = Vacuum UV Solar Spectrometer, 891, 893

W

WAAC (Wide-Angle Airborne Camera), 1830

WAC (Wide Angle Camera), 543

WAOSS (Wide-Angle Optoelectronic Stereo Scanner), 1829

WAOSS-B (Wide-Angle Optoelectronic Stereo Scanner), 801

WARP (Wideband Advanced Recorder Processor), 1031

WAS (Whole Air Sampler), 1574

WASS (Wide Angle Star Sensor), 1099

Water Vapor / Temperature Sensor, 1571

WATI = Wind and Temperature Spectrometer, 234

WATS = Wind and Temperature Spectrometer, 204

WAVES = Radio Plasma Wave Experiment, 981

WBD = Wide Band Data, 885

WBS = Wide-Band Spectrometer, 961

WEFAX = Weather Facsimile (a widely used retransmission service), 617, 646, 737

WFC (Wide-Field Camera), 209

WFI (Wide Field Imager), 1800, 1801

WFI = Wide-Field Imager, 17, 352, 353, 529

WHiRL = Wide-angle High-Resolution Line-imager, 1830

WHISPER = Waves of High Frequency and Sounder for Probing of Density by Relaxation, 884

Widefield Radiometer, 722, 723

WiFS = Wide Field Sensor, 16, 420, 421

Wild RC10, 1598, 1702, 1750

Wild RC10A, 1598, 1702

Wild RC20, 1702, 1750

WINDI = Wind Doppler Imaging Interferometer, 262, 1861

WINDRAD = Wind Radiometer, 1831

WindSat (Wind Microwave Radiometer), 197

WIS = Wedge Imaging Spectrometer, 24, 1381, 1832

WLC (White-light Coronagraph), 845

WOX (Water Ozone Experiment), 1671, 1856

WTE (Whale Tracker Experiment), 508

WVR = Water Vapor Radiometer, 575

X

X-MIR Inspector, 145

X-RADAR (X-band Radar Instrument), 30, 861

X-SAR (SAR for X-band Measurement, 851

XBT (Expendable Bathy-Thermograph), 1868, 1917

XDEX (X-Ray Detector Experiment), 1184

XF (Xenon Flashlamp), 1064

XIPS (Xenon Ion Propulsion System), 1286

XPAA (X-band Phased Array Antenna), 83, 1030

XPS (XUV Photometer System), 241

XRP = X-Ray Polychromator (=BCS+FCS), 954

XRS (X-Ray Spectrometer), 457

XRS = Solar X-Ray Sensor, 620

XRT (X-Ray Telescope), 1297, 1476

XSAR (X-band SAR instrument), 30, 293

XSM (X-ray Solar Monitor), 1107

XSM (X-ray Sky Monitor), 422

Y

YES (Young Engineers' Satellite), 1122

Z

ZL-A = Langmuir Probe Experiment, 867

ZL-A-S = Langmuir Probe, 868, 877
