Poseidon-2 (Solid-State Radar Altimeter). Poseidon-2 is a dual-frequency nadir-looking radar altimeter with the objective to map the topography of the sea surface for calculating ocean surface current velocity and to measure ocean wave height and wind speed. Poseidon-2 is a CNES-sponsored instrument developed by ASI (Alcatel Space Industries) as prime contractor. ¹⁰⁴⁴⁾ Poseidon-2 is of SSALT heritage on TOPEX/Poseidon (chapter E.21). SSALT is being upgraded for the Jason radar altimeter mission by adding a second C-band frequency of 5.3 GHz (Ku-band at 13.575 GHz), as well as changing to digital technology and using a new radiation-hardened microprocessor (the altimeter electronics are split into two boxes, the processing unit and the RF unit). The processing unit includes a chirp generator, baseband demodulator, spectrum analyzer, instrument control unit and interfaces. The RF unit performs the up-conversion to Ku- and C-bands, the high power solid-state amplification, the low-noise amplification of the received echoes, and its mixing with a reference chirp. The C-band channel provides direct ionospheric correction for the primary Ku-band measurement and uses a 1.2 m antenna on the nadir side of the S/C.

Instrument parameters: transmitted pulse width of 105 μ s; PRF of 2100 Hz (1800 for Ku-band and 300 for C-band); maximum RF output power to antenna of 38.4 dBm (Ku-band) and 42 dBm (C-band); mass = 70 kg for dual-frequency configuration; duty cycle = 100%; power = 78 W, thermal control by conduction to mounting surface and by radiation within the instrument; thermal operating range = -5 – 35°C ; IFOV = 20° cone centered at nadir.

The major evolutions of the Poseidon-2 altimeter with respect to SSALT are:

¹⁰⁴³⁾ "Jason-1," ESE Reference Handbook of NASA, 1999, pp. 120-123

¹⁰⁴⁴⁾ L. Rey, G. Carayon, et al., "Poseidon-2, the new generation altimeter for JASON mission," Proceedings of IGARSS'99, Hamburg, Vol. III, June 28-July 2, 1999, pp. 1503-1505

- Addition of the second frequency (C Band) to obtain direct ionospheric correction.
- The digital chirp generator to allow a selectable bandwidth necessary for the C band channel and a better phase knowledge
- Increase of the emitting power to keep an acceptable link budget (the size of the antenna has been decreased with respect to Topex/Poseidon)
- A 128 points FFT transform to obtain a better mispointing evaluation and then reduce the pointing requirements
- Use of a rad hard microprocessor to provide a better radiation tolerance and thus increase the operational availability of the sensor. This microprocessor is also more powerful to increase the on-board processing capability of the altimeter.

Transmission frequencies	5.3 GHz (C-band), 13.575 GHz (Ku-band)
Transmitted pulse width	105.6 μ s
Bandwidth	320 MHz (Ku-band), 320/100 MHz (C-band)
PRF (Puls Repetition Frequency)	1800 Hz (Ku-band), 300 Hz (C-band)
Peak output power	8 W for Ku-band, 25 W for C-band
Max. RF power output to antenna	38.4 dBm Ku-band, 42 dBm for C-band
Noise figure	3.2 dB (Ku-band), 0.9 dB (C-band)
Data rate	22.5 kbit/s including waveform data and onboard parameters

Table 285: Poseidon-2 parameters

DORIS (Doppler Orbitography and Radiopositioning Integrated by Satellite), a CNES/Thomson development. DORIS is a precision orbit determination system providing position and ionospheric correction for Poseidon-2. The DORIS flight segment consists of a two-channel, two-frequency (401.25 MHz and 2036.25 MHz) Doppler receiver capable of tracking signals from a worldwide network of about 50 ground beacons. The Jason DORIS receiver is the same second generation device as the one developed for the ENVISAT mission. Its main functional improvements over first-generation receivers are its capability to receive two beacons simultaneously and to produce on-board the orbit ephemeris in real time with a precision of 1 m. The receiver is controlled by an ultra-stable oscillator delivering the reference frequency with a stability of 5×10^{-13} over a 10-100 second interval and delivering an on-board time output within 0.1 ms accuracy. Two DORIS instrument mass is 31 kg, power = 30 W. For the DORIS concept description, see also chapter E.21.1

JMR (Jason Microwave Radiometer), a JPL instrument of TMR heritage, see chapter E.21). JMR is a passive microwave radiometer measuring the brightness temperatures in the nadir column at 18.7, 23.8, and 34 GHz, providing path delay correction for the altimeter (the brightness temperatures are converted to path-delay information). The 23.8 GHz channel is the primary water vapor sensor, the 34 GHz channel provides a correction for non-raining clouds, and the 18.7 GHz channel provides the correction for effects of wind-induced enhancements in the sea surface background emission. The JMR receivers employ MMIC (Microwave Monolithic Integrated Circuit) technology (built by TRW) for high reliability, low power and low mass. Three temperature controlled noise diodes are used for gain calibration in all the radiometers. JMR consists of a collecting aperture shared with Poseidon-2, a multifrequency feed assembly that illuminates the collecting aperture, multi-channel microwave receivers, a data unit, power supplies, and ground support equipment. Instrument parameters: beamwidth = 1.2° at 18.7 GHz, 1.0° at 23 GHz, and 0.7° at 34 GHz; temperature resolution < 1 K; system temperature = 800 K; mass=27 kg; power = 31 W; data rate = 100 bit/s; thermal control by conduction through the mounting feet of the satellite structure; thermal operating range = 5-35°C.

BlackJack (GPS Flight Receiver). The instrument is of GPS/MET (Microlab) heritage (of a design as flown on CHAMP) and is being provided by NASA/JPL and built by Spectrum Astro Inc. of Gilbert, AZ. BlackJack is a 16-channel GPS receiver with the objective to provide supplementary positioning data to DORIS in support of the POD (Precision Orbit De-

termination) function and to enhance and/or improve gravity field models. Radial accuracies of 1-2 cm are obtained in post-processing. BlackJack is a fully redundant unit. Each unit is comprised of an omnidirectional antenna, low-noise amplifier, crystal oscillator, sampling down-converter, and a baseband digital processor assembly, communicating through a 1553 bus interface. Instrument mass = 10 kg (2), power = 17.5 W. BlackJack can track up to 16 GPS satellites simultaneously in dual-frequency mode. From these signals, BlackJack acquires measurements of the GPS carrier phase providing range measurements with an accuracy of about 1 mm; the absolute pseudo range (defined as the absolute range plus receiver time offset from GPS time) has an accuracy of about 10 cm. BlackJack provides also on-board solutions for S/C position and time, accurate to about 50 m and 150 ns, respectively.

LRA (Laser Retroreflector Array), a JPL instrument of TOPEX/Poseidon heritage, built by ITE Inc. under GSFC contract. LRA provides a reference target for laser tracking measurements, which are necessary to calibrate the POD system and the altimeter throughout the mission. The LRA is placed on the nadir face of the satellite. It is a totally passive unit that consists of nine quartz corner cubes arrayed as a truncated cone with one in the center and the other eight distributed azimuthally around the cone. LRA provides a FOV of about 100°. The LRA instrument mass is 2.2 kg.

Parameter	Topex/Poseidon	Jason-1
S/C mass	2500 kg	490 kg
S/C power	1000 W	450 W
Platform mass	980 kg	245 kg
Platform power	500 W	300 W
Payload mass	385 kg	120 kg
Payload power	380 W	147 W
Altimeter mass	230 kg	70 kg
Altimeter power	260 W	78 W

Table 286: Comparison of mass/power budgets for the Topex/Poseidon and Jason-1 S/C ¹⁰⁴⁵⁾

E.15 LAGEOS-I (Laser Geodynamics Satellite)

LAGEOS-I ¹⁰⁴⁶⁾ = Laser Geodynamics Satellite (NASA). Launch: May 4, 1976 with a Delta launch vehicle from Vandenberg.

Orbit: Near-circular orbit, altitude = 5950 km, inclination = 110°.

Objective: First NASA satellite dedicated wholly to laser ranging. LAGEOS was designed to act as a permanent reference point so that the Earth’s progress could be tracked relative to the satellite (in contrast to the traditional system of tracking satellites relative to the Earth). The USGS uses LAGEOS to measure continental drift (plate tectonics, crustal deformations).

The first four years until 1980 were devoted to determining Lageos’ precise orbit and to building up a global network of 14 Earth stations. By accurately measuring the time for a laser pulse to travel to the satellite and return, the position of the laser system could be determined to about 10 cm. Under NASA’s Crustal Dynamics Project (started in 1979), 56 investigators from 12 countries were making repeated measurements between their locations and Lageos.

The Lageos satellite is an aluminum sphere with a brass core. Its 426 prisms, called cube-corner reflectors, give it an appearance of a golf ball (60 cm diameter and 411 kg mass). The

¹⁰⁴⁵⁾ Y. Menard, Ph. Escudier, “Cruising the Ocean from Space with Jason-1,” EOS/AGU Transactions, Vol. 81, No 34, Aug. 22, 2000, p. 1 and pp. 390-391

¹⁰⁴⁶⁾ Jane’s Spaceflight Directory 1988-89, Fourth Edition, pp. 83-84

three-dimensional prisms reflect laser beams back to the source, regardless of the angle from which they come.

Since the LAGEOS-I orbit is known to extremely high accuracy, the location of a laser ranging station on the surface of the Earth can be determined to a precision of less than 1 cm (by measuring the time for a laser pulse to travel from the laser ranging station to the satellite and return).

Figure 179: Model of the LAGEOS sphere with its reflectors

E.15.1 LAGEOS-II

LAGEOS-II^{1047),1048),1049)} is a collaborative NASA-ASI mission (ASI built LAGEOS-II based on the same design as the NASA-produced LAGEOS-I), a follow-up of LAGEOS-I. LAGEOS-II has a mass of 405 kg, a diameter of 60 cm, and a total of 426 laser reflectors. Shuttle (Columbia, STS-52) launch from Cape Canaveral: Oct. 22, 1992 (NASA).

Italy developed and provided IRIS (Italian Research Interim Stage), a solid-fueled booster, which carried the satellite from the Shuttle's parking orbit into the required Lageos II orbit.

Orbit: LAGEOS-II and LAGEOS-I are deployed in prograde (LAGEOS-II: 52.6° inclination) and retrograde (LAGEOS-I: 110° inclination) orbital planes. Near-circular orbit, altitude = 5950 km.

Objectives: LAGEOS-II is an integral part of the Crustal Dynamics Project (CDP). Study of the Earth's crust in the Mediterranean region. Research in solid Earth geophysics [study of global and local tectonic processes, polar motion and Earth rotation, determination of Universal Time (UT-1), the recovery of Earth and ocean tidal parameters, and geopotential modelling].

¹⁰⁴⁸⁾"Columbia Successfully Lofts Italian Lageos Satellite," Space News, Oct. 26-Nov. 1, 1992, p. 13

¹⁰⁴⁹⁾NASA/ASI Lageos II brochure

LAGEOS-II is an identical S/C to LAGEOS-I. LAGEOS-I and -II are passive satellites dedicated exclusively to laser ranging (no on-board attitude control).

Both LAGEOS satellites are tracked by a global network of fixed and transportable lasers from some 65 sites. The current precision for laser systems varies from 15 cm to less than 1 cm for single-shot range measurements.

The data available to the investigators consist of both preprocessed and analyzed data (i.e. station positions, baselines, and Earth rotation parameters as a function of time). Data will be archived in the Crustal Dynamics Data Information System (CDDIS) at GSFC. The facility is accessible for interactive log-ins through SPAN, INTERNET, etc.

E.16 MAGSAT

MAGSAT is a Johns Hopkins APL/NASA/USGS satellite mission for the survey of the Earth's Magnetic Field. Launch: Oct. 30, 1979 on a Scout vehicle from VAFB, CA. Objectives: collection of data for improved modeling of the time-varying magnetic field generated within the core of the Earth, and to map variations in the strength and vector characteristics of crustal magnetization. ^{1050) 1051) 1052)}

The S/C consists of two distinct parts: the payload module and the base module (containing the subsystems for data handling, power, communications, commanding, and attitude control). The base module is comprised of spare parts from the SAS-C (Small Astronomy Satellite) S/C. The magnetometers were deployed after launch to a position 6 m behind the spacecraft.

Orbit: Sun-synchronous polar orbit; inclination = 96.76° ; perigee = 352 km, apogee = 578 km, period = 93.9 minutes. The satellite remained in orbit for seven and a half months until June 11, 1980.

MAGSAT collected scalar (total-field) and three orthogonal vector components of the magnetic field. During its seven and one-half months in orbit (October 1979 to June 1980), this satellite provided the most accurate measurements of the global field ever obtained, and the first measurements of the vector field in low-Earth orbit.

Sensors: the sensors were mounted on an instrument platform at the end of the 6 m magnetometer boom to eliminate the effect of spacecraft fields. The basic MAGSAT mission required knowledge of the magnetic field orientation to a total system accuracy of < 20 arc-seconds.

- **Scalar Magnetometer** (PI: R. A. Langel), cesium vapor type, with an accuracy of about 0.5 nT. The sensor developed internal oscillations in its lamp circuitry shortly after launch, which prevented full data recovery and which, at times, slightly degraded its accuracy. Its data were, however, sufficient to provide in-flight calibration for the vector magnetometer (8 magnetic field strength measurements/s), except during the last few weeks of operation.
- **Vector Magnetometer** (built at GSFC), fluxgate type, with an accuracy of < 3 nT for each component < 3 nT (after in-flight calibration). The instrument consisted of three fluxgate ring-core sensors mounted on a MACOR (machinable ceramic) structure.

The on-board attitude determination system required two star cameras, two Attitude Transfer System (ATS) optical heads (for pitch/yaw and roll). Two ATS (pitch/yaw and roll)

mirrors were mounted on the back of the vector magnetometer at the end of the boom, providing a reflected beam of light for accurate magnetometer axis determination. A precision sun sensor was mounted in addition on the vector magnetometer for redundant measurements.

Data: MAGSAT carried two on-board tape recorders to allow 10 hours of recorded data to be dumped to a NASA ground station during a pass. The data are available in several formats from the National Space Science Data Center (NSSDC) at GSFC and at NOAA/NGDC (subset of NASA data).

E.17 MIMOSA (Microaccelerometric Measurements of Satellite Accelerations)

MIMOSA is a microsatellite of the Czech Republic, designed and developed at the Astronomical Institute of Ondrejov. The project is funded by the Grant Agency of the Czech Republic. The overall mission objective is to obtain total density distributions in space and time of the upper ionosphere by sensitive measurements of the non-gravitational orbital perturbations (atmospheric drag, solar radiation pressure). The data obtained will serve for analytical model improvements of the upper atmosphere. The project builds on non-gravitational research conducted with the instrument MACEK in previous short-duration missions on the Russian satellite Resurs-F1 (launch June 23, 1992) and on Shuttle flight STS-79 (Sept. 16 - 26, 1996). An improved version of MACEK is the only science instrument onboard MIMOSA. 1053) 1054) 1055) 1056) 1057) 1058)

The design of the MIMOSA spacecraft structure employs a 26-sided symmetrical polyhedron (maximum diameter of 617 mm, the shape is nearly spherical to eliminate the effects of a possible lift) with a high area-to-mass ratio for overall measurement sensitivity (smooth surface for drag measurements). The outer surface is covered with 17 solar panels of 200 mm x 200 mm in size. The inside of the S/C features six subsystems: Balancing masses, ACS (Attitude Control Subsystem), PDU (Power Distribution Unit), Data Management and Store Unit, Telemetry and Telecommand System, and Service Module.

- The balancing mass system consists of three movable masses (1.5 kg each) in each of the main S/C axes with a moving range of ± 20 mm. The objective is to align the center of S/C gravity with that of the proof-mass cavity to better than $0.5 \mu\text{m}$.
- For all gravity measurement operation periods, the S/C is not stabilized, it is orbiting and rotating freely. However, the tumbling or spin of the spacecraft can be readjusted/retarded by magnetic coils (a telecommand action by ground control) whenever the spin of 0.01 radians/s is exceeded. ACS employs eight solar sensors to determine the sun direction to an accuracy of 0.5° . In addition, there is a fluxgate magnetometer and for attitude measurement. Actuation is provided by three magnetic coils to eliminate the initial spin rate. MACEK measurement periods require a residual spin below 0.01 radians/s. In addition, a GPS receiver [MPE-1 (Miniature PLGR Engine) model, where PLGR (Precision Lightweight GPS Receiver)] in PPS mode is being used for orbit determination.

A S/C power of 11 W is provided. Lithium-ion batteries with a capacity of 14 Ah are used during orbital eclipse phases. The S/C mass is 55 kg.

RF communication. The uplink is in UHF-band at 450 MHz the data rate is 1.2 kbit/s. The dual downlink employs S-band (2.2 GHz, data rate at 20/80 kbit/s, bi-phase FM modulation) and VHF-band (137 MHz, data rate at 5 kbit/s). Data of up to 2 MByte can be stored on-board in solid-state memory. The spacecraft control center and ground station is located at the Astronomical Institute. The ground station is in Panska Ves, Czech Republic (the Panska Ves station served already as the ground station for the MAGION satellites).

A launch of MIMOSA is planned for 2002 on an Eurockot launch vehicle from Plesetsk.

Orbit: elliptical orbit, initial perigee = 350 km, initial apogee = 1400 km, inclination = 63.5° . The MIMOSA spacecraft mission is subjected to a decaying orbit, measuring the orbital and attitudinal accelerations (non-gravitational forces) with an expected life time of about nine years. The elliptical orbit selection emphasizes the predominance of drag forces in the lower altitudes, as well as the overriding influence of the solar radiation pressure in regions near the apogee.

Sensor complement:

MACEK (Mikroakcelerometr) is the Czech name for the electrostatically compensated microaccelerometer instrument. MACEK is an accelerometer with six degrees of freedom and a cubic proof-mass. The objective is to detect accelerations to a magnitude of 10^{-10} m/s^2 .

Parameter	SI value of acceleration	Value expressed in "g - notation"
Input range	$\pm 4 \times 10^{-4} \text{ ms}^{-2}$	$\pm 40 \mu\text{g}$ (micro g)
Input frequency	1 mHz to 100 mHz (milliHz)	1 mHz to 100 mHz
Scale factor	25 kV/ms^{-2}	$0.25 \text{ V}/\mu\text{g}$
Bias	$< 1 \times 10^{-5} \text{ ms}^{-2}$	$< 1 \mu\text{g}$
Temperature coefficient	$2.6 \times 10^{-8} \text{ ms}^{-2} / ^\circ \text{C}$	$2.6 \times \text{ng}/^\circ \text{C}$
Measurement resolution	10^{-10} ms^{-2}	0.01 ng
Axis misalignment	$5 \mu\text{rad}$	$5 \mu\text{rad}$

Table 287: Performance parameters of the MACEK instrument

The major element of the MACEK accelerometer is the cubic proof-mass (29.96 mm) moving in a cubic cavity of 30 mm size. The cavity is created by six prism blocks. The cube and

prism blocks are made of a special quartz glass and slightly chrome-plated such that appropriate patterns on the prism blocks and the cube make up the electrodes. The cube is kept within the geometric center of the cavity. During periods of measurement, the cube position is detected by capacitive sensors and stabilized in all six degrees of freedom. The signal of the stabilizing forces provides the magnitude and direction of the acceleration measured.

The total instrument mass is 5.61 kg (2.67 kg sensor head, 2.94 kg electronics box). The sensor head power is 0.6 W, the power for the electronic box is 5.9 W. The sensor head dimensions are: 15 cm x 15 cm x 18 cm. The electronic box dimensions are: 14 cm x 20 cm x 23 cm.

E.18 Ørsted

A Danish geomagnetic research microsatellite mission [named in honor of the Danish scientist Hans Christian Ørsted (1777-1851) who discovered electromagnetism in 1820] developed by a consortium of organizations including the University of Copenhagen, the Technical University of Denmark (DTU), the Danish Meteorological Institute, the Danish Space Research Institute (DSRI), and Computer Resources International. The mission objective is to perform highly accurate and sensitive measurements of the geomagnetic field and global monitoring of the high energy charged particles in the Earth's environment. The data is used to improve geomagnetic models, to study auroral phenomena, and for correlation with Earth-based measurements in order to study the relationship between the external field and the energy coupling of the magnetosphere-ionosphere system. ^{1059) 1060) 1061) 1062) 1063)}

Figure 181: The Ørsted S/C model

Ørsted is in the low-cost microsatellite class, it was launched Feb. 23, 1999 (after almost two years in storage) as a secondary payload to ARGOS of the US Air Force on a Delta II rocket

from VAFB. S/C mass = 61 kg, power = 54 W (22 W average load), S/C stabilization by a gravity gradient boom (8 m boom containing the star imager and magnetometers) and active magnetic torquing (three-axis magnetorquer coils maintain yaw to within 10°). Attitude determination via ASC (Advanced Stellar Compass) a star imager camera, with sun sensors and magnetometers as backup. The satellite has a box-like shape (34 x 45 x 68 cm) and is covered by solar panels (GaAs), 54 W of average power. NiCd batteries provide power in eclipse. Design life of at least one year (three year goal). Ørsted is supposed to fill the gap in magnetic measurements after Magsat (launch of Magsat in 1979, see E.16).

Data: Science data sampling rates: 1 to 100 samples/s. On-board data storage and downlinking every 12 hours or less. Uplink and downlink in S-band (2.114 GHz and 2.296 GHz, respectively). Maximum downlink rate is 256 kbit/s. There are three downlink stations in Denmark.

Orbit: Slowly drifting elliptical polar orbit, perigee = 646 km, apogee = 864 km, inclination = 96.5°. Local equator crossing times at 2:30 AM/PM, drifting at -23 minutes/month.

S/C body dimensions	340 mm x 450 mm x 680 mm
Power	GaAs body-mounted solar panels, 54 W EOL. Two power control units, two 6-cell NiCd battery packs, 6 Ah
Primary structure	H-beam with honeycomb platforms
Attitude control	Gravity gradient and magnetorquers. ACS
Communication	S-band with ESA standard packet TM/TC. Cold redundant TX/RX units
On-board computers	Two, each with 16 MByte storage, 80C186, 16 MHz CPU
Orbit position	Redundant GPS
Boom	8 m deployable 3 longeron (the boom is pointing in the zenith direction)
Thermal control	Passive
S/C mass	61 kg

Table 288: Overview of the Ørsted satellite parameters

Sensor complement:

Scalar Magnetometer (of LETI and CNES, the sensor is provided free of charge by France). Overhauser proton-precession magnetometer [coils for proton resonance excitation and detection, and a resonator for Electronic Spin Resonance (ESR) pumping of a nitro-oxide solution] for measuring magnetic field scalar values with an absolute measurement error of less than 1 nT. Measurement range: 16,000 - 64,000 nT; sampling rate = 1 Hz. Provides in-flight calibration for the vector magnetometer. Sensor mass = 1 kg. The instrument is boom-mounted at a distance of 8 m. The instrument mass is 2.5 kg, power = 3 W.

Vector Magnetometer (DTU). The instrument is a compact spherical coil (CSC) triaxial fluxgate magnetometer which measures magnetic field vectors at an angular resolution of 1 arcsec and an absolute measurement error of less than 1 nT. Dynamic range: ±65,536 nT; resolution: 0.25 nT, 100 vector samples/s burst mode, 10 vector samples/s normal mode. Sensor mass = 300 g. The sensor is boom-mounted at a distance of 6 m from the satellite. The instrument mass is 2.1 kg, power consumption = 1.1 W.

CPE = Charged Particle Experiment (Danish Meteorological Institute). The instrument consists of six solid-state particle detectors for high energy measurements of electrons (30 keV - 1 MeV), protons (200 keV - 30 MeV), and α-particles (1-100 MeV). Detectors look in different directions with a FOV of 15-45°.

ASC (Advanced Stellar Compass) of DTU, Lyngby, Denmark. The objective is to provide an attitude reference instrument with a precision of a few arcseconds aboard the satellite (to measure the magnetic field with a vector precision of a fraction of a nT). The instrument is a CCD star imager for determining the pointing vector for the CSC fluxgate magnetometer with a resolution of 6 arcsec (3 σ) or less. ASC is boom-mounted close to the position of

the vector magnetometer. The camera of the star imager is a 752 x 588 pixel CCD device. ASC consists of a camera head unit (CHU) connected to a DPU (Data Processing Unit), i.e. a microcomputer fitted to a frame-grabber. The CHU acquires star images within its FOV, while the DPU provides the processing power to perform image analysis, pattern recognition, data reduction, and communication. The total mass of ASC is 1.647 kg, the power consumption is 4.5 W.^{1064) 1065)} ASC is also flown (or going to be flown) on the following missions: Astrid-2, TEAMSAT, CHAMP, SAC-C, ADEOS-II, GRACE, and PROBA.

TRSR (TurboRogue Space Receiver), a special GPS receiver provided by NASA/JPL (Trimble Tans II + modified JPL Turbo Rogue). The objective is to a) accurately determine the position of the satellite, and b) the instrument observes in parallel ionospheric electron content, and provides atmospheric soundings permitting the derivation of atmospheric profiles of density, pressure, and temperature (refractive occultation monitoring). TRSR supports both C/A and P code and P-codeless (cross-correlation) operation. It provides parallel dual-frequency code and cross-correlation tracking, and data output of up to eight GPS satellites simultaneously. The TRSR sampling rate is 10 Hz. The instrument has a mass of 4 kg, power = 7-15 W.

E.19 Starlette

Starlette¹⁰⁶⁶⁾ is a CNES 'Solid Earth' mission, a passive satellite dedicated to geodetic and geophysical studies with SLR (Satellite Laser Ranging) observation support. Starlette was launched Feb. 6, 1975 from Kourou on a Diamant B vehicle. Starlette is the world's first passive laser satellite for solid Earth research.

Orbit: Altitude varies between 810 km (perigee) and 1105 (apogee) km, inclination = 50°, projected orbital life = 2000 years.

Objectives: Studies of the gravity field of the Earth (both long term average values and temporal variations due to Earth's tides).

Satellite: sphere with a radius of 12 cm; mass = 47.29 kg; coefficient of reflectivity = 1.1 (approx.). The core parameters are:

- shape: isocaedron
- metal: alloy of uranium 238 and 0.2% of vanadium
- density: 18.7
- satellite mass: 35.5 kg

The skin features are:

- shape: twenty spherical caps with triangular bases, fixed on the faces of the isocaedron
- metal: alloy of aluminum and 5% magnesium

Measurement campaigns require the support of the worldwide SLR network.

E.20 Stella

Stella is a CNES satellite mission launched on Ariane as a passenger experiment (piggy-back) along with the SPOT-3 launch on September 26, 1993. Stella was put on top of Ariane's the third stage with a special device, including a spring to give the required increment of velocity and a spin of 5 to 8 rev/minutes (spin axis perpendicular to the ecliptic).

1064) J. L. Joergensen, C. C. Liebe, "The Advanced Stellar Compass, Development and Operations," *Acta Astronautica*, Vol. 39, No. 9-12, 1996, pp. 775-783

1065) A. Eisenman, C. C. Liebe, "Operation and Performance of a Second Generation, Solid-State, Star Tracker, The ASC, *Acta Astronautica*, Vol. 39, No 9-12, 1996, pp. 697-705

1066) M. Lefebvre, "Stella," *CSTG Bulletin* No. 11, Title: New Satellite Missions for Solid Earth Studies, 1989, pp. 25-32

Orbit: Sun-synchronous quasi-circular polar orbit, altitude = 780-800 km, inclination = 98.2°, orbital life: several centuries.

Objectives: Studies of the gravity field of the Earth. Contribution to the modelling of non-gravitational forces. Contribution to the modelling of Earth and ocean tides in conjunction with other passive laser satellites (LAGEOS-I and -II, ETALON-1, and -2, Starlette, AJI-SAI). Contribution to modeling temporal variations of the gravity field due to geophysical causes like post glacial rebound, allowing determinations of mantle viscosity and possible geographical variations, again in conjunction with tracking data from other laser satellites.

Satellite: Stella is an exact twin of Starlette. Sphere with a diameter of 24 cm, mass of 47.29 kg, etc. Tracking requirement of the worldwide SLR network (international cooperation and active participation is desired).

E.21 TOPEX/Poseidon

TOPEX/Poseidon (Topography Experiment for Ocean Circulation). A NASA(JPL)/CNES joint Earth observation mission. Launch: Aug. 10, 1992 (Ariane 4 launch vehicle from Kourou). Poseidon was originally a separate CNES Mission, but was later combined with TOPEX (1985). TOPEX/Poseidon is the heart of the WOCE (World Ocean Circulation Experiment) program; it was also used for TOGA/COARE (see Part Q). Nominal Life: 3-5 years. TOPEX is regarded as the SEASAT successor mission. Satellite mass = 2402 kg, solar power = 3.4 kW (plus three 50 Ah batteries). Hydrazine propellant system for orbit maintenance. ¹⁰⁶⁷⁾ ¹⁰⁶⁸⁾ ¹⁰⁶⁹⁾ ¹⁰⁷⁰⁾ ¹⁰⁷¹⁾ ¹⁰⁷²⁾

The TOPEX/Poseidon S/C design is based on the Fairchild Multimission Modular Satellite (MMS). The S/C is three-axis stabilized (nadir pointing) via reaction wheels and torque rods. Attitude determination via Earth sensors, sun sensors, star cameras, IRU, magnetometers. The S/C consists of the MMS platform and the instrument module housing the sensors. The MMS consists of the following elements: a command and data handling subsystem which includes the main on-board computer; the attitude determination and control subsystem, for maintaining the spacecraft attitude; and the electrical power subsystem, which contains the solar array and three batteries. The command and data handling subsystem houses three tape recorders for collecting engineering telemetry and instrument data. The S/C has a variety of communication antennas (steerable high-gain antenna dish and two omni antennas) to link the mission with TDRSS, with the DORIS tracking system and with GPS.

Objectives: Dedicated altimetry mission. Combination of high altimetric precision and high orbital accuracy for the purpose of ocean topographic mapping. Measurements of sea surfaces for modeling of global changes in ocean circulation and sea level (global panoramic maps of sea-surface topography). Development of climate models for long-term forecasts (in the order of a season or longer). Requirements: Precision orbit.

Orbit: Circular non-sun-synchronous orbit; 1334 km altitude (2 hour period), inclination = 66°, 10-day repeat orbits.

Note: The satellite orbit tracking coverage provided by the laser and DORIS is not continuous in time, hence, orbit computation based on dynamical equations is required to produce precise orbit for the mission. Observed orbit accuracy: 3 cm (rms for the radial distance).

Figure 182: The Topex/Poseidon S/C model (zenith view)

As of August 1995 the primary TOPEX/Poseidon mission has been completed. The data set from this prime mission has provided oceanographers with the first global data set on the Earth's oceans. The satellite subsystems and sensors are healthy, offering the opportunity of four to seven years of extended operational service.¹⁰⁷³⁾

Sensor complement:

- **ALT** = Radar Altimeter (of GEOS-3, Seasat, and Geosat heritage, ALT is also referred to as NRA = NASA Radar Altimeter). ALT uses a linear FM chirp pulse centered at 13.6 GHz (Ku-band) and at 5.3 GHz (C-band), the dual-frequency design is used to correct for ionospheric path delays (first spaceborne dual-frequency altimeter). The range difference measured at these two frequencies provided a first-order correction for the influence of the ionosphere. The ALT instrument consisted of a signal processor, an RF section, and an antenna assembly. ALT was designed and built by JHU/APL, managed by GSFC. It is the prime sensor for the measurement of sea surface heights, wave heights, and surface wind speed. The Ku-band and C-band bandwidth is 320 MHz, with C-band selectable at 100 MHz; the antenna control pointing accuracy is 0.14° (1-sigma). ALT mass = 206 kg, power = 237 W, altitude measurement accuracy of 2.4 cm. Simultaneous measurements at both frequencies so that ionospheric range delay can be directly estimated from the two measurements.¹⁰⁷⁴⁾

Note: The altimeter antenna (1.5 m parabolic antenna, beam width = 1.1° for Ku-band and 2.7° for C-band) is shared between ALT and SSALT - with ALT using 88% of the time. The data rate of ALT is 9.8 kbit/s.

- **TMR** = Topex Microwave Radiometer (JPL). TMR is of Nimbus-7 heritage. Operation at 18, 21, and 37 GHz to measure the total water vapor content along the altimeter

¹⁰⁷³⁾ TOPEX/Poseidon Internet homepage

¹⁰⁷⁴⁾ A. R. Zieger, et al., "NASA Radar Altimeter for the TOPEX/Poseidon Project," Proceedings IEEE, Vol. 79, No. 6, June 1991, pp. 810-826

pulse path to correct for water-vapor-induced range delay. The uncertainty in the altimeter range measurement made by such a system under normal ocean conditions is expected to be less than 5 cm at 7 km spatial resolution (3 cm at 100 km resolution). Mass = 50 kg, power = 25 W. TMR used a 79 cm diameter nadir-pointed offset paraboloid reflecting antenna to measure atmospheric emissivity. It also used a cold black-body calibration with a cold sky horns looking at right angles to the sun line. The instrument consisted of RF/data modules, power supply modules, cold horns, and multifrequency feed horn. The RF/data modules and power supply modules were located directly beneath the feed horn. The instrument was thermally controlled by louvers and replacement heaters. The footprint of the 21 GHz channel was about 35 km. Measurements of the columnar water vapor along the satellite ground track had an accuracy of 0.2 gm/cm^2 over a range of 0.2 to 6.0 gm/cm^2 . TMR data provided corrections to altimeter height data for the effects of atmospheric water vapor to an uncertainty of 1.2 cm.

- **GPSDR** = GPS Demonstration Receiver system for direct position measurement, JPL (manufacturer: Motorola); Demonstration of GPS differential ranging as an experiment. The GPS receiver measures incoming signals from the GPS satellites and uses in addition ITRF (International Terrestrial Reference Frame, i.e. a set of reference ground stations) measurements for DGPS results. GPSDR operates at 1227.6 MHz and at 1575.4 MHz. Mass = 28 kg, power = 29 W, altitude accuracy < 10 cm. TRANET orbit determination (with the ground network) was dropped in favor of DORIS and laser approaches. (Note: GPSDR is not able to receive P-code measurements; full accuracy is achieved when GPS antispoofing is turned off).
- **SSALT** = Single-Frequency Solid-State Altimeter. (1-frequency of 13.65 GHz). Experimental sensor (of CNES, built by Alcatel/Espace) to demonstrate the concept of low-power, low-mass, low data rate (1/7 the rate of ALT due to extensive on-board processing) and low-cost altimeter for future Earth observing missions. Ionospheric range correction is provided by a model that makes use of simultaneous DORIS measurements. Measurement accuracy = 2.5 cm. SSALT mass = 24 kg, power = 49W. SSALT consists of two packages: the processing and control unit (PCU), and the radio frequency unit (RFU). The Poseidon altimeter sends a pulse generated by a surface acoustic wave generator with a 300 MHz bandwidth and 900 MHz frequency to the sea surface. The pulse is frequency converted to 13.65 GHz after generation. The pulses are amplified before transmission. The received pulses are amplified and an FFT analyzer computed the power spectrum of the signal. The signal is then sent through a microprocessor which performs the waveform computations. The output data is related to the sea state and wind speed.
- **LRA** = Laser Reflector Array, JPL. This passive sensor is used by a ground laser network (of 10-15 SLR stations) to track the position of the satellite for precision orbit determination (verification of altitude measurements). Mass = 29 kg, LRA accuracy depends on laser station characteristics.
- **DORIS** = Doppler Orbitography and Radiopositioning Integrated by Satellite (CNES-GRGS-IGN development). ¹⁰⁷⁵⁾ ¹⁰⁷⁶⁾

E.21.1 DORIS

DORIS is a one-way microwave tracking system for the determination of precise orbits (3-10 cm radial distance and 0.3 mm/s in range rate accuracy). The concept is based on a ground segment (of globally positioned tracking stations) and a space segment (i.e. DORIS as a passenger payload in a satellite consisting of a receiver, an ultra-stable oscillator, and an antenna). There is also a control center as part of the ground segment, located at CNES.

¹⁰⁷⁵⁾ "Other Satellite-Based Microwave Systems," Lecture Notes in Earth Sciences - The Interdisciplinary Role of Space Geodesy, Springer Verlag I. Mueller, S. Zerbini, chap. 5, p. 161

¹⁰⁷⁶⁾ DORIS - Precision Satellite-Based Orbit Determination, CNES brochure

The on-board receiver measures the Doppler shift of ‘uplink beacons’ in two frequencies ($f_1 = 2036.25$ MHz, $f_2 = 401.25$ MHz), which are transmitted continuously by the DORIS ground network of stations (50). One measurement is used to determine the radial velocity between spacecraft and beacon, the other to eliminate errors due to ionospheric propagation delays. Only one beacon can be received by the space segment at any time (Note: a second generation receiver starting with DORIS/ENVISAT will be able to treat simultaneously two beacons). Orbit determinations with a precision of < 5 cm on the radial distance component are achieved on the TOPEX/Poseidon mission.

The DORIS on-board package comprises a receiver, (or radial velocity measurement unit, consisting essentially of two receiving chains; total mass = 17 kg, power = 20 W; size = 385 x 280 x 210 mm), an ultrastable crystal oscillator, and an omnidirectional antenna. IFOV = 125° centered on nadir; data rate = 200 bit/s; duty cycle = 100%; thermal control by conduction to mounting surface and by radiation within the instrument module; thermal operating range = -10 - 50° C.

The DORIS ground segment comprises:

- the DORIS Control Center (DCC) at CNES
- a beacon installation and management center, managed by IGN. A network of Orbit-Determination Beacons (ODBs) is positioned throughout the world.
- Precision orbit determination computations performed by CNES (Earth’s gravitational field computation on the basis of DORIS data by GRGS).

An ODB comprises two transmitters (one operating at 401.25 MHz, the other at 2036.25 MHz), an ultrastable oscillator, and a microprocessor performing the necessary control and management functions, transmission of timing, housekeeping, and failure diagnosis. An ODB also includes an antenna and three meteorological sensors (atmospheric pressure, air temperature, and relative humidity); these parameters are needed for atmospheric propagation delays. An ODB message carries meteorological data, the beacon ID, and information concerning the beacon operating status. The complete message lasts 0.8 seconds and is repeated once every 10 seconds.

A second class of beacons is termed Ground Location Beacons (GLBs). These are at positions that are either unknown or not known to sufficient accuracy. GLBs use the results of high-precision orbit determination as input for the precise determination of ground positions. GLBs are functionally identical to ODBs. Each GLB transmits independently of all others for 10 seconds, once, twice, or three times every minute, but only while the satellite is in range. These beacons are used for precise positioning applications. Since October 1994 DORIS measurements are included in IERS (International Earth Rotation Service).

The master beacon (MB) is the link between DCC and the on-board package. On each pass the DCC transmits instructions for on-board programming and time-tagging information. DORIS time is based on the on-board receiver clock which is related to UTC using master beacon measurements.

DORIS application: All-weather global tracking, ground-beacon positioning, estimate of the total content of ionospheric free electrons. DORIS is flying on-board SPOT-2 and -3, TOPEX/Poseidon; it is scheduled to be on SPOT-4 and on ENVISAT.

Data: The geophysical data produced by the Topex/Poseidon mission (as well as by SPOT-2, -3, etc.) are accessible to the international scientific community through US and French national data centers (IERS/DORIS database operated by IGN). The French data center for oceanography is called AVISO (CNES). The data products include:

- Sea surface topography
- Significant wave height
- Surface wind speed
- Ocean tides
- Vertically integrated atmospheric water vapor

- Vertically integrated ionospheric electron content

E.22 WESTPAC (Western Pacific Satellite)

WESTPAC, formerly known as WPLTN (Western Pacific Laser Tracking Network) satellite, is a commercial Australian communications and research satellite owned by Electro Optic Systems Pty Limited (EOS), Queanbeyan, NSW, Australia. The S/C was designed and built by ISDE (Institute of Space Device Engineering) of Moscow. A wide range of research capabilities have been included into the S/C design, in addition to its communications function. The objective of the passive satellite is to enhance the contribution of satellite laser ranging (SLR), in particular to space geodesy in the Western Pacific, to serve in the development of free space optical communications, and also to study the Fizeau effect that occurs when laser light is reflected from a satellite travelling at orbital velocities. Its primary mission is to act as a target with intrinsically very stable range biases for calibrating ground station biases and satellite signatures. WESTPAC was launched as a secondary payload to RE-SURS-O-4 on July 10, 1998 on a Zenit launcher from Baikonur, along with other secondary payloads [FASat-Bravo (Chile), TMSat (Thai Microsatellite), SAFIR-2 (OHB Bremen), TechSat/Gurwin-II (Israel)].^{1077) 1078)}

Figure 183: The WESTPAC-1 S/C model

The WESTPAC satellite is spherical in shape (24.5 cm in diameter, mass of 23.8 kg) with 60 laser reflectors mounted and evenly spaced to its outer surface (each separated by 26°). The retroreflector design utilizes the Fizeau effect to correct for velocity aberration effects instead of normal dihedral angle spoiling techniques. The Fizeau corner-cubes have a re-

¹⁰⁷⁷⁾Information provided by C. Smith of EOS Pty Limited, Canberra, Australia

¹⁰⁷⁸⁾Armand Fizeau (1819 - 1896) is a French physicist noted for the first experimental determination of the speed of light in 1849. He used a beam of light reflected from a mirror 8 km away. The beam passed through the gaps between the teeth of a rapidly rotating wheel. The speed of the wheel was increased until the returning light passed through the next gap and could be seen. Then "c" was calculated to be 315,000 km/s. Leon Foucault improved on this a year later by using rotating mirrors and got the much more accurate answer of 298,000 km/s. Fizeau's technique was good enough to confirm that light travels slower in water than in air.

fractive index of 1.62, they were built by ISDE. Each cube is recessed so that the average 0.7 cubes retroreflect on any given shot. The prism mirrors reflect any incident laser light back in the incoming direction, irrespective of the incident angle. The distinguishing features of the WESTPAC design include:

- Only a single corner-cube reflects on any shot; in fact on average only 0.7 cubes are active
- Its response is optimized for 1.54 μm wavelength, to provide for fully eyesafe ranging at any power
- A new process was developed to obtain the center-of-mass correction within 0.5 mm accuracy (the retroreflectors are positioned 91.0 mm from the center of mass)
- The corner-cube design and material assumes the Fizeau Effect which, if real, will decrease return signal levels dramatically at 532 mm wavelength.

To minimize size variations due to temperature changes as the satellite travels from sun to shade during its orbit, WESTPAC is covered in a special thermal stabilizing white coating.

Orbit: Sun-synchronous circular orbit, altitude = 835 km, inclination = 98°.

Part F Meteorology - GEO (Geosynchronous Earth Orbit) Missions

F.1 Elektro-M-1(Elektro-Modified-1)

Elektro-M-1 is the planned geostationary meteorological mission of Rosaviakosmos, a successor spacecraft to GOMS (also known as Elektro-1). The overall mission objectives are:

- To provide multispectral imagery (hydro-meteorological data) of the atmosphere (including the cloud-covered sky) and of the Earth's surface within the coverage region (visible disk) of the spacecraft
- To collect heliospheric, ionospheric, and magnetospheric data
- To provide the needed communication services for the transmission/exchange of all data with the ground segment
- To provide the services of data collection for the DCPs (Data Collection Platforms) in the ground segment.

Figure 184: Illustration of the Elektro-M-1 spacecraft

The Elektro-M-1 spacecraft is being built by NPO Lavochkin (Chimki) of Moscow. The S/C is three-axis stabilized. A pointing accuracy of $<0.05^\circ$ is provided; the angular drift is $<5 \times 10^{-4}^\circ/\text{s}$. Two deployable solar arrays provide a power of 1 kW (the mean power consumption of the S/C is about 700 W). The total total mass of the spacecraft is 870 kg. The S/C design life is ≥ 10 years. A launch of Elektro-M-1 is planned for 2006.

Orbit: geostationary orbit at the location of 76° East (over the Indian Ocean).

BRTK (On-board RF Communications System). The objectives are to provide all data transmission, relay, and retransmission services with the ground segment. These consist of the following functions:

- The sensor data downlink to CPPI (Ground Acquisition and Distribution Center) is in X-band (7.5 GHz) at a data rate of 2.56-15.36 Mbit/s
- Data reception from ground segment DCPs at 400 MHz (UHF), or DCP data relayed via LEO satellites at a frequency of 470 MHz. This data is transmitted from Elektro-M-1 to the CPPI in S-band at 1.7 GHz.
- On-board reception of processed hydro-meteorological data products in X-band (8.2 GHz) and relay of this data in HRIT LRIT and WEFAX formats (in S-band at 1.7 GHz) to all customers
- Exchange of hydro-meteorological data and remote sensing data between regional centers in X-band (at 8.2 and 7.5 GHz) with data rates of up to 15.36 Mbit/s
- Data reception of COSPAS-S&RSAT messages at 406 MHz and retransmission of these messages at 1.54 GHz.

Sensor complement: ¹⁰⁷⁹⁾

Multispectral radiometer. The objectives are to obtain solar reflected imagery and brightness temperature measurements from TOA (Top of Atmosphere) and of the Earth's surface (ocean and land). In addition, the tropospheric moisture content is determined. An image of a sub-region of the disk of size yy km x zz km can be obtained in parallel. The instrument data rate is 2.56 - 15.36 Mbit/s.

Band name	Spectral range	Spatial resolution	Comment
VNIR	0.5-0.8 μm (2 channels)	1 km	Cloud cover (solar reflective band)
MWIR1	3 - 4 μm	1 km	Nighttime and cloud cover
MWIR2	5.7 - 7 μm	4 km	Water vapor
TIR1	10.2 - 11.2 μm	4 km	SST (Sea Surface Temperature) and water vapor
TIR2	11.2 - 12.5 μm	4 km	SST and water vapor

Table 289: Some radiometer instrument specifications

RMS (Radiation Measurement System). The objective of this instrument suite is to obtain particles (particle count of protons, electrons and alpha particles), to measure the sun's X-ray radiation, the solar constant, and to measure the magnetic field components.

The translation of Boris Zhukov gives simply a few measurement ranges. I do want a description of the various instruments, including their names.

Registration of:

Electrons: 0.05–50 keV, 0.15–3.2 MeV

Protons: 0.05–50 keV, 5–40 MeV, >25 MeV, >90 MeV, >600 MeV

X-rays: 3–10 keV

Solar UV radiation at 121.6 nm,

Magnetic field – <300 nT

Solar constant instrument.

- Instrument2:
- Instrument3:

Data Collection System:

¹⁰⁷⁹⁾The scant information provided by the Russian contact doesn't permit a real description of the project

F.2 Feng-Yun-2 (Geostationary Satellite Series)

Feng-Yun-2, or FY-2, is a geostationary meteorological satellite series of the Peoples Republic of China (PRC), organized and operated by NSMC (National Satellite Meteorological Center) of CMA (China Meteorological Administration) and built by the Shanghai Institute of Satellite Engineering. The S/C is spin-stabilized at 100 rpm with a despun antenna platform (similar in design and operation to the GMS series of Japan). The FY-2 spacecraft bus is 2.1 m in diameter with a height of about 1.6 m, S/C on-orbit mass = 593 kg. Power (280 W) is generated by surface-mounted solar cells. The observation objectives are:

- Acquiring daylight visible cloud maps, day-and-night infrared cloud maps and water vapor distribution maps
- Data collection from meteorological, oceanic and hydrological observational platforms
- Broadcasting of stretched digital cloud maps, low resolution cloud maps and weather map information
- Obtaining cloud top and sea surface temperatures as well as the wind field distribution by data processing.

Note: ¹⁰⁸⁰⁾ The first FY-2 satellite series, FY-2A, was undergoing final check-out on 2 April 1994, before being mated to its launch vehicle, when a fire and explosion erupted, destroying the vehicle.

Figure 185: The FY-2 S/C model

F.2.1 FY-2A

A second identical satellite, also referred to as FY-2A, was built by the Shanghai Institute of Satellite Engineering and launched by a Long March 3 (CZ-3) booster from Xichang on June 10, 1997. The first imagery of S-VISSR was received on July 13, 1997. FY-2A data can be received by all international users.

¹⁰⁸⁰⁾A. Lawler, "Blast at Xichang Derails China's Weather Effort", Space News, May 2-8, 1994, p. 3

On 8 April 1998, FY-2A ceased transmission of S-VISSR images, to resume for a few hours on 10 April, due to a problem with the S-band antenna on the spacecraft. CMA managed to regain Earth lock and ranging with the S-band antenna for 12 hours on 14 April 1998, but there were no regular S-VISSR re-transmissions during the summer of 1998. However, CMA could still get raw image downlinks a few times per day, and they would make one full-earth picture on the ground each day, but not broadcast it. As of October 1998, CMA resumed a partial but regular communication service of six transmissions per day.¹⁰⁸¹⁾

Orbit: Geosynchronous orbit at position: 105° eastern longitude.

Sensor:

S-VISSR (Stretched - Visible and Infrared Spin-Scan Radiometer), an optomechanical system. Scanning modes: a) normal scanning; b) optional scanning; c) single line scanning. A picture frame (normal scanning) = 30 minutes, a scan (North-South) = 2500 steps. The telescope collects radiation during each scan and focuses it on the detectors in the focal plane using primary and secondary mirrors. The Si photodiode detector array has four elements mounted normal to the scan direction, providing a 5 km wide instantaneous observation coverage on each scan line, matching the scan line width of the IR detectors with only one detector element. The HgCdTe detectors are cooled by radiation coolers to a temperature of 100 K. A complete scan of 20° x 20°, covering the full Earth disk, is obtained every 30 minutes by means of the S/C spin motion (100 rpm from E-W) and the step action (2500 steps from north to south) of the scan mirror.

Parameter	Visible	Infrared	Water vapor
Spectral band (μm)	0.55 - 1.05	10.5 - 12.5	6.2 - 7.6
No. of detectors/channels	4 (+4 spare)	1 (+1 spare)	1 (+1 spare)
Scan lines	2500 x 4	2500	2500
Spatial resolution	1.25 km x 1.25 km IFOV=35 μrad	5 km x 5 km IFOV=140 μrad	5 km x 5 km IFOV = 140 μrad
Detectors	Si photodiode	HgCdTe	HgCdTe
Data quantization	6 bits	8 bits	8 bits
Noise performance	SNR=6.5 (albedo=2.5%) SNR= 43 (albedo=95%)	NEDT=0.5-0.65 K (300 K)	NEDT= 1 K (300 K)
Scan step increment	140 μrad (N-S scanning)		
Temporal resolution	30 minutes (frame time)		

Table 290: Some characteristics of S-VISSR

The FY-2 ground segment (geostationary satellites) consists of the following facilities: 1) CDAS (Command and Data Acquisition Station); 2) DPC (Data Processing Center); 3) SOCC (Satellite Operations and Control Center); 4) ranging stations (one primary and three secondary stations, including one in Australia); 5) DCPs (Data Collection Platforms); 6) MDUS (Medium-scale Data Utilization Station) and SDUS (Small-scale Data Utilization Station) stations.

Channel	Frequency	Modulation	Power	Bandwidth
S-VISSR	1687.5 MHz	PCM/BPSK, NRZ-M	57 dBm	2 MHz
LR-Wefax	1691.0 MHz	AM/FM	57 dBm	260 kHz
S-Fax	1699.5 MHz	AM/FM	46 dBm	26 kHz

Table 291: Some downlink characteristics of FY-2A

FY-2 series communication: The FY-2 satellites broadcast their data to the ground, this includes S-VISSR, WEFAX and S-FAX data. S-VISSR data are received at MDUS, while

¹⁰⁸¹⁾<http://202.106.103.181/s-vissr.htm>

WEFAX and S-Fax (domestic use only) data are retransmitted to SDUS stations only. The S-FAX link transmits processed satellite image data, other weather data and administrative information via S-band to domestic users in China.

Digital and cloud map transponder: Frequency: 1.7/2.0 GHz; EIRP (dB_w) original cloud map and stretched cloud map: 57.5; EIRP (dB_w) weather map broadcast: 46. The data rate of S-VISSR is 660 kbit/s. Since the signal characteristics of the S-VISSR instrument data are the same as those of the VISSR instrument of the Japanese GMS series (except the frequency), the user stations receiving GMS VISSR data are also capable of receiving S-VISSR data, simply by changing the antenna pointing and frequency of the receiver local oscillator.

Data Collection System (DCS) of the FY-2 Series

The DCS provides operational collection services for data collection platforms (DCPs) within its field of view. The overall system is composed of the following subsystems:

- The space segment: a DCS platform on the FY-2 satellite consisting of: a UHF/S-band transponder, a mechanically despun S-band antenna, and a UHF receive antenna. Data collection transponder: Frequency = 401/468 MHz; EIRP = 47.3 dB_w; No. of channels: 133, 100 of these channels are for domestic use and 33 international channels. DCS offers a capability and a new digital S-band fax service (CCITT G3) for domestic distribution of charts and imagery.
- The deployed DCPs (Data Collection Platforms) in the ground segment. The regional DCPs are stationary DCPs installed on buoys, islands, rivers, mountains or ships.
- The ground-based NSMC (National Satellite Meteorological Center) which collects and processes the DCP data and distributes it via GTS to the user community.

F.2.2 FY-2B

The second Chinese GEO satellite FY-2B was launched on June 26, 2000 from the Xichang launch center with the Long March 3 vehicle.¹⁰⁸²⁾

The FY-2B S/C is identical to the previous FY-2A satellite and carries the same payload (S-VISSR, and DCS). The S/C is spin-stabilized with a spin rate of 100 rpm. The on-orbit dry mass is 600 kg, the launch mass is 1200 kg. The S/C design life is 3 years.

The daytime visible image can be used to derive the reflectance of cloud top and the earth surface, the nighttime infrared image can observe the thermal radiance, while the water vapor image can estimate the water vapor amount in the atmosphere. The satellite also broadcasts low resolution WEFAX image and collects data from automatic data collection platforms. Free transmission of S-VISSR data and WEFAX imagery are open to all users within the FY-2B transmission coverage.

Orbit: Geosynchronous orbit at position: 105° eastern longitude.

Channel	FY-2, A, B	FY-2, C, D, E
VIS (Visible)	0.50 - 1.05 μm	0.50 - 0.75 μm
IR1 (Infrared 1)	10.5 - 12.5 μm	10.5 - 11.5 μm
IR2		11.5 - 12.5 μm
IR3		3.5 - 4.0 μm
WV (Water Vapor)	6.3 - 7.6 μm	6.3 - 7.6 μm

Table 292: Spectral layout of the VISSR instrument beyond FY-2B

Current plans call for VISSR instrument improvements beyond FY-2B, featuring five channels instead of three. In addition, the power supply of each S/C will be increased to accommodate the demand.

¹⁰⁸²⁾<http://202.106.103.181/>

F.3 GMS (Geostationary Meteorological Satellite)

GMS = Geostationary Meteorological Satellite of JMA (Japan Meteorological Agency) and NASDA. GMS is also known by the name of Himawari. The GMS series satellites represent a link in World Weather Watch (WWW) sponsored by the World Meteorological Organization (WMO). The operational meteorological program has the following satellites:

GMS-1 F1	Launch: July 14, 1977	NASA Delta 2914 vehicle	Position: de-orbit
GMS-2 F2	Launch: Aug. 11, 1981	N-II vehicle of NASDA	Position: de-orbit
GMS-3	Launch: Aug. 3, 1984	N-II vehicle of NASDA	Position: 120° East
GMS-4	Launch: Sept. 6, 1989 Operations until Feb. 2000	H-I vehicle of NASDA	Position: 140° East
GMS-5	Launch: Mar. 18, 1995	H-II vehicle, NASDA	Position: 140° East

Table 293: GMS program overview

The mission objectives of the GMS program are:

- 1) Weather watch by VISSR: a) imaging the Earth's surface, cloud distribution and atmospheric water vapor distribution, and observation of meteorological phenomena such as typhoons, cyclones, fronts, etc. b) meteorological parameter extraction such as temperature on both Earth surface and cloud tops, cloud top height, cloud amount, cloud motion, etc.
- 2) Collection of meteorological data from DCPs (Data Collection Platforms) installed on ships, buoys, aircraft, and other land weather stations.
- 3) Direct broadcast of cloud images: a) dissemination of digital image data (stretched VISSR data) via satellite repeater to MDUS (Medium Scale Data Utilization Station) users. b) dissemination of analog processed image data (WEFAX data) via satellite to SDUS (Small Scale Data Utilization Station) users.
- 4) Monitoring of solar particles

GMS-4 is a spin-stabilized satellite (100 rpm) weighing 725 kg (satellite diameter = 214.6 cm, height = 345 cm). The S/C consists of a despun Earth-oriented antenna assembly and a spinning section rotating at 100 rpm. Despun S-band and UHF antennas provide high gain for on-orbit communications with ground stations.¹⁰⁸³⁾

Attitude information is provided by Earth horizon and sun sensors. The spacecraft transmits its data in L-band (1.7 GHz) to JMA (Japan Meteorological Agency).

Sensor complement:

- **VISSR** (Visible and Infrared Spin-Scan Radiometer), built by Hughes SBRC. Spectral bands: 0.50 - 0.75 μm (visible), and 10.5 - 12.5 μm (infrared). Resolution: 1.25 km (visible) and 5 km (infrared). The VISSR is used to obtain visible and infrared spectrum mappings of the Earth and its cloud cover. Four photomultiplier tube detectors (PMTs) and redundant sets convert the visible spectra into four-channel analog signals. A cooled (95 K) HgCdTe detector (also redundant) converts infrared spectra into an infrared signal (10.5–12.5 microns) at 5 km resolution. The resulting data stream is then fed into the VISSR Digital Multiplexer (VDM) unit. A complete 20° x 20° scan area to cover the full Earth disk can be accomplished in 30 minutes utilizing the GMS's 100 rpm spin motion for west-east scans and 2500 steps (140 μrad each) of motor-actuated VISSR mirror scan for north-south scans. Imaging takes 25 minutes, mirror retrace another 2.5 minutes, and a spacecraft stabilization 2.5 minutes.

¹⁰⁸³⁾ M. Homma, M. Minowa, M. Kobayashi, M. Harada, "Geostationary Meteorological Satellite System in Japan" in 'Monitoring Earth's Ocean, Land, and Atmosphere from Space,' Volume 97 AIAA, 1985, pp. 570-583

VDM (VISSR Digital Multiplexer). VDM is a high-speed pulse code modulation (PCM) encoder. It converts VISSR signals into digital form and multiplexes them with image and message synchronization data.

- **SEM** (Space Environment Monitor, NOAA sensor). Spectral bands: 1 - 500 MeV (protons); 8 - 390 MeV (alpha particles); >2 MeV (electrons). SEM measures three kinds of solar particles: protons, alpha particles, and electrons.
- **DCS** (Data Collection System) from ground platforms (see METEOSAT and NOAA-GOES)

F.3.1 GMS Data Collection System (DCS)

The GMS DCS provides operational collection services for data collection platforms within its field of view. The overall system is composed of the following subsystems:¹⁰⁸⁴⁾

- 1) The space segment: a DCS platform on GMS satellites consisting of: a UHF/S-band transponder, a mechanically despun S-band antenna, and a UHF receive antenna.
- 2) The deployed DCPs (Data Collection Platforms) in the ground segment
- 3) The ground-based MSC (Meteorological Satellite Center)

The DCS on-board GMS provides a transponder with a passband that is divided into 133 communication channels separated at intervals of 3 kHz. The system has the ability of simultaneous communication through all channels. The 133 channels are divided into two blocks: 100 are for regional use, and 33 are for international use. Each DCP is allocated one of the 133 parallel channels. Since the DCPs transmit either according to a schedule, or under 'alert' conditions, many platforms can use a single 3 kHz channel sequentially. A message from a DCP in the ground segment is relayed via the GMS on-board DCS to a ground-based MSC which is responsible for the coverage area. - The platforms (DCPs) transmit (uplink) their data in the 402 MHz UHF band to the GMS on-board DCS, where it is converted to S-band (1694 MHz) and retransmitted (downlink) to a ground facility CDAS (Command and Data Acquisition Station) and relayed via GTS to MSC. There, the DCP messages are collected, processed, disseminated, formatted into bulletins and distributed via GTS to the platform owners.

As of the end of 1995, 448 DCPs in the ground segment are regularly serviced by GMS. The DCPs which can be operated by the system are of two types:

- self-timed DCPs which transmit their data automatically at preset time slots driven by an internal stable clock
- interrogational DCPs which transmit their data only when an interrogation command is received at the DCP.

The GMS DCS is part of an international network in the framework of WWW (together with Meteosat and GOES series satellites); this allows a further classification:

- International DCPs (IDCPs) which are mobile (Lagrangian type free-floating in the medium) and whose data may be collected by any one of the satellite operators. The allocated frequency band for the IDCP operation is 402.0-402.1 MHz for the uplink and 1694.3-1694.4 MHz for the downlink.
- Regional DCPs (RDCPs) which are under the responsibility of and operated by a specific satellite operator. The allocated frequency band for the RDCP operation is 402.1 - 402.4 MHz for the uplink and 1694.4 - 1694.7 MHz for the downlink.

The data transmission rate for both types of platforms is 100 bit/s.

¹⁰⁸⁴⁾Information provided by T. Hiraki of JMA, Tokyo

Communication Link	UHF (Uplink to GMS DCS)	S-band (DCS downlink)
Frequency	402.0-402.4 MHz	1694.3-1694.7 MHz
Type of modulation	PCM/PSK ($\pm 60^\circ$)	PCM/PSK ($\pm 60^\circ$)
EIRP	43.0 dBm	11.3 dBm
Free space loss	176.7 dBm	188.3 dBm
RCVR off-beam loss	0.4 dB	0.6 dB
RCVR input power level	-134.1 dBm	-177.6 dBm
RCVR system noise temperature G/T	-19.0 dB/K	27.2 dB/K
RCVR C/T	-153.1 dB/kHz	-150.4 dB/kHz

Table 294: DCP link budget for GMS operation

F.4 GOES (Geostationary Operational Environmental Satellite)

A NASA/NOAA weather satellite series. NASA, under contract from NOAA, manages the program acquisition (design, development and launch of the satellite); NOAA owns and operates the satellites and provides the services to the user community. All GOES first and second-generation satellites have an operational design life of nominally 5 years.

Figure 186: The GOES First Generation S/C model

Background: ¹⁰⁸⁵⁾ ATS-1 (Applications Technology Satellite) was the first US geostationary satellite (launched December 6, 1966) with the ability to “see weather systems” by imaging the full-disk Earth every half hour with a spin scan camera. Operational use of ATS-3 (launched November 6, 1967) imagery at NSSFC (National Severe Storm Forecast Center) and at NHC (National Hurricane Center) followed in 1972. A total of six spacecraft were part of the ATS series. The prime objective of the series was to test new technologies (spin stabilization, gravity gradient stabilization, demonstration of data collection from remote terminals, etc.) for communications and to investigate the geostationary orbit environment.

¹⁰⁸⁵⁾ W. P. Menzel, J. F. W. Purdom, “Introducing GOES-I: The first of a Generation of new Geostationary Operational Environmental Satellites,” Bulletin of the American Meteorological Society, Vol. 75 No. 5, May 1994, pp. 757-781

NASA developed two Synchronous Meteorological Satellites (SMS-1, -2), which were launched on May 17, 1974 and February 6, 1975. A total of eight additional “GOES” satellites in the same series were funded by NOAA, the first being GOES-1 launched on October 16, 1975. The last satellite in this initial series (1st generation) was GOES-7.

Spacecraft	Launch	Comment
SMS-1 (SMS-A)	May 17, 1974	First operational geostationary weather satellite, S/C mass = 627 kg, full-disk images of western hemisphere every 30 min.
SMS-2 (SAMS-B)	Feb. 6, 1975	
GOES-1 (GOES-A)	Oct. 16, 1975	S/C mass of 293 kg.
GOES-2 (GOES-B)	Jun. 16, 1977	
GOES-3 (GOES-C)	Jun. 16, 1978	
GOES-4 (GOES-D)	Sept. 9, 1980	GOES-4 VAS failed in Nov. 1982. The VAS instrument of GOES-4 was able to provide the first vertical temp. and moisture measurements from GEO
GOES-5 (GOES-E)	May 22, 1981	
GOES-6 (GOES-F)	Apr. 28, 1983	
GOES-G	May 3, 1986	Launch failure
GOES-7 (GOES-H)	Feb. 26, 1987	First GOES with an S&RSAT system flown
GOES-8 (GOES-I)	Apr. 13, 1994	First second generation S/C (3-axis stabilized); S&RSAT became operational on GOES-8
GOES-9 (GOES-J)	May 23, 1995	
GOES-10 (GOES-K)	April 25, 1997	In the initial mission, the S/C suffered a solar array malfunction. A recovery procedure was performed to invert the S/C and operate the solar array in the reverse direction. The S/C became operational in July 1998. It replaces GOES-9 which had problems with its attitude control system. GOES-10 is positioned at 135° W.
GOES-11 (GOES-L)	May 3, 2000	GOES-11 was launched into a storage orbit
GOES-12 (GOES-M)	July 23, 2001	GOES-M is the last of the 2nd generation S/C built by SS/L
GOES-N	2003	
GOES-O	2005	
GOES-P	2007	
GOES-Q	2010	
GOES-R	2012	

Table 295: GOES S/C launches ¹⁰⁸⁶⁾

The GOES system serves a region covering the central and eastern Pacific Ocean, North, Central, and South America, and the central and western Atlantic Ocean to the coast of Africa. Pacific coverage includes Hawaii and the Gulf of Alaska. This is accomplished by a two operational satellite configuration, GOES-East (75° West) and GOES-West (135° West). A common ground station at Wallops, Virginia, supports the interface to both satellites. The NOAA/NESDIS SOCC (Satellite Operations Control Center) in Suitland Maryland, provides spacecraft operations and all services to the user community. The GOES ground segment also uses seven satellite field service stations, located at: Anchorage, Honolulu, Kansas City, Miami, New Orleans, San Francisco, and Washington, D.C.

Delivery of products involves ground processing of the raw instrument data for radiometric calibration and Earth location information, and retransmission to the satellite (GOES) for relay to the data user community. The processed data are received by the National Weather Service (NWS, at Camp Springs, MD) and the NWS forecast offices, including the National

¹⁰⁸⁶⁾Note: For a number of years the designation GOES Next (N) was used to identify the first of the satellites that would follow the GOES I-M series. It was also thought this GOES N would be the start of a totally new generation satellite series. However, during the time frame of about 1992-95, NOAA has come to realize that a new satellite series would take at least a decade to develop, manufacture, and launch. This new situation made NOAA realize it would need a few more clones of the current GOES I-M series to maintain continuity of GOES service prior to the GOES Next being available. What has evolved is a program that will likely buy 3-4 additional GOES I-M satellites beyond the GOES I-M series. These would then be labeled GOES N through Q. GOES R would be the first of a new generation of three-axis stabilized satellites. (Information: R. Heymann of NOAA).

Hurricane Center at Miami, FL, and the National Severe Storms Forecast Center at Kansas City, Missouri. Processed SOCC data are also received by DoD installations, universities, and numerous private commercial users.

Note: The GOES-I-M series¹⁰⁸⁷⁾ is a change from the spinning S/C design of GOES-7 and before to a three-axis stabilized S/C to increase the observational dwell times and to achieve other improvements.

Application: Weather forecast, meteorology, derivation of temperature and moisture profiles, monitoring severe storms and tropical cyclones (hurricanes), etc.

According to NOAA convention all satellites are designated with a letter prior to achieving orbit. The letter name is converted into a number on achieving orbit. For instance, GOES-J, launched on May 23, 1995, was redesignated as GOES-9 on May 31, 1995 on achieving geosynchronous orbit.

Sensor complement of first-generation S/C series:

VISSR = Visible Infrared Spin Scan Radiometer (built by Hughes SBRC). Measurement (scanning) in eight channels in the visible range and two channels in the infrared spectrum. VISSR acquires imagery as it spins west-to-east at 100 rpm aboard a spin-stabilized S/C, step scanning north to south on each spin to provide cloud imagery and data for determining cloud and surface temperatures and wind fields. The instrument uses a Ritchey-Chretien telescope of 40.6 cm diameter, f/7.2; spectral bands: 0.55 - 0.72 μm (VIS) and 10.5 - 12.6 μm (TIR); detectors: S-20 (PMT (8), HgCdTe (2 at 90 K); resolution = 0.9 km in VIS and 7 km in TIR. Instrument mass = 63.2 kg for the scanner module and 7.0 kg for the electronics module. The VISSR instrument has been flown on five US satellites (SMS-1, -2, GOES-1 through -3) and five GMS (NASDA/JMA) satellites (GMS-1 through -5).

VAS = VISSR Atmospheric Sounder (built by SBRC).^{1088) 1089) 1090)} This VISSR successor instrument has been flown on GOES-4 through -7). VAS is a radiometer with eight visible channel detectors and six thermal detectors that detect IR radiation in 12 spectral bands (two of the detectors are used primarily for imaging and four for atmospheric sounding). The instrument uses a Ritchey-Chretien telescope of 40.6 cm diameter, f/7.2 (VIS), f/1.0 (IR); detectors: S-20 (PMT (8), InSb; HgCdTe; spectral bands: 0.55 to 0.70 μm (VIS) and 12 channels in IR in μm [1) 14.734, 2) 14.480, 3) 13.984, 4) 13.984, 5) 1.333, 6) 4.525, 7) 12.658, 8) 11.173, 9) 7.261, 10) 6.725, 11) 4.484, 12) 3.945]; the spatial resolution is 0.9 km in the VIS range and 7-14 km in the IR range. Instrument mass = 68 kg. Full Earth-disk coverage is accomplished by spinning in the west to east direction at 100 rpm. The VAS sensor has three operational modes:

- 1) The VISSR operating mode (same as that of the original VISSR)
- 2) The multispectral imaging (MSI) operating mode. Measurement of relatively frequent (eg., half hourly) full Earth-disk imagery of atmospheric water vapor, temperature, and cloud distribution, as well as variations in the surface skin temperature of the Earth.
- 3) In the dwell sounding mode (DS) up to 12 spectral filters can be positioned in sequence into the optical train while the scanner dwells on a single N-S scan line. This allows data to be obtained on the Earth's atmospheric water vapor and CO₂ bands. Note: the DS mode cannot be used simultaneously with either the VISSR or MSI mode.

DCS = Data Collection System. This on-board system gathers and relays environmental data transmissions that originate at remote automatic Data Collection Platforms (DCPs)

1089) J.R. Greaves, W.E. Shenk, 'The Development of the Geosynchronous Weather Satellite System,' in Monitoring Earth's Ocean, Land, and Atmosphere from Space, Volume 97, 1985, pp. 150-181

1090) Space Sensors, brochure of Hughes Santa Barbara Research Center (SBRC), January 1994

for obtaining in situ data. These platforms can be set to transmit data in four modes: at fixed times; in response to interrogation; in an emergency mode during which the platform signals for a GOES interrogation within 1 minute; and in an adaptive random reporting mode. The DCS collected data are retransmitted from satellite to small ground-based regional data utilization centers. The system also allows for the retransmission of narrow-band **WE-FAX** (Weather Facsimile) data to existing small, ground-based APT (Automatic Picture Transmission) receiving stations from a larger facility.

Background: The WEFAX service has been a feature of the GOES system since 1975. The service uses the S/C as a transponder to transmit low-resolution imagery sectors as well as conventional weather maps to users with low-cost reception equipment. There are literally hundreds of WEFAX reception stations that use the GOES WEFAX service. With the GOES VAS system, the WEFAX service was provided at UHF frequencies and was not continuous since it interfered with other S/C functions. The WEFAX service with GOES I-M is a continuation of the previous service, however, transmissions are continuous, and the transmission frequency has changed from UHF to S-band at 1691.0 MHz, with a signal bandwidth of about 30 kbit/s. Up to 13 maps or images can be transmitted through the GOES I-M system every half hour.

F.4.1 NOAA-GOES Data Collection System (DCS)

The Data Collection System (DCS)^{1091),1092),1093)} on NOAA-GOES satellites provides an operational data collection service for a large number of land-, air- and sea-based data collection platforms (DCPs). Geostationary satellites (like GOES) offer the advantage of continuous coverage; however, their coverage is not global, but limited to the GOES service region. The overall system is composed of the following subsystems:

- 1) The space segment: a DCS platform on two operational GOES satellites (GOES-East, and GOES-West). Each GOES S/C is equipped with two DCS transponders, one active and one as backup.
- 2) The deployed Data Collection Platforms (DCPs) in the ground segment
- 3) The NESDIS DCS ground receive system CDA (Command and Data Acquisition Station) at Wallops Island, Virginia.
- 4) The DAPS (Data Collection System Automatics Processing System) at CDA.

The Space Segment: DCS

The DCS on-board GOES uses the GOES S/C for the relay of data from remotely located in-situ sites at or near the Earth's surface to properly equipped receiving stations in radio view of the GOES satellites. Each GOES provides an RF link between the DCP and CDA. They up-convert DCP data from UHF (401.9 MHz) to S-band (1694.5 MHz) for transmission to CDA, and down-convert the CDA -DCP interrogate signal from S-band (2034.9 MHz) to UHF (468.8 MHz).

The DCS uses 400 kHz of satellite transponder bandwidth. This bandwidth is subdivided (by frequency division multiplexing) into 200 domestic channels with a 1.5 kHz channel separation (channels 1-200), and 33 international channels (channels 202 - 266, even numbered only) with a 3 kHz channel separation. The 33 international channels are common to those of METEOSAT, GMS and GOMS spacecraft.

The DCS has the capacity for handling at least 25,320 messages from DCP sites via the spacecraft transponder in each one-hour period. This figure is based on the present capabil-

1091) "The Geostationary Operational Satellite Data Collection System," NOAA Technical Memorandum NESDIS 2, June 1983

1092) "Users Guide for Random Reporting - An Introduction to GOES Random Reporting Services," NOAA, April 1985

1093) User Interface Manual, Version 1.1, for the 'Data Collection System Automatic Processing System (DAPS),' Integral Systems Inc., Sept. 1990

ity to assign 30-second transmission windows for each of the 200 domestic channels, i.e., 120 windows per hour over 200 channels ($120 \times 200 = 24,000$), plus 33 international channels ($33 \times 40 = 1320$), $1320 + 24,000 = 25320$. - With advances being made in the stability and accuracy of timing oscillators, transmission windows of 15 seconds may become standard in the future. The data transmission rate for all operational modes is currently (1995) 100 bit/s. Prototype 300/1200 bit/s DCPs are being developed and should become operational by 1996.

Data Collection Platforms in the Ground Segment

All DCPs serviced by GOES must be type-certified by NOAA-NESDIS. The types available to the user community have the following functional capabilities:

- Self-timed DCPs (this is the most common mode of use)
- Self-timed and random reporting DCPs
- Random reporting DCPs
- Interrogated DCPs
- Self-timed and interrogated DCPs
- Random and interrogated DCPs

1) Self-timed DCPs. - These are simple platforms containing a transmitter and a pre-programmed self-timer to report at a specific time and intervals to the GOES. The sensor measuring cycle is independent of the DCP reporting cycle. Sensor data may be recorded at the DCP prior to a message transmission to GOES. The reporting frequency from a DCP may vary from a few minutes to a few hours.

2) Self-timed and random reporting DCPs. - Same functionality of 1) with the addition of capability of transmitting over a secondary channel when environmental conditions require more frequent reporting than offered under self-timed operation.

3) Random reporting DCPs. - The platform contains a transmitter that broadcasts at random time (threshold reporting, set by the user). During normal periods a random reporting DCP is expected to report up to three times per day that it is properly functioning.

4) Interrogated DCPs. - Scheduled transmissions initiated from the CDA at NESDIS (the schedule is stored at CDA). This type of DCP contains a receiver and transmitter. The receiver detects its own DCP ID upon message reception from CDA. Upon detection of its ID the DCP transmits all data accumulated since the last reporting sequence. Interrogated DCPs may be interrogated as often as every 5 minutes or as infrequently as once per day. In addition some interrogated DCPs have a second or alert reply channel that may be used for threshold reporting. Interrogated DCPs may be reconfigured by CDA command when requested by the user.

5) Self-timed and interrogated DCPs. - This type of DCP operates in a self-timed mode under normal conditions. When a message is not received at the DCP's normal reporting time, an interrogation address is sent via the DAPS to the DCP and a reply is expected over the interrogate reply channel.

6) Random and interrogated DCPs. - This mode of operation is used to monitor special events (such as seismic events). When the event condition reaches a pre-set level, a random transmission is sent through the GOES S/C. Only the DCP ID (address) is transmitted. When the ID is received by the DCS system at the CDA, an interrogate ID is transmitted through the GOES S/C. The interrogate ID can be used as a notification of the event, to change a DCP's mode of operation, or to cause certain functions to be performed.

NOAA-NESDIS Ground Segment

The NOAA ground system consists of the RF front-end equipment and the DCS computer equipment or DAPS (GOES DCS Automatic Processing System). The messages received

from the DCPs are routed to the DAPS, which provides all required processing and dissemination functions including data storage and distribution to the user community.

DCS Access Method

Data transmission from a DCP in the ground segment to the DCS on-board GOES is generally initiated (i.e. self-triggered) by the ground segment DCPs (except for the few interrogated DCPs). All of the 200 channels on-board GOES are in listening mode, being available all the time. The assigned transmission times of the DCPs are actually time intervals (slots) of 1 minute duration.

As of the end of 1993, NOAA service records list 7728 activated DCPs being serviced by GOES S/C, out of a total of 11,927 DCPs that are assigned to the GOES user community at large.¹⁰⁹⁴⁾ - There are six DCPs of the type 'interrogated' serviced by NOAA/NESDIS and used for seismic and tsunamic warning. In addition there are another 15 DCPs which use the interrogate mode as backup to the self-timed mode and to command these DCPs to perform specific functions under specific conditions.

Figure 187: Schematic overview of the GOES Data Collection System

F.4.2 NOAA-GOES SEM Instruments

The **SEM** = Space Environment Monitor instrument package on each of the GOES satellites provides data which are processed by SEL (Space Environment Laboratory, Boulder CO) of NOAA in near real-time for space environment forecasts. The SEM instruments survey the sun and monitor the solar-terrestrial electromagnetic environment that affects a number of Earth activities [operational reliability of ionospheric radio (satellite communications, navigation systems), over-the-horizon radar, electric power transmission, crews on-board of high-altitude aircraft and space stations].

Each SEM package is composed of four separate sensor systems: two energetic particle sensors (EPS, HEPAD), a magnetometer, and a solar soft X-ray sensor. Starting with GOES-L

¹⁰⁹⁴⁾Information provided by M. J. Nestlebusch of NOAA/NESDIS

the SEM package will be extended by a fifth instrument, the SXI. Note: the GOES series SEM package differs considerably from the POES series SEM package.

EPS = Energetic Particle Sensor. Objective: monitoring solar protons and alpha particles produced during flares, and continuous monitoring of electrons at geostationary orbit. Measurement in seven channels for high proton fluxes, six channels for alpha particle fluxes, and in three channels for electron flux (note: electron fluxes were not measured from GOES-6 and GOES-7).

HEPAD = High Energy Proton and Alpha Particle Detector. Objective: monitoring the very high energy protons and alpha particles in large solar flares, and continuous monitoring of galactic cosmic rays. HEPAD uses the phenomenon of Cerenkov radiation which occurs when an incident particle travels at speeds greater than the local speed of light in a high refractive index material, in this case fused silica.

Channel Designation	Particle Type	Nominal Energy Range (MeV)	GOES-7 Nominal Energy Range (MeV)
P1	Proton	$\leq 0.8 - 4$	0.6 - 4.2
P2		4 - 9	4.2 - 8.7
P3		9 - 15	8.7 - 14.5
P4		15 - 40	15 - 44
P5		40 - 80	39 - 82
P6		80 - 165	84 - 200
P7		165 - 500	110 - 500
A1	Alpha	4 - 10	3.8- 9.9
A2		10 - 21	9.9 - 21.3
A3		21 - 60	21.3 - 61.0
A4		60 - 150	60 - 180
A5		150 - 250	160 - 260
A6		300 - 500	330 - 500

Table 297: Summary of HEPAD channel outputs (GOES-I - M)

Magnetometer of SEM package. Objective: measurement of the magnitude and direction of the ambient magnetic field. Three boom-mounted orthogonal sensors for the three components. Sensitivity of 0.2 nT, measurement range of ± 1000 nT.

XRS = Solar X-Ray Sensor. Objective: measurement of the solar X-ray spectrum in two broad energy bands: 1-8 and 0.5-4 Å. The X-ray sensor continuously looks into the sun direction. The collimator and ion chamber assembly are mounted on a single axis positioner, which in turn is mounted on the S/C solar yoke.

SXI = Solar X-Ray Imager (starting with GOES-M), developed at MSFC. Objective: provision of full disc solar imagery in the soft X-ray spectrum allowing identification of multiple solar features including solar flares, active regions, coronal holes, etc. SXI uses a grazing incidence mirror to image the sun in the spectral range from 6 - 60 Å. Image resolution: 512 x 512 pixels. Each pixel has a FOV of 5 arc seconds. Data rate: 100 kbit/s. SXI normally pro-

duces an image every 10 minutes with an option of producing one image per minute. A filter wheel permits the pass band of the system to be modified to provide additional spectral information.

F.4.3 NOAA-GOES Second Generation

GOES-I-M series sensors: Starting with GOES-I (GOES-8 on-orbit) each satellite carries two separate so-called second generation instruments, an imager and a sounder, providing simultaneous imaging and sounding capabilities. All GOES S/C (starting from GOES-I) are of three-axis, body-stabilized design capable of continuously pointing the optical line of sight of the imaging and sounding radiometers to the Earth. GOES S/C are built and integrated by Space Systems/Loral (SS/L) for NASA/GSFC; the sensors are provided by ITT Aerospace of Fort Wayne, IND. NOAA is the owner and operator of all GOES S/C. ¹⁰⁹⁵⁾ ¹⁰⁹⁶⁾ ¹⁰⁹⁷⁾

Figure 188: The GOES Second Generation S/C model starting with GOES-I

A single-wing solar array (silicon cells) on the S/C rotates about the satellite pitch axis to track the sun during orbital motion, generating a minimum of 1057 W at summer solstice. A conical solar sail on top of the 17 m boom of the S/C is used to balance the torque caused by the solar radiation pressure (a trim tab on the solar wing provides fine control). ¹⁰⁹⁸⁾

Orbit: Geostationary at an altitude of about 35,786 km above the equator. Two satellites in two different locations are operated in parallel. GOES-E is positioned at 75° western longitude, GOES-W at 135° western longitude.

The GOES I-M system performs the following basic functions:

- Acquisition, processing, and dissemination of imaging and sounding data
- Acquisition and dissemination of SEM (Space Environment Monitor) data
- Reception and relay of data from ground-based DCPs (Data Collection Platforms)
- Continuous relay of WEFAX and other data to users
- Relay of distress signals (alerts via S&RSAT) from people, aircraft, or marine vessels to the search & rescue ground stations.

Figure 189: The GOES Imager instrument

Sensor complement:

GOES Imager = Multispectral Imaging Radiometer, built by ITT A/CD of Fort Wayne, IN. Objective: Operational meteorology and climatology (one channel in the VIS and four channels in the IR range). The GOES Imager measures radiant and solar-reflected energy from sampled areas of the Earth. The instrument consists of electronics, power supply, and sensor modules. The sensor module containing the telescope, scan assembly, and detectors, is mounted on a baseplate external to the spacecraft, together with the shields and louvers for thermal control. By means of a servo-driven, two-axis gimbaled mirror scan system in conjunction with a Cassegrain telescope, the imager's channels can simultaneously sweep an 8 km north-to-south swath along an east-to-west/west-to-east path, at a rate of 20° (optical) east-west per second. Resolution: = 1km in the VIS range and 4 km in the IR region (except for the $6.5\text{-}7.0 \mu\text{m}$ MWIR channel at 8 km resolution). A normal full Earth disk scan ($18^\circ \times 18^\circ$) is done in 25 minutes (a 3000 km x 3000 km area can be scanned in 3.1 minutes, a 1000 km x 1000 km area in 40 seconds). The instrument can produce full-Earth disk images, sector images that contain the edges of the Earth, and various sizes of area scans completely enclosed within the Earth scene using a new flexible scan system. Scan selection permits rapid continuous viewing of local areas for monitoring of regional phenomena. The key fea-

tures of the imager are summarized in Tables 299 and 301. The pointing accuracy of the GOES Imager is within a 4 km radius at nadir. ¹⁰⁹⁹⁾

Spectral Channels	1 (VIS)	2 (MWIR)	3 (MWIR)	4 (TIR)	5 (TIR)
Prime Measurement Purpose	Cloud Cover	Nighttime Clouds, Fires, Volcanoes	Water Vapor	Surface Temp. Clouds	Low-level moisture, clouds
Wavelength (μm)	0.55 - 0.75	3.80 - 4.00	6.50 - 7.00	10.20 - 11.20	11.5 - 12.50
Measurement Range	1.6 to 100% albedo	4 to 320 K	4 to 320 K	4 to 320 K	4 to 420 K
S/N or NEΔT	150:1	1.4 K at 300 K	1.0 K at 230 K	.35 K at 300 K	.35 K at 300 K
Detector Type	Silicon	InSb	HgCdTe	HgCdTe	HgCdTe

Table 299: GOES Imager performance

Channel No	Spectral Range (μm)	Measurement Range	Measurement Objective
1	0.55 - 0.75	1.6 to 100% albedo	Cloud cover
2 (GOES-I/J/K)	3.80 - 4.00	4 - 320 K	Nighttime clouds (space-340 K)
2 (GOES-L/M)	3.80 - 4.00	4 - 335 K	Nighttime clouds (space-340 K)
3 (GOES-I/J/K/L)	6.50 - 7.00	4 - 320 K	Water vapor (space-290 K)
3 (GOES-M)	13.0 - 13.7	4 - 320 K	Cloud cover and height
4	10.20 - 11.20	4 - 320 K	SST and water vapor (space-335 K)
5 (GOES (I/J/K/L)	11.50 - 12.50	4 - 320 K	SST and water vapor (space-335 K)
5 (GOES-M)	5.8 - 7.3	4 - 320 K	Water vapor

Table 300: GOES Imager channel allocations for the various S/C in the series

GOES Sounder = Infrared sounder for operational meteorology and climatology (19 channel discrete-filter radiometer). Objective: atmospheric soundings. Data products are: vertical temperature and moisture profiles, layer mean temperature and moisture, cloud height and amount, total precipitable water, surface temperatures, lifted index, gradient and wind derived from horizontal temperature and moisture fields. Resolution: 8 km. The GOES Sounder is of HIRS/2 heritage providing similar instrument operation and performance. A filter wheel rotating ten times per second provides for data sampling at ten steps per second (the filter wheel brings the spectral filters into the optical path of the detector array, thereby providing channel definition). The detector filter arrangement makes use of four spectral bands (see Table 302). The Sounder's multi-element detector array assemblies simultaneously sample four separate fields or atmospheric columns, i.e., four detectors are simultaneously irradiated in each band, providing an output from four Instantaneous Geometric Fields of View (IGFOV). In this manner the system can sample four 8 km IGFOV each 0.1 seconds. - The data products of the sounder are planned for use in numerical weather forecast models. They provide data coverage in oceanic regions lacking conventional observations.

Both Imager and Sounder employ a servo-driven, two-axis gimballed mirror systems in conjunction with a 31 cm Cassegrain telescope (separate sensors with independent operation). Each instrument has a flexible scan control, enabling coverage of small areas as well as global scenes (Earth's full disk), and close-up, continuous observations of severe storms.

Figure 190: The GOES Sounder instrument

An on-board ‘Image Navigation and Registration’ (INR) system provides good pointing accuracy, i.e. geographical location capability of the imager and sounder pixels in near real-time.¹¹⁰⁰⁾ The INR system removes the apparent image-to-image motion resulting from orbital motion, satellite attitude deviations, and satellite thermal distortions. This is achieved by continuously steering the instrument scan mirrors to compensate for this motion. Compensation signals are generated in the attitude and orbit control system based on predicted

¹¹⁰⁰⁾ Note: Image navigation refers to the determination of the location of a pixel within an image in terms of Earth’s longitude and latitude; registration refers to stability of maintaining pointing of each pixel to a specific Earth location within an image and between repeated images.

orbits and attitude parameters that are transmitted to the satellite at least once each day from a ground station. The parameters are generated using image landmarks, star views, and satellite range data collected throughout the day.

Figure 191: GOES second generation scan operations

In addition, the GOES I-M missions carry the **SEM** subsystem (see description under F.4.2), **S&RSAT**, **DCS** and **WEFAX**. The SEM consists of the following instruments:

- Magnetometer, similar to the versions on previous GOES satellites (except for two redundant magnetometers), each with three separate orthogonal probes.
- Solar XRS (X-Ray Sensor), similar to the previously flown designs; however, it is continuously pointed at the sun by virtue of being mounted on the solar array yoke, and on top of a positioner that tracks the sun in the north-south direction.
- The EPS and HEPAD are functionally identical to those flown on previous GOES satellites, except for the additional two electron channels and a reduced entrance aperture of the D4 dome detector.

- The SXI is part of the SEM subsystem starting with GOES-M.
SXI = Solar X-Ray Imager. Objective: Solar storm warning. SXI measures solar X-ray emissions.

Product Type	Vert. Resolution	Horiz. Resolution	Absolute Accuracy	Relative Accuracy
Temperature Profile	3-5 km	50 km	2-3 K	1 K
Land	---	10 km	2 K	1 K
Sea	---	10 km	1 K	0.5 K

Table 303: Sounder products, resolutions and accuracy

S&RSAT on GOES, referred to as **GEOS&R** (Geostationary Search and Rescue):¹¹⁰¹⁾ S&R capability (the distress signal detection function) was first introduced on GOES-7 as a research/demonstration program to introduce the technology into the COSPAS-S&RSAT system (see I.6). S&R is now an operational GOES service of the GOES-I - M series.

The S&RSAT design differs somewhat between GOES-7 and the new GOES-8 series. On GOES-7, -8, and -9, S&RSAT receives signals with the GOES UHF antenna. On GOES-7, both the DCP data and the S&RSAT data are transmitted back through the same downlink transmitter, the S-band antenna. The GOES-7 downlink frequency is 1698 MHz. On GOES-8 (and follow-on satellites), the S&RSAT downlink transmission is through a separate S&RSAT (L-band) helix antenna. On GOES-8, the uplink frequency for S&RSAT is 406 MHz and the downlink frequency is 1544.5 MHz; and for the DCP reporting mode (DCPR), the uplink frequency is 401 MHz with the DCPR downlink at 1694 MHz. - The GEOS&R system is also being considered for future Meteosat as well as for the GMS satellite series.

Data Link Type	Source	Uplink (MHz)	Downlink (MHz)	Destination
Command	CDA/DSN	2034		S/C
Telemetry + SEM	S/C		1694	CDA, SEL-Boulder CO, DSN
Ranging	DSN, STDN	2034	2209	S/C, DSN
WEFAX	CDA	2033	1691	Users/APT
DCPI	CDA	2034	468	DCP
DCPR	DCP	401	1694	CDA/Users
S&RSAT	ELT/EPIRB	406	1544	S&RSAT Ground Station
MDL (diagnostic data)	S/C		1681.5	SOCC/SEL
PDR (Processed Data Relay at 2.111 Mbit/s)	CDA	2027.7	1685.7	Users (via S/C)
Image Raw Data (2.62 Mbit/s)	S/C		1676	CDA

Table 304: Overview of GOES communication links

GOES Data Transmission: Direct broadcast and relay in S-band. - UHF-band at 401, 406 and 468 MHz. The UHF-band is used to receive environmental data from the DCPs. It is also used for S&R service provision.

Operating Mode	Imaging & Sounding	SEM Package	Communications	Attitude Control
Sunlight (Normal)	on	on	on	Earth pointing with INR
Eclipse	off	on, except XRS off	on, except WEFAX and MDL off	Earth pointing without INR
Launch Operations (Transfer Orbit)	off	off	off	Earth pointing during maneuvers, otherwise sun pointing
On-Orbit Storage	off	off	off	Earth pointing without INR

Table 305: GOES second generation satellite on-orbit operating modes

F.4.4 Next-Generation Imager for the NOAA GOES Series

NOAA and NASA plan to replace the current GOES Imager in the long-term perspective with a new instrument, called **ABI** (Advanced Baseline Imager). As of 2000 the project is in the definition/requirements phase. NOAA anticipates that the first ABI instrument will be available for flight on GOES-Q, with a projected launch readiness date of 2008. ¹¹⁰²⁾

The following four requirements of the NWS (National Weather Service) are considered with highest priority:

- Continuous instrument operation capability during eclipse phases of the GEO orbit
- Simultaneous observation capability for the modes “full-disk” and “CONUS” (Contiguous USA).
- Improvement of the temporal instrument imagery resolutions.
 - Full-disk Earth observation within 15 minutes
 - CONUS, or the equivalent of a nadir-viewed rectangle (3000 km x 500 km) every 5 minutes (goal of 1 minute)
 - Imagery of minimum size 1000 km x 1000 km (nadir) every 30 seconds
 - A capability must exist to observe concurrently the CONUS and full-disk imagery along with all other imaging activities, such as space locks, blackbody calibrations, and star observations
- Improvement of the spatial resolution of the imagery. The current GOES Imager spatial resolution (1 km in VIS and 4 km in IR) must be doubled for ABI. The intent is to allow for better identification and tracking of cloud and moisture signatures.

The band selection has been optimized to meet all cloud, moisture, and surface observation requirements. The phenomena observed and the various applications are:

- VIS band (0.64 μm): Daytime cloud imaging, snow and ice cover, severe weather onset detection, low-level cloud drift winds, fog, smoke, volcanic ash, flash flood analysis, hurricane analysis, winter storm analysis
- SWIR band (1.6 μm): Daytime cloud/snow/ice discrimination, total cloud cover, aviation weather analysis for icing, smoke from low-burn-rate fires
- MWIR band (3.9 μm): Fog and low-cloud discrimination at night, fire identification, volcanic eruption and ash, daytime reflectivity for snow/ice
- MWIR band (7.0 μm): Middle-tropospheric water vapor tracking, jet stream identification, hurricane track forecasting, mid-latitude storm forecasting, severe weather analysis
- TIR band (11.2 μm): Continuous day/night cloud analysis for many general forecasting applications, precipitation estimates, severe weather analysis and prediction, cloud drift winds, hurricane strength and track analysis, cloud top heights, volcanic ash, winter storms, cloud phase/particle size (in mid-band products)
- TIR band (12.3 μm): Continuous cloud monitoring for numerous applications, low-level moisture, volcanic ash trajectories, cloud particle size (in mid-band products)
- TIR band (13.3 μm): Cloud top height assignments for cloud-drift winds, cloud products for ASOS supplement, tropopause delineation, cloud opacity.

¹¹⁰²⁾“GOES Advanced Baseline Imager, Technical Requirements Document,” GSFC, S-415-200, March 2000

Requirement		Threshold
Spatial resolution	VIS (0.64 μm)	0.5 km (14 μrad IFOV)
	All other bands	2 km (56 μrad IFOV)
Spatial coverage	Full disk	4 per hour
	CONUS (3000 km x 5000 km) Mesoscale (1000 km x 1000 km)	12 per hour Every 30 s, may impact CONUS or full disk
Operation during eclipse		Yes
Data timelines (when scanning is complete)		CONUS: <1 minute Full disk: <6 minutes
Simultaneity		Within 5 s for all bands at any FOV Within 30 s for any adjacent (n/S) pixels Within 15 s for any adjacent (E/W) pixels
Number of spectral bands		8 (threshold), 12 (goal) Star sensing capability required
Spectral bands (μm), 8 bands at minimum		0.64 ± 0.05 , 1.61 ± 0.03 ; 3.9 ± 0.1 ; 6.15 ± 0.45 ; 7.0 ± 0.2 ; 10.7 ± 0.5 ; 12.0 ± 0.5 ; 13.3 ± 0.3
Spectral bands (μm), goal of four additional bands		0.86 ± 0.05 , 1.375 ± 0.015 , 8.5 ± 0.2 , 10.35 ± 0.25
Navigation		<1.0 km (28 μrad)
Registration within frame		<1 km (28 μrad)
Line-to-line registration		<25 km (7 μrad)
Registration image to image, VIS, IR		<0.75 km (<21 μrad), <1.0 km (<28 μrad)
Band-to-band co-registration, VIS-IR, IR-IR		<1.0 km (<28 μrad), <15% of FOV
On-orbit calibration	VIS, (goal)	Pre-launch to $\pm 5\%$, On-board to $\pm 3\%$
	IR	0.2 K repeatability, 1.0 K absolute accuracy
IR band linearity		$\pm 1\%$
Total instrument mass, power, volume		<125 kg, <256 W, <0.8 m ³
Instrument data rate		<15 Mbit/s
Lifetime	Ground storage	2 years
	On-orbit storage	2 years
	Mean mission life	8.4 Years
	Design life	10 years

Table 306: Requirements overview for the ABI instrument

Application spectrum of the four additional bands.

- VIS band (0.86 μm): This band provides synergy with AVHRR/3 band 2. The band is used for determining vegetation amount, aerosols and ocean/land studies.
- SWIR band (1.38 μm): This band is similar to a MODIS band. It does not see into the lower troposphere due to water vapor sensitivity, thus it provides excellent daytime sensitivity to very thin cirrus.
- TIR band (8.5 μm): This band permits the detection of volcanic cloud with sulfuric acid aerosols, thin cirrus in conjunction with 11 μm band and determination of cloud microphysical properties with the 11.2 μm and 12.3 μm bands. This includes a more accurate delineation of ice from water clouds during day or night
- TIR band (10.3 μm): The band permits the determination of microphysical properties of clouds with the 11.2 and 12.3 μm bands. This includes a more accurate determination of cloud particle size during the day or night.

F4.5 Next-Generation Sounder for the NOAA GOES Series

No information could be obtained from the NOAA/GOES project. The GIFTS instrument on the EO-3 mission is a technology demonstration for the next-generation GOES sounder.

F4.6 LMS (Lightning Mapper Sensor)

The LMS mission consists of an optical imaging instrument of GHCC (Global Hydrology and Climate Center) at NASA/MSFC (Huntsville, AL) to be flown on a GOES spacecraft in 2004. The prime objective is to measure from a geosynchronous orbit the total lightning ac-

tivity on a continuous basis (under both day and nighttime conditions) over the Americas (North and South) and portions of the adjoining oceans. LMS in GEO permits the study of the electrosphere over dimensions ranging from the Earth’s radius down to individual thunderstorms. The instrument is capable of detecting all types of lightning phenomena at a nearly uniform coverage. Near real-time data transmission to MSFC is required for processing and quality assurance and redistribution of the data within 20 seconds of reception. 1103)

The LMS instrument consists of a staring imager optimized to detect and locate lightning. The major subsystems of the instrument are: an imaging system, a focal plane assembly, real-time event processors, a formatter, power supply, and interface electronics. The imaging subsystem is a fast f/1.2 telescope with a 12 cm aperture diameter and a 1 nm bandwidth interference filter. A broadband blocking filter is placed on the front surface of the filter substrate to maximize the effectiveness of the narrowband filter.

Spectral wavelength	777.4 nm
FOV, IFOV	8° x 5°, 8 km at nadir
Threshold	<4.0 J m ⁻² sr ⁻¹ A lightning event is identified whenever the selected signal difference threshold is exceeded.
SNR, dynamic range	6, >100
Detector array size	700 x 560 pixels
Detection efficiency, false alarm rate	>90% of total events, <5% of total events
Measurement accuracy	Location: 1 pixel; intensity: 10%; time tag at frame rate
Instrument mass, power	35 kg, 110 W
Data downlink communication	Data rate: 80 kbit/s; modulation: PCM; quantization = 12 bit

Table 307: Specification of the LMS instrument

Event filtering approaches: The daytime lightning signals tend to be buried in the background noise; hence, special techniques are implemented to maximize the lightning signal relative to this background noise.

- Spatial filtering is used which matches the IFOV of each detector element in the LMS focal plane array to the typical cloud-top area illuminated by a lightning stroke (i.e., in the order of about 10 km). This results in an optimal sampling of the lightning scene relative to the background illumination.
- Spectral filtering is obtained by using a narrowband interference filter centered on a strong optical emission line (e.g., OI at 777.4 nm) in the lightning spectrum. This method further maximizes the lightning signal relative to the reflected daylight background.
- LMS employs temporal filtering which takes advantage of the difference in lightning pulse duration which is on the order of 400 μs versus the background illumination which tends to be constant on the time scale of seconds. In an integrating sensor, such as LMS, the integration time specifies how long a particular pixel accumulates charge between readouts. The lightning SNR improves as the integration period approaches the pulse duration. An integration time of 2 ms (technological limit) is used to minimize pulse splitting and maximize lightning detectability.
- Since the ratio of the background illumination to the lightning signal often exceeds 100 to 1 at the focal plane, a fourth technique, a modified frame-to-frame background subtraction is implemented to remove the slowly varying background signal from the raw data coming off the LMS focal plane. Each real-time event processor generates an estimate of the background scene imaged at each pixel of its section of the focal plane array. This background scene is updated during each frame readout sequence and, at the same time, the background signal is compared with the off-the-focal-plane signal on a pixel-by-pixel basis. When the difference between these signals exceeds a selected threshold, the signal is identified as a lightning event and an event processing sequence is initiated.

RTEP (Real-Time Event Processor). The large data rate of about 5 Gbit/s is read out from the focal plane of LMS into several RTEPs for event detection and data compression. Each RTEP detects weak lightning flashes from the intense but slowly evolving background. The RTEP continuously averages the output from the focal plane over a number of frames on a pixel-by-pixel basis to generate a background estimate. It then subtracts the average background estimate of each pixel from the current signal of the corresponding pixel. The subtracted signal consists of shot noise fluctuating about zero with occasional peaks due to lightning events. When a peak exceeds the level of a variable threshold, it triggers comparator circuits and is processed by the rest of the electronics as a lightning event.

E.5 GOMS (Geostationary Operational Meteorological Satellite)

GOMS-1 = Geostationary Operational Meteorological Satellite (referred to as ‘**Elektro-1**’ in Russia).^{1104), 1105), 1106), 1107), 1108)} Russian RKA program series (ROSGIDROMET/Planeta operator), built by VNIIEM, Moscow. The first GOMS satellite (GOMS-1) was launched October 31, 1994 (by a Proton carrier vehicle) from Baikonur.

Figure 192: The GOMS S/C model

- 1104) "Space System with Geostationary Meteorological Satellite (GOMS)," Paper of Planeta, Moscow, Nov. 1990
- 1105) S. A. Stoma, Yu. V. Trifonov, "Geostationary Space System 'ELECTRO' (GOMS): Preconditions for Creation and Structure," Space Bulletin, Vol. 2, No. 3, 1995, pp. 2-6
- 1106) O. M. Miroshnik, et. al., "A Drama in Orbit with a Happy Ending," Space Bulletin, Vol. 2, No. 3, 1995, pp. 7-10
- 1107) Yu. V. Trifonov, "S/C ELECTRO On-board Control Complex," Space Bulletin, Vol. 2, No. 3, 1995, pp. 11-14
- 1108) Yu. V. Trifonov, A. V. Gorbunov, "Prospects for the ELECTRO Space System Development," Space Bulletin, Vol. 2, No. 3, 1995, pp. 14-15

Satellite: mass = 2650 kg (including payload of 950 kg), power = 1.7 kW (average); GOMS is designed as a three-axis stabilized (fly-wheel) spacecraft with orientation to the Earth and along the velocity vector; orientation knowledge is through the polar star sensor and the sun sensors. Design life = 3 years (replacement on operational need). Orientation accuracy = $\pm 2\text{-}5$ arcmin.

The GOMS-1 S/C experienced orientation/stabilization problems during its initial phase of operation. These problems were eventually fixed by February 1, 1995. Since then GOMS has been in its operational testing phase. Operational status: GOMS-1, also referred to as Elektro-1, ended all spacecraft operations in Nov. 2000.

GOMS-1 Orbit: Geostationary, position = 76° East (over the Indian Ocean)

Objectives:

- to acquire television images in real time of the Earth's surface and cloud cover within a radius of 60° centered at the subsatellite point in the visible and IR regions of the spectrum
- to measure temperature profiles of the Earth surface (land and ocean) as well as top-of-cloud-cover temperatures
- to measure the radiation state and magnetic field of the space environment at the geostationary position
- to transmit via digital radio channels television images, temperature and radiation as well as magnetometric information to the main and regional data receiving centers
- to acquire information from Russia and international data collection platforms (DCPs), located in the GOMS visibility range, and to transmit the information obtained to all receiving and processing centers (RPCs)
- to call for the DCPs to transmit information to the satellite
- to retransmit the processed meteorological data in the form of facsimile or alphanumeric information from the receiving processing centers to the receiving stations of the independent data users via GOMS
- to provide an exchange of high-speed digital data (retransmission via GOMS) among all regional centers within Russia (Federal Service for Hydrometeorology and Environmental Monitoring).

Figure 193: Data collection and distribution scenario for GOMS

Sensor complement:

STR = Scanning TV Radiometer providing imagery in VIS and IR bands. Objectives: observation of clouds and underlying surface in VIS and IR spectra and temperature data of underlying surface, determination of top of clouds.

Spectral bands: 0.46 - 0.7 μm (VIS), 10.5 - 12.5 μm (IR-1), 6-7 μm (IR-2, starting with GOMS-2); Number of scan lines per frame = 8000 (VIS) and 2500 (IR); IFOV (VIS) = 31.5 μrad , IFOV (IR)=160 μrad ; FOV = 13500 x 13500 km; spatial resolution = 1.25 km (VIS) and 6.5-8.0 km (IR). The imaging session frequency is 30 min; the length of one take (frame time) is 15 minutes. Direct data transmission rate = 2.56 Mbps.

RMS (Radiation Measurement System), RMS consists of instruments for heliogeophysical measurements, radiation and magnetic parameters). FOV = 13,500 x 13,500 km. Objective: registration of particles (protons, electrons, α -particles), measurement of X-ray radiation from the sun, measurement of magnetic field vector components.

- Density of electron fluxes with energies in four bands from 0.04 - 1.7 MeV
- Density of proton fluxes with energies in four bands from 0.5 - 90 MeV
- Density of alpha particles with energies from 5 - 12 MeV
- Intensity of the galactic cosmic radiation with energies > 600 MeV
- Solar X-ray radiation intensity with energies from 3 - 8 keV
- Intensity of solar UV radiation in four wave bands up to 1300 \AA
- Magnetic induction vector component quantities along 3 axis with ± 180 nT interval

F5.1 Radio Complex for Data Collection, Transmission and Relay

- GOMS Communication Characteristics
 - transmission of TV images and heliogeophysical information from the satellite to the receiving and processing centers - RPCs (Radio channels I and II).
 - carrier frequencies: 1685 MHz (S-band) and 7465 MHz (X-band)
 - data transmission rate = 2.56 Mbps
 - Radio channel III: transmission of data from DCPs; frequencies: 401 - 403 MHz; transmission of data is possible through 33 international and 100 Russian channels at rates of 100 b/s.
 - Radio channels IV and V: retransmission of information obtained from DPCs to RPCs; frequencies: 1697 ± 1 MHz (S-band) and 7482 ± 1 MHz (X-band)
 - Radio channels VI and VII: transmission of facsimile information in standard WEFAX format and alphanumerical data from RPCs to GOMS. Frequencies: 2115 ± 1.5 MHz and 8195 ± 1.5 MHz. Data transmission rate = 1200 b/s
 - Radio channel VIII: retransmission of facsimile and alphanumerical data from GOMS to independent receiving stations. Frequency: 1691 ± 1.5 MHz
 - Radio channel IX: transmission of high-speed digital information from RPC to GOMS. Frequency: 8190 ± 5 MHz; data rate up to 0.96 Mbit/s
 - Radio channel X: transmission of high-speed digital information from GOMS to the RPCs. Frequency: 7.465 ± 2.5 MHz; data rate up to 0.96 Mbit/s
 - Radio channel XI: calling for DCP from GOMS. Frequency: 469 ± 1 MHz
 - Radio channel XII: transmission of DCP request from RPC to GOMS. Frequency: 2119 ± 1 MHz
- GOMS Data Receiving and Transmitting Modes
 - Channels I and II operate 24 - 48 times per day; each session lasts 15 minutes
 - Channels III, IV and V operate by commands calling for DCP information
 - Channels VI, VII and VIII operate continuously
 - Channels IX and X function in the interval when channels I and II are not active
 - Channels XI and XII operate on request

F.6 INSAT

INSAT¹¹⁰⁹⁾ = Indian National Satellite system is a joint venture, conceived in the 1970s, of the following departments/agencies of the government of India: DOS (Department of Space), DOT (Department of Telecommunications), IMD (Indian Meteorological Department), AIR (All India Radio). DOS is responsible for the operation of the INSAT space segment. IMD operates a Meteorological Data Utilization Center (MDUC, at Delhi) for the dissemination and distribution of INSAT meteorological images and ancillary data.

Figure 194: The INSAT S/C model

F.6.1 INSAT-1 Satellite Series

INSAT is a multipurpose operational satellite system series (geostationary) employed for meteorological observation over India and the Indian Ocean, as well as for domestic telecommunications (nationwide direct TV broadcasting, TV program distribution, meteorological data distribution, etc.). The INSAT-1 series satellites were built by Ford Aerospace Corporation (USA) to Indian specifications.

¹¹⁰⁹⁾ 'Space Applications,' DOS Annual Report 1990-91. pp. 13-23

Sensor: (Meteorological Package)

VHRR = Very High-Resolution Radiometer. Spectral ranges: 0.55 - 0.75 μm (VIS) and 10.5 - 12.5 μm (IR). Resolutions: 2.75 km for VIS and 11 km for IR channels, respectively. Scanning time/image = 30 minutes. Scanned field: full frame mode (20° E-W and 20° N-S); sector scan mode (20° E-W and 4.5° N-S).

Data Collection System (DCS): This system gathers and relays environmental data (meteorological, hydrological and oceanographic) from unattended land- and ocean-based automatic data collection platforms (DCPs). The global data receive frequency (platforms to satellite) is 402.75 MHz (UHF-band). As of 1991 over 100 DCPs were installed.

Mission	Comment
INSAT-1A	Launch: April 1981;
INSAT-1B	Launch: Aug. 30, 1983; position: 74° East; the satellite is used as a standby for INSAT-1D.
INSAT-1C	Launch: July 22, 1988 (Ariane vehicle). The satellite lost Earth lock on Nov. 22, 1989 and is inoperable since then.
INSAT-1D	Launch: June 12, 1990 (US Delta vehicle); position: 74° E

Table 308: Overview of INSAT-1 satellite series

F.6.2 INSAT-2 Satellite Series

This satellite family is considered the second generation INSAT series for the nineties (built by ISRO). Like the INSAT-1 series, the INSAT-2 series is a multi-purpose satellite family for telecommunication, television broadcasting and meteorological services. The S/C is three-axis stabilized and uses a box-shaped structure based around a central cylinder of 0.89 m diameter with asymmetrical five-panel solar wings (23 m span). Power = 1.18 kW (EOL). Orbit maneuvers are supported by an integral apogee boost motor, there are also 16 attitude control thrusters. On-orbit mass is 911 kg.

The INSAT-2 operational satellites have enhanced capabilities. The INSAT-2 meteorological sensor VHRR has a 2 km resolution in VIS and 8 km resolution in the IR spectral ranges. The INSAT-2C launch with Ariane occurred on Dec. 6, 1995, the INSAT-2D launch with Ariane 44L occurred on June 3, 1997 (along with Inmarsat 3F4), the INSAT-2E launch took place on April 2, 1999. The meteorological instrument on the spacecraft features an additional band in the water vapor absorption spectrum of 6.8 μm .

VHRR = Very High-Resolution Radiometer. VHRR is an improved version over that of the INSAT-1 series. The instrument can be operated in any one of the following modes: ¹¹¹⁰⁾

- Full scan mode (20° x 20°): This covers the entire Earth disk and some space around in 33 minutes (can be positioned in steps of 0.35° in east-west direction).
- Normal scan mode: Coverage of at least 50° N to 40° S latitude (in 23 minutes)
- Sector scan mode: The sector can be positioned anywhere in the Earth disk along the N-S direction (in 7.2 minutes). ¹¹¹¹⁾

The VHRR instrument consists of three packages: the EOM (Electrooptics Module), the electronics package-1, and the electronics package-2. The electrooptics module houses the scan assembly, the optics assembly, and the radiant cooler assembly. The VIS and IR detectors with their amplifiers are also part of the electrooptics module. The electronics package-1 contains the signal processors for all channels, data formatter, power distribution, and timing logic circuits. The scanner electronics, the DC/DC converter regulators, patch temperature controller and the analog telemetry processor are part of the electronics package-2.

¹¹¹¹⁾ G. Joseph, et al., "INSAT-2 Very High Resolution Radiometer for Meteorological Observations," Journal of Spacecraft technology, Vol. IV, No. 1, Jan. 1994, pp. 183-207

The optical subsystem uses an all-reflective Ritchey-Chretien telescope (folded optics, the primary mirror is a concave hyperboloid with an aperture of 202 mm and f/2.0, the secondary mirror is a convex hyperboloid with an aperture of 62 mm; focal length of the system is 1594 mm). The convergent light beam, reflected from the secondary mirror, is incident on the dichroic beam splitter which is mounted at 45° to the telescope axis. The VIS radiation uses two arrays of four silicon photodiodes each providing a 2 km resolution at nadir (scan mirror is oscillating is 0.5 Hz). The IR detector assembly consists of two HgCdTe photoconductive detectors mounted in the passive radiant cooler. The IR detector is operated at 105 K. The scan mirror is mounted on a two-axis gimballed scan structure which generates 2-D images by sweeping the detector IFOV in the E-W and N-S directions. Each E-W/W-E scan generates one IR line of 8 km width and four VIS lines each of 2 km width.

Spectral band: VIS	0.55 - 0.75 μ m; Integrated out-of-band response <3%
Spectral band: TIR	Inter detector mismatch <5% 10.5 - 12.5 μ m; Integrated out-of-band response <3% Out-of-band response peak <0.1%
Spatial resolution VIS	56 μ rad (or 2 km x 2 km)
Spatial resolution TIR	224 μ rad (or 8 km x 8 km)
Radiometric performance: SNR	>6 for VIS at 2.5% albedo
Radiometric performance: NEDT	<0.25 K at 300 K for TIR channel
Dynamic range of IR channel	4-340 K
Dynamic range of VIS channel	0-100%
Misregistration between VIS and TIR	<56 μ rad
Modulation Transfer Function (MTF)	>21% for TIR; >23% for VIS channel

Table 309: Specification of the VHRR instrument

Mission	Comment	Payload (Meteorological)	Power, Battery
INSAT-2A	Launch: July 9, 1992, Ariane-IV, at 74° East, Mass = 905 kg	VHRR, DCS, SAS&R	1.16 kW summer solstice NiCd, 18 Ah, 28 cells
INSAT-2B	Launch: July 22, 1993, Ariane-IV, at 93.5° East, Mass=905 kg	VHRR, DCS, SAS&R	
INSAT-2C	Launch: Dec. 6, 1995, Mass = 980 kg, co-located with -2B		1.735 kW, summer solstice NiCd, 24 Ah, 28 cells
INSAT-2D	Launch: June 3, 1997, Ariane 44L, Mass = 980 kg, the S/C lost Earth lock in October 1997	VHRR, DCS, SAS&R	
INSAT-2DT	Transponder leased from ArabSat to continue the INSAT-2D services to the users		
INSAT-2E	Launch: Apr. 2, 1999, Ariane 4, Mass = 1150 kg, 12 year design life with a goal of 15 years	VHRR, CCD Camera, DCS, SAS&R	2.5 kW at equinox NiH ₂ , 60 Ah, 27 cells

Table 310: Overview of INSAT-2 satellite series

INSAT VHRR Data Distribution: The INSAT-1/2 VHRR data is distributed in near real-time to/from 22 SDUCs (Secondary Data Utilization Centers) throughout the country.

INSAT Data Availability: As of Dec. 16, 1997 a major shift in ISRO data policy occurred when representatives of NASA, NOAA and ISRO signed an agreement in a Washington DC meeting, for ISRO to provide full-sized INSAT weather data to the world meteorological community in digital format and without delay. The agreement calls also for the USA to make Earth and atmospheric data available to India. ¹¹¹²⁾

The INSAT-2 series flies a data collection system (DCS) with a data relay transponder (DRT) for environmental data. It is also furnished with **SAS&R** (Satellite Aided Search and Rescue) system. SAS&R provides an emergency alert capability for the Indian subcontinent and beyond as part of the international satellite aided search and rescue program (see also chapter I.6). India has signed an agreement with the international COSPAS-S&RSAT council for the use and operation of LUTs (Local User Terminals) and an MCC.

¹¹¹²⁾ W. Ferster, "Policy Shift Paves Way for India-U.S. Imagery Deal," Space News, Jan. 5-11, 1998, p. 18

F.6.2.1 INSAT-2E

General description of the INSAT-2E satellite bus system. The S/C mass at launch is 2550 kg (dry mass of 1146 kg). The S/C power is 2.5 kW at equinox provided by solar panels with an area of 20.52 m² (GaAs solar cells). Battery: NiH₂, 60 Ah, 27 cells. The S/C design life is 12 years. The INSAT-2E communication payload carries 17 transponders, 12 operating in the normal C-band frequency and five in the lower extended C-band. Seven of the normal C-band transponders have wide beam coverage, the remaining ten have zonal coverages. ¹¹¹³⁾

Orbit: Geostationary, location at 83° eastern longitude.

S/C structure (Figure 194):

- The S/C main body is a cuboid of dimension: 1930 mm x 1770 mm x 2375 mm. The deployed S/C length is 25.78 m.
- The main cylinder of 1175 mm diameter and 2375 mm length accommodates fuel and oxidizer tanks
- North & south equipment panels are of size 2300 mm x 1930 mm. They are attached to the main cylinder using shear frames
- Cutouts are provided for the solar array drive assembly on the south deck and for the solar sail on the north deck

S/C mechanisms:

- Deployment mechanisms include single-sided solar panel, solar sail and shaped reflectors
- Two flaps offsetting seasonal variations in solar pressure; it is operated by a shaped memory alloy spring

Thermal system:

- The thermal design requires heat dissipation of about 1700 W
- Use of embedded heat pipes adopted to optimize the thermal system mass
- The thermal control system is complemented by the use of optical solar reflectors, multi-layer insulation blankets, thermal coatings, thermal tapes and heaters
- Appropriate thermal management for NiH₂ battery to maintain its temperature between $\pm 10^{\circ}\text{C}$.

Power system:

- Single-sided deployable solar array (GaAs/Ge cells) on the south side of the S/C with four panels of size: 2.7 m x 1.9 m
- EOL power of 2143 W
- Two 60 Ah NiH₂ batteries provide the eclipse requirement of 1800 W for full communication payload operation
- Two independent power buses with cross-strap capability, each bus regulated to 42+0.5 V by sequential switching
- Bus selection scheme provided for platform subsystems

Telemetry, Tracking and Command (TT&C) system:

- C-band telemetry and telecommand links with the subsystems deriving their heritage from earlier INSAT-2 S/C
- Near omni radio visibility during transfer orbit phase
- Normal and dwell mode telemetry possible by ground command
- Simultaneous dwelling on any of the 16 channels
- The system is capable of providing 2048 on/off commands and 64 data commands
- Provision of variable execution pulse width command feature
- The ranging accuracy is 50 m during transfer orbit and 30 m during on-orbit phase

¹¹¹³⁾ ISRO brochure of INSAT-2E, provided by George Joseph

Attitude and Orbit Control System (AOCS):

- The AOCS subsystem is comprised of microprocessor-based electronics (Mil-Std-1750A), attitude sensors, inertial reference unit, momentum/reaction wheels, magnetic torquer, solar flap and RCS (Reaction Control System) thrusters
- The propulsion system uses bi-propellants with 440 N LAM (Liquid Apogee Motor) for orbit raising and a total of 16 RCS thrusters for orbit and attitude control (fuel for a mission life of 12 years). Anti Earth viewing thrusters provide a backup for LAM
- The attitude sensor configuration supports all requirements. The north-facing Earth sensor is used during transfer orbit to maintain Earth lock. Redundant Earth sensors serve the same purpose during the on-orbit phase. The digital sun sensor, used in the transfer orbit, has a FOV of 37°. Four CASS (Coarse Analog Sun Sensors) are used, four Pi sun sensors are backup for CASS.
- AOCS pointing accuracies: pitch and roll = 0.2°, yaw = 0.4°
- Some special features of AOCS are:
 - Fault detection and identification logic for change over to redundant system
 - Safe mode operation in case of Earth lock loss
 - Long pulse detection logic which prevents unduly long during thruster firing
 - Remote programming for unforeseen requirements
 - Inertial reference unit with three gyros in orthogonal axis provide accumulated angle and rate information
 - Two momentum wheels provide stiffness to the S/C along the pitch axis. Redundancy for one wheel failure is provided by the reaction wheel along the yaw axis.

Meteorological payload of INSAT-2E: ¹¹¹⁴⁾ ¹¹¹⁵⁾

VHRR/2 (Very High Resolution Radiometer). This ISRO instrument is an enhanced version of the two-band VHRR flown on INSAT-2A/2B (see description above, F.6.2). A third band was added, the water vapor band [MWIR (Mid-Wave Infrared)], which is flown on the INSAT-2E spacecraft for the first time. The water vapor band is used for estimating water-vapor-tracer winds at the mid-troposphere, identifying subsidence/convection zones, and indirectly estimating the atmospheric correction to SST (Sea Surface Temperature) for the TIR channel. ¹¹¹⁶⁾

Spectral band: VIS	0.55 - 0.75 μm ; Integrated out-of-band response <3% Inter detector mismatch <5%
Spectral band: TIR	10.5 - 12.5 μm ; Integrated out-of-band response <3% Out-of-band response peak <0.1%
Spectral band: MWIR (Water vapor)	5.7 - 7.1 μm
Spatial resolution VIS	56 μrad (or 2 km x 2 km)
Spatial resolution TIR and MWIR	224 μrad (or 8 km x 8 km)
Radiometric performance: SNR	>6 for VIS at 2.5% albedo
Radiometric performance: NEDT	<0.25 K at 300 K for IR channel
Dynamic range of TIR/MWIR channels	4-340 K
Dynamic range of VIS channel	0-100%
Misregistration between VIS and IR	<56 μrad
Modulation Transfer Function (MTF)	>21% for IR and TIR; >23% for VIS channel

Table 311: Specification of the VHRR/2 instrument

VHRR/2 consists of the following major subsystems: scan mechanism assembly, radiant cooler, Optics assembly, and camera electronics.

- Scan mechanism assembly: The scanner consists of a two-axis gimbal-mounted beryllium mirror. The gimbal is servo-driven in two orthogonal axes. The mirror swings me-

¹¹¹⁴⁾ V. S. Iyengar, C. M. Nagrani, et al., "Meteorological imaging instruments on-board INSAT-2E," Current Science, Vol. 76, No 11, June 10, 1999, pp. 1436-1443

¹¹¹⁵⁾ Special Section: INSAT-2E, Current Science, Vol. 76, No 11, June 10, 1999, pp. 1431-1450

¹¹¹⁶⁾ P. S. Desai, "Satellite Meteorology in India: Accomplishments and Challenges," Space Forum, Vol. 5, No. 1-3, 2000, pp. 203-216

chanically $\pm 5^\circ/\text{s}$ (E-W fast scan) to provide an optical sweep of 20° (N-S) to the detector FOV to generate one line/s. In the other axis (N-S), the mirror is stepped through $224 \mu\text{rad}$ for each scanning line. In addition to the 20° (N-S) stepping, there is a provision to rotate the mirror through 90° to view the blackbody. There is also an offset capability in the E-W direction to position the Earth disk at the center of the image for longitudinal S/C positions between $70\text{--}100^\circ$ E.

- Radiant cooler. A passive system is used to cool the infrared detectors to an operating temperature of $105\text{--}115$ K.
- Optics assembly: The system consists of a telescope, dichroic beam splitter, infrared collimating lens, infrared relay optics, and VIS band optical elements. The telescope is a Ritchey-Chretien type instrument with a 200 mm diameter concave hyperboloid primary mirror and a 56 mm diameter secondary mirror, the separation distance is 285 mm. The convergent radiation beam from the secondary mirror is intercepted by a dichroic mirror which reflects 85% of IR energy and transmits 75% of the visible energy without distortion of the wavefront. The transmitted VIS band energy is reflected by a fold mirror onto an array of CCD detectors, while the reflected IR energy is collimated prior to exiting the telescope. This permits independent performance optimization of the TIR and IR (water vapor) bands in the radiant cooler/detector system.
- Camera electronics: The subsystem provides the following functions: a) digitization of the detector outputs, b) control of the IR detector temperatures, c) generation of clock and other control pulses, d) formatting of data, and e) instrument monitoring. The source data is coregistered and digitized to 10 bits.

The 2-D image of the Earth is generated by sweeping the IFOV of the detectors by rotation of the scan-mirror gimbals in two orthogonal axes. For every sweep of the mirror, four contiguous lines of VIS, and one line of TIR and IR bands each, are generated in the E-W direction. At the end of a sweep, the mirror is stepped south through an angle equivalent to eight km in ground distance. Three operational modes are provided:

- Full frame mode. An image of $20^\circ \times 20^\circ$ (TFOV) is generated within 33 minutes, covering the full disk of the Earth.
- Normal frame mode: Same coverage in E-W direction as in full frame mode; however, the N-S scan is 14° covering latitudes from 50° to 40° S in 23 minutes.
- Sector frame mode: This capability provides 4.5° coverage in N-S direction (about 2800 km with 351 scan lines) in 7.2 minutes. The E-W extent remains unchanged as in full and normal frame modes. The sector may be positioned anywhere within TFOV in steps of 0.5° (312 km or 39 lines) in N-S direction.

Instrument calibration: cold space views at the east/west ends are used for establishing reference radiance for all three bands. A full calibration of the TIR and IR bands is provided by swinging the mirror to view a blackbody cavity.

Status: The VHRR/2 instrument of INSAT-2E failed already in 1999. ¹¹¹⁷⁾

CCD Camera. The experimental instrument uses a linear CCD detector array with three spectral bands (see Table 312). Applications of the instrument data are in meteorology as well as in vegetation mapping. Of the three bands, the first two being similar to the NOAA AVHRR bands 1 and 2, provide “vegetation index” observation; the third band is used for snow-cover, snow-cloud discrimination and for aerosol measurements. A linear silicon array is used for the VIS and VNIR bands, while a InGaAs array is used for the SWIR band. The camera provides a nadir spatial resolution of ≤ 1 km in all three bands. The swath of the CCD Camera is 6300 km. The source data is coregistered and digitized to 10 bits. The data rate of the CCD Camera is 1.3 Mbit/s (QPSK modulation).

The CCD Camera is a first-time introduction on INSAT-2E. It permits greater accuracy in cyclone tracking and also affords monitoring of local severe storms. Plans for the third-gen-

¹¹¹⁷⁾ K. S. Jayaraman, “India Approves Nation’s 1st Dedicated Weather Satellite,” Space News, Dec. 11, 2000, pp. 3, 20

eration INSAT series call for a tandem operation, in which two members, INSAT-3A and -3D are earmarked for meteorology. While the INSAT-3A meteorological payload is still very similar to that flown on INSAT-2E (VHRR/2), the INSAT-3D payload will feature an enhanced VHRR instrument with six channels and a higher spatial resolution; two of the channels provide a split window for the TIR bands at 10.3-11.3 μm and 11.5-12.5 μm . This feature will be used to improve SST estimates.

Spectral bands	0.62 - 0.68 μm , VIS band 0.77 - 0.86 μm , VNIR (Visible Near Infrared) band 1.55 - 1.69 μm , SWIR (Shortwave Infrared) band
Spatial resolution	1 km x 1 km
MTF	≤ 0.23
Dynamic range	0-100% albedo
Noise performance	SNR ≤ 128 at 100% albedo
Coverage	6250 km x 300 km per scan line (max. number of lines = 31)
Image repetivity	One scan line per minute
Instrument mass, power	< 55 kg, < 50 W

Table 312: Specification of the CCD Camera

The CCD Camera consists of the following elements: scan mechanism assembly, optics and detector assembly, and camera electronics.

- Scan mechanism assembly: Features a gimballed scan mirror which sweeps FOV in two orthogonal axes. The fast sweep generates 300 video lines over a 6300 km east-west direction every minute (with a fast retrace capability). The 0.4° south stepping of the mirror after each east-west scan provides the generation of successive image strips. The TFOV (Total Field of View) of the mirror is $\pm 13^\circ$ in the E-W and $\pm 10^\circ$ in the N-S direction, while the actual image is $\pm 5^\circ$ in E-W and $\pm 5^\circ$ in the N-S direction. The actual image may be positioned anywhere within the mirror TFOV.
- Optics and detector assembly: The assembly consists of the scan mirror, telescope, dichroic beam splitters, fold mirror, lens doublet and bandpass filters. The front-end optics, namely scan mechanism and telescope, is identical to that of VHRR (except that the telescope performance has been upgraded to provide a FOV of $\pm 0.25^\circ$ at twice the spatial frequency of VHRR). The VIS and VNIR silicon CCD detectors have 2048 element linear arrays, as well as the InGaAs photodiode detector (cooled) for the SWIR band. The outputs of the three line arrays, providing a total of 900 pixels, are processed to construct 300 image pixels for each band.
- Camera electronics: The subsystem provides: a) clock and bias inputs to the detectors, b) processes and digitizes the detector outputs., c) formats the video signal along with auxiliary information, d) monitors the instrument; e) interfaces with other subsystems, and f) controls the SWIR detector temperature through a feedback loop.

Meteorological payload data transmission:

The VHRR data in PCM NRZ-S format is BPSK modulated, the data rate is 526.5 kbit/s. The data of the CCD Camera in PCM NRZ-L format is QPSK modulated, the data rate is 1.3 Mbit/s. Both meteorological payloads have a common up convertor and a redundant transmitter for a downlink through a 4.5 GHz carrier. A separate 0.9 m diameter Earth view antenna on-board the S/C is providing transmission services for the meteorological data.

Data from the INSAT series instruments are acquired, processed and disseminated by IMD (India Meteorological Department), the main data center and operator the INSAT series. A DCS (Data Collection System) is flown on all INSATs for collecting and relaying data from platforms in the ground segment.

Total number of channels	17
Normal C-band channels	12
Uplink frequency	5850-6410 MHz
Downlink frequency	3625-4185 MHz
Lower extended C-band channels	5
Uplink frequency	6450-6650 MHz
Downlink frequency	3425-3625 MHz
Downlink coverage:	Wide beam (channel 6, 8, 10, 12, 14, 15, and 17), zonal beam all other channels
Uplink coverage:	Wide beam
Transmit EIRP	36 dBW for all channels
RF output power	60 W (wide beam); 32 W (zonal beam)

Table 313: Characteristics of the INSAT-2E communication payload

F.6.3 INSAT-3 Satellite Series

The INSAT-3 series of ISRO is a multipurpose spacecraft with an all Ku-band transponder layout for direct-to-home television and roof-top data communication. The satellites incorporate state-of-the-art communication technology such as high power antennas, steerable beam and digital compression/decompression capabilities. The solar panel of the INSAT-3A S/C uses an advanced rigid deployable sun-oriented array of GaAs/Ge cells with an area of 26.5 m². The series is planned for launch from 2000 onwards.

Mission	Comment	Meteorological Payload	Power, Battery, Other
INSAT-3B	Launch March 21, 2000 on Ariane-5 from Kourou, co-located with INSAT-2E at 83° East	None	3.45 kW at equinox, NiH ₂ , 70 Ah, 27 cells
INSAT-3A	Launch planned for 2002	VHRR/2, DCS, SAS&R	
INSAT-3C	Launch planned for Sept. 2001		36 transponders, 24 in C-band, 12 in extended C-band
INSAT-3D	Launch planned	VHRR/3, DCS, SAS&R	

Table 314: Overview of INSAT-3 satellite series

F.6.3.1 INSAT-3B

INSAT-3B is the first of the five satellites that was launched in the INSAT-3 series (built by ISRO). The satellite structure resembles a cuboid of 1.93 m x 1.7 m x 1.65 m and, with the two solar panels deployed (total area of 23 m²), it measures 14.7 m in length. The sun tracking solar panels generate 1.7 kW of power. A 24 Ah Ni-Cd battery supports the payload operations during eclipses. INSAT-3B is three-axis body-stabilized using momentum/reaction wheels, earth sensors, sun sensors, an inertial reference unit and magnetic torquers. It is equipped with unified bi-propellant thrusters. The satellite has two deployable antennas and three fixed antennas that carry out various transmit and receive functions. The antennas have a pointing accuracy of $\pm 0.2^\circ$ in pitch and roll axes, and $\pm 0.4^\circ$ in yaw axis. The satellite uses a passive thermal control system. The S/C mass is 2070 kg at launch, with 1100 kg of hydrazine propellant for orbit raising, station keeping and on-orbit attitude control. The S/C design life is 10 years. ¹¹¹⁸⁾

INSAT-3B was launched successfully on March 21, 2000 from Kourou on an Ariane-5 vehicle (along with a passenger payload called Asia Star of the US company World Space), putting INSAT-3B into GTO (Geostationary Transfer Orbit).

Orbit: Geostationary orbit at 83° East, co-located with INSAT-2E.

¹¹¹⁸⁾<http://www.isro.org/insat3b.htm>

The INSAT-3B communication payload provides 12 extended C-band channels, each having a bandwidth of 36 MHz. The Ku-band payload provides three channels, having a bandwidth of 77/72 MHz. The Mobile Satellite Service transponders operate in C/S band frequencies. Compared to INSAT-2C/2D, the power of extended C-band transponders on board INSAT-3B has been increased from 10 W to 15 W and that of Ku-band from 20 W to 55 W. - The INSAT spacecraft series missions are operated by the MCF (Master Control Facility) at Hassan in Karnataka, India. MCF has a network of six Satellite Control Earth Stations (SCES) to acquire its data.

F.6.3.2 INSAT-3A

INSAT-3A is a multipurpose satellite like its predecessors supporting the functions of communications and meteorology. A launch of the spacecraft is planned for early 2002.

Meteorological payload:

The meteorological instruments are identical to those of the INSAT-2E instruments, namely VHRR/2 and the CCD Camera.

F.7 METEOSAT

Background: METEOSAT is the European meteorological program that was initiated by ESA in 1972 (actually the beginnings of European space meteorology goes back to 1968 under ESRO). Meteosat-1 was the first European meteorological geosynchronous satellite, launched on November 23, 1977. The next satellite in this preoperational series, Meteosat-2, was launched on June 19, 1981. The success of the Meteosat program led a large group of European nations to establish firm plans for sustained operations by an independent agency. On May 24, 1983, 16 countries signed the EUMETSAT convention, which came into force in June 1986. On January 1, 1987, responsibility for the operation of the Meteosat satellites was transferred from ESA to EUMETSAT. Since then ESA continues to build and operate the MOP (Meteosat Operational Program) series as a EUMETSAT contractor. In a 1993 agreement, EUMETSAT was given the full operational mandate. This means that EUMETSAT provides all operational functions and services of its satellites (with a dedicated EUMETSAT ground segment) established in 1995. ^{1119) 1120) 1121) 1122) 1123) 1124)}

The prime objective of EUMETSAT is to establish, maintain and exploit European systems of operational meteorological satellites. In 1994 EUMETSAT commenced two new programs: MSG (Meteosat Second Generation), a geostationary program with operational services starting in 2000; EPS (EUMETSAT Polar System) with the MetOp services starting in the year 2003. The space segment of both of these programs is being developed in cooperation with ESA.

Meteosat itself is part of a global network of geostationary meteorological satellites distributed around the equator. All activities regarding satellite and operations are coordinated by the CGMS (Coordination of Geostationary Meteorological Satellites) committee represented by WMO and the countries providing the satellites [Europe (EUMETSAT), USA (NOAA), Russia (NPO Planeta), Japan (JMA), India (ISRO), China]. - Meteosat satellites are normally positioned at 0° longitude (Meteosat-3 was reassigned and positioned in re-

cent years at 75° western longitude in support of GOES coverage - Extended Atlantic Data Coverage Mission) . The coverage of Meteosat satellites is Europe, Africa and the Atlantic Ocean.

Figure 195: The Meteosat S/C model

Prototype satellites of the preoperational program:	
Meteosat-1	Launch: Nov. 23, 1977; service operation until Nov. 1979
Meteosat-2	Launch: June 19, 1981; service operation from Aug. 12, 1981 until Aug. 11, 1988 as prime satellite, re-orbiting in December 1991.
Meteosat-3	(initially designated as P2); Launch: June 1988 (2 years). Note: this satellite was also positioned over the West Atlantic as a temporary replacement for GOES.
EUMETSAT (MOP) Missions:	
Meteosat-4	MOP-1, Launch: March 6, 1989; first image of MOP-1 on April 19, 1989
Meteosat-5	MOP-2, Launch: March 2, 1991; 1998 repositioning to 65° East for INDOEX campaign support
Meteosat-6	MOP-3, Launch: Nov. 20, 1993
Meteosat-7	MOP-4, Launch: Sept. 3, 1997 (nominal life = 5 years), Meteosat-7 is part of the Meteosat transition program toward MSG (Meteosat Second Generation)

Table 315: Overview of Meteosat missions

Spacecraft: Meteosat is a spin-stabilized S/C (dual-spin configuration at 100 rpm). It features a cylindrical body of 2.1 m in diameter (toped by a drum-shaped section and further smaller cylinders), the overall length is 3.195 m. The main cylindrical body contains most of the payload. Its outer surface is covered with solar cells (more than 8000 cells mounted on five standard panels). The surface of the drum-shaped section is covered with an array of radiating dipole antenna elements. Electronics within the drum activate the individual elements in sequence, in reverse order to the S/C spin sense. The drum constitutes an electronically despun portion of the S/C, namely the antenna whose function is to ensure that S-band communications are always directed towards Earth. - Two Earth horizon sensors and two sun sensors provide attitude information. The S/C has four main thrusters (10 N) and two 2 N thrusters as actuators (hydrazine propellant) for orbit/attitude control. The S/C dry mass is 322 kg (plus 39 kg of hydrazine). ¹¹²⁵⁾

Application: Weather forecast, meteorology, climatology (sea surface temperature monitoring, cloud cover statistics, wind and rainfall assessment). Collection of environmental data.

¹¹²⁵⁾“The METEOSAT System, EUM TD 05, March 1996, brochure provided by EUMETSAT

An image is provided in 1/2 hour periods in the visible range and in the IR and WV regions. The first three missions were part of the preoperational program. MOP (Meteosat Operational Program); the MOP phase extends to the end of 1995. MOP is considered the first Meteosat generation (nominal life=2 years for METEOSAT-4 to -6).

Sensor:

The observation payload consists of a high-resolution radiometer (image generation in the thermal infrared region (TIR), in the water vapor absorption bands (WV), and in the visible range (VIS).

VISSR (Visible and Infrared Spin Scan Radiometer, platform spin rate: 100 rpm), also referred to as **MSR** (Multispectral Radiometer) and **MVIR** (Meteosat Visible and Infrared Radiometer). Objectives/applications: Earth and atmospheric monitoring, operational meteorology, climatology. Basic climatological data sets and precipitation index are derived daily. Measurements: cloud coverage, cloud motion winds, cloud top heights, upper tropospheric humidity, precipitation and sea surface temperature.

The optical system of VISSR consists of a scanning Ritchey-Chretien telescope with a primary aperture of 400 mm diameter (140 mm secondary aperture) and focal lengths of 3650 mm for VIS and 535 mm for WV and IR ranges. A series of mirrors is used to collect the incoming radiation and to focus it onto the corresponding detectors (silicon photodiodes for VIS, HgCdTe detectors for IR and WV). The HgCdTe detectors are cooled to 90 K by a passive system. The S/C scans the full Earth disk within a 30 min period. Scanning from east to west is achieved by through the S/C spin. Scanning from south to north is achieved by small incremental steps in the pointing of the telescope.

Calibration is provided by two black bodies located on opposite sides of the main optical path, one is kept at 290 K, the other is kept at 340 K. In addition, cold space views are obtained during normal imaging operations.

Spectral ranges (3 bands)	0.5 - 0.9 μm (VIS), visible band 5.7 - 7.1 μm (WV), emission of water vapor 10.5 - 12.5 μm (TIR) thermal infrared
FOV	18° (0.314 rad)
IFOV	0.065 mrad (VIS), 0.14 mrad (WV, TIR)
Ground pixel size	2.5 x 2.5 km for VIS, (5 x 5 km for WV and TIR)
Image lines	5000 (VIS), 2500 (WV, TIR)
Pixel samples per line	5000 (VIS), 2500 (WV, TIR)
Line duration, line recurrence	30 ms, 600 ms
Number of pixels/image	25 Mega pixels (VIS), 6.25 Mega pixels (WV, TIR)
Image duration, image recurrence	25 min (scanning), 30 min (duty cycle = 100%)
Data transmission rate to ground	333kbit/s (normal mode), 2.7 Mbit/s (burst mode)

Table 316: VISSR parameter specifications

Meteosat Communications:

- S-band in the frequency range of 2098 - 2110 MHz.
 - Transmission of raw image data from the S/C to Fucino (primary ground station).
 - TT&C data
 - Transmission of DCP reports
 - Uplink of image dissemination data from the primary station to the S/C
 - Uplink of MDD (Meteorological Data Distribution) data from a ground station
- L-band in the frequency range of 1675 - 1696 MHz. The L-band is for user-related functions for the following services:
 - WEFAX analog image dissemination and DCP retransmissions (1691.0 MHz)

- HRI (High Resolution Image) digital image dissemination, with a few WEFAX transmissions (1694.5 MHz)
- Meteorological data distribution with up to four channels spaced at 30 kHz (1695.605 - 1695.935 MHz)
- UHF-band in the frequency range of 402.0 - 402.2 MHz. DCPs (Data Collection Platforms) may be given access to one of the 66 uplink UHF channels at 3 kHz separation.

E7.1 Meteosat Data Collection System (DCS)

The Meteosat DCS provides an operational collection service for a large number of data collection platforms within its field of view (about 80° great circle of arc of its subsatellite point). The overall system is composed of the following subsystems:¹¹²⁶⁾

- 1) The space segment: a DCS platform on Meteosat satellites consisting of: a UHF/S-band transponder, an electronically despun S-band antenna, a UHF receive antenna and, as a backup, an S-band toroidal pattern transmit antenna.
- 2) The Data Collection Platforms (DCPs) in the ground segment
- 3) The Meteosat ground station (ESA Odenwald station) and DCP processor at ESOC Darmstadt

The DCS on-board Meteosat provides a transponder with a pass band that is divided into 66 communication channels (3 kHz per channel). A message from a DCP in the ground segment is relayed via the DCS to the Meteosat ground station. Each DCP is allocated one of the 66 parallel channels. Since the DCP transmit either according to a schedule, or under 'alert' conditions, many platforms can use a single 3 kHz channel sequentially. The platforms (DCPs) transmit (uplink) their data in the 402 MHz UHF band to the Meteosat DCS, where it is converted to S-band (1675 MHz) and retransmitted (downlinked) to the Meteosat ground station. There, the signals received are checked for quality before being transmitted to ESOC for processing and distribution. At ESOC, all DCP messages are collected, processed, disseminated in near real time and distributed to the platform owners. The distribution of DCP data can also be achieved via the 'DCP Retransmission' service.

Data Collection Platforms.

Meteosat services about 1000 DCPs in the ground segment. The coordinated DCS design approach from Meteosat (Eumetsat), GOES (NOAA) and GMS (JMA) allows the reports from DCP carried on ships, aircraft and other mobile platforms, moving from one satellite coverage area to another, to be received and transmitted by one of the satellites in the network (and transmitted via terrestrial lines throughout the world).

Meteosat services three basic types of DCPs (Eumetsat requires certification and licensing of all DCPs):

- 'Self-timed' DCPs, which transmit their data at regular intervals based on an internal clock (this is the most common type of platform in use)
- 'Alert' DCPs, which transmit a small amount of data when a particular parameter has been exceeded. The transmission time of 'alert' DCP messages is limited to about 10 seconds in order to decrease the probability of overlapping messages on the same channel.
- 'Hybrid' DCPs, which are a combination of 'alert' and 'self-timed' DCPs.

DCP transmissions are limited to about 1 minute, each transmission is termed a DCP message. One DCP message may contain several sets of information or 'reports.' A message format consists of the following contiguous elements:

- unmodulated carrier for 5 seconds

¹¹²⁶⁾ "Meteosat Data Collection System," March 1990, ESOC

- a 250-bit preamble (alternating '0' and '1' - to acquire the bit rate and lock onto it)
- a 15-bit synchronization word
- the DCP address (a 31-bit Bose-Chaudhuri-Hocquenghem (BCH) coded word)
- the data field (up to 5192 bits, - 'alert' DCPs are limited to 184 bits of data)
- the 31-bit End of Transmission (EOT) sequence.

The DCP RF uplink is in UHF band (between 402.001 and 402.199 MHz). The Meteosat DCS transponder permits up to 33 international [in common with GOES and GMS spacecraft (402.0025 - 402.0985 MHz)] and 33 regional channels (402.1015 - 402.1975 MHz) for DCP reports. The carrier is phase modulated by the signal bit stream, the modulation index being 60°.

'Self-timed' DCPs report according to a schedule agreed to by the DCP owner and the operations center. Depending on the application this may range from several times per hour to once every 24 hours. Each hour is divided into 40 time slots; each report must be completed within its given time slot. Since the maximum duration of a report is about one minute, at least 30 seconds are available as a guard time to accommodate any drift in the DCPs internal clock.

'Alert' DCPs transmit on channels which are free of self-timed DCPs. Although the duration of an alert message is limited to about 10 seconds, it is of course possible that two or more alert reports will overlap on the same frequency channel. The event of such an overlap entails the loss of both messages. In order to reduce this overlap probability, alert platforms repeat their messages several times at fixed time intervals.

DCS Access Method.

Data transmission from a DCP to the Meteosat DCS is generally self-triggered by the DCP. All DCS receivers are in listening mode trying to lock onto any message that is being assigned to them by the DCPs on a random access basis. The mean availability of the DCS is >95%, a user can expect that more than 95% of the messages transmitted by his DCP is being received, processed and distributed.

DCP Data Processing. The data handling system performs the following functions (starting in 1995):

- Completeness checks for constituting blocks and DCP address recognition
- Storing of DCP messages and processing information onto a database
- Monitoring of reporting DCPs with respect to a predefined schedule (check of transmission chain)
- A log of received and processed messages, including anomalies
- Processing of DCP data and bulletin preparation for distribution
- Archiving of DCP data. Retrieval for DCP users
- Generation/storage of a performance analysis.

All geostationary meteorological satellites series (METEOSAT, NOAA-GOES, GMS (JMA), etc. use DCS (or variations thereof. Note: the ARGOS-DCS concept on polar-orbiting NOAA-POES S/C with the corresponding PTTs (ground) differs in uplink frequency, message length and format).

F.7.2 Meteosat DCP Retransmission System

DCP users may also directly receive their (DCP and/or WEFAX) data if a Secondary Data User Station (SDUS) is operated on their home premises. This service is offered to users at any point within the Meteosat telecommunication range. DCP data received at the Meteosat ground station are preprocessed and routed to ESOC. Those DCP data intended for direct retransmission are selected and routed to a special processing unit in the ground station. The selection is made by using look-up tables of DCP addresses. All DCP data listed in

these look-up tables are buffered and transmitted in a time-sharing mode over one of the Meteosat transponder channels used for image transmission (1691, 1694.5 MHz). DCP data is transmitted in time slots between image transmissions. The time slot is 27 seconds between two WEFAX transmissions. DCP data transmission may be continuous if there is no transmission of WEFAX images or ranging. The bit rate during transmission is 12.5 kbit/s; on average, there are 15 transmission slots of 27 seconds per hour.¹¹²⁷⁾

WEFAX (Weather Facsimile) transmissions are in a format compatible with the APT (Automatic Picture Transmission) service of the NOAA-GOES and POES series. The WEFAX transmission format consists of the following elements:^{1128),1129)}

- Start signal (300 Hz), 3 seconds
- Phasing signal, 5 seconds
- Image (800 lines), 200 seconds
- Stop signal (450 Hz), 5 seconds

Consecutive WEFAX transmissions are scheduled in 4-minute slots. This leaves a break of 27 seconds between two WEFAX transmissions. In these 27 second intervals, the stored DCP reports are disseminated, the individual reports being packed into HDLC frames.

1129) "Meteosat High Resolution Image Dissemination," ESOC paper, Oct. 1989

F.7.3 MOSAIC

All weather services rely heavily on the timely distribution of meteorological observations and derived products. These requirements have stimulated the development of a meteorological data distribution service. The principal Meteosat missions can be combined by the user to provide an integrated data access system. This concept is known as 'Meteosat Operational Systems for data Acquisition and InterChange' (MOSAIC). Since 1991 users can readily combine satellite imagery, local reports from the data collection system, as well as conventional meteorological data and forecasts. Meteosat acts in this setup simply as a relay for most data distribution services (direct broadcast). The MDD (Meteorological Data Dissemination) system is one facet of MOSAIC; it provides a service with enormous distribution potential, particularly across Africa and the Middle East.¹¹³⁰

MDD (operational since 1992) consists of three elements: the uplink sites, the Meteosat transponder (relay), and the user reception stations. The initial two operational uplink sites are at Bracknell (UK Meteorological Office) and at Rome (Italian Meteorological Service). A third uplink started operations in 1994 (Toulouse, France). The data sets disseminated via MDD channels consist of meteorological information in the form of alphanumeric characters, bit-oriented data streams, and graphical information - all of which use a common data transmission protocol.

MDD offers four downlink channels from Meteosat in S-band (1695 MHz), each with a transmission rate of 2400 bit/s. The channel spacing is 31.2 kHz with a bandwidth of ± 10 kHz for each channel. The following center frequencies are either in use or reserved for future extension:

- Channel 1: 1695.6938 MHz
- Channel 2: 1695.7250 MHz (Bracknell, UK)
- Channel 3: 1695.7562 MHz (Toulouse, France)
- Channel 4: 1695.7874 MHz (Rome, Italy)

MDD transmission from the source to the receiving stations is as follows:

- The GTS (Global Telecommunication System of WMO) is used for the acquisition by the MDD uplink station (see Figure 196)
- The link protocol in the ground segment is X.25 (CCITT)
- The data blocks are received by the MDD uplink preprocessor (encryption and FEC)
- The data are uplinked via Meteosat relay function to the receiving stations
- Each MDD receiving station acquires the data blocks, preprocesses them and reassembles the data into WMO bulletins or meteorological charts.

Application: an extensive range of operational meteorological charts covering Africa, the Middle East, Europe, Asia, parts of the Americas, and all intervening oceans is broadcast through the MDD service from Bracknell.

F.8 MSG (METEOSAT Second Generation)

The first generation METEOSAT series of EUMETSAT is planned to be replaced by a second generation series (MSG) with a launch of the first satellite (MSG-1) in early 2002, to be followed by at least two more satellites, ensuring operational continuity for at least 12 years. The MSG programme definition started in 1993 with a phase C/D started in 1995. The programme is funded by the European Space Agency (ESA) and the European Organization for the Exploitation of Meteorological Satellites (EUMETSAT) according to the following share of responsibilities:

- ESA develops the MSG-1 prototype satellite according to EUMETSAT requirements and acts, on behalf of EUMETSAT, as procurement agent for MSG-2/-3 satellites

¹¹³⁰) "MOSAIC Meteorological Data Distribution," EUMETSAT, EUM UG 01

- EUMETSAT contributes one third of the MSG-1 funding, and funds procurement of MSG-2/-3, finalizes and maintains end user requirements, procures all launch services including launchers, develops the ground segment, ensures consistency between segments (space, ground, and launch service segments) and operates the MSG system.

The MSG system, as follow-on to the Meteosat first generation system, is designed to support nowcasting, very short and short range forecasting, numerical weather forecasting and climate applications over Europe and Africa, with the following mission objectives:

- Multispectral imaging of the cloud systems, the Earth surface and radiance emitted by the atmosphere, with improved radiometric, spectral, spatial and temporal resolution as compared to the first generation Meteosat
- Extraction of meteorological and geophysical fields from the satellite image data for the support of general meteorological, climatological and environmental activities
- Data collection of data from data collection platforms (DCP)
- Dissemination of the satellite image data and meteorological information upon processing to the user community in a timely manner for the support of nowcasting and very short range forecasting
- Support to secondary payloads of scientific or pre-operational nature (GERB) and Search & Rescue (called GEOSAR) in supporting operations which are not directly relevant to the MSG program
- Support to the primary missions (e.g. archiving of data generated by the system MSG, for successful operation of the system etc.).

Figure 197: Illustration of the MSG satellite

The MSG satellites are being built by a European industrial consortium led by Alcatel Space Industries (ASI) of France. ^{1131) 1132) 1133)}

MSG satellites are spin-stabilized (cylindrical in shape, similar to the first generation S/C series) with a rotation speed of 100 rpm. The S/C body is a cylindrical-shaped solar drum, 3.2

¹¹³¹⁾ W. Veith, "The MSG Satellite and its Subsystems," Proceedings of the 2000 EUMETSAT Meteorological Satellite Data Users' Conference, Bologna, Italy, May 29-June 2, 2000, pp. 15-32

¹¹³²⁾ S. Rota, "The METEOSAT Second Generation," Proceedings of the EUMETSAT Meteorological Satellite Data User's Conference, Copenhagen, Denmark, Sept. 6-10, 1999, pp. 25-32

¹¹³³⁾ <http://www.esa.int/msg/>

m in diameter and 3.7 m in height (2.4 m body) with stepped cylinder. The major subsystems of the platform are: AOCS (Attitude and Orbit Control Subsystem), EPS (Electrical Power Subsystem), UPS (Unified Propulsion Subsystem), and DHSS (Data Handling Subsystem)

- AOCS: Attitude is measured by means of Earth sensors and sun sensors. AND (Active Nutation Damping) is used during GTO; there is no AND in the GEO phase. In addition, AOCS provides synchronization signals to keep the SEVIRI, GERB, and the electronically de-spun antenna Earth-pointing.
- EPS: Solar power of 600 W EOL is provided to the S/C bus 28 V power bus. Two NiCd batteries provide 1200 Wh for ecliptic operations support.
- UPS: A bi-propellant unified propulsion system of two 400 N apogee engines is used for a 3-burn insertion from GTO into GEO. Four tanks hold up to 976 kg of propellant. About 810 kg are used for the GEO insertion of MSG.
- DHSS: The system consists of three units: CDMU (Central Data Management Unit) and two RTUs (Remote Terminal Units).

The satellite itself is built in a modular way around three main sub-assemblies: The SEVIRI instrument is located in the central compartment; the communication payload, including antennas and transponders, are positioned in the upper compartment; while the platform support subsystems are located in the lower compartment. The S/C design life is seven years. Total S/C mass = 2040 kg, power = 600 W (EOL).

Orbit: Geostationary orbit at 0.0° longitude (held to within 1° by thrusters). Two satellites are simultaneously in orbit (one operating and one in cold redundancy) to assure availability. The MSG-2 launch is planned 18 months after MSG-1 to provide a two-satellite operational system.

Application: Operational meteorology and climate monitoring.

Sensor complement:

SEVIRI (Spinning Enhanced Visible and Infrared Imager), designed and built by Astrium SAS, France.¹¹³⁴ SEVIRI is the principal on-board instrument, an imaging radiometer for imaging and sounding (12 channel instrument as defined in Table 317). Its operating principle is based on collecting radiation from a target area and focusing it on detectors sensitive to 12 different bands of the electromagnetic spectrum by means of a telescope. This is followed by the electronic processing of the signals provided by the detectors. Channels VIS 0.6 μm , VIS 0.8 μm , IR 1.6 μm and HRV are referred to as “warm”, while channels IR 3.9 to IR 13.4 μm are referred to as “cold.” The cylindrical instrument has a diameter of about 1 m and a height of 2.1 m along the spin axis of the satellite. Instrument mass = 260 kg, power = 153 W. The instrument functional architecture is based on four main assemblies:

- TSA (Telescope and Scan Assembly) including the calibration unit and the refocusing mechanism. TSA employs a three-mirror telescope of compact design. The primary mirror is concave a-spherical with a diameter of 510 mm. The secondary mirror is concave a-spherical of 200 mm diameter. The tertiary mirror is convex a-spherical of 60 mm diameter. The total length of the telescope structure is 1.3 m. All mirrors are light-weighted and manufactured from Zerodur. The rotating scan mirror assembly uses a linear spindle drive with a stepping motor, providing continuous bi-directional image scanning. North to south scan of the Earth: scan capability of 22° in N-S direction and 18° in E-W direction. At each satellite revolution, three image lines are acquired (9 lines for the High Resolution Visible channel) for a total of about 1250 lines in a repeat cycle of 15 minutes. Each nominal raw image consists of 3750 lines, each one containing about 3834 pixels except for HRV channel for which a nominal raw image consists of 3750 lines with 5751 pixels per line.

The calibration unit permits calibration of the IR channels by inserting a CRS (Black-

¹¹³⁴J. Schmid, “The SEVIRI Instrument,” Proceedings of the 2000 EUMETSAT Meteorological Satellite Data Users’ Conference, Bologna, Italy, May 29-June 2, 2000, pp. 23-32

body Calibration Reference) source into the optical beam at the focal point of the primary mirror. A flip-flop type mechanism is employed based on a DC voice coil motor. A refocusing mechanism is included in the SEVIRI telescope to correct, on an occasional basis, for potential defocus after launch and during lifetime. It consists of a stepper motor, a transmission gear box and a roller screw to provide the translation. ¹¹³⁵⁾

- FPCA (Focal Plane and Cooler Assembly). FPCA is a passive two-stage cooler providing an 85 K environment for the IR channels.
- EUA (Electrical Unit Assembly), consists of FCU (Functional Control Unit), DE (Detection Electronics) including the MDU (Main Detection Unit), the PU (Preamplifier Unit) and the detectors. EUA controls SEVIRI and processes its data. The DE consists of the detectors and the front-end electronics.

Channel		Nominal spectral band (μm)	NEAR or NEAT	Max Dynamic range *
Name	Center of λ (μm)			
HRV	Broadband (silicon response)		1.07 W/(m ² sr μm) at 1.3 W/(m ² sr μm)	460 W/(m ² sr μm)
VIS 0.6	0.635	0.56-0.71	0.53 W/(m ² sr μm) at 5.3 W/(m ² sr μm)	533 W/(m ² sr μm)
VIS 0.8	0.81	0.74-0.88	0.49 W/(m ² sr μm) at 3.6 W/(m ² sr μm)	357 W/(m ² sr μm)
IR 1.6	1.64	1.50-1.78	0.25 W/(m ² sr μm) at 0.75 W/(m ² sr μm)	75 W/(m ² sr μm)

IR 13.4	13.4	12.40-14.40	1.8 K at 270 K	300 K

Table 317: Channel definitions of the SEVIRI instrument

The overall SEVIRI design is based on a compact telescope and scan assembly, allowing the implementation of a large passive cooler which improves IR detector performances by lowering their operating temperature. The imaging SEVIRI radiometer is equipped with a patented three-mirror (3M) telescope of compact design (focal length of 5367 mm) which allows the insertion of a small black body for full-pupil calibration. The primary mirror (M1) is a concave circular ellipsoid (centered on the satellite axis). M1 is a 500 mm diameter mirror with a baffled central hole of 90 mm diameter. ¹¹³⁶⁾ It is followed by a magnifying two-mirror assembly including the secondary mirror (M2), which is a concave ellipsoid centered on the satellite axis, and the tertiary mirror (M3) which is a convex spherical mirror. The M2/M3 assembly is a compact "light-tight" configuration allowing easy alignment. - The 12 channel detectors are positioned at the focal plane using a total of 42 detectors. Each channel has an array of 3 detector elements, with the exception of the HRV channel which has 9 detectors. The eight IR channels have HgCdTe detectors, they are passively cooled. The VIS channels feature photo-voltaic silicon diodes while the NIR channels have InGaAs photovoltaic diodes. - Data quantization is done inside the MDU (Main Detection Unit) by a 12-bit ADC, for an effective 10-bit resolution at the electronic outputs, after digital dynamic offset and fine gain correction. Auxiliary data are added to the detector data for image processing on ground.

The Earth's radiation enters the instrument at every revolution through a 50 cm x 80 cm aperture. The nominal repeat cycle of 15 minutes was the driver in selecting the number of

detectors per channel and the spin rate (100 rpm). Twelve minutes are allocated to the imaging phase, leaving three minutes for calibration, retrace and stabilization. The 1 km sampling at SSP of the High Resolution Visible (HRV) channel is achieved by using 9 broadband detection elements. The other channels are sampled at 3 km SSP by using 3 narrow-band detection elements per channel.

Earth frame East-West	18.40° (321.5 mrad.), HRV: 9.2° (160.7 mrad)
Earth frame North-South	18.01° (314.4 mrad.)
Scan range North-South	20.0° (384 mrad., 1527 steps)
Scan line step	51.88 arcsec (251.5 µrad., 9 km at SSP)
Scan mechanism step	25.94 arcsec (125.8 µrad., 9 km at SSP)
Spin rate	100 rpm
Line cycle	0.6 s
Imaging time per line	30.672 ms (5%); HRV: 15.336 ms
Earth imaging time	12.5 minutes
Calibration, retrace and stabilization	2.5 minutes
Repeat cycle	15 minutes

Table 318: Some SEVIRI imaging parameters

SEVIRI employs the classical calibration approach using deep space as cold source and a known on-board source as a warm reference. The on-board blackbody temperature is used to determine the correction factor accounting for the different levels of background flux. The deep-space view is performed via the full optical path by commanding the acquisition of a sufficient number of samples during that part of the S/C revolution, when neither the Earth nor the sun (or moon) is in the FOV of SEVIRI. ¹¹³⁷⁾

Channel groups	Scanning parameters	Data rate before stretching	Data rate after stretching
3 VNIR channels (2 VIS + 1 IR)	3 detectors per channel 3834 pixels per line 10 bits per pixel	11.25 Mbit/s	0.5751 Mbit/s
8 IR channels	3 detectors per channel 3834 pixels per line 10 bits per pixel	30.00 Mbit/s	1.5336 Mbit/s
1 HRV (High Resolution Visible) channel	9 detectors per channel 5751 pixels per line 10 bits per pixel	33.75 Mbit/s	0.8627 Mbit/s
Total		75 Mbit/s	2.9714 Mbit/s

Table 319: Projected data rates of the SEVIRI instrument

GERB (Geostationary Earth Radiation Budget), ¹¹³⁸⁾ ¹¹³⁹⁾ ¹¹⁴⁰⁾ ¹¹⁴¹⁾ PI: J. Harries, Imperial College, London. GERB is an AO (Announcement of Opportunity) instrument, and provided on a national funding basis by a consortium led by the UK (NERC), Belgium (OSTC) and Italy (ASI). RAL of UK provides overall instrument management, systems engineering and other services. The objective is to monitor the Earth's radiation budget (global climate change, food production and natural disaster prediction) measuring at the top of the atmosphere (continuous temporal sampling), in particular the shortwave and longwave regions

of the spectrum, essential for the understanding of the Earth's climate balance. The instrument is composed of two elements, the IOU (Instrument Optical Unit) and the IEU (Instrument Electronics Unit), featuring the following basic design:

- Three-mirror anastigmatic system + one rotating and one flat folding mirror
- Wide-band linear detector array
- Continuously rotating scan mechanism
- Channel separation via quartz filter
- Blackbody for thermal calibration
- Solar diffuser for shortwave calibration
- Passive thermal design
- Structure based on solid optical bench

At the core of the GERB instrument is a broadband, three mirror telescope housed in the IOU. This views the Earth with a black wideband detector array, providing measurements of the Earth's output radiation in a total band, and a shortwave band. Shortwave measurements are accomplished by using a quartz filter to block the wavelengths beyond 4 μm . The longwave band is obtained by subtraction. GERB removes the effect of S/C spin (100 rpm) by means of a rotating mirror, this increases the length of available exposure time per spin. The detector consists of a 256-element blackened thermoelectric array, mounted in the N-S direction. This arrangement provides an image column per S/C rotation; a complete image is obtained by successive measurements of columns. Every 15 minutes a complete dataset of both, solar and total spectral band, is obtained for the entire area visible from geostationary orbit. The great advantage of GERB is its ability to sample a large region of the globe with high time resolution. GERB instrument data provides close synergies with other instruments such as CERES, ScaRaB, and with SEVIRI on MSG (observations from both geostationary and polar-orbiting satellites).¹¹⁴²⁾

Spectral bands (2)	0.32 - 4.0 μm (Shortwave) Solar band	0.32 - 30 μm (Longwave) Total band
Radiometry:		
Absolute accuracy (each pixel)	$<2.4 \text{ Wm}^{-2} \text{ sr}^{-1}$ (i.e., $<1\%$)	$<0.4 \text{ Wm}^{-2} \text{ sr}^{-1}$ (i.e., $<0.5\%$)
Noise (each pixel, 15 min av.)	$<0.8 \text{ Wm}^{-2} \text{ sr}^{-1}$	$<0.15 \text{ Wm}^{-2} \text{ sr}^{-1}$
Dynamic range	0-380 $\text{Wm}^{-2} \text{ sr}^{-1}$	0-90 $\text{Wm}^{-2} \text{ sr}^{-1}$
FSR (Full Scale Radiance)	240 $\text{Wm}^{-2} \text{ sr}^{-1}$	77 $\text{Wm}^{-2} \text{ sr}^{-1}$
IFOV or pixel size (resolution)	44.6 km x 39.3 km (NS x EW) at nadir	
Coverage, cycle time	Full Earth disk, all channels in 5 minutes	
Co-registration	Spatial: 3 km with respect to SEVIRI at satellite sub-point Temporal: within 15 minutes of SEVIRI at each pixel	
Spectral and MTF	Performance specified by templates	
Sensor mass; power; data rate	25 kg; 35 W average; 50.6 kbit/s (L-band)	

Table 320: GERB instrument performance parameters

Instrument calibration:^{1143) 1144) 1145)} Extensive pre-calibrations were provided on the ground. In-flight calibration is provided by a blackbody source and a solar transmission diffuser. For zero reference space views are used. An image is obtained by measuring the signal difference between views of the on-board blackbody and the Earth-view at every rotation of the satellite using the thermoelectric detector. Possible degradation of the shortwave spectral response can be corrected by means of occasional comparisons with an on-board solar-illuminated integrating sphere.

S&R (Search and Rescue) payload within the S&RSAT/COSPAS system. Provision of transparent relay function for search and rescue operations (a 406 MHz transponder is carried by the MSG satellites).

DCS (Data Collection System) on-board collection system (see also F.7.1). The current data rate of 100 bit/s for each DCP (Data Collection Platform) in the ground segment will continue to be supported by MSG operations. MSG supports a significantly increased number of simultaneously relayed messaging channels.

Nr. of channels supported	Channel bandwidth	Frequency Range (MHz)	Usage
210	1.5 kHz	401.7025 - 402.0010	Neighboring satellites' regional DCP band (contingency relay only, no MSG processing)
33	3.0 kHz	402.0025 - 402.0985	International DCP band
224	1.5 kHz	402.1015 - 402.4360	MSG regional DCP band

Table 322: Some DCS performance characteristics of the MSG satellites

F.8.1 MSG Ground Segment (Stations)

The MSG ground segment is composed of:

- MCC (Mission Control Center) located at ESOC in Darmstadt, Germany
- PGS (Primary Ground Station) located in Usingen, Germany
- BRGS (Backup and Ranging Ground Station) located in Maspalomas, Gran Canary Island, Spain
- An application ground segment, which extracts meteorological and geophysical products from the calibrated and geolocated image data generated by MCC, and performs data management functions. The application ground segment is composed of MPEF (Meteorological Product Extraction Facility) and U-MARF (Unified Meteorological Archive and Retrieval Facility), both are located at EUMETSAT HQ in Darmstadt, and a distributed network of SAFs (Satellite Application Facilities). There are five SAFs using MSG data, they are:
 - SAF on Ocean and Sea Ice hosted by France
 - SAF on support to Nowcasting & VSRF hosted by Spain
 - SAF on Climate Monitoring hosted by Germany
 - SAF on Numerical Weather Prediction hosted by the United Kingdom

¹¹⁴⁶⁾R. Francis, V. Gärtner, "The Transition from MTP to MSG operations for the End-User Community," Proceedings of the EUMETSAT Meteorological Satellite Data User's Conference, Copenhagen, Denmark, Sept. 6-10, 1999, pp. 55-60

- SAF on Land Surface Analysis hosted by Portugal
- User Ground Segment. This comprises all MSG user stations. These are receive-only systems, operated by the users, which make use of either LRIT (Low Rate Information Transmission) or HRIT (High Rate Information Transmission) from the MSG satellites.

F.8.2 MSG Communication Services and Data Distribution

The MSG ¹¹⁴⁷⁾ communication payload consists of three subsystems, namely the antenna subsystem, the transponder subsystem (including the S&R transponder), and the TT&C subsystem.

Parameter	Raw Data	HRIT	LRIT	DCP	S&R
Uplink frequency (MHz)	N/A	2015.65	2101.5	402.06	406.05
Downlink frequency (MHz)	1686.83	1695.15	1691.0	1675.281	1544.5
Useful signal bandwidth (MHz)	5.4	1.96	0.66	0.75	0.06
Bit rate	7.5 Mbit/s	2.3 Mbit/s	290 kbit/s	100 bit/s	400 bit/s
Modulation	QPSK	QPSK	BPSK	PM	PM

Table 323: Summary of MSG communication-link characteristics

Antenna	Type	Function	Reference Coverage	Polarization
L-band	EDA (Electrically Despun Antenna)	Raw data transmission HRIT & LRIT transmission DCP transmission S&R transmission	Elevation >5° Zone B Europe Europe	Linear horizontal
S/L-band	Slotted waveguide TPA (Toroidal Pattern Antenna)	HRIT & LRIT reception Raw data transmission (backup)	Europe	Linear horizontal
UHF-band	Crossed dipoles circular array EDA	DCP reception S&R reception	Full Earth coverage	Circular right-hand
S-band TT&C	Printed quadrifilar TPA	Telecommand reception Telemetry transmission Tracking	Azimuth 360° Elevation 120° from north axis	Circular

Table 324: Specification of some MSG antenna parameters

HRIT/LRIT Dissemination Service: A primary objective of the service is to deliver image data for nowcasting within a few minutes of the end of acquisition of each image, therefore the timeliness of data delivery is an issue of utmost importance.

Two dissemination channels are defined within the MSG system to broadcast data to end-users via (Low Rate and High Rate Information Transmission (LRIT/HRIT) schemes. Both channels multiplex image data from the SEVIRI and foreign satellites together with meteorological products and DCP data (link), within the limits of the defined packetized data rate. The limited channel capacity requires the use of data compression in order to maximize the amount of information to be transmitted. ¹¹⁴⁸⁾

The HRIT data stream has a capacity of 1 Mbit/s which allows the reception of the disseminated level 1.5 data in quasi real-time and full spatial and temporal resolution. It is segmented, encrypted and JPEG-compressed for the purpose of transmission. The compression is lossless for all channels and lossy for the HRV (High Resolution Visible) channel.

¹¹⁴⁷⁾ K. D. McMullan, "The MSG Mission Communications Payload, including the Search and Rescue Transponder," Proceedings of the EUMETSAT Meteorological Satellite Data User's Conference, Copenhagen, Denmark, Sept. 6-10, 1999, pp. 106-113

¹¹⁴⁸⁾ D. Just, Y. Buhler, "Data Compression for METEOSAT Second Generation," Proceedings of the EUMETSAT Meteorological Satellite Data User's Conference, Copenhagen, Denmark, Sept. 6-10, 1999, pp. 131-138

The LRIT data stream capacity is 128 kbit/s. The images are all compressed in a lossy manner (by about a factor of 8) in full spatial resolution with the image data rounded to 8 bits representation. The current baseline is that only every second image is disseminated.

Parameter	LRIT	HRIT
Length of coded VCDU	1020 octets	
Center frequency	1691.0 MHz	1695.15 MHz
Bandwidth	0.660 MHz	1.960 MHz
Polarization	linear horizontal	
Packetized data rate	128 kbit/s	1 Mbit/s
Total coded data rate	293.9 kbit/s	2.3 Mbit/s
Modulation	PCM/NRZ/BPSK	PCM/NRZ/QPSK
Pulse shaping	Raised cosine filter Roll-off factor 1.0	Raised cosine filter Roll-off factor \leq to 0.7
Coding	Concatenated coding, Reed-Solomon (255,223)+convolutional (1/2 rate, k=7)	
Coding gain	9.4 dB	
Eb/No for required probability of frame loss	2.8 dB	
Achieved margins in case of nominal S/C and user station	Worst case 0 dB Nominal case 3 dB	

Table 325: Physical link parameters of the HRIT/LRIT service

Data Product	Description
Level 1.0	SEVIRI and GERB data as observed by the satellite (raw data)
Level 1.5	Geometrically corrected, navigated, Earth located and calibrated SEVIRI data
Level 2.0	Geophysical parameters extracted from level 1.5 SEVIRI data by MPEF and SAFs
Level 3.0	Further products derived from level 2.0 SEVIRI data by some SAFs

F.9 MTSAT (Multifunction Transport Satellite)

MTSAT is a Japanese geostationary multi-purpose satellite program, procured by JMA (Japan Meteorological Agency) and JCAB (Japan Civil Aviation Bureau), and funded by the Japanese Ministry of Land, Infrastructure and Transport, with the following overall objectives: 1149) 1150) 1151)

- 1) **Aeronautical mission.** To augment the air-traffic control services through enhanced communication and position information to Japan's (and the Asia-Pacific region) air traffic capability. The objective is to provide a satellite-based service, referred to as CNS/ATM (Communication, Navigation, Surveillance / Air Traffic Management) by utilizing the GNSS and augmentation services for satellite navigation. The CNS/ATM concept makes use of the ADS (Automatic Dependent Surveillance) function which automatically reports the current aircraft position measured by GNSS to ATC (Air Traffic Control Center).
- 2) **Meteorological mission.** MTSAT is a successor program to the GMS (Geostationary Meteorological Satellite) series - representing the next-generation weather-watch satellite series. The advanced meteorological observation capabilities include data collection services for a large user community.

1149) "Meteorological Observation with the Multi-functional Transport Satellite (MTSAT)," brochure of JMA

1150) MTSAT, brochure of JCAB

1151) A press kit "Launch and Tracking & Control of the Multifunctional Transport Satellite (MTSAT)" was provided by T. Moriヤマ of NASDA

Figure 198: Illustration of the MTSAT-1R spacecraft

The MTSAT series uses the services of GPS satellites in order to provide (supplementary) enhanced aeronautical communication, air navigation, GPS augmentation and differential correction services. Several ground stations complement the space segment (There are two JCAB stations and a separate JMA ground station. The JMA station includes satellite monitoring and control functions, communications functions and image processing and dissemination functions.

The overall MTSAT space segment is composed of two spacecraft, MTSAT-1R and MTSAT-2. MTSAT-1R is scheduled for launch in 2003, MTSAT-2 in 2004.

Background: MTSAT-1 was launched on Nov. 15, 1999 with an H-2 vehicle from the Tanegashima Space Center, Japan. However, a launch failure of the H-2 vehicle (No 8) occurred due to an abnormal burning of the first stage resulting in a destruction of the entire vehicle. As of March 2000, Space Systems/Loral (SS/L) of Palo Alto, CA, received a follow-up contract from Japan's Ministry of Transport¹¹⁵² to build a replacement satellite, MTSAT-1R. In addition, Japan's Ministry of Transport ordered MTSAT-2 from MELCO (Mitsubishi Electric Company) of Tokyo, Japan.

F.9.1 MTSAT-1R

The MTSAT-1R spacecraft bus, built by SS/L, uses a three-axis, stabilized FS 1300 platform. The overall S/C configuration consists of a box-like main structure, a single-wing solar array mounted on the south face of the structure, a solar sail in the north direction, and two large L-band antennas mounted on the east and west faces. The overall length of the S/C is 33.05 m. The attitude control subsystem uses a bias momentum method to stabilize the S/C. Attitude is measured by an Earth sensor. A boom-mounted solar sail in the opposite direction of the solar array, serves as attitude actuator by providing a counterbalance to the solar pressure. A trim tab is mounted on the outer edge of the solar array offering a control mechanism. The solar array, consisting of three panels, uses GaAs cells and continuously tracks the sun in order to maximize power output. Power of 3087 W (EOL) is provided. The NiCd battery has 22 cells for eclipse phase power. The bi-propellant propulsion subsystem uses 12

¹¹⁵²) Note: As of Jan. 1, 2001, the Japanese Ministry of Transport changed its name to: Japanese Ministry of Land, Infrastructure and Transport (MLIT).

thrusters (22 N each) for attitude control. In addition a thruster of 490 N provides control for initial orbit raising. The planned S/C mass at launch is 3251 kg with 1883 kg of propellant mass.¹¹⁵³⁾

Aeronautical Payload: Frequency bands and EIRP (Effective Isotropic Radiated Power)	L-band 6 spot beams: 43 dBW, (1.5/1.6 GHz) L-band 1 global beam: 40 dBW L-band GNSS: 31 dBW Ku-band 4 spot beams: 22-27 dBW, (12/14 GHz) Ka-band 3 spot beams: 22-27 dBW, (20/30 GHz)
Meteorological Payload: Frequency bands and EIRP	S-band global: 55 dBm UHF global: 44 dBm
TT&C (Telemetry Tracking & Command): Frequency bands and EIRP	USB (Unified S-band): 27.5 dBm (USB is used for orbit raising and contingency operations via the omni-directional telemetry and command antenna) S-band global: 35.5 dBm Ku-band spot: TBD, downlink 12 GHz, uplink 14 GHz
Spacecraft mass	About 1,400 kg of dry mass, about 3,300 kg of launch mass
Length of S/C, S/C power	33 m (total length), 3 kW
Spacecraft design life	10 years for aeronautical mission 5 years for meteorological mission

Table 327: Some parameters of the MTSAT-1R spacecraft

Orbit: Geostationary orbit between 130-140° eastern longitude.

F.9.1.1 Aeronautical Mission

The objective is to use a spaceborne augmentation system to improve the management of Japan's civil air traffic. Faced with the constant growth in air transport in South-East Asia and the special geographical factors in this region, the Japanese Ministry of Transport represented by the Japanese Civil Aviation Bureau (JCAB) has opted for a full-scale implementation of a satellite-based Communication, Navigation, Surveillance/Air Traffic Management (CNS/ATM) concept. This concept is based on the use of a geostationary satellite in order to overcome the limits imposed by traditional terrestrial navigation aids.

The MTSAT aeronautical mission provides three basic functions for its area of coverage: communications, navigation, and surveillance.

1) Communications

Voice/data interchange between aircraft and control tower. Air traffic communications use the L-band and the AMSS (Aeronautical Mobile Satellite Service) protocol which is specific to mobile telecommunications. Links between the Earth segment and satellite segment use the Ku-band and Ka-band.

MTSAT significantly improves the quality and capacity of voice and data communications to/from aircraft compared to conventional systems. In addition, it permits direct communication between any two aircraft in a region as well as to ground control centers.

2) Navigation by satellite - referred to as SBAS (Satellite-Based Augmentation System)

MTSAT serves as a geostationary wide-area augmentation system for all GPS signals in its large area of coverage by transmitting:

- GPS-like signals (ranging function)
- GPS health and integrity conditions obtained by ground monitoring stations (GMS)
- Ranging errors (differential correction function) - these are the conventional DGPS services

The GPS wide-area signal augmentation provided by MTSAT makes all regional navigation seamless, very reliable, available, more accurate, and continuous. This service is referred to

¹¹⁵³⁾Information provided by Ken Faller of Space Systems/Loral

as **MSAS** (MTSAT Satellite-based Augmentation System). The MSAS architecture is composed of the following ground-based elements: MRS (Monitor and Ranging Stations), GMS (Ground Monitor Stations), and MCS (Master Control Stations). In addition, there are two GES (Ground Earth Station) in the system, namely the Kobe Aeronautical Satellite Center and the Hitachi-Ota Aeronautical Center), providing operational support.

MSAS information on the real-time condition of the GPS constellation is transmitted to each aircraft via the integrity function of MSAS, while the differential correction function provides ranging error data to each aircraft. MSAS uses advanced technologies such as satellite orbit ranging, and ionospheric and tropospheric delay estimation assumption to ensure the reliability of these functions.

MTSAT-1R navigation payload SBAS: The navigation payload is built by Alcatel Space Industries of France under subcontract to SS/L.

3) **Air traffic surveillance**

MTSAT-1R is the key element of the Japanese GNSS (Global Navigation Surveillance System). The S/C features an ADS (Automatic Dependent Surveillance) relay service with the objective to transmit accurate positioning data for aircraft obtained by GPS (or GLO-NASS) to achieve higher-quality control. The data is transmitted at regular intervals to ground control centers via MSAS. ADS enables positioning information of aircraft to be displayed on control consoles, permitting ground control personnel to verify the aircraft position anywhere along its flight path. Such data include aircraft identification, four-dimensional position, and supplementary data to the air traffic control facility. The links between the ground and the satellite use the Ku-band and Ka-band; links between the aircraft and the satellite use the L-band.

The overall design of the “aeronautical mission” with its three basic functions provides redundancies. However, these redundancies are deliberately designed into the space segment as well as into the ground segment to provide an operational system that satisfies every aspect of the ICAO (International Civil Aviation Organization) requirements in terms of reliability, availability, and accuracy.

F.9.1.2 Meteorological Mission

The Meteorological Mission of MTSAT succeeds the observational function of the current GMS (Geostationary Meteorological Satellite) series. GMS-5 (with VISSR), the latest in the series, was launched March 18, 1995 has exceeded its design life already in 2000. It may run out of fuel in less than a year and will very probably not be able to continue its service until the launch of MTSAT-1R.

JAMI (Japanese Advanced Meteorological Imager). The overall objective of the meteorological mission is to provide an improved functionality and continuous service of meteorological observables (timely, high-quality, full-disk multispectral imagery for operational weather needs) for Japan and for the countries in the area of MTSAT coverage (East Asia, and Australia). The JAMI instrument is being developed by Raytheon SBRS under contract to Space Systems/Loral. The JAMI performance enhancements include: ¹¹⁵⁴⁾

- Coverage of the 0.55 μm to 12.5 μm spectral region using four infrared (IR) bands and one solar reflective band (VNIR)
- Large-format arrays enable faster full disk coverage rate with slower scan rate. The benefits of slower scan rate include longer dwell times, higher detector resolution, and a longer scanner life
- Full disk coverage with calibration scans in 24 minutes
- Onboard calibration system for all bands

¹¹⁵⁴⁾Information provided by Dominick M. DellaValle of SBRS, Goleta, CA

Figure 199: Illustration of the JAMI instrument

JAMI's design is based on advanced imager technologies that have already been space-qualified and flown in Raytheon-built hardware:

- Uses a two-axis gimbaled scan mirror with qualified optical and mechanical elements which have been derived from many Raytheon programs with demanding requirements for spaceflight operation including: MODIS, GOES/GMS (Imager/VISSR), Landsat (TM, ETM+), and TRMM/VIRS
- Photovoltaic HgCdTe focal plane arrays that incorporate qualified designs with direct flight experience in TRMM/ VIRS, Multispectral Thermal Imager (MTI), and MODIS. Active cooling of the focal plane detector arrays is provided.
- Processing hardware and software was derived from MODIS and incorporates processing algorithms which have already been proven on Landsat, Hubble Space Telescope, and many other spaceflight programs
- Equipped with an onboard blackbody calibrator that has already been qualified and spaceflight proven on TRMM/ VIRS and MODIS with four years of on-orbit operation

Spectral bands	VNIR: 0.55 - 0.90 μm (cloud cover) MWIR1: 3.5 - 4.0 μm (nighttime cloud cover) MWIR2: 6.5 - 7.0 μm (water vapor) TIR1: 10.3 - 11.3 μm (SST and water vapor) TIR2: 11.5 - 12.5 μm (SST and water vapor)
Scanner	Two-axis scan system
Detectors	Monolithic silicon (visible) Photovoltaic HgCdTe (all infrared regions)
Ground resolution	0.5 km in VNIR (Visible Near Infrared), 2 km in infrared regions
Data rate	2.8 Mbit/s
Instrument mass, power	163.7 kg (including 16.7 kg of interconnecting harness), 169 W

Table 328: JAMI instrument specifications

Communication of meteorological data: Imagery obtained is transmitted to a ground station, referred to as CDAS (Command and Data Acquisition Station) where some information, such as calibration tables, are added. In addition, HiRID, HRIT (High Rate Information Transmission), and LRIT (Low Rate Information Transmission) products, quite similar to the EUMETSAT products, are generated and distributed. The data are transmitted in S-band (downlink frequency: 2026-2035 MHz, uplink frequency: 1677-1695 MHz). An S-

band slot array antenna is used for downlink transmissions while an S-band horn antenna is employed for uplink reception. The S-band downlink carries the raw imager data, the image products that are being retransmitted after generation by CDAS, the data received from the CDP (Data Collection Platforms), and spacecraft telemetry data.

MTSAT broadcasts processed data and imagery to users throughout the Asia-Pacific region, including airports, weather forecasting agencies and ships at sea.

F9.1.3 DCS (Data Collection System)

The MTSAT series supports the collection of environmental data in its ground segment with a corresponding on-board DCS (Data Collection System), in the same manner as provided by the GMS series. The ground segment platforms are referred to as DCP (Data Collection Platform) which are automated remote weather stations.

The DCS is part of IDCS (International DCS) coordinated with other meteorological satellite operators. The DCP data are collected through the MTSAT spacecraft and rectified to the WMO codes at MSC and distributed to users through GTS.

- IDCP (International DCP). The IDCP, a self-timed system, supports mobile DCPs at various locations (on ships, aircraft and balloons) which may move from the coverage of one geostationary meteorological satellite to another.
- RDCP (Regional DCP). The MTSAT S/C supports regional DCPs located on moored buoys, on remote islands, on mountains, etc. - and mobile DCPs in its own coverage area. MTSAT provides 100 channels for the RDCP function. RDCPs are interrogation-type system.

There are two types of DCPs: 1) Self-timed DCPs which transmit observation data automatically on scheduled times. 2) The interrogation DCPs transmit observation data by an interrogation command from the MSC.

The interrogate command is uplinked to the satellite via CDAS in S-band, and then repeated by the satellite in UHF. The UHF signal is broadcast to DCPs in a global pattern using a dipole antenna. The same antenna receives the uplinked UHF signal from the DCPs. The DCP signal is retransmitted to CDAS via the same S-band downlink that carries the imager data, from where it is sent by terrestrial microwave link to MSC.

In addition, the DCS is used to transmit Tsunami Earthquake emergency information and seismic intensity data.

Frequency bands allocated	402.0 - 402.1 MHz (IDCP) 402.1 - 402.4 MHz (RDCP)
Data rate	100 bit/s
Power	43 - 46 dBm
Data modulation	PCM/PSK ($\pm 60^\circ$)

Table 329: Specification of DCPs

Part G Meteorology - LEO (Low Earth Orbit) Missions

G.1 DMSP (Defense Meteorological Satellite Program)

Background:^{1155), 1156), 1157)} DMSP is the meteorological long-term program of the US Department of Defense (DoD) which originated in the mid-1960s with the objective to collect and disseminate worldwide cloud cover data on a daily basis. DMSP was originally known as DSAP (Defense System Applications Program) and as DAPP (Defense Acquisition and Processing Program).^{1158) 1159)}

From mid-1965 to early 1970, the series of DMSP satellites was known as the Block 4 series. S/C of this series were of the shape of a spin-stabilized octagon with a mass of about 150 kg. The payload consisted of two vidicon cameras for collecting high-resolution TV pictures (resolution: 2.4 km at image center to about 16 km at the edge of a picture). Some later S/C also had a low-resolution VIS (0.4 - 4 μm) and infrared (8.0 - 12 μm) sensor. From these, better sensors emerged with first attempts to combine reflected and emitted energy for the cloud analysis problem.

Beginning in early 1970, a new generation of satellites was inaugurated, the Block 5 series. These were three-axis stabilized spacecraft that initially employed a scanning radiometer as imaging sensor (two channels). The VIS channels had a spectral band from 0.4 - 1.1 μm and the lower resolution channel (approx. 3.6 km at nadir) also had a low-light level amplification system. These two design factors considerably enhanced the utility of the system.

Table 330: Chronological overview of DMSP series satellites

The overall DMSP satellite program is composed of three elements: the space segment, the C3S (Command, Control and Communications Segment), and the user segment. DMSP is

managed by SMC (Space & Missile Systems Center) at Los Angeles Air Force Base, El Segundo, CA.

DMSP employs the concept of total system integration from spacecraft operation through data reduction and interpretation. The space segment is controlled by the Air Force Space Command (AFSPC) through command sites centered in Colorado Springs, CO. By the end of 1992, 22 Air Force terminals, all equipped to receive Block 5 image data, were deployed worldwide.

Some DMSP satellite characteristics: The satellites are built by LMMS (Lockheed Martin Missile & Space) company. They are three-axis stabilized. Pointing of the satellites is maintained by three orthogonal reaction wheel assemblies. A precision mounting platform provides a pointing accuracy of 0.01° . The S/C structure has a diameter of about 1.2 m and a length of about 3.7 m. The S/C mass of Block 5D-2 is about 820 kg in orbit, including the sensor payload of 250 kg. The S/C mass of Block 5D-3 is about 1210 kg, including 310 kg of payload.

DMSP satellites are launched from Vandenberg AFB. Real-time commands and stored command files are relayed via commercial communication satellites to Command Readout Stations (CRSs) which then relay these commands to the DMSP satellites. Data may also be relayed via tracking stations [located in Hawaii, New Hampshire and Thule (Greenland)]. The meteorological data are processed by centralized users at the Air Force Global Weather Center, Fleet Numerical Meteorology and Oceanography Center (FNMOC), and deployed tactical assets.

The Block 5D-1 satellites were flown from 1976 to 1980. The first Block 5D-2 satellite was launched in 1982. Block 5D-2 satellites are the designated satellites until the late-1990s when the first of the Block 5D-3 satellite series was launched (F-15 launch on Dec. 12, 1999). The block 5D-3 satellites are projected to carry an upgraded complement of sensors to the 5D-2 configurations. The required pointing accuracy of 0.01° is achieved by star sensing and three orthogonal gyroscopes measuring short-term variations in the S/C attitude.

NPOESS (National Polar-orbiting Operational Environmental Satellite System): The DoD DMSP program and the NOAA-POES program convergence takes place in two phases.

- First phase: Starting in May 1998, all DMSP satellite operational command and control functions of AFSPC (Air Force Space Command) were transferred to a tri-agency Integrated Program Office (IPO) established within NOAA. NOAA was given the sole responsibility of operating both satellites programs, POES and DMSP (from NESDIS, Suitland, MD).
- During the second phase, the IPO will launch and operate the new NPOESS satellites that will satisfy both the DoD and Department of Commerce (DOC/NOAA) requirements.

Orbital Parameters of DMSP: ¹¹⁶⁰⁾

Sun-synchronous orbits, altitude = 811 - 853 km (833 km nominal), inclination = 98.9° , period = 101.6 minutes, there are normally two satellites in operation at any one time (one in a morning and one in a late morning equatorial crossing time).

G.1.1 Description of Block 5D-2 and 5D-3 Sensors ¹¹⁶¹⁾

OLS = Operational Linescan System (primary sensor on each satellite, built by Northrop Grumman, Westinghouse Corporation). Objective: day and night cloud cover imagery. The OLS instrument consists of two telescopes and a photomultiplier tube (PMT). The detectors sweep back and forth in a “whiskbroom” fashion (a “flying spot design” is employed - a

¹¹⁶⁰⁾ R. Massom, “Satellite Remote Sensing of Polar Regions,” Applications, Limitations and Data Availability, Belhaven Press, London

subset of whiskbroom scanners, O.3.2). The continuous analog signal is sampled at a constant rate so the Earth-located centers of each pixel are roughly equidistant, i.e., 0.5 km apart, 7,325 pixels are digitized in the cross-track direction.

Swath width = 3000 km from a nominal 833 km orbit altitude. OLS provides global coverage in both visible (L data) and IR (T data) modes. Fine resolution data with a nominal linear resolution of 0.56 km are collected as needed day and night by the IR detector, and as needed during daytime, by a segmented silicon diode detector (LF data). A high resolution photometer tube is used for nighttime visible imagery (used for fire detection).

- Band 1: VIS wavelength = 0.4 - 1.1 μm (0.58 - 0.91 μm FWHM)
- Band 2: TIR wavelength = 10.0 - 13.4 μm (8 - 13 μm , old prior to 1979), resolution = 0.56 km for fine resolution data (stored data is smoothed to 2.7 km resolution), continuous data collection, polar stereographic image products have ground resolution of 5.4 km. Swath = 3000 km. The IR system counts are automatically calibrated to vary between 190 and 310 K of effective blackbody or brightness temperatures.
- The PMT is sensitive to radiation from 0.47 - 0.95 μm (0.51 - 0.86 μm FWHM).

The scanning telescope of OLS is a f/5.8 Cassegrain design with a 20.3 cm clear aperture and an effective collecting area of about 185 cm². The telescope has an effective focal length of 122 cm. Two telescope calibration mirrors intercept the normal FOV at the edge of scan with hot and cold loads of known temperatures. The light from the telescope is split into two channels by a beam splitter, and sent via relay optics to the visible and infrared focal planes, as well as to the photo multiplier tube that provides useful nighttime visible imagery (approx. 0.5 - 0.85 μm half-power response point bandpass) down to a lunar illumination level of about a quartermoon. The telescope images over a scan angle of $\pm 56.25^\circ$ which corresponds to a swath width on the ground of 2960 km (some overlap at the equator from orbit to orbit). Glare suppression is built into the system by a variety of sun shades, field stops, low scatter surfaces, and aperture stops. This minimizes the amount of data lost in the orbit due to sunlight saturating the visible detectors. OLS provides the ability to command gain adjustments to overcome slow degradation of the thermal transmission of the system. The system is designed to produce near-constant high resolution imagery for most DOD applications because the location of clouds, fog, ice floes, etc., is much more important than accurate radiometry. The near constant resolution across the swath is accomplished through a combination of the natural rotation of the detector footprint and detector segment switching. On-board data smoothing (averaging) can be done to reduce the data rate by a factor of 25, smoothing electronically the pixels in the cross-track direction and digitally averaging in the along-track direction. However, smoothing is only done in cases to cope with current recorder limitations. When this mode is used, the original high-resolution imagery cannot be recovered.

OLS utilizes three types of detectors:

- A silicon photoconductive diode is used for daytime VIS imagery. Three segments in the detector provide for a nearly constant resolution across the swath. Two smaller segments are used for scan angles $> 41^\circ \pm \pm^\circ$, all three segments are summed in the middle portion of the scan about nadir.
- A two-segment HgCdTe photoconductive detector is used for the TIR channel. The detector is cooled to 108 K by a cone cooler. The two detector segments are used on the far right and left parts of the scan and are summed over the middle portion of the scan (within $\pm 41^\circ$).
- A single PMT detector is used for nighttime visible data [a GaAs opaque photocathode and multiple dynode PMT).

Glackin, "Defense Meteorological Satellite Program capabilities through the end of this century and requirements for the converged DMSP NOAA Systems," European Symposium on Satellite Remote Sensing II, Paris, France, Sept. 25-28, 1995, published in SPIE Vol. 2578

SSM/I = Special Sensor Microwave Imager. ¹¹⁶²⁾

The SSM/I is a seven-channel, four-frequency, linearly-polarized, passive microwave radiometer which measures atmospheric, ocean, and terrain microwave brightness temperatures (similar to NIMBUS-7 SMMR) which are converted into environmental parameters such as: sea surface winds, rain rates, cloud water, precipitation, soil moisture, ice edge, and ice age. SMM/I data is used to obtain synoptic maps of critical atmospheric, oceanographic and selected land parameters on a global scale. The archive data consists of antenna temperatures recorded across a 1400 km swath (conical scan), satellite ephemeris, Earth surface positions for each pixel and instrument calibration. The electromagnetic radiation is polarized by the ambient electric field, scattered by the atmosphere and the Earth's surface, and scattered and absorbed by atmospheric water vapor, oxygen, liquid water and ice. ¹¹⁶³⁾

Channel Nr.	Center Frequency (GHz)	Wavelength	Footprint (km) along x cross	Polarization	NEDT (K)	Environmental Response

Table 331: Specification of some SSM/I parameters

Figure 201: The scan geometry of the DMSP SSM/I sensor¹¹⁶⁴⁾

The SSM/I instrument was built by Hughes Space and Communications Co. It consists of an offset parabolic reflector (61 cm x 66 cm) that is fed by a seven-port horn antenna. The re-

¹¹⁶²⁾J. W. Sherman, "The Near-Term Suite of Satellite Sensors to Support Developing Countries' Climate and Global Change Photograms," Proceedings of the Twenty-Fourth International Symposium on Remote Sensing of the Environment, ERIM Ann Arbor MI., Volume I, 27-31 May 1991, pp. 27-28

¹¹⁶³⁾J. P. Hollinger, J. L. Pierce, G. A. Poe, "SSM/I Instrument Evaluation," IEEE Transactions on Geoscience and Remote Sensing, Vol. 28, No. 5, pp. 781-790, 1990

¹¹⁶⁴⁾The rotating antenna sweeps the surface in two alternating modes - one in which all four frequencies are recorded, and another in which only 85 GHz data are recorded. The use of a single antenna results in different ground resolutions for each frequency.

flector and feed are mounted on a drum which contains the radiometers, digital data subsystem, mechanical scanning subsystem, and power subsystem. The drum assembly rotates about the axis of the drum. A small mirror and a hot reference absorber are mounted on the assembly.

The SSM/I sensor executes a 45° conical scan of the Earth's surface from nadir. This gives a nominal incidence (zenith) angle of 53.1° to the Earth's surface from the nominal orbit. Only part of the possible 360° scan in azimuth is used to collect data. The active azimuth scan angle is 102.4° is ahead of the S/C for an afternoon ascending orbit and behind the S/C for a morning ascending orbit. The sensor electronics perform an integration and hold sequence on each channel, timed so that the odd 85 GHz reading is centered with the 37 GHz reading. The sensor conically scans the Earth and atmosphere at a scan rate of 31.9 scans/min (or 1.88 s/scan). The sampling scheme results in 128 samples (called scene stations) per scan for the 85 GHz channels, and 64 scene stations per two scans for the other channels. The footprint sizes are listed in Table 331. The footprints are sampled every 25 km for the 19, 22, and 37 GHz channels, and every 12.5 km for the 85 GHz channel.

Each scan consists of a cold reading, a warm load reading, and the scene stations. The cold reading utilizes a view to deep space (3 K black body), and the warm load temperature (variable over an orbit) is read by three precision thermistors. Each sensor has a different set of coefficients that enters into the retrieval algorithms.

SSM/T-1 (Special Sensor Microwave Temperature Sounder), in operation since 1979, first flown on F-4, built by the Aerojet Corporation. The SSM/T-1 is a seven channel passive microwave sounder consisting of a rotating 7 step antenna reflector (rotating once every 32 seconds), a Dicke-switched seven channel radiometer, a digitizer, and signal processor.. It measures the Earth's surface and atmospheric emission in the 50 to 60 GHz oxygen band. The SSM/T-1 is a cross-track nadir scanning radiometer having a FOV of 14.4°. At nominal altitude (833 km) the subtrack spatial resolution is an approximate circle of 174 km diameter at nadir elongating to an ellipse of 305 x 313 km at the extreme viewing angles toward the limb. There are seven total cross-track scan positions separated by 12° with a maximum cross-track scan angle of 36°. Swath width = 1500 km (data coverage gap between successive orbits). The SSM/T-1 is a step and stare type sensor which dwells on each of the seven scene stations, then observes a cold (3 K) reference, followed by a warm (300 K) reference. The daily data volume is 1.5 MByte per satellite.

Channel Nr.	Frequency (GHz)	Peaking altitude (km)	NEDT (K)

Table 332: Parameters of the SSM/T-1 instrument

SSM/T-2 (Special Sensor Microwave Water Vapor Profiler-2)

The SSM/T-2 is a modification of SSM/T-1 for water vapor sounding. It was built by the Aerojet Corporation. The first flight of the instrument took place on F-11 in 1991. The instrument is a cross-track scanning, five channel, passive total power microwave radiometer system which consists of a single, self-contained module with a step-scan motion in the cross-track direction of $\pm 40.5^\circ$. The SSM/T-2 scan mechanism is synchronized with the SSM/T-1 so that the beam cell patterns of the two sensors coincide. The observation rate is 7.5 scans/minute. There are 28 observations (beam positions) per scan for each of the five channels, with each observation having a spatial resolution of about 48 km. All five channels have coincident centers. The swath width is about 1500 km.

The instrument employs a single offset parabolic reflector with a 6.6 cm diameter projected aperture. The reflector is shrouded to eliminate the possibility of rays from the sun striking either of the calibration paths and causing unwanted thermal gradients. The feedhorn is a corrugated pyramidal horn with a flare designed to minimize phase center separation over the bandwidth (91 to 183.3 GHz), while providing a spherical wave illumination of the reflector. To achieve the cross-track scanning, the reflector alone rotates. The rotation of the reflector produces a rotation of the plane of polarization of the upwelling scene which is permitted provided that the polarization remains identical for the two window channels and 183.3 ± 7 GHz. These channels must have the same polarization characteristics because they measure contributions from both the atmosphere and the surface. During each scan period, and for all five channels at 28 discrete earth viewing positions, four discrete calibration measurements of a hot-load target (about 300 K), and cosmic background radiation (about 3 K) are monitored.

Channel Nr.	Frequency (GHz)	Peaking altitude (km)	NEDT (K)	Beam width
1	183.310 ± 3.000	8	0.6	3.3°
2	183.310 ± 1.000	6	0.8	
3	183.310 ± 7.000	10	0.6	
4	91.655 ± 1.250	0	0.6 window channel	6°
5	150.0 ± 1.250	2	0.6	3.7°

Table 333: Parameters of the SSM/T2 instrument

The sensor has footprints at nadir (resolutions) ranging from 48 km (for highest frequency) to 120 km. The noise levels (NEDT) for the five channels are 0.6 K to 0.8 K. The peaking measurement heights from 0 to 10 km vary because they are dependent on the total atmospheric water content. This variation, together with the changing viewing geometry, complicates the retrieval of water vapor profiles. Like the SSM/T-1, the SSM/T-2 is a step stare system, but with 28 steps per scan versus 7. The scan period has been decreased to 8 seconds per scan from 32 seconds. Each scan consists of a warm load reading, a cold load reading, and 28 scene stations. - The data is used to determine water vapor mass in seven layers, and specific and relative humidity at six levels. When combined with the SSM/T-1 data, meteorological conditions can be analyzed, such as types of cloud formations, icing potential, and the location of weather systems, based on differences in air mass temperature and moisture.

SSMIS (Special Sensor Microwave Imager Sounder), built by the Aerojet Corporation, a subsidiary of GenCorp of Sacramento, CA. SSMIS = SSM/I + SSM/T-1 + SSM/T-2 (Block 5D-3 sensor). In the Block 5D-3 satellite era, the Block 5D-2 passive microwave sensor suite is combined into a single new sensor package - the SSMIS (see Ref. 1157). SSMIS measures microwave energy from the Earth's surface and atmosphere at 24 discrete frequencies from 19 to 183 GHz. The sensor generates a conical scan pattern at 45° from nadir. This scan pattern, combined with the 144° clear field of regard, results in a constant angle of incidence on the Earth of 53.1° and a swath width of 1,700 km. Improvements include 24 channels of data which are all coincident, increased resolution range, increased FOV, and enhanced ground processing software. The sensor adds one additional channel over the SSM/T to improve the measurement of the tropopause temperature and height. The frequencies chosen (channels 1-7 and 24) provide near uniform coverage in height to about 32 km. With the addition of five more channels (channels 19-23), the temperature retrievals are extended up to about 80 km. - The instrument has a mass of 96 kg, power = 135 W, the data rate is 14.2 kbit/s. The antenna has a diameter of 61 cm, the beam width is in the range: 0.4°-1.9°.

The scene spacing for the sounder channels has been improved from 120 km to 480 km of the earlier instruments to 50 km for the lower atmosphere and to 75 km altitude for the upper atmosphere measurements. SSMIS uses almost the same channels as SSM/I for the environmental parameter extraction. The frequency of 85 GHz was changed to 91 GHz to save

an extra channel in the system. SSMIS augments the rain retrieval and cloud amounts with channel 8 at 150 GHz.

Channel Nr.	Center Frequency (GHz)	Footprint (km) along x cross	Polarization	NEDT (K)
1	50.3	25.8 x 17.5	Horizontal	0.4
2	52.8	25.8 x 17.5	Horizontal	0.4

Table 334: SSMIS frequency and resolution characteristics

Parameter	Accuracy goals (rms)
Lower atmosphere	4 K at 1000 mb (millibar)
Temperature profiles	3 K at 850 mb
Determine 15 temperatures from 1000–10 millibars; determine 14 thickness between levels)	1 K at 700-10 mb
Upper atmosphere	5 K at 10 - 0.2 mb
Temperature profiles	7 K at 0.2 - 0.3 mb
Tropopause temperature, pressure	3 K, 20 mb
Humidity profiles (specific and relative humidity at six levels and total water vapor mass and water between specific pressure levels	Specific humidity 1.5 grams/kg or ± 20 percent over clear sky or ocean
Ocean wind speed	<2 m/s
Rain rate, rain flag	5 mm/h, flag
Cloud water over ocean	0.10 kg m ⁻²
Soil moisture, ice concentration	$\pm 10\%$, $\pm 10\%$
Ice edge and snow edge	Flag
Water vapor over ocean	Tropics ± 3 kg m ⁻² , mid-latitude ± 2 kg m ⁻² , polar ± 1 kg m ⁻²
Snow water content, land surface temperature	± 3 cm, ± 2.5 K

Table 335: Some parameter accuracy requirements of SSMIS

SSMIS employs a two point (hot and cold load) calibration taken once during each scan of 1.88 seconds duration in all 24 channels. The scan width has been increased from 104° to 144° (FOV) by positioning the sensor farther out board on the S/C. The six separate feed horns for each frequency require the flight software in the sensor to align the data prior to

transmission to the ground (via OLS). SSMIS operates asynchronously with OLS, the data to OLS is transmitted in two blocks/s.

The sounding data is only partially smoothed on-board. The 183 GHz channels are down-linked at 12.5 resolution, they have to be averaged to the 50 km spacing for the sounding retrievals. The 12.5 km data is used for the display of water and vapor data.

SSMIS features redundant Gunn diode oscillators and phase lock loop oscillators. The sensor conically scans the Earth and atmosphere at a scan rate of 31.9 scans/min (or 1.88 s/scan).

G.1.2 Space Environment Sensors

The sensors of the space environmental suite provides data on the geophysical environment of the upper atmosphere and ionosphere.

SSI/ES-2 = Special Sensor Ionospheric Plasma Drift/Scintillation Monitor (PL sensor built by the University of Texas). Measurement of the ambient electron density and temperatures, the ambient ion density, and the average ion temperature and molecular weight at the DMSP orbital altitude. - The instrument consists of an electron sensor (Langmuir probe) and an ion sensor mounted on a 2.5 meter boom. The ion sensor is a planar aperture, planar collector sensor oriented to face the spacecraft velocity vector at all times. In addition to the Langmuir probe and planar collector which make up the SSI/E, the SSI/ES has a plasma drift meter and a scintillation meter. The data volume of SSI/ES-2 is 12 MByte/satellite-day.

SSJ/4 = Precipitation Electron/Proton Spectrometer (PL sensor built by Ampek Inc.). The SSJ/4 is a next generation sensor of the SSJ/3. SSJ/4 has been flown starting with F6 (launch in Dec. 1982) until F15 (launch Dec. 12, 1999). Objective: Measurement of transfer energy, mass, and momentum of charged particles through the magnetosphere-ionosphere in the Earth's magnetic field. The instrument looks toward the satellite zenith. - The SSJ/4 sensor consists of four electrostatic analyzers that record the flux of precipitating ions or electrons at 20 fixed energy channels between 30 eV and 30 keV. The curved plate detectors allow precipitating electrons and ions to enter through an aperture of about 20 x 10 (FWHM). Electrons and ions of the selected energy are deflected toward the target by an imposed electric field applied across the two plates. The two low energy detectors consist of 10 channels centered at 34, 49, 71, 101, 150, 218, 320, 460, 670, and 960 eV. The high energy detector measures particles in 10 channels centered at 1.0, 1.4, 2.1, 3.0, 4.4, 6.5, 9.5, 14.0, 20.5 and 29.5 KeV. Each detector integrates each channel for 0.09 s from high energy channel to low. A complete cycle is sampled each second. The primary sources of the particles precipitating into the upper atmosphere are the northern and southern auroral zones. The daily data volume is approximately 1 Mbyte per satellite. The sensor data also supports missions which require knowledge of the polar and high-latitude ionosphere, such as communications, surveillance, and detection systems that propagate energy off or through the ionosphere.

SSJ/5 = Precipitation Electron/Proton Spectrometer (first flight on F16)
Upgrade of SSJ/4. Detects and analyzes electrons and ions that precipitate in the ionosphere to produce an aurora display. The sensor data also supports missions which require knowledge of the polar and high-latitude ionosphere, such as communications, surveillance, and detection systems that propagate energy off or through the ionosphere.

SSM = Triaxial Fluxgate Magnetometer (PL sensor built by NASA/GSFC).
The SSM measures geomagnetic fluctuations associated with solar geophysical phenomena (i.e., ionospheric currents flowing at high latitudes). In combination with the SSI/ES (or SSI/ES-2) and the SSJ/4, the SSM provides heating and electron density profiles in the high-latitude ionosphere. SSM takes and reports 12 readings/s for the Y and Z axes. Only 10 readings of the 12 readings per second are reported for the X axis due to telemetry limita-

tions. The SSM's axes are aligned with the spacecraft's axes where X is downward and aligned to local vertical within 0.01 degree, Y is parallel to the velocity vector for spacecraft with ascending node in the afternoon/evening sector, and Z is away from the solar panel and anti-parallel to the orbit normal vector.) The measurement range is ± 65535 nT for each axis, with a one-bit resolution of 2 nT. The first SSM flight started with F12 (launch 29.8, 1994).¹¹⁶⁵⁾

Note: The magnetic field has three sources: 1) the magnetic field from the solid Earth, 2) the magnetic field from electrical currents flowing in the ionosphere and magnetosphere, and 3) the magnetic field from the spacecraft. Measurement of source 2 is the principal objective of the SSM, the measurement of source 1 is a secondary objective, and measurement of source 3 is a nuisance which is eliminated from the data as much as possible during data processing.

SSB/X-2 = Gamma Ray Particle Detector (built by Sandia National Labs).

The SSB/X-2 is an array-based system which detects the location, intensity, and spectrum of X-rays emitted from the Earth's atmosphere. The array consists of four identical and independent directional detectors.

SSZ = Laser Threat Detector (built by Aerospace)

SSZ is a static Earth-viewing sensor, monitoring electromagnetic radiation.

SSI/ES-3 = Enhanced Ionospheric Plasma Drift/Scintillation Monitor

An upgrade of the SSI/ES-2 sensor. The data supports a variety of HF and UHF communications missions, and is used for atmospheric drag calculations for low Earth orbit satellites.

SSM-Boom = Triaxial Flux Gate Magnetometer

Upgrade to SSM. Measures geomagnetic fluctuations associated with solar geophysical phenomena (i.e. ionospheric currents flowing at high latitudes). Combinations of data from SSI/ES (or SSI/ES-2), SSJ/4, and SSM will provide more complete specification of heating and dynamics of the high-latitude ionosphere and neutral atmosphere.

SSULI = Special Sensor Ultraviolet Limb Imager (built by JHU/APL and sponsored by NRL). The optical instrument is a spectrograph with the objective to measure extreme and far ultraviolet radiation (vertical profiles) from the Earth's limb. The primary observations, ranging from 80 - 170 nm, with 1.5 nm resolution, are of radiation from atomic oxygen and nitrogen, and molecular nitrogen, resulting in direct measurements of the electron density vertical profile as well as ion and neutral densities. The vertical profiles in the upper atmosphere and ionosphere are obtained by viewing the Earth's limb at a tangent altitude of approximately 50 km to 750 km. The LORAAS (Low Resolution Airglow/Aurora Spectrograph) instrument on ARGOS (Launch Feb. 23, 1999) is a SSULI prototype instrument. LORAAS data of ARGOS is being used to validate SSULI algorithms that convert raw measurements into useful environmental parameters that characterize the upper atmosphere. The first SSULI instrument will be flown on the F-16 S/C in Jan. 2001.

SSULI is mounted on the +x panel of the spacecraft. The sensor consists of a folded telescope, a scan mirror assembly with a mounting interface to the UV Wadsworth spectrograph, collimator, grating (focuses the radiation onto the detector and disperses the light into a spectrum from 80 - 170 nm, detector (imaging microplate detector with a wedge and strip anode that characterizes photon events). A scanning mirror sweeps the FOV across the Earth limb to obtain vertical profiles. The scan is performed in the orbital plane, looking either forward or aft. The primary scan mode extends from 10° to 27° below the satellite horizon (with the capability to go from 10° to 40° in an alternate scan mode), forming vertical images of the Earth's atmosphere from 750 km to 50 km every 90 seconds. The scan rate is faster at high tangent altitudes and slows down at lower altitudes where there is more

¹¹⁶⁵⁾<http://www-vsbp.plh.af.mil/projects/dmsp/ssm12ins.html>

structure in the airglow. The intensity at these wavelengths is so low, both sensors count individual photons on the focal plane using wedge and strip microchannel plate detector technology. ¹¹⁶⁶⁾ ¹¹⁶⁷⁾

Figure 202: The SSULI optical path

Radiation into SSULI is reflected off the scan mirror to a grid collimator. The radiation is dispersed off a grating into its spectral elements, focused onto a detector, and converted into an electrical signal. The SSULI electronics use this charge to determine the wavelength and amplitude of the photons striking the detector.

Spectral range	80 to 170 nm with a resolution of 1.5 nm or less
IFOV (Instantaneous Field of View)	0.1° vertical and 2.4° horizontal
FOR (Field of Regard)	30° x 2.4°
Scanning range	10° - 40° below of spacecraft horizon (y-direction)
Scanning rate	up to 6° per second
Sensitivity	0.5 counts per second per Rayleigh at 83.4 nm

Table 336: SSULI parameter specification

Parameter	Species	Wavelength
Dayside ionosphere	O ⁺	834 Å
Dayside ionosphere	O	911 Å, 1304 Å, 1356 Å
Dayside neutral density	O	989 Å, 1304 Å, 1356 Å, 1641 Å
Dayside neutral density	N ₂	1085 Å (N ⁺), N ₂ LBH bands
Dayside neutral density	O ₂	Schumann-Runge, Absorption of N ₂ LBH
Nightside neutral density	O	1356 Å
Temperatures		Emission scale heights

Table 338: SSUSI performance parameters of imaging spectrograph (SIS)

SSUSI = Special Sensor Ultraviolet Spectrographic Imager (built by JHU/APL)¹¹⁶⁸⁾¹¹⁶⁹⁾
SSUSI is a nadir-pointing instrument that measures UV radiation from the Earth's atmosphere and ionosphere, it also measures visible radiation (airglow and terrestrial albedo). The instrument consists of three subassemblies:

- SIS (Scanning Imaging Spectrometer)
- NPS (Nadir-looking Photometer System)
- Support module

SIS in turn consists of a cross-track scanning mirror at the input to the telescope (folded design) and spectrograph optics. There are redundant 2-D photon-counting detectors at the focal plane (detector size: 16 pixels in along-track and 160 pixels in the cross-track direction). The detectors employ a position sensitive anode to determine the photon event location. The scan mirror sweeps the 16 pixel footprint from horizon to horizon, producing one frame in 22 seconds. The imaging mode performs simultaneous measurements in five wavelength bands from 115 - 180 nm. The imaging mode scan cycle consists of a limb-viewing section followed by an Earth viewing (nadir) section. Limb-viewing imagery is collected from -72.8° from nadir to -63.2° from nadir. The limb-viewing section has a cross-track resolution of 0.4° per pixel, it consists of 24 cross-track pixels and 8 along-track pixels (at five bands). The Earth-viewing section has a cross-track resolution of 0.8°.

NPS consists of three nadir-looking photometers. It operates in the visible portion of the electromagnetic spectrum, monitoring airglow at 427.8nm and 630nm and the terrestrial albedo near 630nm. NPS operates only on the nightside of the orbit. Its data determine the auroral oval location and provide information to help determine electron densities in the F-layer, energy deposition in the auroral region (day and night), photoelectrons, neutral composition, and equatorial electrojet. Each photometer unit includes an integrated detec-

Table 340: NPS detector parameters

G.1.3 Early Sensors of the DMSP Program

These were the instruments of the early phase of the DMSP program. They are no longer operational, but kept for reference.

SSL = Lightning Detector (old series).

The SSL was a “one-of-a-kind” experiment. Night operation to detect lightning flashes in the 0.4 - 1.1 μm range. FOV = 1200 x 1200 nmi.

SSB = Gamma Tracker. (old series)

Used to track fallout and nuclear debris entrained in the atmosphere from 10 to 15 km. The sensor detected the fission gammas emitted by the debris.

SSE = Temperature Sounder. (old series)

Eight channel scanning filter radiometer. Six of the channels measure in the 15 μm carbon dioxide band, one in the 12 μm window, and the last in the rotational water vapor band near 20 μm . Radiance measurements of the Earth’s atmosphere are processed to obtain vertical temperature profiles.

SSJ = Auroral Electron and Ion Spectrometer

The SSJ counted ambient electrons with energies ranging from 50 eV - 20 keV. It determined the number of electrons having energies within certain sub-ranges of the 50 eV to 20 keV spectrum by utilizing a time-sequenced variable electrostatic field to deflect the particles toward the channeltron detector.

SSJ/3 = Auroral Electron and Ion Spectrometers.

The SSJ/3 is a next generation sensor of the SSJ. The SSJ/3 was flown on all Block 5D-1 spacecraft with the exception of F-1. Objective: Measurement of transfer energy, mass, and momentum through the magnetosphere-ionosphere in the Earth’s magnetic field.

SSI/E = Topside Ionospheric Plasma Monitor.

The SSI/E measures ambient electron density and temperatures, ambient ion density, and

average ion temperature and molecular weight at the DMSP orbital altitude. The instrument consists of an electron sensor (Langmuir probe) and an ion sensor mounted on a 2.5 m boom. The ion sensor is a planar aperture, planar collector sensor oriented to face into the spacecraft velocity vector at all times.

SSJ* = Space Radiation Dosimeter. The SSJ* measures the accumulated radiation dose produced by electrons in the 1 - 10 MeV energy range, protons of greater than 20 MeV, and the effects of the occasional nuclear interactions produced by energetic protons. Accumulated dose was measured over a period of one year (minimum).

SSD = Atmospheric Density Sensor.

The SSD provides a measure of major atmospheric constituents (nitrogen, oxygen, and ozone) in the Earth's thermosphere by making Earth limb observations of ultraviolet radiation from the thermosphere. The sensor measured the radiation emitted from excitation of molecular nitrogen by impinging solar radiation.

SSC = Snow Cloud Discriminator.

The SSC sensor is a pushbroom scan radiometer. Wavelength 1.51 - 1.63 μm (IR). A binary system, it was used to determine the presence of snow versus clouds. It is a proposed concept sensor intended to help determine if machine processing could make a snow/cloud distinction. The along-track scan is provided by the forward motion of the S/C, while the 40.2° cross-track scan is provided by a linear array of 48 detector elements at the image plane of a wide-angle lens.

SSB = Gamma X-Ray Detector.

SSB/A = X-Ray Spectrometer.

The SSB/A detects X-rays and gamma rays from bomb debris or those X-rays produced by the Bremsstrahlung process when electrons precipitate from the Earth's radiation belts. By sensing these X-rays, the SSB/A provides the location of the aurora as it orbits the Earth.

SSB/O = Omnidirectional Gamma Detector.

The SSB/O was an experiment to determine if more accurate atmospheric measurements could be obtained by measuring the co-orbiting particles and the upward flux and subtracting it from the subsatellite scene. The experiment was extremely successful. The SSB/O was sensitive to X-rays in the energy range of approximately 1.5 keV.

SSB/S = Scanning X-Ray Detector.

The SSB/S detects the location, intensity and spectrum of X-rays emitted from the Earth's atmosphere. The detector consists of three sensors.

SSB/X, SSB/X-M = Gamma Ray Detectors.

The SSB/X is an array-based system which detects the location, intensity, and spectrum of X-rays emitted from the Earth's atmosphere. The array consists of four identical and independent directional detectors. The SSB/X-M and SSB/X-2 follow from the SSB/X and are also gamma-ray and particle detectors. The SSB/X-M and SSB/X-2 consist of two identical and independent gamma-ray detectors and three particle detectors (capable of detecting gamma-ray bursts).

SSH = Infrared Spectrometer. The IR spectrometer is a multispectral sounder for humidity, temperature, and ozone measurements. The SSH provides soundings of temperature and humidity and a single measurement of ozone for vertical and slant paths lying under and to the side of the subsatellite track. The SSH made a set of radiance measurements in narrow spectral channels lying in the absorption bands of carbon dioxide, water vapor, and ozone. The radiance measurements were mathematically inverted to yield vertical temperature profiles, water vapor, and total ozone content.

SSH-2 = Infrared Temperature and Moisture Sounder.

The SSH-2 provides soundings of temperature and humidity for vertical and slant paths ly-

ing under and to the side of the subsatellite track. SSH-2 is physically identical to SSH, but with different (and tighter) filter bands. 16 frequency bands in the range of 3.7 - 30 μm . Resolution = 60 km. Swath width = 2240 km.

G.1.4 DMSP Data Availability - Visible and Infrared Imagery

NOAA/NESDIS-NSIDC¹¹⁷⁰⁾ and -NGDC¹¹⁷¹⁾ (Boulder, CO) have established a collection of digital satellite imagery acquired from the DMSP series of the US Air Force under NOAA-NESDIS contract. Hence, DMSP imagery data are available for the general user community (among them the SSM/I, SSM/T and SSM/T-2 sensor data). These data are prepared from a global, digital intensity file used operationally by the Air Force in forecasting and are subsequently archived at NGDC [DMSP imagery are archived after operational use (usually 45 to 60 days)]. A digital archive of DMSP data has been operational at NGDC since April 1992 (NGDC receives two 5 GByte tapes in compressed format every day). Archival services are continually upgraded.

Parameter	Spatial Resolution (km)	Range of Values	Quantization Levels	Absolute Accuracy
Ocean surface wind speed	25	3 - 25	1	± 2 m/s
Ice: area covered	25	0 - 100	5	$\pm 12\%$
Ice: age	50	1. year, multiyear	1 yr, >2 yr	None
Ice: edge location	25	N/A	N/A	± 12.5 km
Precipitation over land ares	25	0 - 25	0,5,10,15,20, ≥ 25	± 5 mm/hr
Cloud water	25	0 - 1	0.05	± 0.1 kg/m ²
Integrated water vapor	25	0 - 80	0.10	± 2.0 kg/m ²
Precipitation over water	25	0 - 25	0,5,10,15,20, ≥ 25	± 5 mm/hr
Soil moisture	50	0 - 60%	1	None
Land surface temperature	25	180 - 340 K	1	None
Snow water content	25	0 - 50 cm	1	± 3 cm
Surface type	25	12 types	N/A	N/A
Cloud amount	25	0 - 100%	1	$\pm 20\%$

Table 341: Environmental products of the SSM/I sensor¹¹⁷²⁾

The imagery collection consists of three positive transparency products produced by USAF.

- 1) Limited coverage (at 0.6 km resolution) is available for selected areas
- 2) Global coverage is available on single-orbit strips (at 2.7 km resolution)
- 3) Mosaics compiled from several orbits, with latitude and longitude grids added, are available globally (at a resolution of 5.4 km).

Mosaics are the only pre-gridded product available. Single-orbit strips can be custom gridded for an additional fee. Each of these products has been produced since 1973, except the mosaics, which were available from December 1975 on.

Parameter	AMSU-A (flown on NOAA-15)	SSM/I (flown on DMSP series)
Window channels (GHz)	23.8, 31.4, 50.3, 89.0	19.4, 22.2, 37.0, 85.5
Polarization	Mixed	V & H (V only for 22.2)
Scan geometry	Cross-track $\pm 48.33^\circ$	Conical 45°
Field of View (FOV)	Varies with angle about 48 km at nadir about 150 km at limb	Varies with frequency about 15 km at 85.5 GHz about 60 km at 19.4 GHz
Swath width	about 2000 km	about 1400 km

Table 342: Comparison of AMSU-A and SSM/I channels

The AMSU-A (Advanced Microwave Sounding Unit) instrument of the NOAA POES series was first flown on NOAA-15 (launch May 13, 1998).¹¹⁷³⁾ Its primary objective is to provide significantly improved temperature soundings compared to its predecessor (MSU). However, since AMSU-A features similar window channels as the SSM/I sensor, it permits also the determination of surface and hydrological products similar to those derived from SSM/I.

NOAA/AVHRR-2 Sensor	System Parameter/ (Applications)	DMSP/OLS Sensor
1.1 km LAC 4.0 km GAC (degraded at edges) good good	spatial resolution (sea ice leads) (meteorology)	0.55 km 'fine' 2.7 km 'smooth' (const. across swath) better better

IR yes (10 bit) VIS no (pre-launch, drifts)	absolute calibration	IR yes (8 bit) VIS no (continued gain adjustment)
no N/A developmental N/A	visible-band dynamic range/ nighttime operation (auroral characteristics) (biomass burning, NESDIS, NASA (moonlit clouds/snow)	yes yes added potential with unique visible band good
no N/A N/A	coincident passive micro- wave (snow/ice, rain rate) (surface wind/soil moisture)	yes good good
no no	coincident space environ- ment measurements (auroral image feature + electron flux)	yes yes

Table 343: Comparison of two sensors - NOAA AVHRR/2 and DMSP/OLS¹¹⁷⁴⁾

G.2 EPS (EUMETSAT Polar System)

The EUMETSAT Polar System (EPS) consists of the ESA-developed MetOp (Meteorological OPERational) series of spacecraft and an associated ground segment for meteorological and climate monitoring from polar, low Earth orbit, providing “morning” service for operational meteorology. Within the framework of international agreements, the NOAA POES series will continue to provide the “afternoon” service. The MetOp series, although an independent development, is complementary to: a) the NOAA POES system, b) the EUMETSAT/ESA MSG (Meteosat Second Generation) system, and c) the ESA ENVISAT system, where MetOp completes the mission objectives of the original POEM-1 mission.

Background: European needs for meteorological observations in polar (“morning” and “afternoon”) orbits have been generously provided by NOAA S/C and payloads (including some instruments developed in Europe) over the last quarter century. The EPS (EUMETSAT Polar System) is the European contribution to the joint European/US operational po-

¹¹⁷³⁾D. Moore, L. Zhao, et al., “The new NOAA Microwave Surface and Precipitation Product System,” Proceedings of the EUMETSAT Meteorological Satellite Data User’s Conference, Copenhagen, Denmark, Sept. 6-10, 1999, pp. 325-329

¹¹⁷⁴⁾Courtesy G. Scharfen, NOAA/NESDIS/NSIDC

lar system, through **IJPS (Initial Joint Polar System)**. A cooperation agreement between NOAA and EUMETSAT was signed in November 1998. The EPS and POES systems form together the IJPS to provide global meteorological data from the series. With EPS, EUMETSAT is committed to take over the morning orbit service from NOAA. On the other hand, NOAA will continue to provide the POES series afternoon service. Both services are coordinated and integrated, on the basis of exchange of data, instruments and operational services (see also G.15.3).¹¹⁷⁵⁾

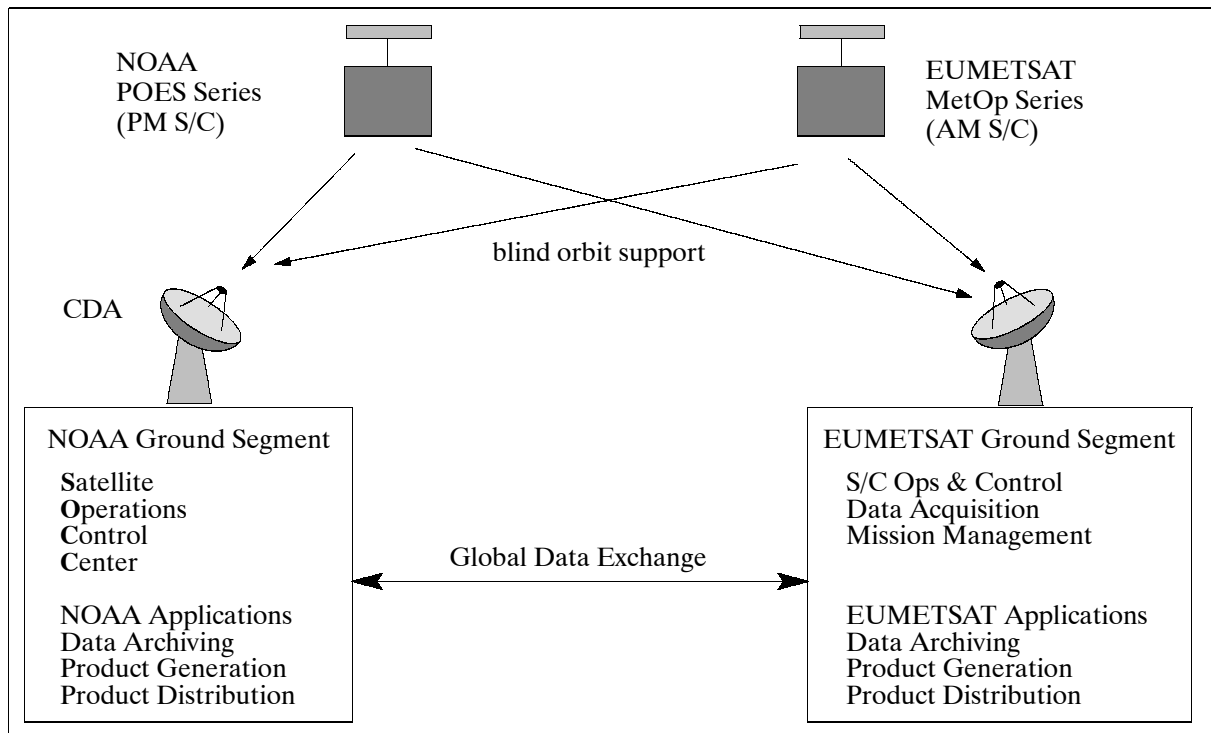

Figure 203: Integrated concept of NOAA/EUMETSAT meteorological polar satellites

The prime objectives of the EPS MetOp mission series are as follows:

- To ensure continuity and availability for operational purposes of polar meteorological observations from the “morning” orbit to the global user community
- To provide enhanced monitoring capabilities (complimentary to ENVISAT) to fulfil the requirements to study the Earth climate system as expressed in a number of international cooperative programs such as: GCOS (Global Climate Observing System), IGBP (International Geosphere and Biosphere Program), and WCRP (World Climate Research Program). The aim is to provide continuous, long-term data sets.

EPS is an end-to-end system composed of a space segment and a full ground segment. The third satellite in this series, MetOp-3, is not formally part of IJPS, because its planned launch date falls already into the era of the US NPOESS (National Polar-orbiting Operational Environmental Satellite System) era, representing in itself the merged US POES (civil) and DMSP (military) series.

Within the European framework, the ESA program developing MetOp-1, and the EUMETSAT procurement of MetOp-2/3, is under the responsibility of a joint ESA/EUMETSAT team. EUMETSAT is also directly responsible for the delivery of the following payloads: MHS, IASI, ARGOS/ADCS, SEM, AMSU-A HIRS/4, and AVHRR/3. The last four payloads are contributed by NOAA under the IJPS agreement: CNES develops the IASI instrument with joint funding from EUMETSAT, and provides the Argos/ADCS, and in

¹¹⁷⁵⁾A. Ratier, “The EUMETSAT Polar System,” Proceedings of the 1999 EUMETSAT Meteorological Satellite User’s Conference, Copenhagen, Denmark, Sept. 6-10, 1999, pp.3-10

addition, part of the S&RSAT (Search & Rescue) auxiliary payload. EUMETSAT is responsible for the definition of the overall EPS system, the development and operations of the ground segment, and for the operation of the space segment.

G.2.1 MetOp-1 Satellite

MetOp-1 is Europe's first polar-orbiting satellite dedicated to operational meteorology. The MetOp program was originally planned as a much larger satellite concept, called POEM, a successor mission series to ERS-1/2 on the Columbus Polar Platform (PPF design). However, this idea was abandoned at the ESA Ministerial Council in Granada, Spain, in 1992. Instead, Envisat and MetOp were born.¹¹⁷⁶⁾

The overall architecture of the MetOp-1 S/C comprises two largely independent modules, namely SVM (Service Module) and PLM (Payload Module).

- SVM provides the main satellite support/service functions. The SVM provides all the standard service functions of a S/C, like: attitude and orbit control, propulsion, power generation, and the on-board data handling and distribution systems. The SVM design is based on the SPOT MK3 bus (used on the SPOT series, ERS-1/2 and Helios-1A and 1B S/C). SVM is a box-shaped structure interfacing with the launch vehicle and the PLM.
- PLM provides accommodation and supporting subsystems (data handling, power, communications) to the payload complement. The instruments and antennas are mounted on the external panels, while most of the electronics systems are accommodated inside the PLM.

The S/C overall size is: 6.3 m x 3.4 m x 3.45 m (launch configuration) and 17.6 m x 6.7 m x 5.4 m (on-orbit configuration). The S/C is three-axis stabilized using reaction wheels. The pointing knowledge is: 0.07° (x-axis), 0.10° (y-axis), 0.17° (z-axis). The overall S/C mass at launch is about 4300 kg, including 316 kg of hydrazine. The PLM mass is 2232 kg, the SVM mass is 1486 kg. Single sided solar arrays provide a power of 3.890 kW (EOL), the average power over one orbit is 2.280 kW (EOL). Five 40 Ah batteries provide power during eclipse periods. The mission design life is 5 years.

A launch of MetOp-1 on Soyuz-ST from Baikonur is planned for 2005 (MetOp-2 launch in 2008, MetOp-3 launch beyond 2010). Full approval of the EPS (EUMETSAT Polar System) program was granted in September 1998. The prime S/C contractor is Astrium SAS (France), co-contractors are Astrium GmbH, Germany, Alenia, Italy, and Astrium Ltd., UK.

Communication: An omnidirectional S-band coverage provides TT&C support (uplink 2 kbit/s, downlink 4 kbit/s). Instrument data is downlinked in X-band at a rate of 70 Mbit/s. On-board storage capacity of 24 Gbit (solid state recorder with a data rate of 70 Mbit/s) is provided. In addition to on-board recording and X-band downlink capabilities, MetOp supports the real-time broadcast of instrument data to local users by the following means:

- LRPT (Low-Rate Picture Transmission) links with 72 kbit/s in VHF-band for selected instrument data.
- HRPT (High-Rate Picture Transmission) links with 3.5 Mbit/s in L-band. The HRPT broadcast service is very similar to the existing NOAA POES service and enables regional users to receive all data relevant to their area in real time.

The provided VHF low-rate digital direct broadcast service replaces the old analog APT (Automatic Picture Transmission) service of NOAA, employing data compression (modified JPEG compression scheme) to ensure high-quality images. The digital LRPT service retains the VHF frequency and bandwidth of the APT service, but provides three channels of AVHRR data at the full instrument spatial and radiometric resolution.

¹¹⁷⁶⁾ P. G. Edwards, D. Pawlak, "MetOp: The Space Segment for EUMETSAT's Polar System," ESA Bulletin, No 102, May 2000, pp. 7-18

Figure 204: Illustration of the MetOp spacecraft

Data Type	Frequency Domain	Modulation Scheme	Data Rate
TT&C uplink	S-band, 2053.4 MHz	NRZ/PSK/PM	2 kbit/s
TT&C downlink	S-band, 2230 MHz	SP-L/PSK/PM	4 kbit/s
Global data dump	X-band, 7.750-7.900 GHz	QPSK	70 Mbit/s
LRPT downlink	VHF-band, 137.1 MHz	QPSK	72 kbit/s
HRPT downlink	L-band, 1701.3 MHz	QPSK	3.5 Mbit/s

Table 344: Summary of MetOp communication links with the ground segment

On-board data handling employs the CCSDS protocols. A selective encryption capability is used to ensure the commercial and data-denial needs of EUMETSAT and NOAA, respectively. Spacecraft operations are performed by EUMETSAT with the Kiruna ground station serving as prime.

Service provision: The MetOp program, as successor to the NOAA POES morning series, is required to provide a continuous broadcast of its meteorological data to the worldwide user community, so that any ground station in any part of the world can receive local data when the satellite passes over that receiving station. This implies continued long-term provision of LRPT and VHF downlink services.¹¹⁷⁷⁾

Orbit: Near-circular sun-synchronous polar morning orbit (9:30 AM on descending node), mean altitude = 825 km, inclination = 98.704°, repeat cycle = 5 days (71 orbits).

S/C attitude	Three-axis stabilized through reaction wheels Orbit maneuvers through a hydrazine propulsion system Pointing knowledge: 0.07° (x-axis), 0.10° (y-axis), 0.17° (z-axis)
Data handling	Instruments science data acquired as CCSDS packets Science data formatting and multiplexing, encryption for selected instruments Instruments and housekeeping data storage in a solid-state recorder (24 Gbit)
Communications	Omnidirectional S-band coverage (uplink 2 kbit/s, downlink: 4.096 kbit/s) Instrument global data stream downlinked via X-band (70 Mbit/s) Real-time broadcasting of instrument data in HRPT: 3.5 Mbit/s via L-band for all instruments, and LRPT: 72 kbit/s via VHF for selected instruments
On-board power	2210 W from solar panel, average power over one orbit (EOL) Five 40 Ah batteries Unregulated power (22 37.5 V) and 50V regulated power lines for SVM/PLM units Unregulated power lines (22 37 V) for European instruments 28 V regulated power lines for NOAA instruments
Design life	5 years
S/C mass	4179 kg
Propellant mass	315.7 kg of hydrazine, stored in 4 tanks (including residual)
S/C operations	S/C controlled by EUMETSAT (Kiruna ground station) Instruments X-band data downlinked nominally over two ground stations Recorded data downlinked not later than one orbit after recording S/C autonomy required for 36 hours without ground contact

Table 345: Summary of MetOp main features and performances

The MetOp operational meteorological mission objectives consist of:

- Global sounding: To provide information about 3-D temperature and humidity fields in support of operational numerical forecasting systems
- Global imagery: To provide cloud imagery for forecasting applications, sea surface temperatures (SST), radiation budget temperatures. To support the global sounding mission through the identification of cloud-free areas
- Data collection and location: To support WWW objectives by the reception and dissemination of in-situ observations from ocean buoys and similar data collection platforms
- Preoperational data: To provide access to data from instruments which have not yet been declared fully operational
- Global data access: To primarily support global-scale weather forecasting by providing global data to the meteorological services within 2 1/4 hours of observation
- Local data access (HRPT and LRPT): To support regional weather forecasting by providing broadcasted data to local receiving stations when the satellite is in visibility.

The MetOp climate monitoring mission contributions (for GCOS) consists of:

- Imagery and sounding
- Ocean measurements (including surfaces stress and winds)
- Clouds and Earth radiation budget: Radiation is the primary energy source of the climate system and principle heat input source to the oceans
- Sea ice information: The extent of sea ice is an important variable in connection with both ocean heat budget and radiation balance

¹¹⁷⁷⁾ D. Pawlak, C. Bousquet, "MetOp: the space segment of the EUMETSAT Polar System," Proceedings of the 2000 EUMETSAT Satellite Data Users' Conference, Bologna, Italy, May 29-June 2, 2000, pp. 209-213

- Atmospheric minor constituents: Concern over the depletion of stratospheric ozone suggests the importance of maintaining a continuous data set of global total column ozone and vertical profiles
- Precipitation estimates.

The MetOp Earth sciences research mission objectives include data provision to the European science community to advance investigations in fields such as:

- Atmospheric physics: chemistry, radiation and energy balance, clouds
- Oceanography: general ocean circulation and fluxes of heat, momentum and gases; modeling
- Hydrology: water cycle, continental snow and mountain glaciers, land cover, soil moisture, vegetation
- Cryosphere: sea ice, continental ice, modeling

The MetOp surveillance mission contributions to the regular monitoring of application-oriented parameters:

- Environment: pollution control, natural disasters, renewable resources
- Marine: offshore activities, ship routing, fishing, sea ice routing

G.2.2 MetOp-1 Sensor Complement

For a description of AVHRR/3, HIRS/4 and AMSU-A, see chapter G.15.1).

Payload Sensor	Mission Objectives	Sensor Provider
AVHRR/3 (Advanced Very High Resolution Radiometer)	Global imagery, global sounding, ocean measurements (SST), clouds and Earth radiation budget, land measurements	NOAA
HIRS/4 (High Resolution Infrared Sounder)	Global sounding, atmospheric minor constituents, (ozone)	NOAA
AMSU-A (Advanced Microwave Sounding Unit-A - A1 & A2)	Global sounding, sea ice	NOAA
MHS (Microwave Humidity Sounder)	Global sounding, clouds and Earth radiation budget, sea ice	EUMETSAT
IASI (Improved Atmospheric Sounder Interferometer)	Global sounding, ocean measurements (SST), clouds and Earth radiation budget, some atmospheric trace constituents, land measurements	CNES/ EUMETSAT
ASCAT (Advanced Scatterometer)	Ocean measurements, surface stress and surface wind	ESA
GOME-2 (Global Ozone Monitoring Experiment-2)	Atmospheric trace gases (ozone content and profile)	ESA/ EUMETSAT
GRAS (GNSS Receiver for Atmospheric Sounding)	Atmospheric refractive index measurement in limb-sounding mode	ESA/ EUMETSAT
ARGOS (Remote Data Collection System),	Data collection and location; ADCS on-board, PTTs and DCPs in the ground segment	CNES
S&R = Search and Rescue System	Cooperative satellite-based radiolocation system for search and rescue operations. Relay of emergency radio signals to ground stations from aviators, mariners and land travellers in distress.	CNES/NOAA
SEM-2 (Space Environment Monitor-2)	Monitoring of the S/C environment (solar-terrestrial)	NOAA

Table 346: Overview of MetOp-1 payload complement

ASCAT = Advanced Wind Scatterometer [ESA instrument, developed by Astrium GmbH under contract to Astrium SAS, France]. Objective: Determining wind vector fields at sea surface by measuring the backscattering coefficient [normalized radar cross section sigma-zero, also referred to as NRCS] on a global basis. The requirement calls for the measure-

ment of wind speeds in the range of 4-24 m/s with an accuracy of 2 m/s and a direction accuracy of $\pm 20^\circ$.^{1178) 1179) 1180) 1181)}

ASCAT is a real-aperture C-band (5.255 GHz) dual-swath and three-look radar instrument with high radiometric resolution and stability. The design of the system exploits the LFM (Linear Frequency Modulation) measurement principle on the basis of long transmit pulses (about 10 ms) with linear frequency modulation (chirps). This permits the application of low-peak transmission power (about 120 W) and frequency domain processing. ASCAT sequentially illuminates two strips (swaths) of the sea surface (two 550 km wide swaths, one on either side of the satellite ground track). This feature results in fast global coverage capability (twice as fast as ERS-1). Heritage of ERS-1 AMI-SCAT sensor. The major differences between ASCAT and AMI-SCAT are:

- Enhanced coverage due to double swath operation
- Spatial resolution: increased spatial resolution is provided on an experimental basis
- Use of solid-state technology
- Improved radiometric performance (accuracy and inter-beam stability)
- Reduced downlink data rate due to on-board data processing (from 1.4 Mbit/s on AMI-SCAT to 55 kbit/s on ASCAT)
- In addition to the processing of echo signals, the instrument also performs an internal calibration process within each pulse repetition interval
- Reduced power needed for the transmission of continuous-wave pulses (about 120 W of peak power are needed for ASCAT compared to 4.8 kW for AMI-SCAT on ERS-1).

Parameter	Nominal mode	High-resolution mode
Center frequency	5.255 GHz	
Swath width (full performance)	500 km	
Swath width (reduced performance)	550 km	
Swath length	continuous	
Incidence angle mid near at H min	25°	
Localization accuracy	4.4 km	
Polarization	vertical	
Cross polarization	> 20 dB	
Spatial resolution	50 km	25 - 37 km
Spectral resolution	0.0195/km	
Sampling interval	25 km	12.5 km
Radiometric resolution at low wind (minimum backscattering)	2.5 - 7.1%	6.0 - 17.6%
Radiometric resolution at high wind (maximum backscattering)	2.0 - 2.7%	5.0 - 9.1%
Radiometric accuracy	0.47 - 0.55 dB pp	0.48 - 0.56 dB pp
Interbeam radiometric stability	0.33 - 0.41 dB pp	0.33 - 0.41 dB pp
Ambiguity under worst case scenario	0.34 - 3.3%	0.34 - 3.3%
Dynamic range (backscatter coefficients on the ground at near and far swath)	-8.6 - 4.3 (near) dB -28.6 - -8.8 (far) dB	-8.6 - 4.3 (near) dB -28.6 - -8.8 (far) dB
Aliasing error	0.08%	0.08%

Table 347: Performance parameters for ASCAT in nominal and high-resolution modes

The ASCAT instrument consists of the following elements: Antennas (6), SFE (Scatterometer Front End), RFU (Radio Frequency Unit), HPA (High Power Amplifier), DPU (Digital Processing Unit, PDU (Power Distribution Unit), and ICU (Instrument Control Unit).

¹¹⁷⁸⁾ R. V. Gelsthorpe, E. Schied, J. J. W. Wilson, "ASCAT - MetOp's Advanced Scatterometer," ESA Bulletin, No 102, May 2000, pp. 19-27

¹¹⁷⁹⁾ "ASCAT Advanced Scatterometer," ESA brochure

¹¹⁸⁰⁾ F. Rostan, M. Kuntz, S. Schütz, "The Advanced Scatterometer (ASCAT) Ground Processing Prototype," Proceedings of IGARSS'99, Vol. I, Hamburg, June 28 - July 2, 1999, pp. 224-226

¹¹⁸¹⁾ H. Ebner, H. R. Schulte, H. Hölzl, D. Miller, P. Hans, "ASCAT - Advanced Wind Scatterometer," IGARSS'92, Volume I, pp. 435-439

ASCAT uses three antennas for each of the two swaths to obtain wind speed and wind direction measurements with ambiguity present. All six antennas are slotted waveguide aluminum arrays. One antenna in each set is looking sideward at 90° (cross-track direction), one forward at 45° , and one aftward at 135° (see Figure 205). All antennas form a fan beam with narrow azimuth pattern and a relative wide elevation pattern, resulting in a swath of about 550 km. The local incidence angles are between 25° - 65° (mid near at $H \min = 25^\circ$). In each swath a regular grid of points (nodes) is defined where the σ° values are determined. The internode distance is 25 km for nominal resolution, and 12.5 km for high-resolution observations. The wind data at each node are extracted from a wind model. 1182) 1183)

Figure 205: Top view of ASCAT observation geometries

The received echo signal is de-chirped with an image of the transmitted pulse, filtered and down-converted to baseband. The baseband signal is sampled and processed by the on-board digital signal processor. This processing consists of a power spectrum estimation (transformation to the frequency domain and square modulus detection) followed by (spatial) low-pass filtering. This results in echo power spectra, where each frequency corresponds to a specific slant range distance.

ASCAT is calibrated by using an instrument-internal calibration unit which monitors potential variations in transmitted power and receiver gain. External calibration is achieved by using ground transponders and the Amazonian rain forest. 1184)

MHS (Microwave Humidity Sounder), a EUMETSAT instrument, built by Astrium UK. 1185) MHS is a five-channel self-calibrating instrument, providing humidity profiling capability in the frequency range of 89 - 190 GHz. The channels 2-5 provide a humidity sounding capability (water vapor absorption line), while channel 1 measures the Earth's surface temperature and emissivity, in conjunction with the AMSU-A window channels, and detects cloud and precipitation contaminated pixels. The MHS instrument is a total power radiometer which measures the total noise power from the scene. MHS scans in the cross-track direction at a rate of 2.66 seconds (the scan is synchronized with AMSU-A). The Earth view

Cross polarization (%)	1.2	0.6	3.5	3.5	1.9

Table 348: MHS instrument performance parameters

MHS is a compact quasi-optical heterodyne radiometer, consisting of the following elements: reflector, receiver (quasi-optical front end, amplifiers, filters, video detectors), scan mechanism, on-board calibration target, and an electronics unit. The instrument mass is 63 kg, power = 66 W. While the MetOp-specific instruments use the European OBDH (On-board Data Handling) standard interface, MHS is using the MIL-STD-1553 interface. Both of these standards are high-level command and control interfaces, permitting the use of instrument intelligence. ¹¹⁸⁶⁾

Note: Under the MOU between EUMETSAT and NOAA concerning cooperation for polar satellite systems, the MHS instrument is also being flown on the NOAA POES series (EUMETSAT-funded instrument) with a first flight planned on NOAA-N. MHS is used in conjunction with AMSU-A and replaces the AMSU-B in the POES series instrument baseline.

IASI = Improved Atmospheric Sounder Interferometer (CNES/ASI) ^{1187) 1188) 1189)} IASI is a Fourier Transform nadir-viewing imaging interferometer operating in the thermal infrared spectrum from $3.62 (2760 \text{ cm}^{-1})$ to $15.5 \mu\text{m} (645 \text{ cm}^{-1})$ at moderate spectral resolution. The instrument consists of a Fourier Transform Spectrometer (FTS), based on a Michelson interferometer (the flat mirrors are replaced with retroreflecting cube-corners), coupled to an integrated imaging system, permitting the characterization of cloudiness inside the FOV of FTS. Objectives: sounding tropospheric moisture and temperature, measuring column-integrated O_3 , CO_2 , CH_4 , and NO_2 , and measuring some trace gases which drive the budget of tropospheric chemistry and contribute to the greenhouse effect. IASI scans in the cross-track direction with a swath width of about 2052 km ($\text{FOV} = \pm 48.33^\circ$, provision of motion compensation). During the scan the mirror moves to 30 positions, one every 216 ms. $\text{IFOV} = 3.33^\circ \times 3.33^\circ$ (about 48 km x 48 km at nadir). Within each mirror position four sub-FOV's are imaged in a 2×2 matrix form onto four detectors. Each sub-FOV corresponds to a circular field-of-view of 0.84° (diameter about 12 km at nadir). The total scan period of 8 seconds is coordinated with the AMSU-A scan cycle. A calibration (cold-space viewing and updating of calibration coefficients) is performed after each scan cycle. The calibration accuracy is $\leq 0.5 \text{ K @ } 280 \text{ K}$; the inter-channel accuracy $\leq 0.2 \text{ K}$; $\text{NE}\Delta\text{T} < 0.228$ at 280 K for all bands. IASI is considered a preoperational instrument on MetOp-1. Band-1 and -2 detectors are of HgCdTe type (photovoltaic), while the band-3 detectors are of InSb type (photoconductive). Data quantization = 12 bit. On-board processing activities

GOME-2 (Global Ozone Monitoring Experiment-2), of GOME-1 heritage flown on ERS-2. The ESA/EUMETSAT jointly-funded instrument was designed and built by Officine Galileo/Alenia Difesa, Italy. The overall objectives of GOME-2 are: measurement of total column amounts and stratospheric and tropospheric profiles of ozone. In addition: measurement of column amounts of H₂O and other gases involved in ozone photochemistry (like NO₂, OClO, BrO, and possibly ClO in polar spring conditions, and pollutants like SO₂ and HCHO). GOME can also be used to investigate the distribution of atmospheric aerosols and clouds-plus-surface spectral reflectance. ¹¹⁹⁰⁾

The GOME-2 instrument consists of the following modules or units:

- Spectrometer: almost identical to the GOME-1 instrument. The major change for the GOME-2 spectrometer resulted from the accommodation of the more complex PMU (Polarization Monitoring Unit) on GOME-2.
- FPA (Focal-Plane Assembly). There are a total of six FPAs, four are assigned to the spectrometer channels and two to the new polarization channels. Each FPA contains a

¹¹⁹⁰⁾J. Callies, E. Corpaccioli, M. Eisinger, A. Hahne, A. Lefebvre, "GOME-2 - MetOp's Second-Generation Sensor for Operational Ozone Monitoring," ESA Bulletin, No 102, May 2000, pp. 28-36

random-access linear silicon photodiode array, consisting of 1024 elements, which is reverse-biased and operates in charge accumulation mode. The detectors are cooled to -38° C for the spectrometer channels and to 0° C for the PMUs.

- **PMU (Polarization Monitoring Unit):** The new PMU provides polarization information (with sufficient accuracy to correct for the polarization dependence of the instrument) by monitoring the spectral range using 200 pixels with a spectral resolution of between 2.8 to about 40 nm, the integration time is 23 ms. The s- and p-polarized parts of the radiation are measured simultaneously. The s- and p-channels have an identical FOV with the main channel. Note: other major ozone measuring instruments like TOMS, SBUV and OMI disregard the measurement of polarization.

Spectrometer type	Double monochromator with pre-disperser prism and 4 holographic gratings	
Spectral range	240 - 790 nm	
FOV (Filed of View)	0.286° cross-track x 2.75° along-track, or 4 km x 40 km respectively	
Entrance slit dimension	0.2 mm cross-track x 9.6 mm along-track	
Channels and resolution	1: 240 - 315 nm	0.24 - 0.29 nm (resolution)
	2: 311 - 403 nm	0.26 - 0.28 nm
	3: 401 - 600 nm	0.44 - 0.53 nm
	4: 590 - 790 nm	0.44 - 0.53 nm
Polarization	200 detector pixels	
Monitoring unit	312 - 790 nm in 12 programmable bands Spectral resolution: 2.8 nm at 312 nm to 40 nm at 790 nm	
Viewing modes		
Nadir cross-track	1920 km, 960 km, 480 km, 360 km, 240 km, 120 km	
Solar	Fixed angle once per day	
Lunar	Fixed/varying angle, about 6 times per year	
Spectral calibration	Fixed angle (once per day to once per month)	
White light source	Fixed angle (once per day to once per month)	
Dark signal	Fixed angle (night side of the orbit)	
Spatial resolution	40 km x 40 km (with 960 km swath and integration time of 0.1875 s) 40 km x 5 km (for polarization monitoring)	
Instrument data rate	400 kbit/s	
Instrument mass, power	73 kg, 58 W	
Instrument size	656 mm (zenith, nadir) x 848 mm (cross-track) x 468 mm (along-track)	

Table 351: Major parameters of the GOME-2 instrument

- **Calibration unit:** The unit contains two light sources (spectral light and white). The white light source is used to monitor the etalon, present on the cooled detectors. The spectral light source is a hollow cathode lamp filled with a mixture of neon and argon. The calibration unit has in addition a diffuser in support of solar calibrations.
- **SU (Scan Unit):** SU features a rotating mirror, positioning in front of the spectrometer. The mechanical assembly is almost identical to that of GOME-1. The electronics assembly of GOME-2 allows five constant scan profiles and five new scans, compensating for the Earth's curvature and providing a constant linear scan speed on the ground. A new wide-amplitude scan corresponding to 1920 km on the ground, is also implemented. The wider swath permits global coverage in 1.5 days. All scans are reprogrammable. The basic scan timing is 4.5 s in the forward and 1.5 s in the flyback scan.
- **CDHU (Command and Data Handling Unit):** A processor is responsible for all ICU (Instrument Control Unit) functions such as command handling, maintenance of history file, monitoring of instrument parameters and format handling. CDHU provides 12 predefined timelines, each dedicated to a specific orbit sequence.

GRAS (GNSS Receiver for Atmospheric Sounding), manufactured by Saab Ericsson Space of Sweden and co-funded by ESA and EUMETSAT. The objectives are to provide atmospheric temperature and humidity profiles. The data is used in NWP (Numerical Weather

Prediction) models. Radio occultation of the atmosphere is a well-proven technique whose performances have been demonstrated for Earth atmospheres by GPS/MET and its successor TRSR, both instruments were developed at JPL.¹¹⁹¹⁾ The measurement principle is based on the fact that microwave signals passing through the atmosphere up to a LEO satellite at the limb are bent and delayed due to the variations of the refractive index of the various layers of the atmosphere and the ionosphere. The refractive index depends upon the pressure, temperature and humidity of the atmosphere.^{1192) 1193) 1194) 1195)}

GRAS is a dual-frequency GPS high-performance instrument with semi-codeless operating capabilities. The instrument provides carrier, code phase and signal amplitude measurements. The second GPS frequency (L2) is used for ionospheric correction of the signals. GRAS features twelve dual-frequency channels, four for rising and setting occultations and eight for navigation. The navigation channels provide the position of the Metop satellite in real-time. Carrier and code phase data are also provided for the processing of the precise orbit determination of Metop (position and velocity) necessary for the ground processing of the occultation data and in particular the effects on the Doppler caused by the GPS signal passing through the atmosphere and the troposphere. A ground network of GPS receiver tracking stations is used for determining the actual orbits of the GPS satellites. This ground network can operate in differential mode in order to cancel clock error variations. - The GRAS instrument consists of the following elements:

- Antennas. The three GRAS antennas are pointed in the satellite's velocity, anti-velocity, and zenith directions. The velocity and anti-velocity antennas are phased arrays, each containing 18 dual-band patches with a shaped antenna pattern optimized for the occultation of the Earth's limb and its atmosphere.
- RFCU (RF Conditioning Unit). Each of the three RFCUs consists of two extremely steep bandpass filters, a low-noise amplifier and a single down-converter stage.
- GEU (GRAS Electronics Unit). The GEU is built around the ESA-developed AGGA (Advanced GPS/GLONASS ASIC). The AGGA simultaneously performs the final down-conversion, de-spreading, and correlation of four dual-frequency GNSS channels. A number of AGGA observables are delivered to the TSC2102OE DSP, an ESA-funded Digital Signal Processor which performs the functions of: measurement, signal tracking, navigation solution, time management, and measurement data processing.

The GRAS instrument has a mass of 20 kg (together with a 7 kg deployment mechanism for the anti-velocity occultation antenna), and a power consumption of 37 W. The average data rate is 27 kbit/s with a maximum rate of 60 kbit/s.

The GRAS instrument provides more than 500 occultations/day, with quasi-uniform geographical distribution, a vertical temperature sounding of 1K rms, with a vertical resolution of 150 m in the troposphere and 1.5 km in the stratosphere over an altitude range of 5 to 30 km. In addition, GRAS provides an opportunity to establish the height of the tropopause with a vertical accuracy of better than 1 km. The horizontal resolution of the radio-occultation technique, limited by the limb-sounding approach itself, is in the order of 100 km in the troposphere and 300 km in the stratosphere.

Auxiliary data	Observation error characteristics
Earth orientation parameters	TEC
Observation error characteristics	

Table 352: Overview of GRAS level-1 and level-2 products

An enhanced version of the GRAS instrument, called GPSOS (GPS Occultation Sensor), will fly on the NPOESS series of NOAA. Other GRAS versions are also under consideration for other spacecraft such as the GCOM (Global Change Observation Mission) series of NASDA, the ACE (Atmosphere Climate Experiment) microsatellite constellation of ESA's Earth Explorer Program, and the WATS (Water-vapor in Atmospheric Troposphere and Atmosphere Sounding) microsatellite constellation of ESA.

ARGOS/ADCS (Advanced Data Collection System) an advanced ARGOS system (also flown on NOAA-N') provided by CNES (see C.1). The objectives are data collection and location from PTTs (Platform Transmitter Terminal) and DCPs (Data Collection Platform) in the ground segment PTTs and DCPs are both part of the ARGOS ground segment for environmental data measurement.

S&RSAT (Search&Rescue Satellite Aided Tracking System). The S&RSAT payloads are part of an international cooperative satellite-based radiolocation system to support search and rescue operations for aviators, mariners, and land travellers in distress (see I.6). The S&RSAT payload consists of S&RR (S&RSAT Repeater), provided by CRC/Canada; and S&RP (S&RSAT Processor), provided by CNES/France).¹¹⁹⁶

The communication link specification for the ARGOS and S&RSAT services are:

- ADCS data reception at 401.65 MHz
- ADCS data transmission at 466 MHz
- S&RR beacon signal repetition at 121.5 MHz, 243 MHz, and 406.05 MHz
- S&RP-3 data reception at 406.05 MHz (common with S&RR)
- S&RR data transmission at 1544.5 GHz.

SEM-2 (Space Environment Monitor-2), a NOAA-provided instrument package (see G.15.2).

G.3 Feng-Yun-1 (Polar Orbiting Satellite Series)

Feng-Yun (Feng-Yun = wind and cloud) is a meteorological satellite series of China, organized by CMA (China Meteorological Administration).^{1197) 1198)} Within the meteorological program, the odd-numbered satellites (Feng-Yun-1 or simply FY-1) refer to the polar-orbiting LEO series, while the even-numbered S/C (FY-2, FY-4, etc.) refer to the GEO se-

¹¹⁹⁶⁾ Note: Although the original acronym for 'Search and Rescue' is 'SAR' in the context of NOAA (or MetOp) missions, it was changed in this book consistently to 'S&R' in order to distinguish it from the other widely-used meaning of SAR, namely 'Synthetic Aperture Radar,' a sensor type. A consequence is the use of 'S&RSAT' (instead of SARSAT), to use S&RP instead of SARP, as well as to use S&RP-3 instead of SARP-3

¹¹⁹⁷⁾ W. Zhang, "Meteorological satellite program of China," Proceedings of SPIE, Vol. 3501, Optical Remote Sensing of the Atmosphere and Clouds, Sept. 15-17, 1998, Beijing, China, pp. 12-22

¹¹⁹⁸⁾ W. Zhang, "Meteorological satellite program of China," Proceedings of the Asian Conference on Remote Sensing, HongKong, China, Nov. 22-25, 1999, pp. 299-305

ries. The first generation LEO satellite (FY-1) series consists of a total of four S/C. The funding body in China is the Ministry of Aerospace, while CMA (China Meteorological Administration) is the agency in charge of all functions, pertaining to the business of meteorological satellites (management of space and ground segments, etc.).

G.3.1 FY-1A, -1B

The FY-1 series satellite program was initiated in 1977. The S/C (FY-1A and FY-1B) were designed and built by the Shanghai Institute of Satellite Engineering, part of CAST (China Academy of Space Technology); their payloads were developed by the Shanghai Institute of Technical Physics (SITP), part of CAS (China Academy of Sciences).

Both S/C are similar in design. The satellite structure is a hexahedron of size: 1.4 m x 1.4 m x 1.2 m and a mass of 750 kg for FY-1A. The FY-1A bus was increased for the FY-1B satellite. Likewise, total spacecraft mass increased from 750 kg to about 880 kg. Both satellites are three-axis stabilized (attitude control is maintained by a combination of nitrogen cold gas thrusters and reaction wheels, attitude is sensed by gyros and horizon sensors) and powered by two solar arrays (about 3.5 m long each) with a combined rating of 800 W. Nickel-cadmium batteries are used for electrical power storage. The launch of both S/C was performed by Long March 4 (CZ-4) boosters from Taiyuan, China. Launch of FY-1A: Sept. 7, 1988; Launch of FY-1B: Sept. 3, 1990.

Orbit of FY-1A: Sun-synchronous polar orbit with an altitude of 900 km; inclination = 98.9° , equatorial crossing at 3:30 PM on a descending node, period = 102.86 min.

Orbit of FY-1B: Sun-synchronous polar orbit with an altitude of 900 km; orbital period = 102.86 minutes; inclination = 99.1° , eccentricity < 0.005; equatorial crossing at 7:50 AM.

Figure 206: The Feng-Yun-1 S/C model

Sensor complement:

MVISR (Multichannel Visible and IR Scanning Radiometer) developed and built by SITP (Shanghai Institute of Technical Physics). ^{1199) 1200) 1201)} Two identical instruments were used on-board each S/C (which operate alternately). The objectives are:

- To acquire global visible and infrared cloud images for weather forecasting
- To take images of the land surfaces for the monitoring of crops, vegetation, snow coverage, floods, etc.

¹¹⁹⁹⁾H. Gong, Q. Zheng, W. Wang, "The Improvement of the Detecting Property and the Performance of the Very High Resolution Scanning Radiometer on FY-1B Meteorological Satellite," AAS 91-658, pp. 497-503

¹²⁰⁰⁾SITP internal paper written by D. Kuang,, H. Gong, and Q. Zheng

¹²⁰¹⁾Q. B. Zheng, X. R. Xue, "Optical Design of the Remote Sensing Instrument for FY-1 Meteorological Satellite," Chinese Journal of Infrared & Millimeter Waves, Volume 9, Number 2, 1989

- To measure the sea surface temperature (SST)
- To perform an ocean color experiment for the retrieval of chlorophyll distributions (bands 3 and 4).

MVISR is a five-channel optomechanical scanning instrument operated at 360 rpm. The optical system consists of co-axial and co-focal paraboloid primary mirrors with a 20 cm diameter. The beam splitters of the VIS/IR channels divide the incident radiation into TIR, NIR and VIS beams which are projected onto the respective detectors (HgCdTe, single element Si detector, and three-element Si detector). The optical scanner consists of an elliptical Beryllium-based plane mirror and a driving motor. The mirror rotating axis is 45°. IFOV of 1.2 mrad (1.1 km spatial resolution) in HRPT mode and 4 km resolution in APT mode; FOV=55.4°; swath width = 2,860 km. Instrument calibration of the infrared channels is provided by a reference blackbody and by cold-space views in each scan period. The calibration parameters are transmitted as part of every data record. The TIR detector (HgCdTe) is operated at 105 K (cooled by a radiation cooler).

Channel	Wavelength (μm)	Objectives/Primary Use
1	0.58 - 0.68	Daytime cloud and surface imaging
2	0.725 - 1.10	Daytime cloud image and water, ice, snow, and vegetation observation
3	0.48 - 0.53	Ocean color imaging
4	0.53 - 0.58	Ocean color imaging
5	10.5 - 12.5 (TIR)	Diurnal cloud image surface observation and sea surface temperature

Figure 207: MVISR characteristics

Communications in real-time. Capability of on-board data storage. The satellites provided data in three modes: HRPT (High Resolution Picture Transmission) at 665.4 kbit/s, APT (Automatic Picture Transmission), and DPT (Delayed Picture Transmission). The data formats of HRPT and APT are very similar to those of the NOAA series satellites (satellite attitude is included).¹²⁰²⁾

The FY-1 series ground segment consists of three ground stations located in Beijing, Guangzhou and Urumqi; a data processing center is at NSMC (National Satellite Meteorological Center). NSMC broadcasts the FY-1 orbital prediction via GTS so that users throughout the world may receive HRPT and APT data in real time.¹²⁰³⁾

Carrier Frequency	Data Rate Subcarrier Frequency	Modulation Mode	Power
HRPT: 1695.5, 1704.5 MHz	0.6654 Mbit/s	PCM/PSK	5 W
APT: 137.035, 137.795 MHz	2.4 kHz	AM/FM	8 W

Table 353: HRPT/APT transmission channel characteristics of FY-1

Status of missions:

FY-1A (launch Sept. 7, 1988). The S/C went into its predicted orbit and started to make observations on the same day. The imagery was all nominal with an observed SNR higher than the design value. After 39 days of operations, the FY-1A satellite suffered serious malfunctions in its attitude control system and was lost thereafter as a consequence. Another problem was observed on the instrument infrared detectors in form of water vapor contamination, causing the loss of the IR signal.

FY-1B (launch Sept. 3, 1990). The S/C reached its predicted orbit and provided a considerably improved operations environment on the accuracy and stability of S/C attitude as well as for the observing instruments. However, after operations for half a year, the same atti-

¹²⁰³⁾ Ch. Weng, et al, "Remote Sensor on the FY-1 Satellite", Paper IAF-92-099, 43rd Congress of the International Astronautical Federation, August-September 1992

tude problems occurred as with the FY-1A S/C. This time around ground operations were able to rescue the S/C. Observations were continued until late 1992 when again attitude problems brought the mission to an end.

G.3.2 Feng-Yun-1C and -1D

The FY-1C/D S/C are upgraded versions of the FY-1B satellite. A major effort has been made to improve the S/C reliability. The satellite structure is a hexahedron with body dimensions of 1.42 m x 1.42 m x 1.2 m. The deployed length of the S/C is 10.5 m. There are two solar panels, each with a total collecting area of 9.58 m² providing power of 250 W. The S/C is three-axis stabilized with a pointing accuracy of 0.4°. Two MVISR instruments (one redundant) are mounted on the nadir-facing side of the S/C. The S/C mass is 954 kg, the S/C design life is two years. ^{1204) 1205) 1206)}

FY-1C was launched May 10, 1999 [along with the science exploratory satellite named Shi Jian-5 (SJ-5)] on a CZ-4B vehicle from the Taiyuan launch site, China.

Orbit: Sun-synchronous polar orbit, altitude = 863 km, inclination = 98.8°, period = 102.3 minutes, eccentricity < 0.005. ^{1207) 1208) 1209)}

A launch of FY-1D, planned for the fall 2001, was postponed to 2002.

Sensor complement:

MVISR (Multichannel Visible and IR Scanning Radiometer), developed and built by SITP (Shanghai Institute of Technical Physics). The upgraded MVISR is now a 10-channel instrument (the total number of bands was doubled for the -1C and -1D instruments from the previous -1A and -1B instruments). The optomechanical instrument has a scan mirror with a rotation rate of 360 rpm. The aperture of the optical system is 200 mm in diameter. The IFOV = 1.2 µrad, the nadir resolution of all channels is 1.1 km. The instrument FOV is ±55.4° (2800 km swath). The scan rate of MVISR is 6 lines/s, the total number of pixels of every scan line is 2048.

Band No	Spectral Range (µm)	Primary use of data
1	0.58 - 0.68 (VIS)	Daytime clouds, ice and snow, vegetation
2	0.84 - 0.89 (VNIR)	Daytime clouds, vegetation, water
3	3.55 - 3.93 (MWIR)	Heat source, night cloud
4	10.3 - 11.3 (TIR)	SST, day/night clouds
5	11.5 - 12.5 (TIR)	SST, day/night clouds
6	1.58 - 1.64 (SWIR)	Soil humidity, ice/snow distinguishing
7	0.43 - 0.48 (VIS)	Ocean color
8	0.48 - 0.53 (VIS)	Ocean color
9	0.53 - 0.58 (VIS)	Ocean color
10	0.90 - 0.965 (VNIR)	Water vapor

Detector material	Si detector for bands 1,2, 7, 8, 9, 10 HgCdTe for bands 3, 4, 5 and 6
Cooler	Radiant cooler operating at 105 K
Radiometric sensitivity	NEDR $< 3 \times 10^{-4}$, bands 1, 2, 7, 8, 10 NEDR $< 1 \times 10^{-3}$, band 6 (Noise Equivalent Delta Radiance) NEDT < 0.27 K, band 3 NEDT < 0.25 K, band 4, 5 (Noise Equivalent Delta Temperature)
Radiation calibration accuracy	$> 10\%$ for VIS and IR bands, 1.0 K for TIR bands
Scan rate	6 lines/s
Pixels per scan line	2048 for CHRPT and DLPT data 1018 for DGPT data
Data quantization	10 bit
Instrument mass, power	55 kg, 45 W

Table 355: Specification of the MVISR instrument

Communication: The High Resolution Picture Transmission mode of FY-1C and FY-1D is named CHRPT (China HRPT or simply CHRPT), implemented in S-band. The data rate of CHRPT is 1.3308 Mbit/s, the modulation is BPSK/Bi-phase, the polarization is right hand circular, the EIRP = 39.4 dbm. The transmission frequency is 1700.5 MHz. The data format is very similar to that of HRPT of the NOAA satellites. The on-board data storage capacity is increased to 300 minutes of data take (compared to 60 minutes on FY-1A/1B). This offers the provision of a parallel (to CHRPT) low-rate data stream, once per day, of four selected channels with reduced resolution (3.1 km) data, the low-rate transmission rate is 88.72 kbit/s. The low-rate data is referred to as DGPT (Delayed Global Picture Transmission), while the ten-channel data with 1.1 km resolution from anywhere in the world is referred to as DLPT (Delayed Local Picture Transmission). There is no support provided for APT mode communications.

G.3.3 Feng-Yun-3 (FY-3) Satellites

The FY-3 series represents the second generation of Chinese polar orbiting meteorological satellites. The first launch of this series is planned for 2004. The overall objectives of the FY-3 series are:

- To provide global measurements of 3-D thermal and moisture soundings of the atmosphere, and to measure cloud and precipitation parameters in support of NWP (Numerical Weather Prediction).
- To provide global imagery of large-scale meteorological and/or hydrological events and biosphere environment anomalies
- To provide geophysical parameters in support of global change and climate monitoring.

G.4 METEOR-1 Series

“Meteor” is the Soviet/Russian generic name for its Low-Earth-Orbiting (LEO) meteorological satellite family which started operation in 1969 (built by VNIIE, Moscow). Sponsoring agency: ROSHYDROMET, the Russian Federal Service for Hydrometeorology and Environmental Monitoring. Prior to this series there was an experimental Cosmos series with the first orbiting meteorological satellite, “Cosmos-44,” which was launched on August 25, 1964, and was followed by nine analogous Cosmos satellites until 1969, when the series was officially named ‘Meteor-1.’ The designations of the series Meteor-1, -2, and -3 define different payload configurations and different orbits; the Meteor-3 series is presently the most advanced payload generation and the operational series. A total of 25 Meteor-1 satellites were launched from 1969 to 1977 (three to four launches per year, see Table 361). Note:

Meteor-1-18 is also referred to as Meteor-Priroda-1; Meteor-1-25 is also named Meteor-Priroda-2, and Meteor-1-28 is the Meteor-2-2 satellite.^{1210),1211)}

Background:¹²¹²⁾ ROSHYDROMET is the national central agency providing relevant environmental and climate information to the public, various industrial organizations and decision-making bodies. Hydrometeorological services together with the provision of information on environmental pollution are based on the performance of the National Observing System for the State of the Environment and Climate (GSPN). GSPN operates data acquisition facilities (ground network of synoptic, hydrological and upper-air stations, weather radars, aircraft, rocket sounding stations, satellites and ocean ships), telecommunication and processing facilities, analysis and forecasts based on advanced atmospheric and hydrological models.

Application: Meteorological sciences, operational meteorology

Orbit: Non-sun-synchronous polar orbit, average altitude of 650 km for the first nine satellites and 900 km for the rest of the series, inclination = 81-82°.

Sensors:

- **TV** = TV optical instrument (MR-600A). Framing (vidicon technique). Spectral range: 0.4 - 0.8 μm ; swath width = 1000 km; resolution = 1.25-3 km;
- **IR** = TV IR instrument Lastocha. Spectral range: 8 - 12 μm ; swath width = 1000 km; resolution = 15 km;
- **AC** = Radiation Budget Sensor. AC is a narrow-sector device which measures the sun's radiation fluxes, the thermal radiation of the Earth's surface, cloud cover and the atmosphere. Spectral range: 0.3 - 30 μm ; swath width = 2500 km; resolution = 40 km x 50 km.

The Meteor series, somewhat similar to the NOAA-TIROS series, provides a daily weather review for more than two-thirds of the globe, observation of clouds, ice cover and atmospheric radiation; these satellites also permit the study of weather fronts and jet stream currents and monitor of clear-air turbulence (for warning intercontinental airliners, etc.).

G.5 METEOR-2 Series

Soviet/Russian Earth observation satellite series in the field of meteorology. Sponsoring agency: ROSHYDROMET. The Meteor-2 series (developed and built by VNIIEM) came into use in 1975. Until 1990, 21 satellites of this type have been launched. The system comprises two to three satellites continuously operating in near polar orbit with an average altitude of 900 km.

Orbit: Non-sun-synchronous polar orbit, altitude between 850 and 950 km, inclination = 81-82°.

Sensor complement:

The on-board instrument package includes three television-type (frame technique) VIS and IR scanners, a five-channel scanning radiometer and a device (RMK) for measuring radiation flux densities in the near-Earth space (see sensor definition of Meteor-3 series).

The Meteor-2-22 (launch Aug. 31, 1993) satellite carried in addition to its regular payload a unique **Fizeau RRA (RetroReflector Array)** for SLR (Satellite Laser Ranging) applications. SLR tracking of this satellite was used for precise orbit determination until Oct. 1998. The

¹²¹¹⁾ The original text was reviewed by Y. V. Trifonov of VNIIEM, Moscow

¹²¹²⁾ COSPAR-90-Paper by A. Karpov, USSR State Committee for Hydrometeorology, Moscow. Title of paper: "Hydrometeorological, Oceanographic and Earth-Resources Satellite Systems operated by the USSR."

retroreflector array consists of three corner cubes in a linear array with the two outer corner cubes pointing at 45° angles relative to the central cube. The central cube is made of fused silica and has a two-lobe FFDP (Far Field Diffraction Pattern) providing nearly equal intensities for compensated and uncompensated velocity aberration. Both outer reflectors have aluminum coating on the reflecting surfaces and near-diffraction-limited FFDPs. One of the end reflectors is made of fused silica with an index of refraction of 1.46; it provides partial compensation of the velocity aberration. The other end reflector is made of fused glass with an index of refraction of 1.62; it provides a perfect compensation of the velocity aberration. ¹²¹³⁾

G.6 METEOR-Priroda Series

USSR experimental mission series considered predecessor of the Resurs-O1 series (see D.32). Sponsoring agency: ROSHYDROMET. First Earth resources satellite series for continuous imaging from space. First launch: July 9, 1974. In 1983 Meteor-Priroda data were used to determine snow depths for all Soviet agricultural regions, to assist in planning the spring work season and to forecast the harvest. The Meteor-1 series universal platform was also used for the Meteor-Priroda series up to No. 4. Starting with Meteor-Priroda-5, a Meteor-2 platform was employed.

Orbit: Sun-synchronous polar orbit, altitude = 630 km, inclination = 98°, period = 97-98 minutes, repetition cycle = 16 days

Sensor complement:

- **MSS Fragment** (Multispectral Scanning System Fragment). ¹²¹⁴⁾ ¹²¹⁵⁾ Fragment was designed and developed at IKI (Space Research Institute) in Moscow. The instrument is an optomechanical scanning (whiskbroom) system of high resolution [analogous in function to MSS (Multispectral Scanner System) on Landsat]. The optical subsystem (built by VEB Kombinat Carl Zeiss, Jena) employs a Cassegrain telescope with an aperture of 24 cm diameter and a focal length of 1 m. The scan frequency is 13.02 Hz (cross-track direction). The detector system uses an array of 35 photodiodes. There are eight spectral bands: a) 5 bands are in the spectral range of 0.4-1.0 µm, all with a spatial resolution of 80 m; b) 2 bands in the SWIR range of 1.2 - 1.8 µm with a resolution of 240 m, and c) 1 SWIR band in the range 2.0 - 2.4 µm with a resolution of 480 m. The swath width is 85 km; the instrument data rate is 5.6 Mbit/s. Instrument mass = 280 kg; size: 1.66 m x 1.44 m x 0.73 m; power = 220 W. Extensive pre-launch calibrations were conducted in facilities especially built for Fragment. The first and only launch of MSS Fragment took place on Meteor-Priroda-5 on June 18, 1980. Fragment operated onboard the spacecraft for 4 years.
- **MSU-S** = Multispectral Scanner of moderate resolution (two-channels). Spectral range: 0.58 - 0.7 µm, and 0.7 - 1.0 µm, resolution = 140 - 240 m, swath width = 1380 km.
- **MSU-SK** = Multispectral Scanner of moderate resolution with conical scanning. Spectral ranges: 0.5 - 0.6, 0.6 - 0.7, 0.7 - 0.8, 0.8 - 0.9 µm. Spatial resolution = 175-243 m (in VIS) and 500 m (in IR); swath width = 600 km
- **MSU-E** = High-Resolution Multispectral Scanner with Electronic Scanning. Three spectral ranges: 0.5 - 0.7 µm, 0.7 - 0.8 µm, and 0.8 - 1.0 µm. Spatial resolution = 28 x 28 m; swath width = 28 km. Spaceborne CCD detector technology was introduced with

MSU-E, first flown on the Meteor-Priroda-5 (launch June 18, 1980) spacecraft of the former Soviet Union. ¹²¹⁶⁾ MSU-E was built at ISDE (Russian Institute of Space Device Engineering) in Moscow; it featured a CCD line array of 1024 pixels, three parallel line arrays, each of 1024 elements, and provided pushbroom imagery in three spectral bands (visible range). MSU-E provided a nadir view with a FOV of 2.5°. A radiation cooler provided a detector temperature in the range of -30 to -50°C. Instrument mass of 17 kg. No in-flight calibration was performed.

- **MSU-M** = Multispectral Scanner of low resolution; swath width = 2000 km; resolution = 1 km x 1.7 km; four spectral ranges: 0.5 - 0.6, 0.6 - 0.7, 0.7 - 0.8, 0.8 - 1.0 μm .
- **SHF** = Passive MW Radiometer measuring the emission radiation of the atmosphere/ocean system at the following microwavelengths/frequencies: 0.8 cm (37.5 GHz), 1.35 cm (22.22 GHz), 1.55 cm (19.4 GHz), and 4 cm (7.5 GHz). The swath width = 800 - 900 km depending on orbit height. Resolution = 1.2 - 3.0°.
- **SI-GDR** = Spectrometer/Interferometer (German Democratic Republic). An infrared Fourier spectrometer (original designation: PM = Profile Module) with the objective of temperature profile measurements in the atmosphere. Spectral range: 6.25 - 25 μm ; spectral resolution = 5 cm^{-1} ; nadir pointing; resolution = 2.2 x 2.4°.
- **R10M** = Radiation Measurement Complex, analogous to RMK-2

Name of Satellite	Launch Date	Period (min)	Perig. (km)	Apog. (km)	I (°)	Remarks / Sensor Complement
Meteor-P-1	9.7.1974	102.6	877	905	81.2	MSU-M, MSU-S, TV, IR., SHF

Table 356: Overview of the Meteor-Priroda missions

G.7 METEOR-3 Series

Russian Earth observation satellite series. Sponsoring agency: ROSHYDROMET. The first Meteor-3 launch was on Oct. 24, 1985 from Plesetsk using the F2 launch vehicle. The Meteor-3 series is the current generation of Russian meteorological satellites. Nominal lifetime = 2 years.

The spacecraft series incorporates three-axis stabilization (0.5° accuracy) and twin 10-m span solar panels. The orbit is adjusted by ion thrusters. Meteorological data is transmitted to four primary sites in Russia (USSR) in conjunction with about 80 other smaller sites. Internationally compatible Automatic Picture Transmission (APT) was made available on 137 - 138 MHz channels to ground workstations.

Both Meteor-2 and Meteor-3 satellite types provide main and regional centers of Russia and CIS with global data on the distribution of clouds, snow and ice in VIS and IR bands, radiation flux data at least twice daily, atmospheric temperature-humidity sounding data, data on the temperature of the ground surface, cloud-top heights and sea surface temperature.

¹²¹⁶⁾A. S. Selivanov, Y. M. Tuchin, M. K. Naraeva, B. I. Nosov, "Experimental Satellite System for Earth Monitoring," *Issledovanie Zemli iz Kosmosa*, W 5, 1981

Russian plans envisage the development of an integrated hydrometeorological satellite system in the 90s, comprising geostationary and low-orbit satellites. Instruments on-board the geostationary satellites will provide continuous observations of the Earth's disk (footprint) within 60° with respect to a stationary point over the equator.

Orbit: Non-sun-synchronous near-polar prograde orbit, drifting slowly with local time; altitude = 1230 km; inclination = 82.5° ; period = 109 minutes; the higher altitude of Meteor-3 enables an extension of the instrument swath width, thereby providing complete coverage of the Earth's surface.

Figure 208: The Meteor-3 series S/C model

Sensor complement:

1) Television Systems

TV camera systems **MR-2000M** and **MR-900B**. Objective: Observation of daytime Earth cloud cover in the visible spectrum ($0.5 - 0.7 \mu\text{m}$) at a local solar angle not less than 5° . Spatial resolution of 0.7-1.4 km for MR-2000M and 1-2 km for MR-900B. The swath width = 3100 km (MR-2000) and 2600 km (MR-900). The MR-2000M camera provides storage and direct transmission operation. The MR-900B camera has no storage operation mode (only direct transmission). The data acquisition range is stable within a radius of 3000 km. Output products: individual images, photomosaics of images from 2-3 passes over receiving station within 300 km in radius. Global photomosaics of images of various regions of the globe (twice daily), cloud-free photomosaics of arctic and antarctic oceans once in five days.

Parameter	Real-time Mode	Store-and-forward Mode
Swath width (km)	2600	3100
Number of pixels/scan line	900	2000
Number of reproduced brightness levels	50	50

Table 357: TV system parameters

2) Optical Scanning Systems

Klimat= Infrared Radiometer (operational since 1988)¹²¹⁷). An electromechanical device with a scan angle of $\pm 48^\circ$, a swath width of 1300 km, a spatial resolution of 0.45 km x 0.9 km; IFOV=0.7 x 1.4 mrad; surface temperature range = 223-313 K; temperature difference at 300 K, background = 0.2 K. Measurement spectrum: 10.5 to 12.5 μm . Instrument mass = 75 kg. Detectors: CdHgTe cooled to 80 K. Output products: Global photomosaics of Northern and Southern Hemispheres, tropical zone, individual images; digital SST and top-of-cloud height charts, tropical cyclone coordinates, cloud amount data on regular grid over the globe.

SM = Multichannel Spectrometer, also known as “**Device 174 K**” (optical instrument for atmospheric observation). Electromechanical device, scan angle = $\pm 24^\circ$. Scanning 10-channel IR radiometer for atmospheric thermal sounding. Spectral range: 9.65 - 18.7 μm (9.65, 10.60, 11.10, 13.33, 13.70, 14.25, 14.43, 14.75, 15.015, 18.70). Resolution = 42 km; swath width = 1000 km; output products: SATEM messages with atmospheric thermal sounding data (total ozone content)

3) Radiation Measurement System

RMK-2 = Radiation Measurement Complex. Objectives: Registration of flux densities of protons in the 5-90 MeV and electrons in the 0.15-3.0 MeV energy regions.

- Electron and proton flux density. Ranges: $2.5 \cdot 10^{-1}$ - $1 \cdot 10^5$ particles/cm²s, and 0.111 - $4.4 \cdot 10^3$ particles/cm²s
- Radiation dose exposition in the range: $1 \cdot 10^{-7}$ - $5 \cdot 10^{-4}$ particles/s
- Number of channels: 12

Meteor Data: There is a prime network of ground stations in Moscow, Novosibirsk, Chabarovsk, and Tashkent (operator/coordinator: NPO Planeta). There are also 80 APT (Automatic Picture Transmission, compatible with NOAA APT) stations in Russia/CIS receiving Meteor data (on 137-138 MHz). The APT stations provide data reception for Meteor and for NOAA series satellites.

A new feature of the Meteor program is the incorporation of sensors and instruments from other space agencies through international cooperation. The following foreign sensors/payloads are flown or planned on Russian missions:

4) Sensors/systems from other agencies

TOMS (NASA sensor)

A Meteor-3 series S/C (Meteor-3-6) was successfully launched on August 15, 1991 with a NASA sensor on-board.^{1218) 1219) 1220)} A refurbished TOMS sensor (of the original engineering model for Nimbus-7) was part of this payload. The instrument transmits its data to ground stations in the US and Russia on a daily basis (US archive at GSFC, Russian archive in Dolgoprudny outside of Moscow). The orbital lifetime was projected at two years. Objective: Mapping of vertical ozone profiles. TOMS has a swath width of 3100 km. Six spectral bands at: 0.3125, 0.3175, 0.3313, 0.3398, 0.360, and 0.380 μm . The ground resolution is 47 x

47 km at nadir and 62 x 62 km overall. Note: The TOMS instrument failed to provide operational service after December 27, 1994.

ScaRaB (Scanner for Radiation Budget), of CNES [France (CNES, LMD), Russia (Planeta, RKA), Germany (GKSS) are program partners]. ScaRaB is a joint development of a cross-track scanning radiometer. Its objective is the collection of data on shortwave and longwave radiation (reflected solar and emitted thermal radiation) to estimate the Earth's radiation budget at the top of the atmosphere on global and regional scales. The instrument features four channels. Channels 2 and 3 are considered the main channels, while channels 1 and 4 are auxiliary channels. The optical subsystem features four parallel telescopes, one telescope per channel, they are identical except for their filters. ^{1221) 1222) 1223)}

Nr.	Spectral band (channel)	Band description	Filter
1	0.5 - 0.7 μm	Visible channel: scene identification	Interference
2	0.2 - 4 μm	Solar channel: derivation of Earth radiation budget parameters	Fused silica
3	0.2 - 50 μm	Total radiation channel	None
4	10.5 - 12.5 μm	Atmospheric channel scene identification	Interference

Table 358: Spectral bands of ScaRaB

ScaRaB uses BARNES pyroelectric detectors for all bands (placed at the focus of a spherical aluminium mirror), which are sensitive only to the AC component of the signal (i.e. the modulated energy). Hence, chopping is needed for each pixel. This reduces the influence of the self radiation of the telescope and filters. Two mechanical choppers are used (one for two channels), providing a 10 Hz chopping frequency. The four channels, the two choppers, and a filter wheel dedicated to channel 2 and 3, are mounted on a scanning optical bench (rotor). The telescopes are swiveled by the optical bench so that no extra mirror for the scanning is needed. This reduces the likelihood of offsets dependent on the scanning angle.

The spatial resolution of ScaRaB data is 48 x 48 mrad, scan angle = 100°, swath width = 3200 km. ScaRaB points to nadir and scans the full field of view (FOV) within six seconds. In this cross-track mode data are generated continuously.

Parameter	Value	Parameter	Value
IFOV (spatial resolution)	48 mrad x 48 mrad (60 km x 60 km at nadir)	Sampling interval	34 mrad
FOV (swath)	100° (3200 km)	Sampling period	62.5 ms
Pixels per scan	51	Scan period	6 s
Dynamic range (solar)	up to 425 W m ⁻² sr ⁻¹	Useful scan time	3.18 s
Dynamic range (total)	up to 500 W m ⁻² sr ⁻¹	Instrument mass, power	40 kg, 42 W (average)
		Instrument size (mm)	614 x 512 x 320

Table 359: ScaRaB instrument parameters

Calibration subsystem: Gray lamps and blackbodies are used for on-board gain calibration; deep space is used for offset calibration. That subsystem comprises a set of two reference blackbodies for channels 3 and 4, and a set of gray calibration lamps for channels 1, 2 and 3. There is continuous thermal control of the blackbodies. The gray lamps are turned on during the calibration session (typically once per day). In addition, there are short wave references, consisting of two lamps for the calibration of channels 2 and 3 (typical use is once per month). On the ScaRaB/Meteor-3-7 mission, however, the lamp system was damaged so that actual calibration was performed by using the instrument temperature and a pre-

launch established gain-temperature law. The remaining lamps were then used to verify this calibration. During one year of operation, no significant sensor degradation was observed.

ScaRaB has a duty cycle of 100%, data rate=3 kbit/s, data volume=18 Mbit/orbit. An instrument mass memory provides data storage for up to 12 hours. The mass of the instrument is 40 kg, the maximum power use is 70 W.

The data processing system is based on algorithms for transforming the instantaneous measurements of radiances, filtered by the optics and detectors, into estimates of the monthly mean values of the radiant excitations in the solar and thermal domains, at the top of the atmosphere. This requires corrections for non-flat spectral response, anisotropic, and diurnal variations. The estimates are provided on a spatial grid of 250 km.

Parameter	Meteor-3 Series	Meteor-3M Series
Payload mass (kg)	700	900
Orbital altitude (km)	1200 - 1250	900 - 950

G.8 Meteor-3M Series

The Meteor-3M series represents a modernization of Russia’s national meteorological satellite system.¹²²⁶⁾ The US instrument SAGE-III is flown on the Meteor-3M-1 mission. A corresponding cooperative agreement was approved by the Gore-Chernomyrdin Commission on Dec. 16, 1994. Plans for Meteor-3M are to combine the meteorological observations of the Meteor-3 series with the Earth-surface observations of the Resurs series, starting with Meteor-3M-2.

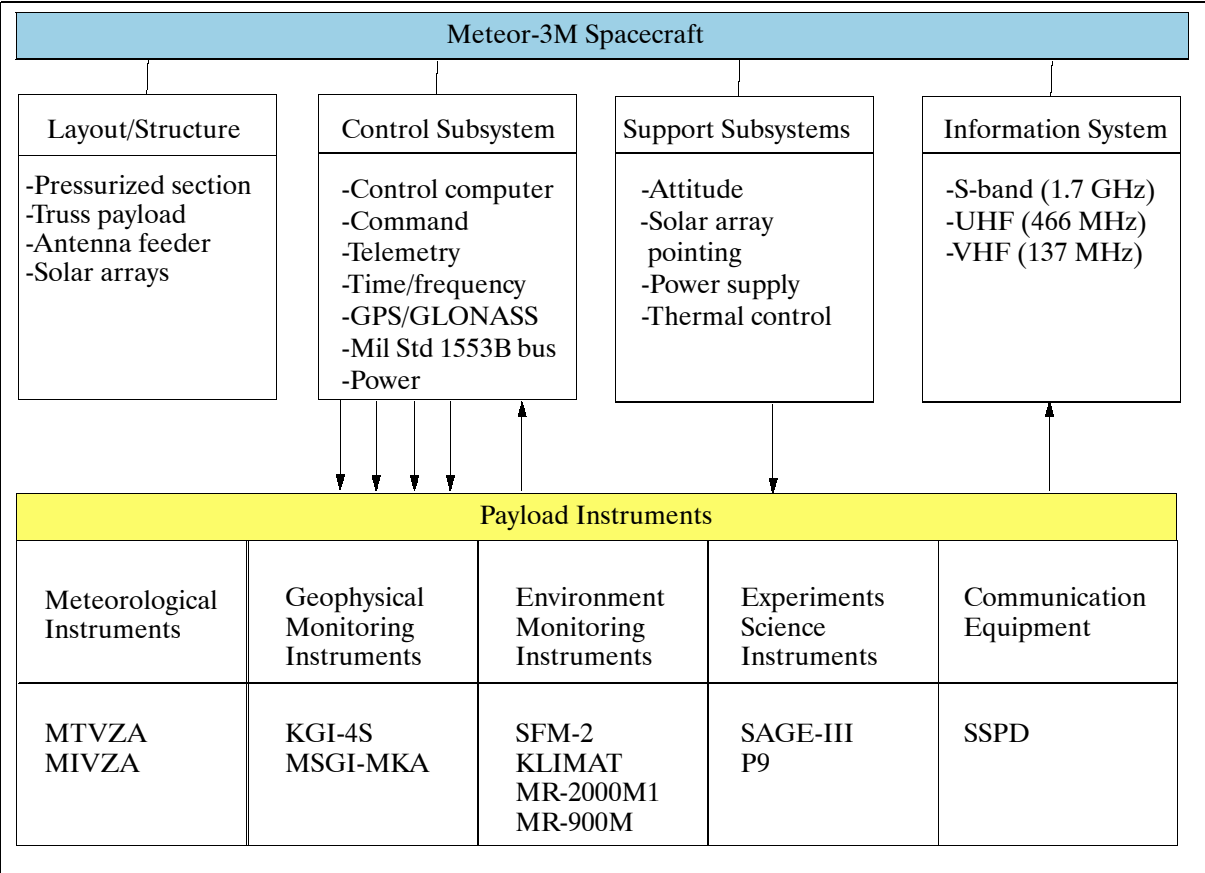

Figure 209: Functional layout of the Meteor-3M satellite

G.8.1 Meteor-3M-1

The Meteor-3M-1 spacecraft structure consists of: a) hermetic container with instrument rack , instrument platform, and c) solar arrays. Most electronics and some service system modules are contained in the hermetic container. Most payload instruments and some service modules are mounted to the external thermally stabilized platform. The spacecraft is three-axis stabilized. The S/C pointing accuracy 0.1°, the angular drift rate is 0.0005°/s. A navigation subsystem (GPS/GLONASS receiver) provides orbit determination and timing services. Solar power of 2 kW (BOL) is provided by two deployed panels which are continuously sun pointed for optimum power generation. The S/C mass is up to 800 kg (up to 370 kg of payload mass), the design life is seven years. The Meteor-3M-1 spacecraft was designed and built by NIIEM (Scientific Research Institute for Electromechanics) in Istra, Russia.

A launch of Meteor-3M-1 is planned for Nov. 2001 on a Zenit-2 launch vehicle from the Baikonur Cosmodrome, Kazakhstan. Secondary payloads on the flight are the Badr-2 satel-

lite of Pakistan, Maroc-Tubsat of Morocco, the Compass spacecraft of IZMIRAN, Moscow, and REFLECTOR (Retroreflector Ensemble For Laser Experiments Calibration Testing & Optical Research), a US/Russian nanosatellite, funded by AFRL and developed by ISDE (Institute of Space Device Engineering), Moscow. The objective of the passive REFLECTOR spacecraft is to support SLR (Satellite Laser Ranging) experiments.^{1227) 1228)}

Orbit: Sun-synchronous circular polar orbit, mean altitude = 830 km, inclination = 98.85°, period = 102 minutes; local time of ascending node is 9:15 AM

Data: On-board information system (OBIS) for recording of instrument data streams up to 150 kbit/s from a single instrument. The solid-state recorder has a capacity of 100 Gbit. OBIS provides time compression of collected streams with the following output options (RF data downlinks). OBIS has a mass of 20 kg and a power consumption of 32 W.

- S-band (N1 digital data streams, 1.67-1.71 GHz broadcast to HRPT-compatible stations at a data rate of 665.4 kbit/s, NOAA-POES series compatible)
- S-band (N2 digital data stream, 1.67-1.71 GHz broadcast to a ground network of AIRS (Autonomous Information Reception Station) at a data rate of 66.54 kbit/s)
- VHF-band (analog data stream, 137.3-137.85 MHz broadcast compatible with APT standard)
- X-band (8.320, 8.064 or 8.192 GHz, digital recorder dump rate of 61.44 Mbit/s and 15.36 Mbit/s to ground stations).

The S/C is being operated by the RSA Mission Control Center in Korolev (Moscow Region), Russia. The SAGE-III data capture and processing is being performed at NASA/LaRC via a WFF (Wallops Flight Facility) ground station.

Sensor complement: The Meteor-3M-1 sensor complement consists of the following instruments: MTVZA, MSU-MR (2 instruments), MSU-SR (2 instruments), IKFS-2, MSGI-MKA, KGS-4S, a DCS (Data Collection System), and SAGE-III of NASA/LaRC.

MTVZA (Microwave Radiometer for Temperature Sounding of the Atmosphere). MTVZA is a passive 20-channel microwave radiometer (similar to NOAA's AMSU-A and -B radiometers). The objective is to provide atmospheric temperature and humidity soundings (water vapor) for cloudy and clear-sky conditions.

Observation region	Parameter	Range of measurements	Error
Ocean	SST	4-30 m/s	±1.0 K
	Surface wind velocity		±2 m/s
Atmosphere	Ice: age (gradations)	up to 45 km 0-5 g/cm ² 0-5 kg/m ² 0-25 mm/h	3-4
	concentration		20%
	boundary		10 km
	Temperature profile		±1.5 K
	Column humidity		±0.25 g/cm ²
Land	Clouds: total amount, balls water content dynamics effec. temperature	up to 1.5 m	±0.2 kg/cm ²
	Rain rate		±3.0 K
	Thickness of dry snow		±5.0 mm/h
	Boundary of snow		±0.2 m ±10 km

Table 364: Performance characteristics of MTVZA

MSU-MR (Low Resolution Multispectral Scanner). The instrument features six spectral bands in VNIR, SWIR, and TIR (0.5-0.7 µm, 0.8-1.1 µm, 1.6-1.8 µm, 3.5-4.1 µm, 10.5-11.5 µm, and 11.5-12.5 µm). The spatial resolution is <= 1 km on a swath of 3000 km. The brightness temperature range is between 213-3313 K. The instrument has a mass of 30 kg and a power consumption of 100 W (max).

MSU-SR (Medium Resolution Multispectral Scanner). The instrument provides three spectral bands in VNIR (0.535-0.575 µm, 0.63-0.68 µm, 0.76-0.9 µm). The spatial resolution is 100 m on a swath of 1200-1600 km provided with two side-by-side instruments. The mass of one instrument is 5 kg with a power consumption of 15 W (max).

IKFS-2 (Infrared Fourier Spectrometer-2). The objective is atmospheric temperature and water vapor sounding. The instrument performs measurements in the spectral range of 5-15 µm; the spectral resolution is 0.5 cm⁻¹. Sampling steps of 150 km are provided on a swath of 2500 km. The pixel resolution at nadir is 35 km. A micro-cryogenic system is used to cool the infrared detectors. The instrument has a mass of 50 kg and a power consumption of 125 W.

Geophysical Monitoring System - consisting of two instruments: 1) **MSGI-MKA** (Spectrometer for Geoactive Measurements), and 2) **KGI-4S** (Radiation Monitoring System).

The **MSGI-MKA** instrument features four channels for the measurement of the following parameters:

- Electron fluxes in the energy range of 0.1-15 keV (high-sensitivity channel)
- Ion (proton) fluxes in the energy range of 0.1-15 keV (high-sensitivity channel)
- Electron fluxes in the energy range of 0.1-15 keV (low-sensitivity channel)
- Monitoring of integral electron fluxes with a threshold energy of 40 keV

The FOV (Field of View) is 10° x 10° for each channel (3) and 20° x 20° for the integral electron flux. The instrument has a mass of 5 kg and a power consumption of 6.8 W.

KGI-4S (Radiation Monitoring System). The objective is to monitor flux densities within the following threshold energy ranges:

- Total proton flux threshold energy of: 5, 15, 25, 30, and 40 MeV
- Total electron flux threshold energy of: 0.17, 0.7, 1.7, 2.0 and 3.2 MeV
- Proton fluxes with threshold energies of: 25 and 90 MeV

The KGI-4S instrument has a mass of 12 kg and a power consumption of 6.8 W (max).

SAGE III (Stratospheric Aerosol and Gas Experiment III), PI: M. P. McCormick, Hampton University, Hampton, VA (formerly NASA/LaRC). ^{1229) 1230) 1231) 1232) 1233)} The instrument was built at Ball Aerospace of Boulder, CO, as prime contractor. SAGE-III was selected to fly on Meteor-3M and on ISS (International Space Station) in 2004. SAGE III is an Earth limb-scanning grating spectrometer to measure vertical profiles of aerosol, ozone and other constituents in the atmosphere. The SAGE-III instrument is part of the NASA EOS mission in characterizing the Earth system.

Background and heritage: SAM [SAM (Stratospheric Aerosol Measurement) was flown on ASTP (Apollo-Soyuz Test Project), July 15-24, 1975, to perform the first successful solar occultation measurement of stratospheric aerosol], SAM II (launch Oct. 24, 1978 on Nimbus-7, see M.17.7), SAGE I, SAGE II). Both SAM and SAM-II were single spectral instruments measuring the aerosol extinction near the 1000 nm wavelength region. Multiple spectral measurements began with SAGE-I, with a launch on the AEM-2 (Application Explorer Mission-2) satellite, Feb. 18, 1979 (see A.5). SAGE-II is an advanced version of SAGE-I with 7 channels at 385, 448, 453, 525, 600, 940, and at 1020 nm. SAGE-II was flown on ERBS with a launch on Oct. 5, 1984 (see A.13). The measurements of SAM-II, SAGE-I and SAGE-II have provided long-term observations of aerosol and ozone for over 20 years.

The SAGE-III instrument has the following science objectives:

- Retrieve global profiles (with 1 to 2 km vertical resolution) of atmospheric aerosols, ozone, water vapor, NO₂, NO₃, OClO, temperature and pressure in the mesosphere, stratosphere and troposphere
- Investigate the spatial and temporal variability of the measured species in order to determine their role in climatological processes, biogeochemical cycles, the hydrologic cycle, and atmospheric chemistry
- Characterize tropospheric and stratospheric aerosols and upper tropospheric and stratospheric clouds, and investigate their effects on the Earth's environment, including radiative, microphysical, and chemical interactions
- Extend the SAM II, SAGE I and SAGE II self-calibrating solar occultation data sets (begun in 1978), enabling the detection of long-term trends

- Provide atmospheric data essential for the calibration and interpretation/correction of other satellite sensors, including EOS- and ground-based sensors.

Figure 210: Illustration of the SAGE-III instrument

Measurement approach: Self-calibrating solar and lunar occultation, with nine spectral channels, from 280 to 1550 nm, to study aerosols, ozone, OClO, NO₂, NO₃, water vapor, temperature, and pressure. The instrument looks at the sun (or the moon) through the Earth’s limb, utilizing a two-axis passive suntracker with a scan mirror, that scans the FOV across the solar disk (obtaining multiple samples at each altitude).

Spectral channels: 9 solar	290-1550 nm
FOV (Field of View)	± 185° in azimuth, -24.81 to -31.02° in elevation from local horizontal
IFOV	1-2 km vertical resolution; ±0.5 km vertical at 20 km tangent height
Thermal control	Passive heaters and thermal electric cooler
Thermal operating range	10-30° C
Data quantization, data rate	16 bit, 100 kbit/s for 8 minutes (three times per orbit)
Duty cycle	Measurements during solar and lunar occultations
Instrument mass, power, size	76 kg (total, 35 kg sensor), 80 W, 73 cm x 45 cm x 93 cm

Table 365: Some SAGE-III instrument parameters

SAGE-III consists of three major subsystems:

- 1) Pointing subsystem: It consists of a scan mirror which acquires the radiant target and performs vertical scanning across the target. The scan mirror is mounted on an azimuth drive which rotates over 360° for pointing in azimuth direction.
- 2) Imaging subsystem. The objective is to produce a focused image of the target at a focal plane where the instrument’s field of view is situated. - A Dall-Kirkham telescope design is used with an f/4 ratio. A slit (1/2 x 5 arcmin), located in the focal plane, serves as aperture and as entrance slit to the grating spectrometer. The entire telescope assembly, including scan mirror, can rotate in azimuth to eliminate the problem of image rotation during azimuth rotation. The target sensor assembly is mounted on the back of

the telescope secondary and on the side of the telescope housing. The target sensor consists of a bi-level photodiode, capable to perform both solar and lunar acquisition with a change in dynamic range of six orders of magnitude.

- 3) Spectrometer subsystem. The objective is to measure solar radiation from 280 to 1040 nm and 1 to 2 nm spectral resolution. An additional photodetector measures radiation at 1550 nm. The spectrometer is a new design, utilizing a holographic, aberration-reduced grating to provide stigmatic imaging at 440 and 868 nm with 1 nm resolution below 450 nm and 2 nm resolution between 740 and 960 nm. The detector array consists of two elements, a Tektronix 800x10 pixel backside-illuminated CCD array (283-1030 nm range) and an infrared photodiode (InGaAs type for measurements at 1550 ± 15 nm) that are spatially co-registered.

Cha. No.	Spectral center or range (nm)	Channel accuracy (nm)	No. of sub-channels	Bandwidth at FWHM (nm)	Cut-off range (nm)	Integration time (ms)	SNR

1020	Aerosol	0-35	5	-	-
1550	Aerosol	0-35	5	-	-

Table 367: SAGE III measurement capability (single profile)

The spectrometer with the CCD array assembly provides continuous wavelength coverage between 290 and 1040 nm with a spectral resolution between 1.2 to 2.5 nm, permitting the measurement of multiple absorption features of each gaseous species and multi-wavelength measurement of broadband extinction by aerosols. Nine channels are routinely uti-

lized in solar occultation measurements and three channels are used in lunar measurements. - Spectral calibration is continuous, combined with the self-calibrating nature of the occultation technique. In addition, the CCD array permits in-orbit wavelength and intensity calibration from observations of the exo-atmospheric solar Fraunhofer spectrum.

The SAGE-III retrieval algorithm is a procedure converting the instrument’s response to solar or lunar flux (about 70-80 spectral bands) into vertical profiles of molecular density of gaseous species, aerosol extinction at eight wavelengths, temperature, and pressure.

Product name	Accuracy: Systematic/random	Vertical coverage
Aerosol extinction at 8 wavelengths (solar)	5% / 5%	0-40 km
H ₂ O concentration	10% / 15%	0-50 km
NO ₂ concentration & slant path column amount	10% / 15%	10-50 km, 10-50 km
NO ₃ concentration (lunar)	10% / 10%	20-55 km
O ₃ concentration & slant path column amount	6% / 5%	6-85 km, 50-85 km
OCIO concentration (lunar)	25% / 20%	15-25 km
Pressure	2% / 2%	0-85 km
Temperature profile (solar)	2 K / 2 K	0-85 km
Cloud presence	N/A	6-30 km

Table 368: Overview of some SAGE-III products

G.9 NPP (NPOESS Preparatory Project)

NPP is a joint NASA/IPO (Integrated Program Office) mission with a planned launch in late 2005 and a mission duration of five years. The two objectives are to demonstrate the performance of three advanced sensors and their associated Environmental Data Records (EDR), such as sea surface temperature, and to provide data continuity for key data series initiated by NASA’s EOS Terra and Aqua missions. Because of this second role, it is sometimes known as a bridging mission. Two of the mission instruments are **VIIRS** (Visible/Infrared Imager and Radiometer Suite) and **CrIS** (Cross-Track Infrared Sounder). Both are under development by the IPO. NASA/GSFC develops a third sensor, namely **ATMS** (Advanced Technology Microwave Sounder). This suite of sensors is able to provide cloud, land and ocean imagery, covering the spectral range from the visible to the thermal infrared, as well as temperature and humidity profiles of the atmosphere. In addition, NASA is developing the NPP S/C and providing the launch vehicle (Delta-2 class). IPO is providing satellite operations and data processing for the operational community; NASA is supplying additional ground processing to support the needs of the Earth science community.¹²³⁴⁾
¹²³⁵⁾

Satellite system overview:

The ACS (Attitude Control Subsystem) provides 3-axis stabilization using 4 reaction wheels for fine attitude control, 3 torquer bars for momentum unloading, thrusters for coarse attitude control (such as during large-angle slews for orbital maintenance), 2 star trackers for fine attitude determination, 3 gyros for attitude and attitude rate determination between star tracker updates, 2 Earth sensors for safe-mode attitude control, and coarse sun sensors for initial attitude acquisition, all monitored and controlled by the spacecraft controls computer. ACS provides real-time attitude knowledge of 10 arcsec (1 sigma) at the S/C navigation reference base, real-time spacecraft position knowledge of 25 m (1 sigma), and attitude control of 36 arcsec (1 sigma). The EPS (Electrical Power Subsystem) uses GaAs solar cells to generate power of about 1.5 kW (EOL). The solar array rotates once

¹²³⁴⁾Information provided by Raynor L. Taylor of NASA/GSFC

¹²³⁵⁾<http://jointmission.gsfc.nasa.gov/>

per orbit to maintain a nominally normal orientation to the sun. In addition, a single-wing solar array is mounted on the anti-solar side of the S/C; its function is to preclude thermal input into the sensitive cryo radiators of the VIIRS and CrIS instruments. A regulated 28 ± 6 VDC power bus distributes energy to all S/C subsystems and instruments. A NiH (Nickel Hydrogen) battery system provides power for eclipse phase operations. The C&DHS (Command & Data Handling Subsystem) collects instrument data (12 Mbit/s max total) via an IEEE 1394a-2000 “firewire” interface, and stores the data on-board. Upon ground command or autonomously, the C&DHS transmits stored instrument data to the communication system for transmission to the ground. Also, the C&DHS generates a real-time 15 Mbit/s data stream consisting of instrument science and telemetry data for direct broadcast via X-band to in-situ ground stations.

The spacecraft is designed to be highly autonomous. For satellite safety, the S/C controls computer monitors spacecraft subsystem and instrument health. It can take action to protect itself (for example, in the event of an anomaly that threatens the thermal or optical safety and health of the S/C, then it can enter into a safe or survival mode and stay in the mode indefinitely until ground analysis and resolution of the anomaly). In addition, the satellite is designed to require infrequent uploads of commands (the instruments operate mainly in a mapping mode and therefore require few commands even for periodic calibration activities, and a sufficiently large command buffer is available for storage of approximately 16 days of commands).

The spacecraft has an on-orbit design lifetime of 5 years (available consumables for 7 years). The S/C mass is about 1400 kg. NPP is designed to support controlled reentry at the end of its mission life (via propulsive maneuvers to lower the orbit perigee to approximately 50 km and target any surviving debris for open ocean entry). NPP is expected to have sufficient debris that survives reentry so as to require controlled reentry to place the debris in a pre-determined location in the ocean.

The launch of NPP is planned for late 2005 on a Delta-2 vehicle from VAFB.

Background: The satellite is in a competitive down-select phase, with preliminary designs presented by two spacecraft developers (Ball Aerospace of Boulder, CO, and SpectrumAstro of Gilbert, AZ). Two preliminary design contracts were awarded in March 2000, and preliminary design reviews took place in late 2000. Award of the spacecraft development contract is planned for 2002, and instrument deliveries to the spacecraft developer are planned for 2004.

Communication of data: The satellite collects instrument data, stores the data onto a solid-state recorder of about 200 Gbit capacity. All data are transmitted either via Ku-band through the NASA Tracking and Data Relay Satellite System (TDRSS) network, or via X-band at 300 Mbit/s to polar ground stations. In addition, the satellite directly broadcasts all instrument data at 15 Mbit/s via an Earth-shaped antenna to in-situ direct broadcast receive terminals (similar to the service provided by the EOS Terra and Aqua satellites). The TT&C function uses S-band communications with uplink data rates of up to 16 kbit/s and downlink rates of up to 128 kbit/s. The NOAA network of polar ground stations will be used for mission operations (back-up TT&C services via TDRSS through S-band omni antennas on the satellite). The performance goal calls for EDR delivery within 3 hours of acquisition. NPP also focuses on ground segment risk reduction by providing and testing a subset of an NPOESS-like ground segment. Developed algorithms can be thoroughly tested and evaluated. This applies also to the methods of instrument verification, calibration, and validation.

Orbit: Sun-synchronous near-circular polar orbit, altitude = 824 km, inclination = 98.7° , equatorial crossing time at 10:30 AM ± 10 minutes on descending node. The repeat cycle is 16 days (quasi 8-day).

ATMS (Advanced Technology Microwave Sounder). A NASA-provided instrument (built by Aerojet of Azusa, CA) with the objective to combine the passive-microwave observation capabilities of three heritage instruments, namely AMSU-A1/A2 and AMSU-B/MHS, into a single instrument with a correspondingly reduced mass and power consumption and with advanced microwave-receiver electronics technologies. ATMS is a passive total power microwave sounder whose observations (measurement of microwave energy emitted and scattered by the atmosphere), when combined with observations from an infrared sounder (CrIS), provide daily global atmospheric temperature, moisture, and pressure profiles.

Table 369: Channel characteristics of ATMS

ATMS will replace instruments currently flying on POES satellites. The new instrument is about one-third the size and mass of the existing microwave sounding instruments (on

1236) R. E. Murphy, R. Taylor, et al., "The NPOESS Preparatory Project: Mission Concept and Status," IGARSS 2001, Sydney, Australia, July 9-13, 2001

POES and on Aqua). This miniaturization of ATMS is enabled by the application of new technologies, principally in the area of microwave electronics. Also, this miniaturization enables the use of smaller spacecraft to fly ATMS and the other required instruments, thereby reducing the cost of future weather and climate research satellites.

ATMS is a cross-track scanning total power microwave radiometer, with a swath width of 2300 km and a spot size of approximately 1.5 km [the native observation resolution is finer than 1.5 km (in fact about 0.5 km), but ground processing performs a spatial averaging computation to increase the SNR]. Thus, the spatial resolution of the ATMS data products is 1.5 km. Two continuously rotating reflectors direct the microwave energy emitted by the atmosphere into four feedhorns, via tuned reflectors. Microwave detectors and associated electronics filter the microwave signal to measure 22 separate channels from 23 to 183 GHz, and convert the channels into electrical signals that are then digitized. The instrument includes on-board calibration sources viewed by the reflectors during each scan cycle. In addition, cold space is viewed during each scan cycle. Both calibrations provide for the highly accurate microwave sounding measurements required by the operational and science applications of ATMS data. The instrument data are transmitted to the spacecraft via a MIL-STD-1553B bus interface. ATMS has a mass of about 66 kg and consumes about 85 W of orbital average power.

On the ground, ATMS raw data are converted into brightness temperature measurements by channel, are radiometrically corrected using calibration data, and are ortho-rectified. ATMS brightness temperatures by channel are then used in conjunction with the corresponding data from the infrared sounder (CrIS) to retrieve atmospheric temperature and humidity profiles for use in data assimilation algorithms for operational or climate research use.

Figure 211: Schematic illustration of ATMS

The instruments **CrIS** (Cross-Track Infrared Sounder) and **VIIRS** (Visible/Infrared Imager and Radiometer Suite) are defined under NPOESS (R.147.3).

Technology demonstrations:

- Use of advanced low noise amplifier technology for atmospheric sounding (ATMS)
- S/C on-board processing using reconfigurable computing and RAM-based field-programmable gate arrays for generation of information products (option).

NASA invited ESA to propose payloads for a possible flight opportunity on the NPP. ESA plans to propose the following candidate instruments: GRAS (GNSS Receiver for Atmospheric Sounding), COALA (Calibration for Ozone through Atmospheric Limb Acquisitions), and SWIFT (Stratospheric Wind Interferometer For Transport studies).

G.10 NPOESS (National Polar-orbiting Operational Environmental Satellite System)

NPOESS is the planned next generation operational US polar-orbiting environmental satellite system, replacing the current generation POES and DMSP satellite constellations. The objective of the NPOESS program is to provide a single, national polar-orbiting remote-sensing capability for meteorological, oceanographic, climatic and space environmental data that will satisfy the operational demands of both the US civilian and military communities.

Background: In the fall of 1993, the US National Performance Review (NPR) and the subsequent Presidential Decision Directive/NSTC-2 (May 5, 1994) called on DOC, DoD and NASA, to “converge” the US civil and military operational meteorological satellite programs (POES of NOAA and DMSP of DoD), in order to reduce duplication of effort and to generate cost savings. In October 1994, an Integrated Program Office (IPO), consisting of a team made up of NOAA, NASA and DoD representatives, was established organizationally under NOAA (with the IPO Headquarters located in Silver Spring, MD) with the explicit objective to integrate their separate meteorological programs into a single program that includes: planning, development, management, acquisition, and operations. A tri-agency MOA (Memorandum of Agreement) was signed in May 1995. The merged program received the name of **NPOESS (National Polar-orbiting Operational Environmental Satellite System)**. The IPO is a tri-agency office reporting through NOAA to an Executive Committee of representatives from DOC, DoD and NASA.

The IPO plan for NPOESS is to have the first satellite ready for launch in the 2008 time frame. As a consequence, the previously planned POES O, P, and Q series satellites have been cancelled, as well as the previously planned follow-on system to DMSP, known as the Block-6 series. In May 1998, the US Air Force Space Command transferred its day-to-day operations of the DMSP spacecraft to NOAA. With this action, NOAA assumed full responsibility for the operation of both the POES and DMSP satellite constellations. NOAA maintains and conducts joint satellite control operations at a collocated operations center where it also conducts operations of NOAA’s GOES (Geostationary Operational Environmental Satellite) series (from Suitland, MD).

G.10.1 NPOESS Transition Period Overview

The merging/evolution of the DMSP- and POES series has the following consequences:

- For the present and continuing into the latter part of the 1st decade of the 21st century, US polar-orbiting operational environmental/meteorological services will continue to be met by “flying-out” the remaining current generation satellites of each series (POES ATN and DMSP-5D3). This “fly-out” will be accomplished in a manner consistent with the current operation of these legacy programs (i.e. orbits, capabilities, etc. will remain unchanged).
- By 2005/6, the already planned merger of the civil US/European polar orbiting systems will consist of a total of two operational satellites (a US “afternoon” spacecraft with a European “mid-morning” spacecraft), a coordinated system, referred to as the IJPS (Initial Joint Polar System), see G.15.3. As stated previously, one orbital plane (the traditional civil “afternoon orbit”) will be provided/operated by NOAA (remaining

POES series up to the NOAA-N' mission), the other orbital plane (the traditional civil “mid-morning” orbit, now maintained by NOAA spacecraft) will be provided by EUMETSAT with the start of the MetOp series (MetOp-1 launch in 2005). The Metop series satellites will be launched into a mid-morning orbit (with the following NOAA-provided instruments: AVHRR/3, HIRS/4, AMSU-A and SEM-2), while the POES series satellites will support the afternoon orbit.

- On the other hand, European-provided instruments are flown on NOAA-POES satellites since 1978, starting with the Argos DCS (Data Collection System) of CNES, and SSU (Stratospheric Sounding Unit), a UK sensor provided by BMO - on TIROS-N (launch Oct. 13, 1978) and subsequent NOAA satellites. The S&RSAT (Search & Rescue Satellite) payload, first flown on NOAA-8 (launch March 28, 1983), is provided by France and Canada. Three AMSU-B (Advanced Microwave Sounding Unit - B) instruments of UKMO are being flown on NOAA-K (NOAA-15, launch May 13, 1998), NOAA-L (NOAA-16, launch Sept. 21, 2000), and NOAA-M satellites. The MHS (Microwave Humidity Sounder), a EUMETSAT instrument, is planned to be flown on on the NOAA-N and N' satellites.
- For the NPOESS transition period, there are also operational polar orbiting satellites of the continuing DoD DMSP series (up to F-20), operated by NOAA that will continue to fly in their traditional orbital planes (early morning and mid-morning).
- The next-generation NPOESS series is planned to begin operations with an initial launch planned in the timeframe of 2008, and full operational capability being achieved around 2013. The overall polar orbiting environmental satellite constellation (beyond 2010) will consist of a total of three US satellites, namely with three NPOESS S/C provided and operated by the IPO, with continuing critical sounding data contributions to be provided by the mid-morning MetOp series S/C provided and operated by EUMETSAT. ARGOS Data Collection (DCS) and Search and Rescue (S&RSAT) systems will also continue to be flown as well.

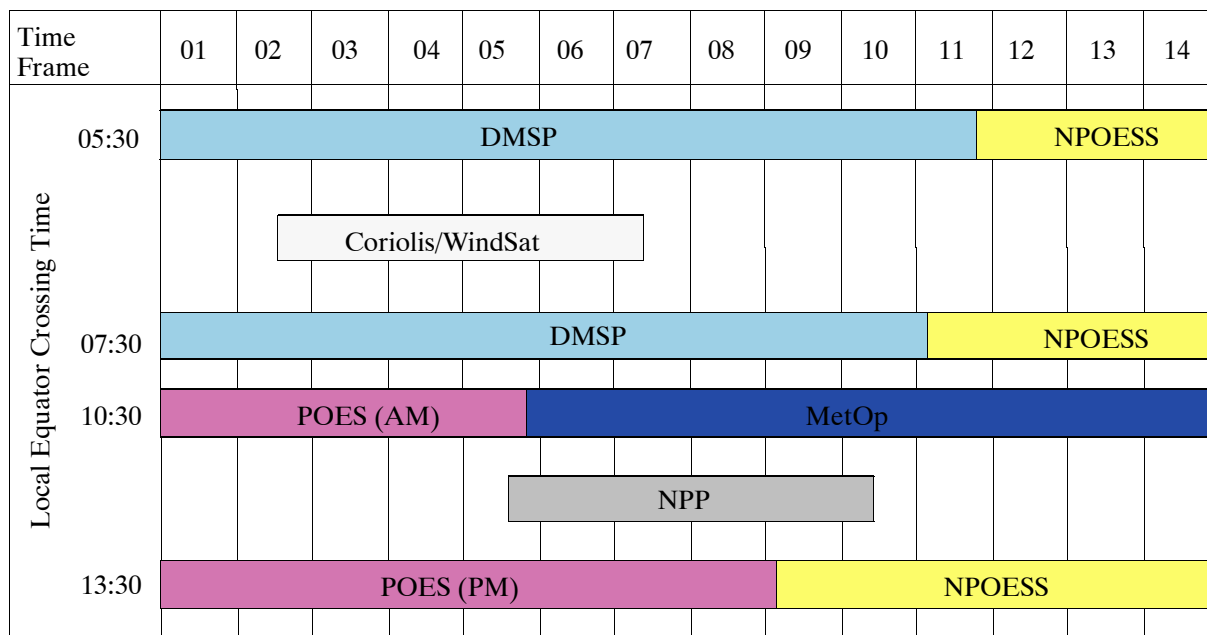

Figure 212: Overview of satellite series transition period

- The NPOESS program is preceded by the launch of a single satellite in 2005, referred to as NPP (NPOESS Preparatory Project) to test the performance of several new NPOESS instruments and to provide climatic data continuity from the Earth Observing System (EOS) satellites (EOS/Terra and EOS/Aqua), operated by NASA.

- The DoD Coriolis mission with the WindSat instrument, implemented and managed by NRL, is a passive microwave technology demonstration mission and considered a further risk reduction project for NPOESS (validation of the CMIS instrument). A launch of Coriolis is planned for early 2002.

The NPOESS system is required to provide an operational remote-sensing capability to acquire and receive in real-time at field terminals global and regional environmental imagery and meteorological, climatic, terrestrial, oceanographic and solar-geophysical and other data in support of mission requirements. The NPOESS data sets will contain a number of variables that are currently not included in operational measurements (such as: radiation budget, total ozone, wind speed and direction, ocean topography, and ocean color) and will offer improved quality for some variables now being measured (such as: atmospheric moisture and temperature profiles, all-weather SST, and vegetation indices).

G.10.2 The NPOESS Satellite

At the current time (2001) two competing contractor teams are accomplishing risk reduction and preliminary designs for the NPOESS spacecraft and ground systems. An engineering, manufacturing, and development contract is planned to be awarded in the 2002 timeframe. The S/C size and payload capacity will be similar to the current POES series. The S/C design requirements call for a 15 year design life (5 years in storage, 3 years of intermittent pre-launch operation, and 7 years of on-orbit design life performance). Requirements call also for up to 21 days of autonomous operation capability with a goal of 60 days. The requirements on RF data transmission call for a nominal data rate of about 12 Mbit/s, LRD (Low Rate Data) of 3 Mbit/s, with an overall system design capacity of up to 20 Mbit/s.

Orbit: Sun-synchronous orbit, nominal altitude = 833 km, inclination = 98.7°. The orbit will be maintained with regard to altitude (± 17 km), inclination ($\pm 0.05^\circ$) and nodal crossing times (± 10 min).

G.10.3 NPOESS Sensor Complement

A key aspect of the convergence effort is the definition, design, development, and implementation of five critical sensor suites that will fly aboard NPOESS (competitive development of the sensor instruments). BATC (Ball Aerospace & Technologies Corp.) is the prime contractor for OMPS and is competing for the CMIS contract. Boeing (formerly HSAC) is also competing for the CMIS contract. ITT Aerospace/CD is the prime contractor for CrIS. Saab Ericsson Space is the prime for GPSOS and Raytheon SBRS is the prime contractor for the VIIRS. The CMIS and VIIRS instruments are planned to fly on the early morning, mid-morning and the afternoon satellites, while the CrIS and OMPS sensors will fly on the afternoon satellites.

VIIRS (Visible/Infrared Imager and Radiometer Suite). An Engineering, Manufacturing, and Development (EMD) contract has been awarded to Raytheon Santa Barbara Remote Sensing (SBRS). VIIRS is an advanced, modular, multi-channel imager and radiometer (of OLS, AVHRR/3, MODIS, and SeaWiFS heritage) with the objective to provide global observations (moderate spatial resolution) of land, ocean, and atmosphere parameters at high temporal resolution (daily). Typical data products of VIIRS include cloud/weather imagery, sea-surface temperature measurements, ocean color characterization, and land-surface vegetation indices (VIIRS is the primary data provider to a total of 24 environmental data records). A swath width of 3000 km is provided (corresponding to $FOV = \pm 55.84^\circ$) with a spatial resolution for imagery related products of no worse than 0.4 km to 0.8 km (nadir to edge-of-scan). The radiometric bands provide a resolution about twice in size to the imagery bands. Note: Most derived data products will be produced at somewhat coarser resolutions by aggregation of on-board data.

The VIIRS instrument employs an all-reflective optics assembly taking advantage of recent optics advances: a) single 4 mirror imager, b) 2 dichroics and 1 fold, c) aluminum DPT-bolt together technology (DPT = Diamond Point Turning). A rotating off-axis and afocal TMA (Three Mirror Anastigmatic) telescope assembly is employed [Note: The telescope rotates 360°, thus scanning the Earth scene, and then internal calibration targets.]. The aperture of the imaging optics is 19.1 cm in diameter, the focal length is 114 cm (f/5.97). The VIIRS optical train consists of the fore optics (TMA), the aft optics [an all-reflective FMA (Four Mirror Anastigmatic) imager], and the back-end optics, which include microlenses for the cooled focal planes. A total of 22 spectral bands have been selected as defined in Table 370. VIIRS features band-to-band registration for all bands (optical alignment of all FPAs). A total of three focal planes and four FPAs (Focal Plane Arrays) cover the spectral range of the instrument, one FPA for DNB (Day-Night Band), one for VNIR, SWIR/MWIR, and TIR. The DNB spectral range of 0.5-0.9 μm CCD detector features four light-sensitive areas (3 with TDI, one without) and near-objective sample spacing.

Figure 213: Illustration of the VIIRS instrument

The VNIR FPA employs a PIN (Positive Insulator Negative) diode array/ROIC (Readout Integrated Circuit) design collocated with the DNB monolithic CCD. All detectors in the SWIR/MWIR/TIR regions employ photovoltaic (PV) detectors with an element spacing of 12 μm . A readout IC (Integrated Circuit) at each FPA provides improved noise levels and built-in offset correction. A cryogenic module (three-stage radiative cooler) provides FPA cooling. Calibration is performed with three on-board calibrators: a) a solar diffuser provides full aperture solar calibration, a solar diffuser stability monitor, and c) a blackbody. A single-board instrument computer provides a processing capability including data aggregation, data compression [lossless (2:1 Rice compression) and lossy (JPEG) algorithms are used], and CCSDS data formatting. The VIIRS instrument has a mass of about 160 kg, power of about 134 W (operational average), peak power of 177 W, and a volume of <1.2 m³. The data rate is 6.7-10.5 Mbit/s (high rate mode) and 220 kbit/s (low rate mode with 10:1 JPEG compression). The VIIRS instrument features a SBC (Single Board Computer) for all instrument operations and control; it communicates with the S/C via an IEEE 1394a cable interface.

VIIRS is an opto-mechanical instrument (like OLS, ETM, and MODIS), it is a whiskbroom scanning radiometer to cover a wide swath. The detector line arrays [16 detectors in each array for the SWIR/MWIR and TIR bands, 32 detectors in the array for the VNIR and DNB (Pan) bands] of the whiskbroom scanner are oriented in the along-track direction. This arrangement provides a parallel coverage of 11.87 km along-track in one scan sweep (cross-track direction). The wide along-track coverage permits sufficient integration time for all cells in each scan sweep. One cross-track scan period is 1.786 s in length. The data quantization is 12 bits (14 bit A/C converters for lower noise).^{1237) 1238)}

Band	Center wave (μm)	Bandwidth (μm)	Comment (driving EDR observation requirements)

CMIS (Conical-scanning Microwave Imager/Sounder).¹²³⁹ The CMIS instrument, of SSM/I (Special Sensor Microwave Imager), SSMIS (Special Sensor Microwave Imager Sounder) and TMI (TRMM Microwave Imager) heritage, is a dual- and single look passive polarimetric microwave radiometer. It is a sensor with a potential aperture just slightly over 2 m (notional) which simultaneously operates over the potential range from 1 to 250 GHz to provide an “all-weather” (i.e., not impacted by clouds) microwave imaging and sounding (profiling) capability. Many microwave radiation frequency ranges exhibit transparency to clouds and other atmospheric obstacles (fog, rain), thus providing forecasters and scientists with an “all-weather” measurement capability. In addition, microwave radiation doesn’t need sun illumination for instrument observation. Hence, the objective of CMIS data is to collect microwave radiometry and sounding data to support a variety of environmental applications and to derive such products as:

¹²³⁹http://www.ball.com/aerospace/npoess_cmis.html

- Ocean wind speed/direction
- Atmospheric temperature and moisture profiles
- Ocean/water imaging and characterization (including SST)
- Cloud imaging and characterization
- Land imaging and characterization

CMIS data provides resolutions from 15 - 50 km at nadir depending on the frequency and the parameter measured. In the summer of 2001 a CMIS instrument contract was awarded to Boeing Satellite Systems of El Segundo, CA.

CrIS (Cross-Track Infrared Sounder). The instrument is being developed by ITT Aerospace/Communications Division of Ft. Wayne, IN, as the prime contractor. CrIS, of HIRS/4 heritage, is a high-spectral and high-spatial resolution infrared sounder for atmospheric profiling functions. The overall objective is to perform daily measurements of Earth's radiation to determine the vertical atmospheric distribution (surface to the top of the atmosphere) of temperature (profiles to better than 0.9 K accuracy in the lower troposphere and lesser accuracy at higher altitudes), moisture (profiles to better than 20-35% accuracy depending on altitude) and pressure (profiles to better than 1.0% accuracy) with an associated 1.0 km vertical layer resolution. The Michelson interferometer sounder has over 1300 spectral channels, it covers a spectral range of 650-2550 cm^{-1} (or 3.5 to 16 μm), with a spectral resolution of 0.6525 cm^{-1} (LWIR), and a ground spatial resolution (IFOV) of 14.0 km. The IFOVs are arranged in a 3 x 3 array. The swath width is 2300 km.

Spectral bands SWIR MWIR TIR (also known as LWIR)	(2155 - 2550 cm^{-1}) or 4.64 - 3.92 μm (1210 - 1750 cm^{-1}) or 8.62 - 5.7 μm (650 - 1095 cm^{-1}) or 15.3 - 9.1 μm
Spectral resolution: SWIR MWIR TIR	(<2.5 cm^{-1}) or 5.4 nm (at 4.64 μm) to 38.4 nm (at 3.92 μm) (<1.25 cm^{-1}) or 92.8 nm (at 8.62 μm) to 40.6 nm (at 5.7 μm) (<0.625 cm^{-1}) or 146 nm (at 15.3 μm) to 51.7 nm (at 9.1 μm)
Number of IFOVs	3 x 3
IFOV diameter	14 km
IFOV motion (jitter)	< 50 $\mu\text{rad}/\text{axis}$
Mapping accuracy	< 1.45 km
Absolute radiometric uncertainty	<0.8% (SWIR), <0.6% (MWIR), <0.45% (TIR)
Radiometric stability	<0.65% (SWIR), <0.5% (MWIR), <0.4% (TIR)
Instrument size	61 cm x 40 cm x 40 cm
Instrument mass, power, data rate	76 kg, 86 W, 1.48 Mbit/s

Table 372: Key performance characteristics of CrIS

The baseline CrIS instrument design consists of nine independent single-function modules: [telescope, optical bench, aft-optics, interferometer, ICT (Independent Calibration Target), SSM (Scene Selection Module), detectors, cooler, processing and control electronics, and instrument structure].

- 8 cm clear aperture
- 4-stage split-patch passive cooler (81 K for LWIR patch temperature, 98 K for MWIR/SWIR patch)
- High-performance PV (photovoltaic) detectors
- 3 x 3 arrays (14 km IFOVs)
- Three spectral bands
- All-reflective telescope
- Proven Bomem plane-mirror Michelson interferometer with dynamic alignment
- Deep-cavity internal calibration target based on MOPITT design
- Two-axis scene selection module with image motion compensation
- A modular design (allowing for future addition of an active cooler and >3 x 3 arrays)

Figure 215: Schematic illustration of the CrIS instrument

OMPS (Ozone Mapping and Profiler Suite). The objective is to measure the total amount of ozone in the atmosphere and the ozone concentration variation with altitude. OMPS is of SBUV/2, TOMS and GOME heritage. Also, the OMPS limb-sounding concept/technology was already tested with ISIR flown on STS-85 (Aug. 7-19, 1997, see J.7) and with SOLSE/LORE flown on STS-87 (Nov 19 - Dec. 5, 1997). The system requirements call for an instrument mass of ≤ 45 kg, an average orbital power of ≤ 45 W, a peak data rate of ≤ 40 kbit/s, and ozone vertical resolution of ≤ 5 km. The vertical resolution requirement demands an instrument design to include a limb-viewing sensor in addition to a heritage-based nadir-viewing sensor. ^{1240) 1241)}

- The nadir sensor wide-field telescope feeds two separate spectrometers, a) for total column observations (mapper) and b) for nadir profiling observations. The total column spectrometer (300-380 nm) has a 2800 km cross-track swath divided into 35 IFOVs of nearly equal angular extent. Measurements from this spectrometer are used to generate total column ozone data with a resolution of about 50 km x 50 km at nadir. - The nadir profile spectrometer (250-310 nm) has a 250 km cross-track swath corresponding to a single cell. Co-registration with the total column spectrometer provides the total ozone, surface and cloud cover information needed for nadir profile retrievals.
- The limb sensor uses a single prism to disperse three vertical slits directed along-track, each separated by 250 km at the limb tangent point. These slits are 150 km high in object space and are sampled at 1 km intervals. To accommodate the very high scene dynamic range, these slit images pass through a beam splitter to divide the scene brightness into three brightness ranges. As a result there are nine limb images of the dispersed slits on the CCD. The measured limb radiances in the ultraviolet, visible, and near-infrared provide data on ozone, aerosols, Rayleigh scattering, surface and clouds that are used to retrieve ozone profiles from the tropopause to 60 km.

OMPS calibration: Solar illuminated diffusers are used for radiometric and spectral calibrations (two diffusers for each sensor). The working diffuser is used weekly and the reference diffuser is used twice annually to monitor the on-orbit degradation of the working diffuser.

The OMPS program will create five ozone data products:

¹²⁴⁰⁾P. H. Graf, I. Becker, et al., "The Preliminary Design of the Ozone Mapping and Profiler Suite (OMPS)," July 2000 as provided on: http://npoesslib.ipnoaa.gov/omps_released_papers.htm

¹²⁴¹⁾http://npoesslib.ipnoaa.gov/Released_papers/OMPS_Flyer2.pdf

- High performance total column environmental data record (EDR) product
- Heritage TOMS V7 total column data records
- High performance ozone profile product
- Heritage SBUV/2 nadir profile data records
- Infrared total column data records from CrIS (Cross-track Infrared Sounder) radiances.

Parameter	Nadir Total Column (Nadir Mapper)	Nadir Profile (Nadir Profiler)	Limb Soundings
Spectral range	300-380 nm	250-310 nm	290-1000 nm
Spectral radiance range [photons/(s cm ² sr nm)]	9 el 3 (380 nm) 8 el 1 (308 nm)	2 el 3 (310 nm) 1.5 el 8 (252 nm)	9 el 3 (600 nm) 5 el 0 (300 nm)
Minimum SNR	1000	35 (252 nm) 400 (310 nm)	320 (290 nm at 60 km) 1200 (600 nm at 15 km)
Integration time	7.6 s	38 s	38 s
Spectral resolution	1 nm FWHM 2.4 samples/FWHM	1 nm FWHM 2.4 samples/FWHM	1.5-40 nm FWHM 1 sample/FWHM
FOV	110° x 0.3°	16.7° x 0.3°	8.5° x 2.7° (3 sets)
Cell size	49 km x 50 km (nadir)	250 km x 250 km	1 km vertical
Revisit time	Daily		4 days (average)
Swath	2800 km	250 km	3 vertical slits along-track and ±250 km

Table 373: Performance parameters of the OMPS spectrometers

GPSOS (GPS Occultation Sensor). The objective is to provide refraction measurement and monitoring of the GPS constellation to characterize the ionosphere. GPSOS is of GPS/MET and GRAS [GNSS (Global Navigation Satellite System) Receiver for Atmospheric Sounding]] heritage. GPSOS is a high-precision GPS instrument consisting of: ¹²⁴²⁾

- One zenith antenna for navigation, together with two high-gain phased array occultation antennas (one for the velocity and one for the anti-velocity direction)
- Three RFCUs (Radio Frequency Conditioning Units) for removal of RFI (Radio Frequency Interference), low noise amplification and down-conversion
- A cold-redundant GEU (GPSOS Electronic Unit), including an ultra-stable oscillator, analog-to-digital conversion, digital down-conversion and GPS signal processing hardware, a DSP (Digital Signal Processor) and a MIL-STD-1553B interface.

SESS (Space Environment Sensor Suite). SESS is the complement of sensors and algorithms used to measure the characteristics of: auroral boundary, auroral energy deposition, auroral imagery, electric field, electron density profile, geomagnetic field, in-situ plasma fluctuations, in-situ plasma temperatures, ionospheric scintillation, neutral density profile, medium energy charged particles, energetic ions, and supra-thermal to auroral energy particles. The data provide information about the space environment necessary to ensure reliable operations of current and future space-based and ground-based systems, to facilitate the analysis of system anomalies that may be the result of space environmental effects, and to aid in the design and efficient operations of future systems that may be affected by the space environment.

Other Payloads: In addition to these payloads, a host of other sensors (to include DCS and S&RSAT) are envisioned to fly on-board NPOESS. Exact definition of these payloads is currently the subject of trade studies being conducted by the IPO's competing system contractors and their exact characteristics must wait until the NPOESS EMD contractor is selected (i.e. their proposed supplementary payload suite is selected). However, it is envisioned that these additional payloads will include an Earth Radiation Budget Suite (ERBS) similar to NASA's CERES instrument, as well as, a Radar Altimeter (Jason-1 heritage), and a TSIS (Total Solar Irradiance Sensor) instrument of TIM (Total Irradiance Monitor) heritage, flown on SORCE (Solar Radiation and Climate Experiment).

¹²⁴²⁾Information provided by Peter Sinander of Saab Ericsson Space AB, Göteborg, Sweden

In addition, NASA is developing for flight on both NPP and NPOESS, the ATMS (Advanced Technology Microwave Sounder). ATMS is an advanced technology (for size/cost reduction) version of the current generation AMSU-A/AMSU-B microwave suite. Performance is planned to be similar to AMSU and as is currently done on POES, ATMS will be hosted with the CrIS to form a combined cross-track IR/MW sounding suite (heritage HIRS/AMSU; AIRS/AMSU).

G.11 TIROS Meteorological Satellite Series (with the POES Program)

The US meteorological satellite program started in 1960 with the launch of TIROS-1 (Television Infrared Observation Satellite), the first true weather satellite. The program proved to be immensely successful. The science community began quickly to realize the riches of information to be obtained from large-scale observation of the Earth. A new era was opened from space, for weather services in particular, as well as for Earth observation in general.

TIROS was a NASA-procured and operated program [other participants: US Army Signal Research and Development Lab, US Weather Bureau, US Naval Photographic Interpretation Center, RCA (S/C manufacturer and integrator of the series)]. The main observing instruments of the TIROS series were TV cameras which provided daily cloud cover pictures for the weather services. Initial downlink transmissions could only be performed offline (data was first stored on-board and later transmitted). Starting with TIROS-8, real-time observational data could be transmitted in APT mode to ground stations. Eventually, APT pictures could be received on fairly simple ground stations anywhere in the world. This broadcasting policy eventually entailed a global user community. Early spacecraft and instrument technologies were rudimentary (coarse resolution data) compared to those of the nineties. But with each succeeding generation of satellites, the remote sensing instruments, as well as the entire infrastructure, evolved and became more sophisticated. New orbital strategies of ‘polar orbit’ and ‘sun-synchronous orbit’ were introduced, first with Nimbus-1 (in 1964), then with TIROS-9 and TIROS-10 in 1965. The infrared cameras of the TIROS series permitted also the study of the Earth’s heat distribution and provided an idea of the amount of heat reflection from the Earth.

With ESSA (Environmental Science and Services Administration), the second generation of spacecraft and instruments, there was a definite need for ‘**operational services.**’ This applied in particular for continuous and frequent coverage and the need for high-resolution global data. The broadcast services of two satellites in orbit were used by an increasing global community.

The primary objective of the 1st-generation TIROS program (M. Tepper, program scientist) was to demonstrate the feasibility and capability of observing the Earth’s cloud cover and weather patterns from space. This was done by testing experimental television techniques that led eventually to a world-wide meteorological satellite information system.

G.11.1 TIROS-1 (TIROS-A)

A NASA spacecraft launched on April 1, 1960 on a standard Thor-Able vehicle from Cape Canaveral, FL. The S/C was of cylindrical shape (18-sided polygon), about 1.1 m in diameter and 0.55 m in height, with a mass of 122 kg. The structure was made of aluminum alloy and stainless steel and was covered on the outside (cylinder and top) by 9200 silicon solar cells. The solar cells served to charge the 21 Ni:Cd batteries. TIROS-1 was spin-stabilized and space-oriented. Hence, observations could only be made when the cameras were pointing toward Earth and when that portion of the Earth was illuminated by the sun. Communication: A single monopole antenna for reception of ground commands extended out from the top of the cover assembly. A pair of crossed-dipole telemetry antennas (235 MHz) pro-

jected down and diagonally out from the baseplate. Mounted around the edge of the baseplate were five diametrically opposed pairs of small, solid-fuel thrusters that maintained the satellite spin rate between 8 and 12 rpm.

Orbit: near-circular orbit, apogee=750 km, perigee=693 km, inclination=48.4°, period=99.2 minutes.

Sensor complement:

Two vidicon television cameras, TV-WA and TV-NA (PI: H. I. Butler), were mounted into the baseplate of the S/C, with their optical axis parallel to the rotation axis of the satellite, providing low-resolution and high-resolution data respectively. The two sensor units were capable of either concurrent or independent operation. The TV cameras used 500 scan-line, 1.27 cm diameter vidicons. A magnetic tape recorder for each camera provided storage of up to 32 frames (images) while the satellite was out of range of the ground stations. Each camera could take 16 pictures per orbit at 128 second intervals. Transmission of the 32-frame sequence was accomplished in 100 s by a 2 W FM transmitter operating at a nominal frequency of 235 MHz. Images of daytime cloudcover were produced for a latitudinal region of $\pm 55^\circ$.

TV-WA (Television-Wide Angle) with a FOV of 104° . At nominal attitude and altitude (approximately 700 km), a picture taken by TV-WA covered a 1200 km x 1200 km at nadir with a spatial resolution of 2.5 to 3.0 km.

TV-NA (Television-Narrow Angle) with a FOV of 12° . The TV-NA instrument had a footprint of 120 km x 120 km with a resolution of 0.3 km to 0.8 km.

TIROS-1 was operational for 78 days (until June 17, 1960), when an electrical power failure prevented further useful TV transmission, producing over 22,000 cloud-cover photographs.

G.11.2 TIROS-2 (TIROS-B)

Launch on Nov. 23, 1960 on a three-stage Delta vehicle from Cape Canaveral, FL. Same S/C structure as for TIROS-1, S/C mass=127 kg. - A new attitude control system was tested which utilized the Earth's magnetic field for S/C orientation. In addition, an infrared horizon sensor was used for attitude sensing. Two infrared radiation experiments, a five-channel medium-resolution scanning radiometer and a two-channel nonscanning low-resolution radiometer for measuring radiation from the Earth and its atmosphere were included. The satellite spin rate was maintained between 8 and 12 rpm by the use of five diametrically opposed pairs of small, solid-fuel thrusters. The satellite spin axis could be oriented to within 1 to 2° accuracy by the use of a magnetic attitude control device consisting of 250 cores of wire wound around the outer surface of the spacecraft. The interaction between the induced magnetic field in the spacecraft and the Earth's magnetic field provided the necessary torque for attitude control.¹²⁴³⁾

Orbit: near-circular orbit, apogee=742 km, perigee=609 km, inclination=48.57°, period=98.3 minutes.

Sensor complement:

The two television cameras, **TV-WA** (Television-Wide Angle) and **TV-NA** (Television-Narrow Angle) of TIROS-1 were flown with some minor changes. The cameras were automatically triggered into action only when they came in view of the Earth. The TV cameras used 500 scan-line, 1.27 cm vidicons. Deposits on the lens of TV-WA caused all its pictures to be of very poor quality. The remaining TV-NA camera operated nominally until February 1, 1961, and sporadically thereafter until September 27, 1961. Tape recorder technique same as for TIROS-1. Over 25,000 usable pictures were transmitted.

¹²⁴³⁾A description of TIROS-2 is presented in the Journal of the British Interplanetary Society, Vol. 19, Pages 386–409, 1963-64.

Widfield Radiometer (PI: R. A. Hanel). The low-resolution, nonscanning, two-channel radiometer measured the thermal and reflected solar radiation from the Earth-atmosphere system. The radiometer consisted of two detectors - one black and one white thermistor bolometer. Each of the detectors was mounted in the apex of a highly reflective mylar cone. The black detector responded equally to reflected solar radiation and longwave terrestrial radiation (0.2 - 50 μm). The white detector reflected solar and visible radiation and measured only longwave thermal radiation (5 - 50 μm). The optical axis of each detector was parallel to the satellite spin axis. The field of view (FOV) of the detectors, when viewing the Earth directly below the satellite, was a circle of 832 km diameter (50° FOV). The area was within the field observed by TV-WA, and thus a direct measure of the heat balance of the Earth-atmosphere system viewed in any of the pictures was provided. The experiment performed normally, but the quality of the data was very poor because the sensitivity of the detectors was lower than expected.

Scanning Radiometer (PI: J. D. Barksdale). The sensor measured the emitted and reflected radiation of the Earth and its atmosphere. The five-channel radiometer scanned the Earth and space as the S/C spun about its axis. The radiometer's bi-directional optical axes were inclined to the satellite spin axis at angles of 45° and 135°. The sensor used bolometer detectors and filters to limit the spectral responses and to provide comprehensive data by measuring radiation intensities in selected portions of the spectrum. The spectral bandwidth of each channel and its associated parameter were: channel 1, 6.0 - 6.5 μm (water vapor absorption), channel 2, 8.0 - 12.0 μm (atmospheric window), channel 3, 0.25 - 6.0 μm (reflected solar radiation), channel 4, 8.0 - 30 μm (terrestrial radiation), and channel 5, 0.55 - 0.75 μm (reflected solar radiation). Initially, all channels performed normally. However, channels 1 and 4 gradually deteriorated and became useless by January 1961. The signal to noise ratio of channels 3 and 5 was extremely low, and the output was highly questionable. Five months of terrestrial radiation measurements were obtained for the latitudinal region of $\pm 55^\circ$ before the radiometer chopper motor failed on April 22, 1961.

G.11.3 TIROS-3 (TIROS-C)

Launch on July 12, 1961 on a three-stage Thor-Delta vehicle from Cape Canaveral, FL. Same S/C structure and attitude control system as for TIROS-2, S/C mass=129.5 kg. The flight control system also optimized the performance of the solar cells and TV cameras and protected the five-channel infrared radiometer from prolonged exposure to direct sunlight.

Orbit: near-circular orbit, apogee=812 km, perigee=742 km, inclination=47.9°, period=100.4 minutes.

Sensor complement:

Low-Resolution Omnidirectional Radiometer (PI: V. E Suomi). Objective: Measurement of the amount of solar energy absorbed, reflected, and emitted by the Earth and its atmosphere. The sensor consisted of two sets of bolometers in the form of hollow aluminum hemispheres, mounted on opposite sides of the spacecraft, whose optical axes were parallel to the spin axis. The bolometers were thermally isolated from but in close proximity to reflecting mirrors so that the hemispheres behaved very much like isolated spheres in space. One bolometer in each set was painted black, and one was painted white. The black bolometer absorbed most of the incident radiation while the white bolometer was sensitive mainly to radiation with wavelengths $> 4 \mu\text{m}$. Reflected and emitted radiation could thus be separated. The sensor temperatures were measured by thermistors fastened to the inside of the hollow hemispheres. The sensor temperatures, taken every 29 s, were an average of the two temperatures from the matched thermistors. The experiment was a success, and usable data were received from July 12, 1961, to October 20, 1961.

Widfield Radiometer (PI: R. A. Hanel). Identical sensor as flown on TIROS-2.

Scanning Radiometer (PI: R. M. Rados). Identical sensor as for TIROS-2. Sensor mass = 2 kg, power = 1 W.

Television Camera System (same as for TIROS-2). The experiment consisted of two redundant pairs of TV cameras (2 **TV-WA** and 2 **TV-NA**), magnetic tape recorders, and TV transmitters. One of the TV-WA cameras failed 13 days after launch. The remaining camera produced useful data until January 23, 1962. The experiment was credited with observing all six major hurricanes of the 1961 season. During the operational lifetime of the experiment, over 24,000 usable pictures were obtained.

G.11.4 TIROS-4 (TIROS-D)

Launch on Feb. 8, 1962 on a three-stage Thor-Delta vehicle from Cape Canaveral, FL. Same S/C structure and attitude control system as for TIROS-2 and -3, S/C mass=129.5 kg. With the exception of the degraded response of the five-channel scanning radiometer, the S/C performed normally until May 3, 1962, when one camera failed. On June 10, 1962, the other camera's tape recorder failed. The scanning radiometer provided usable data until June 30, 1962.

Orbit: near-circular orbit, apogee=840 km, perigee=712 km, inclination=48.3°, period =100.0 minutes.

Sensor complement:

Low-Resolution Omnidirectional Radiometer (PI: V. E Suomi). Identical sensor as on TIROS-3. Usable data were received from February 8, 1962, to June 28, 1962.

Widefield Radiometer (PI: R. A. Hanel). Identical sensor as flown on TIROS-2.

Scanning Radiometer (PI: J. D. Barksdale). Identical sensor as for TIROS-2. Sensor mass = 2 kg, power = 1 W.

Television Camera System (same as for TIROS-2). The experiment consisted of two independent TV cameras (**TV-WA** and **TV-MA**), magnetic tape recorders, and TV transmitters. The TV-MA (Television-Medium Angle) featured a FOV of 80°, resulting in a footprint of 725 km x 725 km and a resolution of 2 km (note: the TV-WA FOV remained at 104°). The experiment performed normal until May 3, 1962, when TV-WA failed. The tape recorder on the remaining camera failed on June 10, 1962. However, limited real-time TV pictures were available up to June 18, 1962, at which time the system was deactivated.

The US Weather Bureau initiated an international facsimile transmission network to share the cloud pictures with weather services around the world.

G.11.5 TIROS-5 (TIROS-E)

Launch on June 19, 1962 on a three-stage Thor-Delta vehicle from Cape Canaveral, FL. Same S/C structure and attitude control system as for TIROS-2, S/C mass=129.5 kg. The larger orbital inclination of 58° extended the effective TV coverage to latitudes of $\pm 65^\circ$.

Orbit: elliptical orbit, apogee=972 km, perigee=586 km, inclination=58.1°, period =100.0 minutes.

Sensor complement:

Television Camera System (same as for TIROS-4). The experiment consisted of two independent TV cameras (**TV-WA** and **TV-MA**), magnetic tape recorders, and TV transmitters. The TV-MA (Television-Medium Angle) featured a FOV of 80°, resulting in a footprint of 725 km x 725 km and a resolution of 2 km. The TV-MA camera failed 17 days after launch.

The remaining TV-WA camera performed normal until May 14, 1963, when the shutter electronics failed. The TV experiment produced over 48,000 meteorologically useful pictures.

G.11.6 TIROS-6 (TIROS-F)

Launch on Sept. 18, 1962 on a three-stage Thor-Delta vehicle from Cape Canaveral, FL. Same S/C structure and attitude control system as for TIROS-2, S/C mass=127.5 kg.

Orbit: near-circular orbit, apogee=713 km, perigee=686 km, inclination=58.32°, period=98.7 minutes.

Sensor complement:

Television Camera System (same as for TIROS-4). The experiment consisted of two independent TV cameras (**TV-WA** and **TV-MA**), magnetic tape recorders, and TV transmitters. The TV-MA (Television-Medium Angle) featured a FOV of 80°, resulting in a footprint of 725 km x 725 km and a resolution of 2 km. The camera system performed normal after launch until November 29, 1962, when the TV-MA camera vidicon failed. The remaining TV-WA camera system failed on October 21, 1963. The experiment transmitted approximately 60,000 meteorologically useful pictures and furnished information leading to many storm advisories in both the U.S. and abroad. The detection of snow cover was tested for the first time.

G.11.7 TIROS-7 (TIROS-G)

Launch on June 19, 1963 on a three-stage Thor-Delta vehicle from Cape Canaveral, FL. Same S/C structure and attitude control system as for TIROS-2, S/C mass=134.7 kg. The S/C performed normal until December 31, 1965, and sporadically until February 3, 1967. The S/C was operated for an additional 1.5 years to collect engineering data. It was deactivated on June 3, 1968.

Orbit: near-circular orbit, apogee=749 km, perigee=621 km, inclination=58.23°, period=97.4 minutes.

Sensor complement:

Television Camera System (same as for TIROS-4). The experiment consisted of two redundant pairs of TV cameras (2 **TV-WA**, each with a FOV of 104°), magnetic tape recorders, and TV transmitters. The experiment yielded numerous meteorologically useful pictures and provided almost continuous hurricane coverage during its approximately 2.5 years of operational lifetime. Beginning early in 1965 and continuing until February 3, 1967, the S/C was programmed to take only the pictures required to supplement the photographic coverage acquired by other satellites in the series.

Low-Resolution Omnidirectional Radiometer (PI: V. E Suomi). Identical sensor as on TIROS-3. Usable data were received from June 19, 1963, to September 13, 1963.

Scanning Radiometer (PI: J. D. Barksdale). Identical sensor as for TIROS-2 -3, and -4. Sensor mass = 2 kg, power = 1 W.

Langmuir Probe (PI: L. H. Brace). Objective: Measurement of electron density and temperature. The cylindrical probe consisted of two concentric electrodes. The inner electrode, of 0.056 cm in diameter and 23 cm in length, was used as a collector. The outer electrode served as a guard electrode and was 0.168 cm in diameter and 10 cm long. The probe was swept through the voltage range 0 to 1.5 v in 2 s. The current at the collector was measured as the voltage was varied, and the signal was stored on a tape recorder and played back upon interrogation by a ground station. The experiment operated normal from launch until July 14, 1963, when an electrical failure prevented the tape recorder from operating normally.

G.11.8 TIROS-8 (TIROS-H)

Launch on Dec. 21, 1963 on a three-stage Thor-Delta vehicle from Cape Canaveral, FL. Same S/C structure and attitude control system as for TIROS-2, S/C mass=265 kg.

TIROS 8 was the first satellite to be equipped with **Automatic Picture Transmission (APT)** capabilities. The APT experiment provided real-time Earth-cloud pictures taken by the satellite to any properly equipped ground receiving station. In addition to the APT camera system, the satellite carried one TV-WA (104° FOV) camera. Pictures taken by TV-WA were transmitted directly or were stored in a tape recorder on board for subsequent playback, depending on whether the spacecraft was within or beyond communication range of either of two ground receiving stations. The S/C performed nominal after launch. Over 50 ground stations participated in the APT experiment, which was terminated by the end of April 1964 due to degradation of the APT camera. The TV-WA camera transmitted useful data until February 12, 1966. The satellite was deactivated on July 1, 1967, after being left on for an additional time period for engineering purposes.

Orbit: near-circular orbit, apogee=765 km, perigee=691 km, inclination=58.5°, period=99.3 minutes.

Sensor complement:

One **TV-WA** (Television-Wide Angle) with 104° FOV (same as for TIROS-4). The system included a two-track magnetic tape recorder, and a transmitter. The experiment performed nominally after launch, and good data were obtained until Aug. 31, 1965. Beginning early in 1965 and until Feb. 12, 1966, the satellite was programmed to take only the pictures required to supplement the photographic coverage acquired by other satellites in the series. After that time, the experiment was activated only for engineering checks until July 1, 1967.

APT (Automatic Picture Transmission - PI: C. H. Hunter). The system consisted of a camera and transmitter combination designed to test the feasibility of transmitting local daytime pictures of cloudcover conditions to properly equipped ground receiving stations on a real-time basis. The camera system consisted of a single camera with a 2.54 cm diameter vidicon. The camera used a 108° FOV and a f/1.8 objective lens, with a focal length of 5.7 mm, and was mounted on the satellite baseplate, with its optical axis parallel to the spacecraft spin axis. The actual picture taking required 8 s, the transmission of the image took 200 s. Earth-cloud images retained on the photosensitive surface of the vidicon were read out at four lines/s to produce an 800-line picture. A 5 W TV transmitter at 136.95 MHz relayed the pictures to local APT stations within communication range. The faceplate of the vidicon had reticle marks that appeared on the picture format to aid in relating the picture to its geographical position on the Earth's surface. At nominal satellite altitude of 700 km, a picture had a footprint of 1200 km x 1200 km with a horizontal resolution of 7.5 km at nadir. The experiment performed nominally, and good quality pictures were obtained until the experiment was terminated owing to degradation of the APT camera. The APT experiment demonstrated the feasibility of using weather satellites to provide meteorologists with local cloudcover data on a near real-time basis requiring only the use of a photo-facsimile machine and a relatively inexpensive antenna and receiver.

G.11.9 TIROS-9 (TIROS-I)

Launch on Jan. 22, 1965 on a three-stage Thor-Delta from Point Arguello. Same S/C structure and attitude control system as for TIROS-2, S/C mass=138.3 kg.

TIROS 9 was the first of the so-called '**Cartwheel**' meteorological TV satellites. That is, the S/C spin axis was maintained normal to the orbital plane. For the first time, the two TV-WA cameras were mounted into the sidewalls of the cylinder, 180° opposite to each other. This concept, also referred to as the **cartwheel configuration**, allowed each camera to observe

the same ground target during each cycle of rotation. - The satellite was still equipped with small solid-fuel thrusters as in the case of previous TIROS S/C. However, the system was used only as a backup. The satellite spin rate and attitude were primarily determined by **QOMAC** (Quarter-Orbit Magnetic Attitude Control) system. QOMAC used the torque developed by interaction of the Earth's magnetic field with a current-carrying loop mounted in the satellite.

A failure in the S/C guidance system placed the satellite in an unplanned elliptical (700 to 2500 km) orbit. The TV system operated normally until April 1, 1965, when one of the TV-WA cameras failed. The other camera operated normally until July 26, 1965, and sporadically until Feb. 15, 1967. **TIROS-9 was the first S/C in the TIROS series to be placed in a near-polar orbit, thereby increasing TV coverage to the entire daylight portion of the globe.**

Orbit: sun-synchronous elliptical polar orbit, apogee=2582 km, perigee=705 km, inclination=96.4°, eccentricity = 0.11693, period = 119.23 minutes.

Sensor complement:

The TV camera system was identical to that flown on all previous TIROS missions, two TV-WA (104° FOV) cameras equipped with 1.27 cm diameter vidicons. Unlike previous TIROS TV cameras, however, the cameras on TIROS-9 were mounted 180° apart on the side of the spacecraft and canted 64° from the S/C spin axis. The cameras were automatically triggered into action only when they came in view of the Earth. The TV system could operate in either real-time or tape recorder mode, depending on whether the S/C was within or beyond communication range of either of two ground receiving stations. The recorder could store up to 48 frames of pictures. Transmission of the 48-frame sequence was accomplished in 120 s using a 5 W FM transmitter operating at a nominal frequency of 235 MHz. At an altitude of 700 km, a picture had a footprint of 1200 km x 1200 km with a spatial resolution of 2.5 to 3.0 km at nadir. From a near-polar orbit, the camera system could provide complete TV coverage of the entire daylight portion of the globe. In spite of an unplanned elliptical orbit, the experiment produced over 70,000 meteorologically useful pictures.

G.11.10 TIROS-10

Launch on July 2, 1965 on a three-stage Delta vehicle from Cape Canaveral, FL. Same S/C structure and attitude control system as for TIROS-2, S/C mass=127 kg.

Orbit: near-circular sun-synchronous orbit, apogee=837 km, perigee=751 km, inclination=98.65°, period = 100.76 minutes. Note: the sun-synchronous retrograde orbit drifted westward about 1° per day (the same rate and direction as the Earth moves around the sun), this provided maximum lighting conditions for observations as well as for battery charging.

Sensor complement: Two TV-WA cameras were mounted on the base plate (as with TIROS-1 to -8) providing more than 400 images per day (each with an area of 1300 km x 1300 km). The TV system operated nominally until Sept. 30, 1965, and sporadically through July 31, 1966, when the spacecraft was deactivated.

G.12 TOS/ESSA Satellite Series (2nd Generation)

TIROS-9 and -10 were test satellites providing improved configurations/technology for TOS (TIROS Operational Satellite) system. Operational use started in 1966. Once in orbit, the TOS satellites were given the name of ESSA (Environmental Science and Services Administration). S/C manufacturer was RCA. Note, ESSA was a predecessor organization of NOAA.

The prime objective of the TOS/ESSA program was to provide ESSA with the capability of observing the Earth's cloud cover and weather patterns from space. The operational system

consists of two polar orbiting sun-synchronous satellites crossing the equator during local morning and afternoon. The even-numbered satellites of the ESSA series provided direct APT transmissions to the ground. The data was used by the meteorological community to prepare operational services for weather analysis and forecasts.

G.12.1 ESSA-1 (TOS-1)

Launch on Feb. 3, 1966 on a three-stage Delta vehicle from Cape Canaveral, FL. The S/C was the same as the one used for TIROS-9. S/C mass of 138 kg.

ESSA 1 was a spin-stabilized operational meteorological S/C. The satellite had essentially the same configuration as that of the TIROS series, i.e., an 18-sided right prism, 107 cm across opposite corners and 56 cm high, with a reinforced baseplate carrying most of the subsystems and a cover assembly (hat). Electrical power was provided by approximately 10,000 solar cells (1 cm x 2 cm) that were mounted on the cover assembly and by 21 Ni:CD batteries. Two redundant wide-angle cameras were mounted on opposite sides of the spacecraft and canted 75° from the S/C spin axis. A pair of crossed-dipole command and receiving antennas projected out and down from the baseplate. A monopole telemetry and tracking antenna extended up from the top of the cover assembly. The satellite was placed in a cartwheel orbital mode, with its spin axis maintained normal to the orbital plane. The satellite spin rate and attitude were determined primarily by MASC (Magnetic Attitude Spin Coil). MASC was a current-carrying coil mounted in the cover assembly. The magnetic field induced by the current interacted with the Earth's magnetic field to provide the necessary torque to maintain a desired spin rate of 9.225 rpm. Five small solid-fuel thrusters mounted around the baseplate provided a second means of controlling the S/C spin rate. The satellite performed normally after launch until October 6, 1966, when the camera system failed. The spacecraft was deactivated on May 8, 1967, after being left on for an additional time period for engineering purposes.

Orbit: near-circular sun-synchronous polar orbit, apogee=845 km, perigee=702 km, inclination= 97.9° , period=100.35 minutes.

Sensor complement:

AVCS (Advanced Vidicon Camera System). A combination of camera, tape recorder, and transmitter that could record and store a series of remote daytime cloudcover pictures for subsequent playback to a ground station. The system was identical to those flown on previous TIROS missions, consisting of two redundant 500 scan-line TV cameras with 1.27 cm vidicons. However, on ESSA 1 the cameras were mounted 180° apart on the side of the S/C and were canted 75° from the spacecraft spin axis (cartwheel configuration for the entire ESSA series). The cameras were triggered into action only when they came into view of the Earth. Each tape recorder had two separate channels, one for storing video signals and one for sun-angle data, which served as a time reference. Up to 32 pictures consisting of five levels of gray could be stored for subsequent playback. At an orbital altitude of 1450 km the cameras covered a footprint of 1200 km x 1200 km with a spatial resolution of about 3.0 km at nadir. The sensor provided over 100,000 usable pictures.

G.12.2 ESSA-2 (TOS-2)

Launch on Feb. 28, 1966 on a three-stage Delta vehicle from Cape Canaveral, FL. The S/C structure was the same as for ESSA-1 with a mass of 286 kg.

Orbit: near-circular sun-synchronous polar orbit, apogee=1418 km, perigee=1356 km, inclination= 101.0° , period=113.57 minutes.

Sensor complement:

APT (Automatic Picture Transmission). The camera system consisted of two redundant APT cameras with 2.54 cm diameter vidicons. Each camera had a 108° wide-angle f/1.8 objective lens with a focal length of 5.7 mm. The two cameras were mounted in cartwheel fashion. The cameras were programmed to take four or eight APT pictures per orbit. The actual photography required 8 s and the transmission 200 s. Earth-cloud images retained on the photosensitive surface of the vidicon were read out at four lines per second to produce an 800-line picture. Two 5 W TV transmitters (137.5 MHz) relayed the pictures to local APT stations within communication range.

The S/C remained operational for 1692 days until deactivated by NASA on Oct. 16, 1970.

G.12.3 ESSA-3 (TOS-3)

Launch on Oct. 2, 1966 on a three-stage Delta vehicle from VAFB (Vandenberg Airforce Base), CA. The S/C was of the same structure as ESSA-1 with a mass of 145 kg. Identical experiments were flown on ESSA-5, ESSA-7, and ESSA-9.

Orbit: near-circular sun-synchronous polar orbit, apogee=1493 km, perigee=1383 km, inclination=101.0°, period=114.6 minutes.

Sensor complement: No APT system. AVCS was essentially the same as flown on ESSA-5, -7, and -9.

Two **AVCS** (Advanced Vidicon Camera System) were flown (redundant camera and tape recorder combination) in cartwheel configuration. Spectral band = 0.45-0.65 μm . Both AVCS featured direct readout and delayed readout capabilities. The Earth-pointing camera used a 108° wide-angle lens (5.7 mm focal length) with an f/1.8 aperture and a 2.54 cm diameter vidicon with 833 scan lines. A video frame consisted of a 0.25 s period of blanked video, followed by 6.25 s of vidicon scan video (833 lines), and a final 0.25 s period of blanked video. Eleven pictures were taken at 260 s intervals to cover the sunlit portion of the Earth (sun elevation greater than 15°). The tape recorder could read out between photographic cycles without losing a picture or interrupting a sequence. At nominal satellite altitude of 1450 km, the AVCS image covered a footprint of 3000 km x 3000 km with a ground resolution of about 3 km at nadir. Over 90,000 AVCS images were transmitted.

FPR (Flat Plate Radiometer). FPR mass = 3kg, power = 4 W. FPR was designed to provide a measurement of the global distribution of reflected solar and longwave radiation leaving the Earth. The FPR system consisted of four detectors, an analog-to-digital converter, and a tape recorder. The detectors had a hemispheric FOV of 2 pi steradians and were mounted on the S/C baseplate facing earthward. The detectors used coated aluminum disks as a sensing element. Two of the disks were white and responded only to infrared energy (7 - 30 μm) radiated from the Earth and its atmosphere. The other two disks were painted black and had a broader band sensitivity (0.3-30 μm). Two disks (one of each type) had a thermistor bolometer mounted on the back surface to measure the disc temperature. The other two disks used thermopiles. An identical experiment was flown on ESSA-5, -7, -9 and NOAA-1. FPR failed on Jan. 20, 1967.

The S/C remained operational for 738 days, it was deactivated by NASA on Dec. 2, 1968.

G.12.4 ESSA-4 (TOS-4)

Launch on Jan. 26, 1967 on a three-stage Delta vehicle from VAFB, CA. The S/C was of the same structure as ESSA-2 with a mass of 285 kg.

Orbit: near-circular sun-synchronous polar orbit, apogee=1443 km, perigee=1328 km, inclination=102.0°, period=113.48 minutes.

Sensor complement: Same APT system in cartwheel configuration as flown on ESSA-2, -6, and 8. One camera failed almost immediately after launch. The other camera obtained data until Dec. 6, 1967.

ESSA-4 remained operational for 465 days (Dec. 6, 1967), it was deactivated by NASA on May 5, 1968.

G.12.5 ESSA-5 (TOS-5)

Launch on April 20, 1967 on a three-stage Delta Vehicle from VAFB, CA. The S/C was of the same structure as ESSA-1 with a mass of 145 kg.

Orbit: near-circular sun-synchronous polar orbit, apogee=1423 km, perigee=1361 km, inclination=101.97°, period=113.63 minutes.

Sensor complement: No APT system. Two AVCS (Advanced Vidicon Camera System) in cartwheel configuration (same system as flown on ESSA-3). AVCS functioned until October 8, 1969, when the satellite was placed in a standby mode.

FPR (Flat Plate Radiometer). Identical instruments were flown on the ESSA-3, -7, and -9 spacecrafts. FPR on ESSA-5 operated nominally until it failed on Sept. 22, 1967.

ESSA-5 remained operational for 738 days (Oct. 8, 1969), it was deactivated by NASA on Feb. 20 1970.

G.12.6 ESSA-6 (TOS-6)

Launch on Nov. 10, 1967 on a three-stage Delta vehicle from VAFB, CA. The S/C was of the same structure as ESSA-2 with a mass of 299 kg.

Orbit: near-circular sun-synchronous polar orbit, apogee=1488 km, perigee=1410 km, inclination=102.12°, period=114.8 minutes.

Sensor complement: Same APT system in cartwheel configuration as flown on ESSA-2, -4, and 8. The APT system operated nominally until Nov. 4, 1969.

ESSA-6 was able to transmit up to eight images daily to individual ground stations. The S/C remained operational for 465 days, it was deactivated by NASA on Dec. 3, 1969.

G.12.7 ESSA-7 (TOS-7)

Launch on Aug. 16, 1968 on a two-stage Delta vehicle from VAFB, CA. The S/C was of the same structure as ESSA-1 with a mass of 145 kg.

Orbit: near-circular sun-synchronous polar orbit, apogee=1476 km, perigee=1432 km, inclination=101.7°, period=114.98 minutes.

Sensor complement: No APT system. Two AVCS (Advanced Vidicon Camera System) in cartwheel configuration (same system as flown on ESSA-3). One AVCS camera failed almost immediately after launch. The remaining camera system failed on July 19, 1969.

Two arrays of radiometers (**FPR**=Flat Plate Radiometer) were also mounted in opposite directions (180° apart) with the objective to measure the global distribution of solar radiation reflected by the Earth's surface and atmosphere. FPR failed on June 23, 1969.

ESSA-7 remained operational for 571 days, it was deactivated by NASA on March 10, 1970.

G.12.8 ESSA-8 (TOS-8)

Launch on Dec. 15, 1968 on a two-stage Delta vehicle from VAFB, CA. The S/C was of the same structure as ESSA-2 with a mass of 297 kg.

Orbit: near-circular sun-synchronous polar orbit, apogee=1473 km, perigee=1410 km, inclination=101.9°, period=114.7 minutes.

Sensor complement: Same APT system in cartwheel configuration as flown on ESSA-2, -4, and -6. ESSA-8 was able to transmit eight to ten images per day to nearly 400 APT ground stations around the world.

The S/C remained operational for 2644 days, it was deactivated by NASA on Mar. 12, 1976.

G.12.9 ESSA-9 (TOS-9)

Launch on Feb. 26, 1969 on a three-stage Delta vehicle from Cape Canaveral, FL. The S/C was of the same structure as ESSA-1 with a mass of 145 kg. ESSA-9 remained operational for 1726 days, it was deactivated by NASA on Nov. 15, 1972.

Orbit: near-circular sun-synchronous polar orbit, apogee=1508 km, perigee=1427 km, inclination=101.79°, period=115.3 minutes.

Sensor complement: No APT system. Two **AVCS** (Advanced Vidicon Camera System) in cartwheel configuration (same system as flown on ESSA-3).

Two arrays of radiometers (**FPR**=Flat Plate Radiometer) were also mounted in opposite directions (180° apart) with the objective to measure the global distribution of solar radiation reflected by the Earth's surface and atmosphere. FPR operation was terminated in May 1970.

G.13 ITOS (Improved TIROS Operational System)

In 1970, a new agency, **NOAA** (National Oceanic and Atmospheric Administration), was created in the Department of Commerce (DOC) to operate the satellites and to improve services. Procurement of satellites and instruments, as well as the launch services, remained the responsibility of NASA/GSFC.

Spacecraft operations of this third-generation series was provided by NOAA, the newly-founded agency of DOC (Department of Commerce) in 1970. The ITOS series more than doubled the TOS series capability - the cameras were now able to observe during nighttime as well as during daytime.

G.13.1 NOAA-1 (ITOS-A, also known as ITOS-1 and TIROS-M)

A NASA spacecraft launched on Dec. 11, 1970 on a two-stage Delta-N vehicle from Point Arguello (VAFB), CA. The primary objective was to provide improved operational infrared and visual observations of the Earth's cloud cover for use in weather analysis and forecasting (double the daily coverage of the ESSA satellites, to provide infrared imagery, cloud top temperature and surface temperature twice a day to APT users). A secondary objective included providing both solar proton and global heat balance data on a regular daily basis. To accomplish these tasks, the S/C carried four cameras, two television cameras for Automatic Picture Transmission (APT) and two Advanced Vidicon Camera System (AVCS) cameras.

Spacecraft: a near-cubical shape (1 m x 1 m x 1.2 m) with three identical solar panels attached generating 250 W. Each panel was 4.2 m in length. The dynamics and attitude control system maintained the desired spacecraft orientation. Three-axis stabilization (two horizon scanners, sun sensors and Freon gas jets provided attitude control). Earth orientation of the satellite body was maintained by taking advantage of the precession induced by the momentum flywheel so that the satellite body precession rate of one revolution per orbit provided the required Earth direction. S/C mass = 352 kg, two APT (Automatic Picture Transmission) links in S-band.

The S/C and experiments performed nominally until the incremental tape recorder failed on May 29, 1971.

Orbit: Near-circular sun-synchronous polar orbit, apogee = 1472 km, perigee = 1422 km, inclination = 101.9°, period = 114.8 minutes.

Sensor complement:

AVCS (Advanced Vidicon Camera System). AVCS was identical to the systems flown on ESSA-3, -5, -7 and -9. AVCS functioned nominally until it was placed in a standby mode on June 22, 1971, when overheating developed in the S/C control system.

SR (Scanning Radiometer), built by SBRC. Instrument mass = 7.9 kg, power = 4.8 W. Two instruments were flown. SR1 resolution = 4 km, spectral band = 0.5-0.72 μm . SR2 resolution = 8 km, spectral band = 10.5-12.5 μm . Swath width of 3000 km. SR consisted of two scanning radiometers, a dual SR processor, and two SR recorders. The sensor permitted the determination of surface temperatures of the ground, the sea, or cloud tops viewed by the radiometer. The SR sensors measured reflected radiation from the Earth-atmosphere system in the 0.52-0.72 μm band (SR1) during the day and emitted radiation from the Earth and its atmosphere in the 10.5-12.5 μm band (SR2) during the day and night.

The SR mirror scanned the Earth's surface perpendicular to the satellite's orbital path at a rate of 48 rpm. As the S/C progressed along its orbital path, each rotation of the mirror provided one scan line of picture. Radiation collected by the mirror was passed through a beam splitter and spectral filter to produce the desired spectral separation. Up to two full orbits of data (145 min) could be stored on magnetic tape for subsequent transmission (1697.5 MHz) to an acquisition station. The data could also be transmitted in real-time to local APT stations. Once the signal was received by the ground station, a continuous picture was formed by using a facsimile recorder whose scan was in phase with the satellite's forward motion. At nominal spacecraft altitude (approximately 1450 km), the SR had a ground resolution of better than 4 km at nadir. The radiometer was capable of yielding radiance temperatures from 185 to 330 K to an accuracy of 4 to 1 K, respectively. The SR instrument functioned nominally until Jan. 5, 1971, when the number 1 scanning radiometer became inoperative owing to failure of the scanning mirror motor. The remaining radiometer was placed in a partial record mode at the end of June 1971 as a result of overheating in the spacecraft attitude control system.

FPR (Flat Plate Radiometer). See description under G.12.3. FPR data were obtained until May 29, 1971, when the incremental on-board tape recorder failed.

SPM (Solar Proton Monitor). Three solid-state detectors monitored the omnidirectional fluxes of solar protons with energies above 10, 30, and 60 MeV, respectively. Two telescopes consisting of solid-state detectors each measured directional fluxes of protons in three energy intervals between 0.27 MeV and 3.2 MeV, protons between 3.2 and 60 MeV, protons above 60 MeV, and alpha particles between 12.5 and 32 MeV. In the polar cap region which was of the greatest interest, the telescopes viewed parallel to, and perpendicular to, the local magnetic field direction. An additional solid-state detector measured directional fluxes of electrons of energies greater than 140 keV. This detector looked in a direction perpendicular to the orbit plane. The detectors worked well until tape recorder failure in May 1971.

APT (Automatic Picture Transmission). Essentially the same system as employed for ESSA-2, -4, -6, and -8. At the nominal satellite altitude of 1450 km, each picture covered approximately 3140 km across-track and 2400 km along-track with a ground resolution of about 3 km at nadir. The APT system functioned nominally until June 20, 1971.

Note: **ITOS-B** (launch on Oct. 21, 1971 on a Delta vehicle from VAFB) failed to achieve a successful Earth orbit. A malfunction in the second stage launch vehicle caused the S/C to reenter the Earth's atmosphere about 1 hour after lift-off. **ITOS-C** had been scheduled for

launch in February 1972. However, because of long delays in equipping the launch vehicle with an onboard inertial guidance computer, the launch was cancelled and the satellite was placed in storage. It was replaced in the launch sequence by the more sophisticated NOAA-2 (ITOS-D) S/C. **ITOS-E** (launch on July 16, 1973 from VAFB, S/C mass = 747 kg) experienced a launch failure.

G.13.2 NOAA-2 (ITOS-D)

The NASA S/C was launched on Oct. 15, 1972 on a Delta 300 vehicle from VAFB, CA. S/C mass = 306 kg. The satellite design was identical to that of NOAA-1. NOAA 2 was not equipped with conventional TV cameras (like AVCS). It was the first operational weather satellite to rely solely upon radiometric imaging to obtain cloudcover data. The VHRR, VTPR, and SR sensors were mounted on the S/C baseplate with their optical axes directed vertically earthward.

Orbit: Near-circular sun-synchronous polar orbit, apogee = 1458 km, perigee = 1448 km, inclination = 101.8°, period = 114.9 minutes.

Sensor complement: No APT system.

VTPR (Vertical Temperature Profile Radiometer). Instrument mass = 23 kg, power = 33 W. Two instruments were flown, resolution = 59 km, swath width = 1364 km. Four spectral bands for VTPR1: 14.92-14.99 μm , 14.65-14.87 μm , 14.29-14.49 μm , and 14.03-14.22 μm . Four spectral bands for VTPR2: 13.70-13.88 μm , 13.30-13.48 μm , 18.38-19.01 μm , and 11.93-12.08 μm . The VTPR instrument consisted of an optical system, a detector and associated electronics, and a scanning mirror. The scanning mirror looked at the Earth's surface perpendicular to the satellite's orbital path. As each area was scanned, the optical system collected, filtered, and detected the radiation from the Earth into the eight spectral intervals. VTPR operated nominally until March 18, 1974.

VHRR (Very High Resolution Radiometer). Instrument mass = 16 kg, power = 25 W. Measurement of SST (Sea Surface Temperature) surface temperatures of the Earth, and cloud tops in daylight as well as at night. Resolution = 0.87 km, swath width = 2580 km, two spectral bands = 0.6-0.7 μm , 10.5-12.5 μm . Revolving mirrors (at 400 rpm) scanned the Earth's surface 180° out of phase (one mirror at a time) and perpendicular to the orbit path. The experiment included two scanning radiometers, a magnetic tape recorder, and associated electronics. The two-channel VHRR operated similarly to the Scanning Radiometer (SR) but with much greater resolution (0.9 km compared to 4 km for the SR at nadir). One VHRR channel measured reflected visual radiation from cloud tops in the limited spectral range of 0.6 - 0.7 μm . This provided more contrast between the Earth and clouds than the SR by reducing the effect of haze. The second channel measured infrared radiation emitted from the Earth, sea, and cloud tops in the 10.5-12.5 μm region. This spectral region permitted both daytime and nighttime radiance measurements.

SR (Scanning Radiometer). Two instruments were flown. SR1 resolution = 3.7 km, spectral band = 0.52-0.73 μm . SR2 resolution = 7.4 km, spectral band = 10.5-12.5 μm . Swath width of 3000 km. Identical instruments were flown on NOAA-1, NOAA-3, and NOAA-4.

SPM (Solar Proton Monitor). An identical instrument was flown on NOAA-1.

All imagery was obtained with scanning radiometers. The last data available of NOAA-2 is from March 19, 1974, the S/C was deactivated on Jan. 30, 1975.

G.13.2.1 NOAA-3 (ITOS-F)

NOAA-3 was launched on Nov. 6, 1973 on a Delta 300 vehicle from VAFB, CA. The objective was to provide VIS and IR images of cloud cover, snow and ice, the sea surface, and to collect information on the vertical temperature and moisture profiles of the atmosphere.

The satellite design was identical to NOAA-1. NOAA-3 (mass of 746 kg) was the first satellite to permit direct broadcast of VTPR data.

Orbit: Near-circular sun-synchronous polar orbit, apogee = 1509 km, perigee=1500 km, inclination = 102.1°, period =116.1 minutes.

Sensor complement: Identical sensors as for NOAA-2, namely: VTPR, VHRR, SR and SPM. All imagery was obtained with scanning radiometers.

NOAA-3 remained operational for 1029 days until deactivated by NOAA on Aug. 31, 1976, the last data available is of Dec. 17, 1974.

G.13.3 NOAA-4 (ITOS-G)

Launch of S/C on Nov. 15, 1974 on a two-stage Delta 2310 vehicle from VAFB, CA. The S/C design and sensor complement was identical to that of NOAA-2. S/C mass of 340 kg.

Orbit: Near-circular sun-synchronous polar orbit, apogee=1457 km, perigee=1443 km, inclination=101.7°, period=114.9 minutes.

NOAA-4 remained operational for 1463 days until deactivated by NOAA on Nov. 18, 1978. Last data available is of Sept. 15, 1976.

G.13.4 NOAA-5 (ITOS-H)

Launch of S/C on July 29, 1976 on a two-stage Delta 2310 vehicle from VAFB, CA. The S/C design and sensor complement was identical to that of NOAA-2. One SR failed on Feb. 24, 1978, the other SR failed on March 16, 1978.

Orbit: Near-circular sun-synchronous polar orbit, apogee=1520 km, perigee=1502 km, inclination=102.1°, period=116.2 minutes.

NOAA-5 remained operational for 1067 days until deactivated by NOAA on July 16, 1979. Last data on March 1, 1979.

G.14 TIROS-N (4th Generation) Satellite Series

TIROS-N through NOAA-D (NOAA-12) are called the TIROS-N series (Being a new development, funded by NASA rather than NOAA, the first satellite in this series retained the NASA name “TIROS”, with the designation “N” being the next letter in that series. NOAA-M was the first satellite in the 4th generation, ITOS, series). NOAA-D was launched out of sequence and later became NOAA-12. An overview of all US meteorological satellite generations is given in Table 374 on page 737. A communications overview of TIROS-N is given in Figure 216 on page 736.

The program has evolved over several generations of satellites (TIROS, TOS/ESSA, ITOS to the TIROS-N series), starting in 1960 with TIROS-1 to the last in this series being the NOAA-14 operational satellite (see Table 374). Along with the general program evolution, there has also been an enormous sophistication in sensor technology, hence in observation capability. A large number of daily atmospheric profiles or “soundings” find their way into global forecasting models.

Since 1978, the operational system consists of two polar orbiting sun-synchronous satellites (ATN series) crossing the equator during local morning (07:30) and afternoon (13:30). Continuous S-band broadcast is provided for an international user community. **Any user with a receiving station has access to the data.**

NOAA-8 through NOAA-14 are called the **Advanced TIROS-N (ATN)** series of the 4th generation meteorological satellites. The improvements of this series consisted of adding instrument capacity to the satellite (stretched platform structure) for growth potential. The S/C dimensions are: 4.18 m x 1.9 m. The size of the solar panel is 2.37 m x 4.91 m. The S/C mass at launch is 1718 kg at launch and 1034 kg in orbit. All S/C in this series are three-axis stabilized.

The TIROS-N and ATN series were a cooperative effort between NASA, NOAA, the UK, and France. for providing day and night global environmental and associated data for regular daily operations.

Background: The program was referred to as **POES** (Polar-orbiting Operational Environmental Satellites) only sometime during the 4th generation series in the 1980s, to distinguish it from the GOES (Geostationary Operational Environmental Satellite) program. The early TIROS series did not have polar orbits, they were not used in the early days of Earth observation.

The NOAA-POES series (Polar-orbiting Operational Environmental Satellites) and the NOAA-GOES series are regarded the backbone of the US meteorological program. Both types of satellites carry data collection systems for the readout of in situ environmental data. In addition to providing standard meteorological readings in remote locations, the data collection systems allow the monitoring of sea conditions through measurements on ocean buoys, readout of data from aircraft and balloons, and the relay of hydrological data on river levels, snow thickness, etc.

G.14.1 TIROS-N Satellite

The TIROS-N series S/C (design heritage of DMSP) features a box-like structure (3.7 m long, 1.9 m wide) of aluminum and titanium with one large solar panel (see Figure 217). The S/C is three-axis stabilized, nadir pointing with control to better than $\pm 0.1^\circ$ using reaction wheels (with a motion rate of less than $0.035^\circ/\text{s}$). A hydrazine propulsion system is used for precision orbital insertion, but is deactivated immediately there-after and is not used for station-keeping or orbit maintenance. The solar panel (2.37 m x 4.9 m) generates power over 1 kW. NiCd batteries provide power during eclipse. The total S/C mass is 1418 kg at launch and 735 kg in orbit. Data transmission with APT and HRPT (High Rate Picture Transmission) capability.

Launch of the experimental S/C on Oct. 13, 1978 on an Atlas E/F vehicle from VAFB, CA.

Orbit: near-circular sun-synchronous polar orbit, apogee=862 km, perigee=846 km, inclination=98.9°, period=102.3 minutes.

Sensor complement:

AVHRR (Advanced Very High Resolution Radiometer). Objective: global daytime and nighttime sea-surface temperatures (SST) and information about ice, snow, and clouds. This first AVHRR sensor is an across-track scanning instrument (built by ITT Aerospace of Fort Wayne, IN). The instrument provides for outputting data in five spectral ranges, however, the initial versions of the instrument supported only four (0.55-0.90, 0.725-1.10, 3.550-3.93, and 10.50-11.50 μm and the fourth channel is repeated in channel five (see description in chapter G.14.11). All four channels had a spatial resolution of 1.1 km, the two IR-window channels had a thermal resolution of 0.12 K at 300 K. The AVHRR and the associated S/C data system is capable of providing data in real-time and recorded modes simultaneously. Real-time or direct readout data were transmitted to ground stations both at low (4 km) resolution via APT and at high (1 km) resolution via high-resolution picture transmission (HRPT).

TOVS (TIROS Operational Vertical Sounder). This designation includes three instruments, namely HIRS/2, SSU, and MSU. The objective is to measure vertical profiles of temperature and water vapor from the Earth's surface to the top of the atmosphere.

- **HIRS/2** (High-Resolution Infrared Sounder). Objective: measurement of atmospheric temperature and humidity. Soundings are taken in a nadir scan from the ground up to altitudes of 40 km. Measurements are made in 19 IR bands and one VIS band with the following center wavelengths in μm : 1) 14.95, 2) 14.71, 3) 14.49, 4) 14.22, 5) 13.97, 6) 13.64, 7) 13.35, 8) 11.11, 9) 9.71, 10) 8.16, 11) 7.33, 12) 6.72, 13) 4.57, 14) 4.52, 15) 4.46, 16) 4.40, 17) 4.24, 18) 4.00, 19) 3.76, and 20) 0.69 μm . Spatial resolution = 30 km (FOV), swath width = 2240 km.
- **SSU** (Stratospheric Sounding Unit, a UK sensor provided by BMO). Temperature measurements in the upper atmosphere are derived from radiance measurements made in three channels using a pressure-modulated gas (CO_2) to accomplish selective bandpass filtration of the sampled radiances. Measurements of temperature profiles, top of atmosphere radiation (from 25 km to 50 km in altitude). Spectral ranges (cm^{-1}): 669.99, 669.63, and 669.36. Spatial resolution: 147.3 km at nadir. Swath width = 1474 km. Data output: 12-bit binary sampled at 0.48 kbit/s.
- **MSU** (Microwave Sounding Unit, a JPL sensor). See MSU description in chapter G.14.11.

SEM (Space Environment Monitor). The SEM package includes three sensors: **HEPAD** (High Energy Proton and Alpha Particle Detector), **MEPED** (Medium Energy Proton and Electron Detector), and **TED** (Total Energy Detector). See description of the SEM package in chapter G.14.12.

DCS (Data Collection System) Argos. See Argos description in chapters G.15.4 and C.1.

TIROS-N remained operational for 868 days until deactivated by NOAA on Feb. 27, 1981.

G.14.1.1 NOAA-6 (NOAA-A)

The S/C was launched on June 27, 1979 on an Atlas E/F vehicle from VAFB, CA. This was the first operational satellite of the TIROS-N series. Repeat cycle: 9 days for nadir viewing. The S/C prior to launch became new names in this series, starting with NOAA-A (not ITOS) to designate the new S/C design. The NOAA-6 S/C is identical to the TIROS-N S/C with a total mass of 723 kg.

Orbit: near-circular sun-synchronous polar orbit, apogee=843 km, perigee=833 km, inclination=98.7°, period=101.5 minutes.

Sensor complement: Same sensor complement as for TIROS-N with a different spectral channel 1 for AVHRR.

AVHRR (Advanced Very High Resolution Radiometer). This AVHRR sensor differs slightly in the first spectral channel from the TIROS-N version (Channel 1 = 0.550-0.68 μm), otherwise the instrument is identical to that of TIROS-N.

NOAA-6 was used as standby after the launch of NOAA-8 (1983). TOVS failed on Oct. 22, 1983. NOAA-6 remained operational until Nov. 16, 1986 and was deactivated by NOAA on March 31, 1987.

G.14.2 NOAA-B

Launch of S/C on May 29, 1980 on an Atlas E/F vehicle from VAFB, CA. The S/C (mass of 1405 kg) failed to achieve proper orbit.

G.14.3 NOAA-7 (NOAA-C)

Launch on June 23, 1981 on an Atlas E/F vehicle from VAFB, CA. Same S/C as NOAA-6 and the same sensor complement except for AVHRR (see AVHRR/2 configuration in Table 375. The S/C mass is 1405 kg.

Table 374: Summary of U.S. civilian env./met. satellites (chronological order)

Figure 217: Typical NOAA POES series S/C models

Orbit: near-circular sun-synchronous polar orbit, apogee=869 km, perigee=852 km, inclination=98.9°, period=101.9 minutes.

TOVS failed on Feb. 7, 1985. The MEPED and HEPAD space environment instruments were turned off April 1, 1982 because of electrical interference with the command and control receiver. NOAA-7 remained operational for 2625 days and was deactivated by NOAA on June 7, 1986 due to a power failure.

G.14.4 NOAA-8 (NOAA-E)

Launch on March 28, 1983 on an Atlas vehicle from VAFB, CA. First of ATN satellite series. The system **S&RSAT** (Search and Rescue Satellite) is flown for the first time (see chapter I.6). Note: Although the original acronym for 'Search and Rescue' is 'SAR' in the context of NOAA missions, it was changed in this book consistently to 'S&R' in order to distinguish it from the other widely-used meaning of SAR, namely 'Synthetic Aperture Radar,' an active sensor type. A consequence is the use of 'S&RSAT' (instead of SARSAT), to use S&RR (Search and Rescue Repeater) instead of SARR, as well as to use S&RP (Search and Rescue Processor) instead of SARP.

Orbit: near-circular sun-synchronous polar orbit, apogee=829 km, perigee=806 km, inclination=98.9°, period=101.2 minutes.

Sensor complement: AVHRR, TOVS (HIRS/2,SSU,MSU), MEPED, TED. Same as for NOAA-6 with the addition of S&RSAT. - AVHRR was capable of operating in both real-time or recorded modes. Real-time or direct readout data were transmitted to ground stations both at low (4 km) resolution via APT, and at high (1 km) resolution via high-resolution picture transmission (HRPT).

NOAA-8 remained operational for 1016 days until deactivated by NOAA on Jan. 9, 1986, following a thermal runaway which destroyed the battery.

G.14.5 NOAA-9 (NOAA-F)

Launch on Dec. 12. 1984 on an Atlas E/F vehicle from VAFB, CA. First test flights for **ERBE** (Earth Radiation Budget Experiment, see description in chapter A.13) and **SBUV/2** (Solar Backscatter Ultraviolet) instruments (G.14.11). S/C mass = 1712 kg.

Orbit: near-circular sun-synchronous polar orbit, apogee=862 km, perigee=842 km, inclination=99.17°, period=102 minutes.

Sensor complement: AVHRR/2, TOVS (HIRS/2, MSU, SSU), ERBE, SBUV/2, S&RSAT, Argos/DCS.

Status 1992 (S/C in standby operation, the power system is considered to be very marginal). Digital tape recorder failed two months after launch. ERBE stopped operation in Jan. 1987. AVHRR has at times exhibited anomalous behavior in its synchronization in MIRS. MSU channels 2 and 3 have failed, and the power system is degraded. SBUV/2 is operating satisfactorily. The satellite is collecting, processing, and distributing SBUV/2 and ERBE nonscanner data. It is also providing S&R data.

NOAA-9 was deactivated on August 1, 1993. It was reactivated on Aug. 23. 1993 after the failure of NOAA-13.

Status 3/2001: S/C deactivated Feb. 20, 1998 in anticipation of the NOAA-15 launch.

G.14.6 NOAA-10 (NOAA-G)

Launch on Sept. 17, 1986 on an Atlas E/F vehicle from VAFB, CA. Same S/C structure as for NOAA-8. S/C mass = 1700 kg.

Orbit: near-circular sun-synchronous polar orbit, apogee=824 km, perigee=803 km, inclination=98.7°, period=101.3 minutes.

Sensor complement: AVHRR, TOVS (HIRS/2, MSU, SSU), ERBE, SBUV/2, SEM (MEPED, TED), S&RSAT, Argos/DCS. The TED on NOAA-10 displayed serious anomalies beginning in late 1987 and data acquired after February 29, 1988 are of marginal quality.

The solid state detectors in the electron portion of the MEPED became noisy after 01 January 1, 1991 and those data were much degraded for the remainder of the mission.

Status 1992 (S/C in standby operation utilizing STIP record mode): The ERBE non-scanner mode is performing well, while the ERBE scanner mode failed in 1989. It has exhibited a scan sticking anomaly that is apparently generic to the instrument. The S&R processor (406 MHz) has failed.

Status 1/1994: in standby operation. Operational instruments: AVHRR, MSU, DCS, HIRS/2, S&R. Status 1/1996: The NOAA-10 S/C was deactivated in March 1995.

G.14.7 NOAA-11 (NOAA-H)

Launch on Sept. 24, 1988 on an Atlas E/F vehicle from VAFB, CA. Same S/C structure as for NOAA-8. S/C mass = 1712 kg.

Orbit: near-circular sun-synchronous polar orbit, apogee=863 km, perigee=845 km, inclination=98.9°, period=102.1 minutes. Ascending orbit at 1:49 PM.

Sensor complement: AVHRR/2, TOVS (HIRS/2, MSU, SSU), SBUV/2, S&RSAT, Argos/DCS.

Status: The AVHRR scan motor failed in Sept. 1994, leaving the instrument inoperative. In Oct. 1994 the SBUV/2 diffuser failed. However, SBUV/2 continues to collect global ozone data. The S/C was placed in standby mode in March 1995.

G.14.8 NOAA-12 (NOAA-D)

Launch on May 14, 1991 on an Atlas E/F vehicle from VAFB, CA. Same S/C structure as for NOAA-N. S/C mass = 1416 kg.

Orbit: near-circular sun-synchronous polar orbit, apogee=825 km, perigee=806 km, inclination=98.7°, period=101.3 minutes. AM orbit.

Sensor complement: AVHRR, TOVS (HIRS/2, MSU, SSU), SEM (MEPED, TED). S&RSAT was not flown.

Status 3/2001: HIRS suffered a significant degradation on May 30, 1997. Otherwise, NOAA-12 supports all other services.

G.14.9 NOAA-13 (NOAA-I)

Launch on Aug. 9, 1993 on an Atlas E vehicle from VAFB, CA. Same S/C structure as for NOAA-8. S/C mass = 1712 kg.

Orbit: near-circular sun-synchronous polar orbit, apogee=825 km, perigee=806 km, inclination=98.7°, period=101.3 minutes.

Sensor complement: AVHRR/2, TOVS (HIRS/2, MSU, SSU), EHIC, MAXIE, SBUV/2, MEPED, TED, S&RSAT, Argos/DCS.

The S/C and its systems operated successfully for 12 days until a circuit failure resulted in a power loss. Hence, the S/C and payload could not be operated and must be regarded a total loss.

The regular payload of NOAA-13 was complemented with two special instruments, MAXIE and EHIC. Both were one-of-a-kind sensors, hence they were not available for NOAA-14 or follow-on missions.

MAXIE = Magnetospheric Atmospheric X-Ray Imaging Experiment (Lockheed and University of Bergen, Norway). MAXIE maps the intensities and energy spectra of X-rays pro-

duced by electrons that precipitate the atmosphere. With mechanical scanning, MAXIE will obtain new high-resolution X-ray imaging data on auroral and substorm processes at a temporal resolution and repetition rate so far not available.

Combined with other data, a more complete analysis of the radiation environment is obtained. Derived products include vertical profiles of ionization and electrical conductivity, as well as the imaging of the aurora in sunlight. These products are used to determine atmospheric scale height and other synoptic information.

EHIC = Energetic Heavy Ion Composition (U. of Chicago and NRC HIA of Canada) EHIC measures the chemical and isotopic composition of energetic particles between hydrogen and nickel over the energy range of 0.5 to 200 MeV/nucleon. The experiment will measure energetic solar flare particles in the polar regions where the Earth's magnetic field connects to the interplanetary field carried in the solar wind. It will also measure trapped energetic particles in the magnetosphere.

The primary objective of EHIC is to obtain elemental and isotopic composition data, which can be used to test models for solar flare ion acceleration, ion transport in interplanetary space, ion entry into the magnetosphere, and nucleosynthetic processes leading to the elemental and isotopic mix found at the sun.

G.14.10 NOAA-14 (NOAA-J)

Launch on Dec. 30, 1994 on an Atlas E vehicle from VAFB, CA. Same S/C structure as for NOAA-8. S/C mass = 1745 kg.

Orbit: near-circular sun-synchronous polar orbit, apogee=861 km, perigee=847 km, inclination=98.1°, period=102.1 minutes. PM orbit.

Sensor complement: AVHRR/2, SBUV/2, TOVS (HIRS/2I, MSU, SSU), SEM, Argos/DCS, S&RSAT

Status 3/2001: All instruments are functional except the S&R (Search & Rescue) repeater which failed immediately after launch. Also the SBUV/2 data is highly degraded due to failures in a grating drive and also due to orbital drift.

G.14.11 Sensor Descriptions of 4th Generation Series

AVHRR (Advanced Very High Resolution Radiometer) is a broadband, four or five channel (depending on model) cross-track scanning whiskbroom instrument (built by ITT Aerospace of Fort Wayne, IN). Data output = 10 bit, spatial resolution = 1.1 km at nadir and 6 km at maximum scan (at the swath edges). IFOV = 1.4 mrad (average), scanning rate = 360 per minute, sampling rate = 2048 per scan, sample step = 0.95 mrad (1.36 samples per IFOV), scan angle (max) = $\pm 55.4^\circ$ from nadir, swath width = 2400-3000 km (depending on S/C orbit). Note: the five-channel configuration is also referred to as 'AVHRR/2.'

AVHRR is comprised of five modules: Scanner module, electronics module, radiant cooler, optical system, and baseplate. - The optical system consists of an afocal reflective Cassegrainian telescope with an aperture diameter of 20.3 cm, combined with secondary optics which separate the radiant energy into discrete spectral bands; these are focused onto the respective field stops. The VIS and VNIR channels (channel 1 and 2) use silicon detectors to measure incident radiation. All IR detectors are cooled to 105 K. Channel No. 3 uses InSb detectors, while channels 4 and 5 use HgCdTe detectors. Radiant cooler: two-stage system.

All five channels of AVHRR are registered so that they all measure energy from the same target location at the same time. All five channels are also calibrated so that the signal amplitude in each channel is a measure of the scene radiance as received at the sensor aperture. The solar channels are pre-launch calibrated, the thermal channels are calibrated

against a laboratory blackbody source. A passive blackbody mounted on the baseplate assists inflight calibration of the thermal bands. No inflight calibration of the VIS and NIR channels is available. Although the calibration varies from instrument to instrument, the design goals for the infrared channels are: NEDT of 0.12 K (@ 300 K) and an SNR of 3:1 @ 0.5% albedo.

Objectives: Measurement of radiance data for investigation of clouds, land-water boundaries, snow and ice extent, sea surface temperature, day and night cloud distribution, vegetation index. The benefit of AVHRR data lies in its high temporal frequency of coverage, global coverage at least once per day. Applications: Operational meteorology, oceanography, climatology, vegetation monitoring, land and sea ice observation.¹²⁴⁴⁾

Channel No.	TIROS-N	NOAA-6, -8, -10	NOAA-7, -9, -11, -12, -14	IFOV (mrad)	Principal use of channel

Table 376: Temporal AVHRR coverage of NOAA POES series satellites

HIRS/2I (High Resolution Infrared Radiation Sounder, built by ITT)

Measurement of atmospheric temperature and humidity. This instrument detects and measures energy emitted by the atmosphere to construct a vertical temperature profile from the Earth's surface to an altitude of about 40 km. Measurements are made in 20 spectral channels in the infrared band (one frequency lies at the high frequency end of the visible range). Nadir scan, swath = 2240 km. Spatial resolution = 20.4 km.

Cha. No	Center frequency (μm)	Cha. No	Center frequency (μm)	Cha. No	Center frequency (μm)	Cha. No	Center frequency (μm)
1	14.95	6	13.64	11	7.33	16	4.40
2	14.71	7	13.35	12	6.72	17	4.24

4	14.22	9	9.71	14	4.52	18	3.76
5	13.97	10	8.16	15	4.46	20	0.69

Table 377: Center frequencies of HIRS/2 channels

¹²⁴⁴⁾A. Schwalb, "The TIROS-N/NOAA A-G Satellite Series," NOAA Technical Memorandum NESS 95, March 1978

MSU = Microwave Sounding Unit (JPL sensor)
 MSU detects and measures the energy from the troposphere to construct a vertical temperature profile to an altitude of about 20 km. Measurements are made by radiometric detection of microwave energy divided into four frequency channels. Each measurement is made by comparing the incoming signal from the troposphere with the ambient temperature reference load. Because its data are not seriously affected by clouds, the MSU is used along with HIRS/2 and HIRS/2I to remove measurement ambiguity when clouds are present. Data output: 12-bit binary at 0.32 kb/s. MSU has been operational since 1978.

Spectral ranges	50.3, 53.74, 54.96, and 57.95 GHz (4 channels)
FOV	95°
Swath width	2348 km
Spatial resolution	105 km at nadir

Table 378: MSU specification parameters

SSU = Stratospheric Sounding Unit, (UK sensor built by Matra Marconi)
 Temperature measurements in the upper atmosphere are derived from radiance measurements made in three channels using a pressure-modulated gas (CO₂) to accomplish selective bandpass filtration of the sampled radiances. Measurements of temperature profiles, top of atmosphere radiation (from 25 km to 50 km in altitude). Spectral ranges (cm⁻¹): 669.99, 669.63, 669.36. Resolution: 147.3 km at nadir. IFOV: 10°. Data output: 12-bit binary sampled at 0.48 kbit/s.

ERBE = Earth Radiation Budget Experiment (on NOAA-9 and -10 only). Measurement of Earth radiation gains and losses. Duty cycle: 100%. See sensor description in chapter A.13.

Figure 218: Schematic optical diagram of the SBUV instrument

SBUV/2 = Solar Backscatter Ultraviolet (on PM satellites only)
 The SBUV/2 sensor is a spectrally scanning UV radiometer (nadir-viewing sensor). Measurement of solar irradiance and scene radiance (backscattered solar energy) over a spectral range of 0.16 to 0.40 μm (sweep mode). Resolution = 170 km (FOV=11.3°). The instru-

ment design is based upon the technology developed for the SBUV/TOMS flown on Nimbus 7. Application: atmospheric chemistry (measurement of trace gases). Sensor objectives:

- to make measurements from which total ozone concentration in the atmosphere can be determined to an absolute accuracy of 1 percent.
- to make measurements from which the vertical distribution of atmospheric ozone can be determined to an absolute accuracy of 5%.
- to measure the solar spectral irradiance from 0.16 to 0.40 μm .

Discrete mode	Measures from 252.0 to 339.8 nm in 12 discrete 1 nm bands
Sweep mode	Continuous scan from 160 to 400 nm
Cloud Cover Radiometer (CCR)	Measures brightness temperature of the Earth's surface at 380 nm

Table 379: Some parameters of SBUV/2

G.14.12 SEM (Space Environment Monitor)

This instrument package is different from the normal Earth-observing payload of the NOAA-POES satellite series. The objective is to provide “space weather” to the user community by measuring the solar wind particle flux and its variations. The package is provided by NOAA/SEC of Boulder, CO. SEM-1 instruments were initially introduced on satellites in geostationary orbit on 1974. SMS-1, a predecessor of the NOAA-GOES series, was the first satellite to carry SEM. NOAA introduced SEM on the POES series as well starting with TIROS-N in 1978.

SEM = Space Environment Monitor (POES series instruments)

SEM is a multichannel, charged-particle spectrometer that measures the population of the Earth's radiation belts and the particle phenomena resulting from solar activity (both of which contribute to solar/terrestrial energy interchange). SEM consists of two or three separate sensor units and a common DPU (data processing unit). The sensor units are TED, MEPED, and HEPAD (occasionally). The lower-energy sensors (TED, plus the proton and electron telescopes of MEPED) have pairs of sensors with different orientations because the direction of the particle fluxes is important for characterizing the energy interchanges taking place. Objectives:

- to determine the energy deposited by solar particles in the upper atmosphere
- to provide a solar storm warning system

TED = Total Energy Detector. Measurement of protons and electrons in 11 bands in the energy range:: 0.3 to 20 keV.

MEPED = Medium Energy Proton and Electron Detector. Performance: Proton: 30 to 2500 keV in five bands. Electron: >30 to > 300 keV in three bands. Ions: > 6 MeV. Omni-proton: > 16 MeV, > 36 MeV, > 80 MeV.

HEPAD = High Energy Proton and Alpha Particle Detector (see F.4.2).

G.15 5th Generation Satellites of NOAA-POES Series

The 5th generation series of polar orbiting NOAA satellites started with NOAA-K (NOAA-15) which was launched on a Titan II vehicle on May 13, 1998 from VAFB, CA into a morning orbit to replace the aging NOAA-12 satellite.

The KLM S/C have significant changes to the previous 4th generation satellites with regard S/C design and payload. The S/C structure comprises four assemblies: IMP (Instrument Mounting Platform), EBM (Equipment Support Module), RCE (Reaction Control Equip-

ment), RCS (Reaction Support Structure), and SA (Solar Array) assembly. To meet the increased power requirements of new instruments, two additional solar panels have been added, the solar array has about 45% more output. The batteries, propulsion tank capacity, the size of the reaction wheels and magnetic coils used for momentum unloading and attitude control, have also increased in capacity. The spacecraft structure has been stiffened primarily to support the heavier AMSU instruments and improve launch vehicle load margins. Several antennas have been relocated and/or built with new materials and processes to improve performance. Flight computer memory has been doubled and the flight software modified to meet new requirements. ¹²⁴⁵⁾

1st generation 1960 - 1965	TIROS series [TIROS-1 (1960) to TIROS-10 (1965)]
2nd generation 1966 - 1969	TOS (TIROS Operational System) series as pre-launch designation. The in-orbit satellite designation was ESSA [ESSA-1 (1966) to ESSA-9 (1969)], after the S/C operating agency.
3rd generation 1970 - 1976	ITOS (Improved TIROS Operational System) series as pre-launch designation. The in-orbit satellite designation was NOAA [NOAA-1 (1970) to NOAA-5 (1976)]
4th generation 1978 - 1994	ATN [Advanced TIROS-N) series. After TIROS-N (1978) the pre-launch designation changed to NOAA-A (the corresponding inflight name was NOAA-6). The pre-launch letter designation was kept throughout. NOAA-14 was the last S/C
5th generation 1998 - 2008	NOAA-15 and -16 (launch May 13, 1998 and Sept 21, 2000, respectively), former NOAA-K and -L), NOAA-M, -N, -N'

Table 380: Overview of the US polar meteorological programs

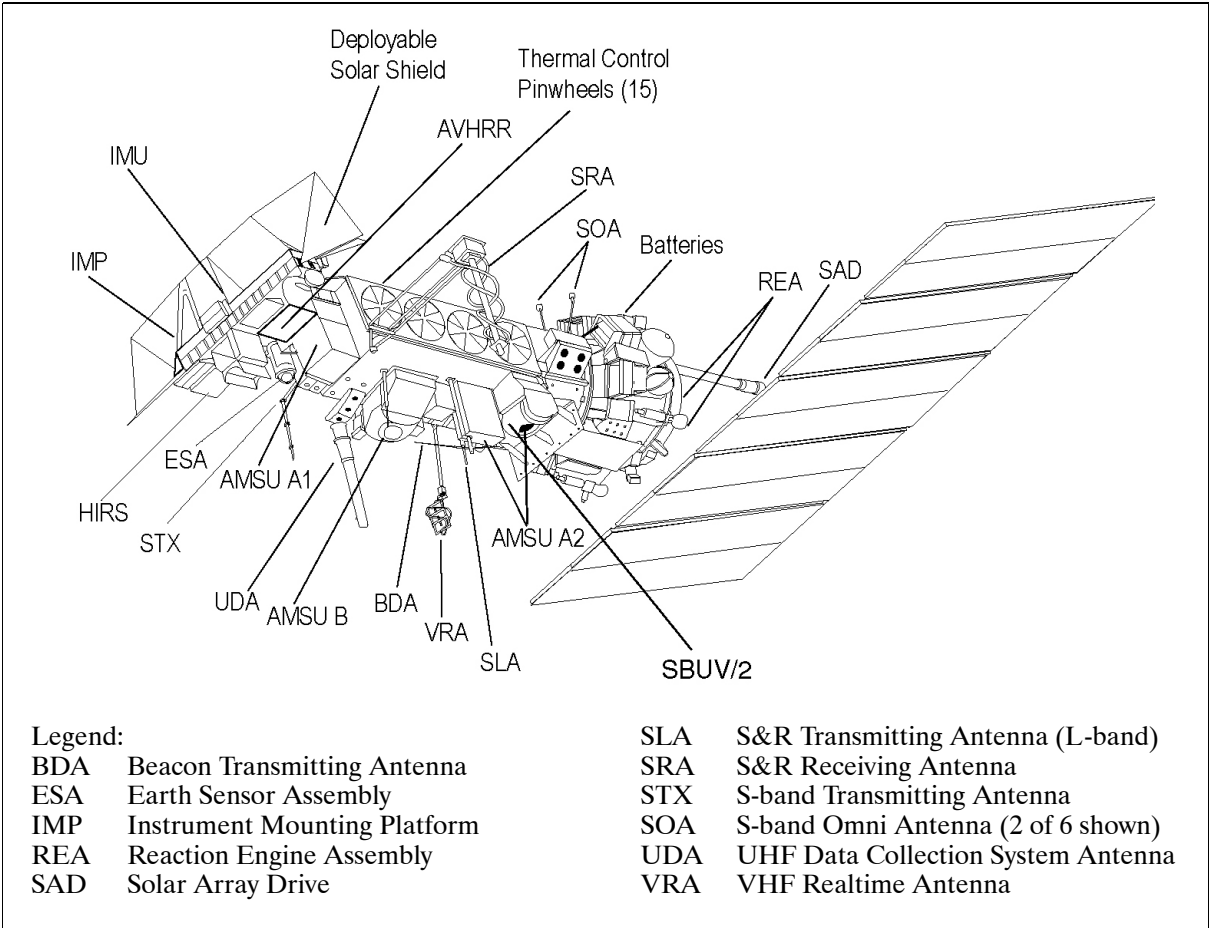

Figure 219: Illustration of the 5th generation satellite configuration

The ADACS (Attitude Determination and Control Subsystem) provides in conjunction with RCS (Reaction Control Subsystem) and the CCS (Command and Control Subsystem)

¹²⁴⁵⁾M. Mignogno, “NOAA Polar Program Plans for Continuous Satellite Coverage,” Proceedings of the 1999 EU-METSAT Meteorological Satellite Data User’s Conference, Copenhagen, Denmark, Sept. 6-10, 1999, pp. 11-15

the functions of the on-orbit attitude control and ascent guidance. It is a zero-momentum system consisting of reaction wheels and Earth, sun, and inertial reference sensors. In the subsystem's attitude–control mode, the Earth Sensor Assembly (ESA) and the sun sensor, together with rates derived from the IMU (roll, pitch and yaw)), furnish the primary attitude reference. Actuation is provided by reaction wheels and cold gas thrusters. Attitude accuracy is 0.2°, knowledge is 0.1° in post-processing. Attitude determination with 3-sigma variation >0.14° is provided onboard the satellite.

Satellite orbit	Sun-synchronous circular, altitude = 833 ± 19 km or 870 ± 19 km, inclination = 98.7° (retrograde)
S/C dimensions (main body)	4.18 m length, 1.88 m diameter, overall length = 7.4 m
S/C mass	1479 kg on orbit, 2232 kg at launch (756 kg propellant)
S/C power (solar array)	833 W min, array size: 2.73 m x 6.14 m (16.76 m ²)
On-board data recording	5 DTR (Digital Tape Recorder), each with a capacity of 0.9 Gbit. Solid-State Recorders (SSRs) will fly on NOAA-M (1 SSR, 4 DTR), and NOAA-N and N' with 3 SSRs each with a capacity of 2.7 Gbit
AKM (Apogee Kick Motor)	Star 37XFP (Thiokol Corporation), used to circularize the orbit after S/C separation. A thrust of 42.38 kN is provided (51 s burn)

Table 381: Some 5th generation NOAA spacecraft characteristics

Satellite communication subsystem: The on-board communication subsystem comprises 14 antennas, 9 transmitters, and redundant receivers, together with associated filters and other RF feed components. The subsystem provides the following functions: (refer to Figure 216)

- Reception and demodulation of S-band TT&C data
- Continuous transmission (broadcast) of TIP data via the VHF Beacon
- Continuous transmission (broadcast) of APT data at VHF-band
- Continuous transmission (broadcast) of HRPT data at S-band
- Transmission of stored LAC, GAC, TIP, and AIP (AMSU Information Processor) data upon command at S-band
- Reception and filtering of DCS signals
- Reception, processing and retransmission of S&R signals.

Type of Service	NOAA-9 through NOAA-N'
GAC (Global Area Coverage) Playback	Reduced resolution AVHRR data (4 km) plus stored TIP data at full resolution soundings. GAC data is derived on-board the NOAA satellite by subsampling and averaging the nominal 1 km AVHRR imagery. It provides daily global coverage recorded on-board and transmitted to a NOAA ground station. About 115 minutes of GAC data can be stored on-board.
LAC (Local Area Coverage)	LAC is nominally 1 km resolution AVHRR imagery (which is normal or 'high' resolution data) recorded with the on-board tape recorder for subsequent transmission to a NOAA ground station. About 11 minutes of LAC data can be accommodated on a recorder. LAC imagery can only be obtained from NOAA/NESDIS.
HRPT (High Resolution Picture Transmission)	Full resolution AVHRR & TIP data, Frequency: 1698 or 1707 MHz, data rate = 665.4 kbit/s, split phase PSK. The imagery is available in a format defined by the ground receiving station.
APT (Automatic Picture Transmission) (LRPT in OPQ era)	Reduced resolution geometrically corrected analog video from two channel of AVHRR, selected by user command. Frequency: 137.50 or 137.62 MHz
Beacon	HIRS, SEM, DCS, SBUV, & Eph

Table 382: Real-time and global data services current/future NOAA POES missions ¹²⁴⁶⁾

Sensor complement of NOAA-15: AVHRR/3, HIRS/3, AMSU-A (A1+A2), AMSU-B, SEM-2, ARGOS (DCS-2), and S&RSAT.

¹²⁴⁶⁾In NOAA terminology, TIP (TIROS Information Processor) data refers to low-rate instrument data multiplexed with satellite housekeeping data. It contains all environmental instrument information except that from the AVHRR and the AMSU.

NOAA-15 orbit: Circular sun-synchronous near-polar orbit; altitude = 833 km; inclination = 98.7°; orbital period = 102.12 min; equator crossing at about 7:30 AM.

Spacecraft	Orbit	Launch or projected launch
NOAA-15 (K prior to launch)	AM orbit	May 13, 1998
NOAA-16 (L prior to launch)	PM orbit	Sept. 21, 2000
NOAA-M	AM orbit	2001 with Titan-2 vehicle
NOAA-N	PM orbit	2004 with Delta-2 vehicle (projected)
MetOp-1	AM orbit	2005 with Soyuz vehicle
NOAA-N'	PM orbit	2008 with Delta-2 vehicle
MetOp-2	AM orbit	2010 with Soyuz vehicle

Table 383: Projected launch dates of POES series and MetOp series S/C

G.15.1 Sensors for the POES K, L, M, N, N' Series

AVHRR/3, HIRS/3 (KLM, HIRS/4 starting with N), AMSU-A, AMSU-B, SEM-2, SBUV/2 (on all PM missions from K through N'), ARGOS (DCS-2), S&RSAT. ¹²⁴⁷⁾

HIRS/3 = High Resolution Infrared Sounder. ¹²⁴⁸⁾ Heritage of HIRS/2I. Objective: measurement of temperature profiles, moisture content, cloud height and surface albedo. HIRS/3 scans the Earth's surface in twenty spectral bands in the range 0.69 - 14.95 μm . The sensor scans across-track in a 'stop-and-stare' mode (discrete stepping) at a scan rate of 6.4 s (56 Earth views per scan). FOV = $\pm 49.5^\circ$ about nadir (swath = ± 1080 km). Collected energy is separated by a beamsplitter into LWIR ($> 6.5 \mu\text{m}$) and SWIR (3.7 to 4.6 μm), passed through field stops and through a rotating filter wheel to cooled detectors. In the SWIR path, a second beamsplitter separates the visible channel to a silicon detector. Three detectors are used to sense the radiation. A silicon photodiode at the instrument temperature (nominally 15° C) detects the visible energy. An InSb detector and a MCT detector (mounted on a passive radiator and operating at 100 K) sense the SWIR and TIR energy. The NESR (Noise Equivalent Spectral Radiance) is given in $\text{W}/(\text{cm}^2 \text{ sr cm}^{-1})$. ¹²⁴⁹⁾

Optical FOV (Field of View)	1.4° for VIS and SWIR; 1.3° for TIR
Telescope aperture	15 cm diameter
Channel to channel registration	TIR: <1.5% of 1.8° step size; SWIR: <1% of cha. 19 FWHM
Earth scan angle, scan steps	$\pm 49^\circ$ from nadir, 56 increments of 1.8°
Step and dwell time	100 ms total
Total scan plus retrace time	6.4 s
Swath width	2160 km
Spatial resolution	20.3 km (1.4° FOV) at nadir; 18.9 km (1.3° FOV) at nadir
Data quantization	13 bit
Data rate	

Table 384: Performance parameters of HIRS/3

IR Calibration of the HIRS/3 is provided by programmed views of two radiometric targets: a warm target (blackbody at 290 K) mounted to the instrument base and a view of space. Data from these views provides sensitivity calibrations for each channel every 40 lines (256 seconds), if commanded. Internally generated electronic signals provide calibration and stability monitoring of the amplifier and readout electronics. Note: The calibration sequencing of HIRS/3 has changed (versus HIRS/2) to remove viewing of the cold internal reference. This allows an additional scan line of data each calibration period. Secondly,

Table 385: Spectral parameters of HIRS/3

HIRS/4 (High Resolution Infrared Sounder). This instrument will fly on NOAA-N, -N', and MetOp 1 and 2, but not on MetOp-3. It has essentially the same features as the HIRS/3, with one significant change. The sampling distance along a scan line remains at nominally 18 km, but the IFOV has been decreased to 10 km from 18 km. This was done to improve the utility of the data near cloud boundaries.

AVHRR/3 = Advanced Very High Resolution Radiometer (3rd generation of AVHRR, heritage of AVHRR/2, built by ITT Aerospace of Fort Wayne, IN). Objectives: day and night imaging in six spectral bands of land, water and top of cloud surfaces, sea surface temperature, ice snow and vegetation cover. The instrument scans in the cross-track direction with a FOV of $\pm 55.37^\circ$ about nadir (swath of 2900 km), IFOV of 1.1 km at nadir (1.3 mrad x 1.3 mrad for all channels). The detectors are passively cooled to < 105 K by a two-stage passive radiant cooler. AVHRR/3 uses a continuously internal rotational scanning mirror which also views deep space and an internal calibration source. Calibration of the IR channels is performed with four internal blackbodies every scan line.^{1250) 1251)}

Telescope	20.3 cm diameter afocal reflective Cassegrainian type
Scan motor	360 rpm hysteresis - synchronous
Scan mirror	21 cm x 29.5 cm elliptical ribbed beryllium
Cooler	Two stage radiant cooler controlled @ 105 K
Data quantization	10 bit
Video sample rate	40 kHz simultaneous sample of all channels
No of samples per scan	2048
Output data rate	200 k word/s max (2 Mbit/s in burst mode, 621.3 Kbit/s average)
Instrument size	80 cm x 36.5 cm x 29 cm
Instrument mass, power	33 kg, 27 W (orbital average) at 28 V

Table 386: AVHRR/3 performance characteristics

¹²⁵⁰⁾ Information provided by G. A. Mandt of NOAA POES Program, "AVHRR/3 Instrument Technical Overview," March 15, 1995 of ITT A/CD

¹²⁵¹⁾ <http://www2.ncdc.noaa.gov/docs/klm/html/c3/sec3-1.htm>

AVHRR/3 adds a sixth channel in the IR range at 1.61 μm (referred to as channel 3a, operating during the daylight part of the orbit). The objective of channel 3a is to aid in improved snow and ice discrimination and aerosol detection. Channel 3b corresponds to the previous channel 3 on AVHRR/2 and operates during the night portion of the orbit. Splitting channel 3 in this way maintains the HRPT format. The data from the six channels is simultaneously sampled at 40 kHz and converted to 10-bit binary values. The data samples are output in a non-continuous burst of 10 space samples, 2048 Earth samples, and 10 internal calibration target samples at 6 Hz, synchronized with the scan mirror.

Figure 220: Illustration of the AVHRR instrument

Channel	Center wavelength (μm)	Spectral Range FWHM (μm)	Channel Noise	Detector Type
1	0.630 (VIS)	0.58 - 0.68	$\text{SNR} \geq 9:1 @ 0.5\% \text{ albedo}$	Silicon
2	0.862 (VNIR)	0.725 - 1.00	$\text{SNR} \geq 9:1 @ 0.5\% \text{ albedo}$	Silicon
3a	1.61 (NIR)	1.58 - 1.64	$\text{SNR} \geq 20:1 @ 0.5\% \text{ albedo}$	InGaAs
3b	3.74 (IR-window)	3.55 - 3.93	$\text{NE}\Delta\text{T} \leq 0.12 \text{ K} @ 300 \text{ K}$	InSb
4	10.80 (IR-window)	10.30 - 11.30	$\text{NE}\Delta\text{T} \leq 0.12 \text{ K} @ 300 \text{ K}$	HgCdTe
5	12.00 (IR window)	11.50 - 12.50	$\text{NE}\Delta\text{T} \leq 0.12 \text{ K} @ 300 \text{ K}$	HgCdTe

Table 387: Spectral parameters of AVHRR/3

AVHRR/3 (like AVHRR/2) is an optomechanical system comprised of five modules: scanner module, electronics module, radiant cooler, optical system, and baseplate unit. - The optical system consists of collecting telescope (an afocal reflective Cassegrainian type telescope with an aperture diameter of 20.32 cm), combined with secondary (relay) optics which separate the radiant energy into six discrete spectral bands; these are focused onto their respective field stops. Polarization effects have been minimized in channels 1, 2 and 3A by passing the optical beam, transmitted by the first VIS/IR beamsplitter, through a second beamsplitter oriented in such a way as to compensate for polarization introduced by the first beamsplitter (the split gain technique increases the sensitivity for snow and ice coverage, aerosol distribution and vegetation index calculation). - The scan motor design is based on an 80 pole hysteresis synchronous motor. It rotates the mirror at a rate of 360 rpm to produce a contiguous scan on the Earth's surface.

The AMSU (Advanced Microwave Sounding Unit) is a 20-channel microwave radiometer. Its primary mission objective is to obtain global temperature and humidity profiles. AMSU is comprised of three separate units: AMSU-A1 (channels 3-15), AMSU-A2 (channels 1 and 2), and AMSU-B (channels 16 - 20). Channels 3 - 14 use the 50 to 60 GHz oxygen band to provide data for vertical temperature profiles up to 50 km. The “window” channels (1, 2, 15, and 16) provide data to enhance temperature sounding by correcting for surface emissivity, atmospheric liquid water, and total precipitable water. Channels 18 - 20 use the 183.3 GHz water vapor absorption line to provide data for the humidity profile. The first flight of AMSU is on the NOAA-15 satellite.

AMSU-A = Advanced Microwave Sounding Unit - A (always consisting of AMSU-A1 and AMSU-A2), was built by Aerojet, a subsidiary of GenCorp of Sacramento, CA for NASA/GSFC. AMSU-A replaces the MSU and SSU instruments flown on previous missions. Objectives: atmospheric temperature profile measurements from the surface up to 50 km in 15 channels. Temperature resolution: 0.25 - 1.2 K. AMSU-A is configured in the following major subsystems: Antenna/Drive/Calibration Subsystem; Receiver Subsystem; Signal Processor Subsystem and Structural/Thermal Subsystem. The Antenna/Drive/Calibration subsystem consists of a conical corrugated horn-fed shrouded reflector, multiplexer, closed-loop antenna scan drive assembly and closed path calibration assembly. The shrouded reflector is rotated once every scan line (8 s) for:

- Each of 30 Earth viewing scene observations
- A view of the cosmic background (about 2.73 K)
- A view of a warm calibration load (about 300K)

During the rotation cycle, the shroud prevents solar reflections from interacting with the warm load and also ensures maximum coupling of the source radiation to the antenna feed. A complete end-to-end in-flight calibration is achieved in a through-the-antenna method, which provides maximum in-flight calibration accuracy. The accuracy of the warm calibration load brightness temperature is $> \pm 0.2$ K. The closed loop antenna scan drive provides beam pointing accuracy within $\pm 0.2^\circ$. A resolver in the antenna drive assembly provides antenna beam position information.

Sensor Unit	Channel No.	Center Frequency (GHz)	Bandwidth (MHz)	Sensitivity NE Δ T (K)	Polarization at Nadir
AMSU-A2 (2 channels)	1	23.8	280	0.3	V
	2	31.4	180	0.3	V
AMSU-A1 (13 channels)	3	50.300	180	0.4	V
	4	52.800	400	0.25	V
	5	53.596 \pm 0.115 (2 bands)	170	0.25	H
	6	54.400	400	0.25	H
	7	54.940	400	0.25	V
	8	55.500	330	0.25	H
	9	57.290344 = Flo	330	0.25	H
	10	Flo \pm 0.217 (2 bands)	78	0.4	H
	11	Flo \pm 0.3222, (\pm 0.048)	36	0.4	H
	12	Flo \pm 0.3222, (\pm 0.022)	16	0.6	H

	20	183.31 \pm 7.00 (2 bands)	2000	0.60	90- θ

Table 388: Spectral parameters of the AMSU-A and AMSU-B instruments ¹²⁵²⁾

The AMSU-A1 instrument has two 8 cm diameter antennas (reflectors without momentum compensation), each with a 3.3° nominal IFOV at the half power points (FWHM). Each

¹²⁵²⁾ Note: The polarization angle is defined as the angle from horizontal polarization (i.e., electric field vector parallel to satellite track) where θ is the scan angle from nadir. In this table, the polarization angle is horizontal when the angle indicated is θ and vertical when $90-\theta$

antenna provides a cross-track scan of $\pm 48.33^\circ$ from nadir with a total of 30 contiguous Earth views (stepped scan positions) per scan line. The total scan period is 8 seconds. The footprint (resolution) at nadir is 50 km. The swath width is approximately 2000 km. Channels 11 through 14 contain 4 pass bands each. Data rate of 3.2 kbit/s. Instrument mass = 100 kg, power = 125 W.

AMSU-A2 has a single 17 cm diameter antenna (reflector with momentum compensation) with a 3.3° nominal IFOV. All other instrument/observation parameters are the same as for AMSU-A1.

AMSU-A utilizes an 8-second scan period with a step and settle scan across the Earth scene while AMSU-B utilizes an 8/3-second scan period with a constant speed scan across the Earth scene.

AMSU-B = Advanced Microwave Sounding Unit - B (three flight instruments are being built and provided to NOAA-K, -L and -M satellites by UKMO, Farnborough, PI: R. Saunders, AMSU-B is built by MMS Bristol, UK). The objective is to obtain humidity profiles in five channels spanning the height range from the surface to about 42 km. AMSU-B covers channels 16 through 20. The highest channels: 18, 19 and 20, span the strongly opaque water vapor absorption line at 183 GHz and provide data on the atmosphere's humidity level.

The AMSU-B consists of a scanning parabolic reflector antenna (30 cm diameter) which is rotated once every 8/3 seconds and focuses incoming radiation into a quasi-optic system which then separates the frequencies of interest into three separate feed horns of the receiver assembly. The receiver subsystem provides further demultiplexing of the 183 GHz signal in order to selectively acquire three defined double sided bands around the 183 GHz signal. The antenna provides a cross-track scan of $\pm 48.95^\circ$ (FOV) from nadir with a total of 90 Earth views per scan line. The instrument's IFOV is 1.1° and the separation between the center of one Earth view to the next is 1.1° . The total scan period is 8/3 seconds. Internal calibration is performed with an internal warm load and cold space (space calibration = 80° from nadir). All channels have a spatial resolution of about 16.3 km at nadir (1.1° IFOV). The swath width is approximately 2200 km. Data rate = 4 kbit/s. The instrument mass is 60 kg, power = 90 W. AMSU-B ensures a twice daily full global coverage. AMSU-B employs the Schottky planar whiskerless diode technology in the mixer of the receiver. - AMSU-B is the first moisture sounder flown in the NOAA polar series. In addition to providing high-resolution atmospheric moisture profiles, AMSU-B is used to produce precipitation and surface products from two window channels. ¹²⁵³⁾

MHS = Microwave Humidity Sounder. MHS is an EUMETSAT instrument provided by the UKMO (UK Meteorological Office). MHS is a five channel self-calibrating instrument providing humidity profiling capability in the frequency range of 89 - 190 GHz. The measured signals are also sensitive to a) liquid water in clouds (cloud liquid water content) and b) graupel and large water droplets in precipitating clouds (qualitative estimate of precipitation rate).

Channel	Center Frequency (GHz)	Max. Bandwidth (MHz)	Sensitivity (K)
1	89.0	2800	1.0
2	157.0	2800	1.0
3	183.311 ± 1.0	1000	1.0
4	183.311 ± 3.0	2000	1.0
5	190.311	2200	1.0

Table 389: Spectral Parameters of MHS

MHS scans in the cross-track direction at a rate of 8/3 seconds (2.67 s) in continuous mode. The instrument's IFOV is 1.1° and the separation between the center of one Earth view to

¹²⁵³⁾ <http://www2.ncdc.noaa.gov/docs/klm/html/c3/sec3-4.htm>

the center of the next is exactly $10/9^\circ$ (1.111°). The circular IFOV has a diameter at nadir of about 16.3 km. The observed swath width is ± 1078 km. MHS technology used: advanced quasi-optics, planar millimetric frontends, precision calibration target, scan mechanism and reflector are combined with low power and mass electronics for minimum mass and power. Thermal control is passive and isolated from the spacecraft. Instrument mass = 63 kg, power = 83 W. The MHS instrument replaces AMSU-B, it is planned to be flown on the NOAA-N and N' satellites, it will also be flown on the MetOp series of EUMETSAT.

SBUV/2 = Solar Backscatter Ultraviolet Radiometer (further development of Nimbus SBUV). This instrument is pointed toward nadir; there are 12 channels between 255 nm and 340 nm. Measurement of ozone profiles and of backscatter radiation. This sensor is used on PM and late AM missions (NOAA-M is planned for a 10 AM descending sun-synchronous orbit. NOAA-16, -N and -N' are planned for 2:00 PM ascending sun-synchronous orbits.)

G.15.2 SEM-2 (Space Environment Monitor-2)

Starting with NOAA-K (NOAA-15, launch May, 13, 1998), NOAA/SEC added an improved SEM package, referred to as SEM-2. SEM-2 has added in-flight calibration capability and improved charged particle energy coverage. The TED measurement range is now from 0.05 keV to 20.0 keV in 16 energy bands. The energy coverage of the proton detector telescope portion of the MEPED is expanded to 6 energy bands, 30 keV to >6900 keV, and a fourth omnidirectional detector has been added to the MEPED to extend the energetic proton energy coverage to >140 MeV

SEM-2 is a multichannel, charged-particle spectrometer that measures the population of the Earth's radiation belts and the particle phenomena resulting from solar activity (both of which contribute to solar/terrestrial energy interchange). SEM-2 consists of separate sensor units and a common DPU (data processing unit). The sensor units are TED, MEPED, and HEPAD (occasionally). The lower-energy sensors (TED, plus the proton and electron telescopes of MEPED) have pairs of sensors with different orientations because the direction of the particle fluxes is important for characterizing the energy interchanges taking place. Objectives:

- To determine the energy deposited by solar particles in the upper atmosphere
- To provide a solar storm warning system. Large, abrupt changes occur in the solar wind. These changes produce changes in the magnetosphere and the ionosphere. This can result in hazards to people such as astronauts, there is also the potential of increased radiation exposure to people in high flying aircraft. Other functions/facilities on Earth effected by solar wind changes are: a) disruption of navigation, b) absorption, even blackout, of radio waves so that radio communication is disrupted; c) induced voltages and currents in electric power circuits leading to circuit breaker trip, damage to equipment, and failure of transformers; d) induced currents in buried pipe lines causing accelerated corrosion; e) damage by electrons and protons to satellite circuits and solar panels.

TED = Total Energy Detector. TED measures proton and electron fluxes in 16 bands in the 0.05 to 20 keV energy range. Two independent measurements of the particle energy flux are made at zero and 30 degrees from the local vertical. The total energy measurement is divided into two ranges: 0.05 to 1 keV and 1 to 20 keV and each measurement is made independently for electrons and protons. TED also measures the maximum differential energy flux density and the energy at which it occurs for each direction and particle type (electron and proton). TED consists of eight Electrostatic Analyzers (ESA), pulse height discriminators (PHD), an In-Flight Calibrator (IFC), two high voltage (HV) supplies, a sweep voltage supply and housekeeping circuits.

MEPED = Medium Energy Proton and Electron Detector. MEPED provides both directional and omni-directional measurements. The directional sensors utilize telescopes

which make independent measurements of the particle types. Directional measurements are made near the local vertical and near 90° to the local vertical. Protons are measured in 6 bands in the energy range: 30 to >6900 keV. Electrons are measured in three bands: >30 to > 300 keV. The omni-directional sensors measure proton energy in the following ranges: >16 MeV, >35 MeV, >70 MeV and >140 MeV. Each sensor consists of a dome of moderating material which absorbs energy from the particle (and so sets the detection energy threshold), a silicon solid state detector, a preamplifier, and a level comparator which responds to particles with enough energy to go through the moderator and produce a pulse from the detector large enough to exceed the level in the comparator.

The MEPED instrument consists of two proton telescopes, (each containing two solid state detectors (SSDs)), two electron telescopes (each containing a single solid state detector and four omni-directional sensors (each containing a single solid state detector)), charge-sensitive preamplifiers, analog signal processors, proton and electron coincidence logic, in-flight calibrator, low-voltage regulators, SSD bias supply and analog housekeeping.

G.15.3 IJPS (Initial Joint Polar System)

Since the early 1990s, NOAA and EUMETSAT have been discussing/planning future polar cooperation with increased European responsibility for the “morning orbit” to ensure continuity of the POES (Polar-orbiting Operational Environmental Satellites) services. The basic intent is to join the space segment of the emerging MetOp program of EUMETSAT with the existing POES program of NOAA into a fully coordinated service, thus sharing the costs of a program for synergetic reasons. The plans came to a common baseline and agreement, referred to as IJPS, in 1998. 1254) 1255) 1256) 1257)

Background: The NOAA 4th-generation polar program (ATN), which started in 1978 with the launch of TIROS-N, is based on the services of two operational satellites flying in complementary sun-synchronous orbits, one in a “morning or AM” orbit, and the second in an “afternoon or PM” orbit. It so turns out that the data from the PM mission is primary in the USA, with the AM mission providing supplementary and back-up coverage. In Europe the converse is true, with the AM mission providing the most timely coverage.

IJPS comprises two series of independent, but fully coordinated polar satellite systems, namely POES and MetOp, to provide for the continuous and timely collection and exchange of environmental data from space. EUMETSAT plans to include its satellites MetOp-1, -2 and -3 for the morning orbit, while NOAA is starting with its NOAA-N and N’ spacecraft for the afternoon orbit of the coordinated system. Plans call for MetOp-1 and NOAA-N to be launched in 2005 and 2004, respectively.

Instruments: Each IJPS satellite series carries a common set of instruments and additional instruments specific for each orbit. The common set of instruments (morning and afternoon orbits) include: AVHRR/3, HIRS/4, AMSU-A (A1+A2), MHS, ARGOS/ADCS, S&RSAT with instruments including S&RR (CRC, Canada)+S&PR-3 (CNES), and SEM-2. The MHS instrument is provided by EUMETSAT for the NOAA and MetOp series. It replaces the AMSU-B in the POES series instrument baseline. As part of the acquisition activities for NOAA satellites, NOAA will also provide all common instrument sets for MetOp satellites (MHS and ARGOS/ADCS excepted).

The MetOp series specific instruments (in addition to the common set) are:

1255) A. F. Durham, “Future Polar Satellite Program Plan for Global Environmental Observations,” IAF 92-0083, 43rd Congress of the International Astronautical Federation, Aug. 28-Sept. 5, 1992 Washington, D. C.

1256) Bruce H. Needham, “Instrumentation and Services for the NOAA Polar-Orbiting Operational Environmental Satellites (POES) in the 21st Century,” NOAA/NESDIS, Office of System Development, Washington D.C., ‘90

1257) “Pre-Phase-A Study of NOAA O, P, Q Spacecraft and Ground Segment LRPT and HRPT Data Handling and Transmission Subsystems” Draft Final Report, Oct. 16, 1990, Atlantic Research Corp. prepared for NASA/GSFC

- IASI (Infrared Atmospheric Sounding Interferometer)
- ASCAT (Advanced Scatterometer)
- GRAS (GNNS Receiver for Atmospheric Sounding)
- GOME-2 (Global Ozone Monitoring Experiment-2)

The NOAA series specific instrument (in addition to the common set) is:

- SBUV/3 (Solar Backscatter Ultraviolet Radiometer)

EUMETSAT data transmission services:

MetOp satellites provide the service of direct broadcasts using LRPT (Low Resolution Picture Transmission) and HRPT (High Resolution Picture Transmission) with selective virtual channel encryption capability for LRPT and HRPT data. EUMETSAT has adopted CCSDS (Consultative Committee on Space Data Systems) packet telemetry standards for LRPT and HRPT transmissions. The MetOp series will also use an X-band downlink for instrument data dumps from the on-board solid-state recorder.

NOAA data transmission services:

NOAA satellites will use APT (Automatic Picture Transmission) and HRPT direct broadcast services as implemented in the POES system.

IJPS satellite operations:

IJPS satellite operations are implemented separately by EUMETSAT and NOAA with the provision of backup/cross-support capabilities for each other in the ground segment. The global data set is shared. Each ground segment provides for S/C control, command and data acquisition, data processing, distribution, and archiving capabilities. Each agency is in full control of its S/C and ground segment operations.

G.15.4 ARGOS on NOAA-POES Satellites

ARGOS Data Collection System (DCS) on NOAA S/C (provided by CNES/France, installed on all ATN family satellites since 1978; the first satellite equipped with ARGOS was TIROS-N.

The ARGOS/DCS supports NOAA in its overall environmental mission objectives, collecting (ground and space) truthing data. The concept uses many ground segment platforms (fixed and moving), i.e. buoys, free-floating balloons, and remote weather stations, and equips them with a Platform Transmitter Terminal (PTT) package. These PTTs collect and process relevant environmental data and transmit them to the NOAA-POES satellites. The on-board ARGOS DCS receives the incoming signal and measures both the frequency and relative time of occurrence of each transmission. The S/C retransmits these data via the CDA (Command and Data Acquisition) stations (one at Wallops Island VA, the other at Fairbanks, AK; there is in addition a downlink station (CMS) at Lannion, France, (see Figure 196) to a central processing facility. The DCS information is decommutated and sent to the ARGOS processing center where it is processed, distributed to the user community, and stored on magnetic tape for archival purposes. (see also Figure 216).

Each ARGOS PTT transmits encoded messages at regular intervals on a 401.650 MHz uplink. Messages transmitted by the various platforms within satellite visibility are received and selected for processing on a random access basis. The satellite DCS computes the Doppler shift on the receive frequency and generates the ARGOS telemetry message which includes PTT identification, sensor data, measured frequency, and time and date of measurement. A small portion of the S/C downlink is reserved for ARGOS data. Each time a satellite is within visibility of one of the three receiving stations, it downlinks the recorded data.

Some ARGOS system characteristics: (see also chapter C.1)

- Minimum platform/satellite elevation angle of visibility: 5°

- Percentage of platforms with four Doppler measurements per day: >85%
- Measured location accuracy: 350 m
- Message capacity for sensor data: 32 to 256 bits
- Messages are of duration <1 s and are transmitted at regular intervals by any PTT
- Uplink operational frequency: 401.650 MHz
- Typical power of PTT uplink: 200 mW at intervals of 90-15 seconds for location (drifting) PTTs and 200-300 seconds for data collection-only (fixed) platforms.

In 1988 an 'Argos World Service' was introduced providing five times daily location reports on vehicles and freight carrying a standard transmitter. The NOAA Argos packages receive all messages within a 5000 km diameter visibility circle at any instant (footprint); four PTTs can be processed simultaneously by NOAA-1 to 12 (and up to J) S/C.

From NOAA-K onwards (satellites and its successors, there is a modified Argos data collection system referred to as **DCS-2** (the predecessor of ADCS). The data transmission rate for DCS-2 changed from 1200 bit/s to 2560 bit/s. The PTT capacity was increased from four to eight, this means eight DRU (Data Recovery Unit) on-board. The data are formatted and stored, then dumped each time the satellites moves within visibility of one of the three ground stations (Wallops, Gilmore Creek, or CMS). VHF and S-band transmitters also perform real-time relay (broadcast) for any user station within visibility.

An advanced ARGOS system (ADCS) having increased receiver sensitivity, higher platform data rates, and "forward" (S/C-to-platform) command transmission capability is planned for NOAA-N' and for the METOP series.

Part H Satellite Radionavigation Systems

H.1 Galileo

Since 1994 the European Union (EU) has been pursuing a strategy aimed at enabling Europe to the development of a Global Navigation Satellite System (GNSS). In early 1999 the EU proposed a strategy with the goal to design, implement and operate its own constellation of navigation satellites within a program by the name of Galileo (in honor of Galileo Galilei, Feb. 15 1564 - Jan. 8. 1642, Italian astronomer and physicist, founder of experimental physics and astronomy). On March 29, 1999, the EU Transport Ministers endorsed the proposed Galileo program at a meeting in Brussels. Major reasons for Europe's decision to build its own navigation system are:

- Current dependence on navigation systems of GPS and GLONASS that are run by military organizations without any means of international control.
- Europe wants its own civil-controlled navigation system for political and security reasons. To be in a position to compete for a fair share in a large global navigation and communication market. The commitment to build and operate the Galileo navigation system represents a strategic, economic, and technological venture for Europe.
- The requirement for safety-critical application services. Galileo should be able to provide a service with a certifiable performance level (which neither independent satellite navigation system can presently do) to support multimodal traffic, sufficient in particular in civil aviation, marine navigation and road transport.

Responsibility and funding for the definition phase of the Galileo System was given to the EC (European Commission) and to ESA. In this arrangement, the EC is in charge of the overall architecture, including the definition of end user requirements. ESA is responsible for the definition of the space segment and related ground segment required for the navigation satellites and their operation. The ESA program (space segment and related control ground segment) is referred to as **GalileoSat**.

The strategic goals of the overall program include:

- The implementation of a navigation satellite constellation and associated ground infrastructure, providing world-wide coverage, modernized-GPS compatible
- International cooperation, with US to assure system compatibility, and with the Russian Federation to benefit from the Russian industry know-how acquired in the framework of GLONASS
- An approach in phases (GNSS-1, GNSS-2)^{1258) 1259)}, including a definition phase until the end of 2000, a development/validation phase mainly financed through public funding (ESA, EC) to be completed by 2006, and an operational phase involving private funding, leading to full Galileo operational capability by 2008.

The main drivers for the Galileo baseline architecture definition are:

- Independence from other navigation systems
- Inter-operability with GPS and GLONASS
- Navigation (position, velocity) and timing services within the “global Earth coverage and space coverage”
- European integrity service for Galileo
- Independence of the integrity system from the ground control system

¹²⁵⁸⁾GNSS-1 (Global Navigation Satellite System-1). The first generation GNSS-1 comprises the following elements: GPS, GLONASS and their augmentation systems [WAAS (Wide Area Augmentation System) of the US, EGNOS (European Geostationary Navigation Overlay System) of Europe, and MSAS (Multi-Transport Satellite Augmentation System) of Japan]. The three segments of GNSS-1 are expected to be operational by 2003.

¹²⁵⁹⁾GNSS-2 (Global Navigation Satellite System-2). The second generation GNSS comprises all elements of GNSS-1 plus Galileo. GNSS-2 is planned to be operational by 2008.

- World-wide dissemination services for:
 - Search and Rescue (S&R) return link data
 - Two-way navigation-related data communication capability (relating to: weather data, alerts to traffic information and accident warnings, etc.)
- GPS+GLONASS integrity provided by the EGNOS MCCs (Mission Control Center)
- World-wide dissemination of additional Galileo/GPS+GLONASS integrity regional messages provided by NEIDS (Non-European Integrity Determination Systems).

On Dec. 21, 2000 the Transport Council made the decision for the Galileo development phase. The overall Galileo concept is conceived to be a cooperative Public-Private Partnership (PPP) program between industry and governments represented by the respective European institutions.

H.1.1 GalileoSat

According to current plans, in the operational phase the Galileo System will consist of at least 27 spacecraft in Medium Earth Orbit (MEO). First demonstration service is planned to start in 2006, and the system is expected to be fully operational by 2008. The overall architecture of Galileo is shown in Figure 221 (without the monitoring and control data flows).

The main design drivers (and some high-level system requirements) for the space segment are: ¹²⁶⁰⁾

SAS (Safety-of-life Access Service) with regard to:

- The satellite constellation design
- The constellation maintenance strategy
- Requirements for availability of any individual satellite

The satellite design is driven by:

- Use of two clock technologies: S-RAFS (Space-Rubidium Atomic Frequency Standard) and S-PHM (Space-Passive H Maser)
- Specified navigation signal frequency plan
- Provision of 6 CDMA (Code Division Multiple Access) integrity uplink channels per satellite
- HPA (High Power Amplifier) with 60 W RF output power (requirement)
- Time critical functions for dissemination of integrity data
- Capacity (data rate) for the dissemination of: a) navigation data, b) navigation-related data, c) S&R return link data, d) integrity data

Navigation Service	Navigation System Error (95%)		Mean Availability
	Vertical	Horizontal	
SAS (Safety-of-life Access Service) Dual frequency	7.5 m	4.5 m	99.6%
GAS (Governmental Access Service) Dual frequency	11.4 m	6.5 m	99.6%
OAS (Open Access Service) Single frequency	28.5 m	16.2 m	99.6%
OAS/CAS (Controlled Access Service) Dual frequency	7.2 m	4.2 m	99.6%

Table 390: Navigation system performance (reference receiver with a 10° masking angle)

Service classes provided:

- 1) A basic service, free of charge, for applications intended for the public at large. This service corresponds to **OAS** (Open Access Service) providing position, velocity and

¹²⁶⁰⁾ Information provided by Hans L. Trautenberg of Astrium GmbH, Munich (viewgraph package), representing the ESA baseline concept as of Feb. 2001

time. The OAS performance competes with GPS services. The S&R (Search & Rescue) service is part of OAS (in fact, S&R messages will be transmitted in all localization services).

- 2) A subscription service, with restricted access, for commercial and professional applications needing superior performance levels and a guarantee of service. This service corresponds to **CAS** (Controlled Access Service), this is also referred to as Commercial Access Service (it requires payment by the service user). CAS provides an improved service consisting of: a) accuracy and integrity service to professional markets, b) ranging and timing service to knowledgeable professionals (surveying, meteorological forecasting, time calibration, etc.).

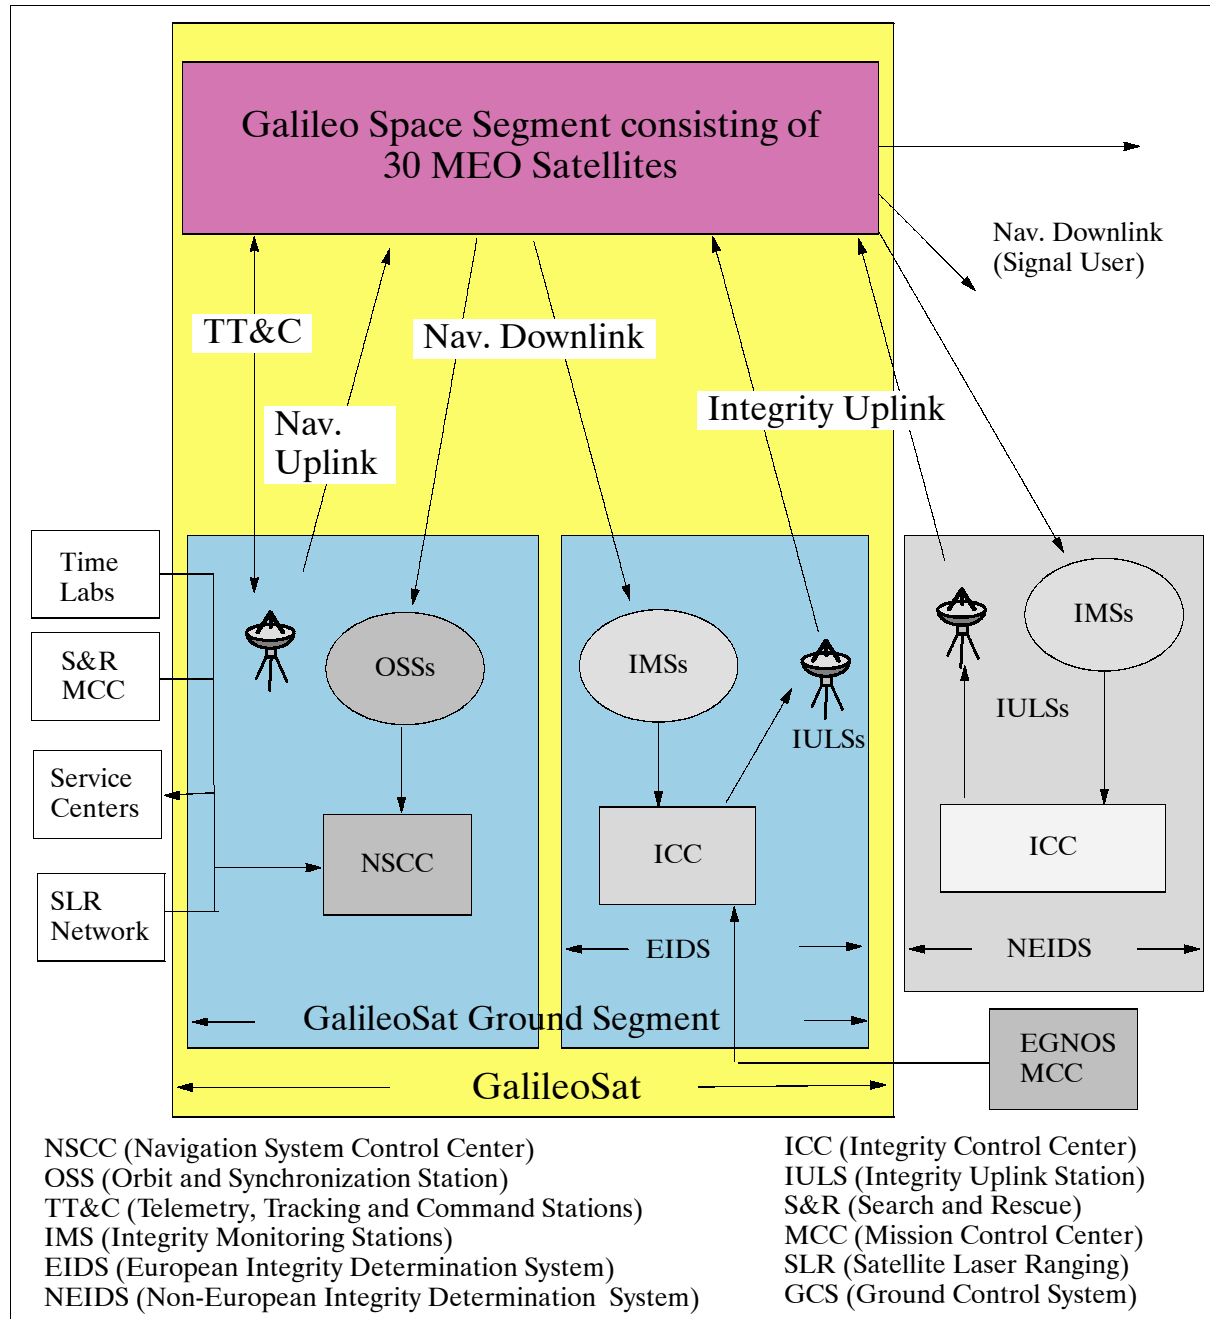

Figure 221: Overview of Galileo high-level architecture

- 3) A restricted, high-level subscription service for applications which must not suffer any interruption or disturbance for reasons of security. This corresponds to **SAS** (Safety-of-

life Access Service) and **GAS** (Governmental Access Service) providing a high integrity service for strategic applications. SAS will be used for all types of safety-relevant applications like: air-traffic assistance, railway and water traffic, network synchronization, power switching, etc. Parts of the SAS message may be encrypted to protect against spoofing.

Integrity SAS system performance

- Protection levels: horizontal = 12.1 m, vertical = 20.6 m
- Mean availability: 99.3%
- Continuity risk: 8×10^{-6} / 15 s [6×10^{-6} / 15 s for SIS (Signal-In-Space)]
- Integrity risk: 2×10^{-7} / 150 s (1.6×10^{-7} / 150 s for SIS)
- Time-to-alert: 6 s (5.2 s for SIS)
- RAIM (Receiver Autonomous Integrity Monitoring) is used to cover local effects
- SISA (Signal-In-Space Accuracy)/SISA-IF is used to cover system contributions

Constellation baseline of 30 satellites in MEO

- 27/3/1 in Walker configuration (nominal state).
- Three S/C are reserved for in-orbit redundancy (quick recovery in case of failure)
- The average orbital altitude of the constellation is 23,616 km, inclination = 56°
- The orbital period is 5/3 revolutions/day.

Note: A Walker constellation [noted T/P/F (where T = number of satellites, P = number of orbital planes, and F characterizes the interplane phasing)] is a symmetrical constellation of T satellites; T/P satellites are evenly spaced on each orbital plane; and P orbital planes are evenly spaced through 360° of ascending node. In this case 27 satellites are in a symmetrical Walker configuration (in three orbital planes), plus one active in-orbit spare per plane.

Cost-effective deployment of the Galileo constellation

- Low number of orbital planes (3)
- Three Soyuz launches (2 S/C per launch) + 3 Ariane-5 launches (8 S/C per launch) in 2006-2007
- For the IOV (In-Orbit Validation) phase, the two first Soyuz launches may be performed two years before.

Maintenance and spare strategy

- Maximize the probability of the nominal constellation state (27/3/1)
- Two main phases:
 - Maintenance phase
 - In case of satellite failure: re-positioning of the in-orbit spare
 - In case of in-orbit spare use (or failure): launch of two S/C with Soyuz
 - Renewal phase:
 - Satellite lifetime of 15 years in service; duration of 20 years
 - Anticipation of EOL failure by constellation renewal after about 10 years
- Evolution of nominal constellation state
 - Probability always > 0.945

Constellation performance ¹²⁶¹⁾

- Galileo stand-alone (elevation $> 10^\circ$)
- Nominal state:
 - Vertical accuracy better than 7.5 m (100% availability)
 - Horizontal accuracy better than 4.5 m (100% availability)

¹²⁶¹⁾ G. Salgado, S. Abbondanza, R. Blondel, S. Lannelongue, "A New Model - Constellation Availability," Galileo's World, Spring 2001, pp. 30-35

- Degraded states:
 - In case of failures the availability still remains high >96-98%
- Galileo+GPS
 - Global improvement of performances and higher robustness to failures
 - Vertical accuracy <4 m with availability >99% over the major part of the world
 - Especially of interest for “urban canyon” environments (i.e.> 25°)
- Evolution of performances versus time
 - Orbital perturbations lead to drifts on S/C positions
 - Worst accuracy degradation kept below 5% with only 1 in-plane maneuver each 5 years

ODTS (Orbit Determination and Time Synchronization) requirements

- Galileo will be usable as a stand-alone system, independently from any other satellite navigation system
- The ODTS contribution to UERE (User Equivalent Range Error) is 65 cm (1 sigma) to meet the system performance requirements
- GalileoSat will establish its own reference system time, referred to as GST (Galileo System Time), and maintain is synchronized with TAI (Time Atomic International)
- Galileo will be synchronized with TAI within 50 ns (offset) on a long-term basis with an uncertainty of less than 33 ns.

ODTS basic principles

- ODTS is one common process to determine the orbit parameters of all satellites and all system clock comparisons (on-board and on-ground) with respect to GST
- Input is collected by a global network of stations performing one-way measurements (pseudo-ranges and carrier-phase observables)
- Processing is centralized and runs in the OSPF (Orbit and Synchronization Processing Facility)
- The ODTS algorithm is based on a dynamic least-squares batch processing offering good robustness and flexibility

ODTS operational scheme

- One-way measurements are collected every 10 s and transmitted with a maximum allowable network delay of 60 seconds
- The centralized processing facility, considering also the PTS's (Precise Time Station - a collection of cesium and hydrogen maser clocks) clock comparisons, computes:
 - The satellite Rubidium clock corrections of 100 minutes validity based on 160 minutes of measurement data
 - The S-PHM (Satellite-Passive H Maser) corrections of 8.3 hours validity based on 14 hours of measurement data
 - Satellite ephemeris of 12 hours validity based on 3 days of measurement data
 - GST using composite clocks
- The process runs periodically to maintain the UERE (User Equivalent Range Error) clock contribution within 1.5 ns (45 cm)
- Then the GST synchronization to TAI (Time Atomic International) is performed (on a daily period)
- All data are archived for offline trend analysis and maintenance

Space segment design features

- Constellation of 30 spacecraft including in-orbit spares
- MEO (Medium Earth Orbit) of 23,616 km with direct orbit injection as baseline
- The spacecraft transmit continuous ranging codes and navigation data
- Ground contact every 100 minutes for upload of timing parameters and navigation data and to perform S/C commanding and monitoring
- Integrity data are uplinked every second by dedicated stations; the data are passed via a separate on-board data path
- The spacecraft offer an autonomous capability in the event of loss of ground contact or other failures
- The spacecraft lifetime is 15 years, the system lifetime is 20 years.

Spacecraft design summary

- The baseline system is designed for the use of MEO spacecraft only (however, optional GEO spacecraft configurations have been studied)
- A common design basis for the MEO and GEO spacecraft has been adopted
- The design draws on experience of previous programs (Globalstar) but makes use of the ESA technology programs for critical developments

MEO S/C parameters		GEO S/C parameters	
Mass	700 kg	Mass	1100 kg
Power	1500 W	Power	1700 W
Dimensions	2.7 m x 1.2 m x 1.1 m	Dimensions	2.8 m x 1.5 m x 1.2 m

Table 391: Satellite budget figures (as of 2001)

Platform structure	<ul style="list-style-type: none"> - Closed box with aluminum sandwich panels and two internal shear webs - All panels are primary structure providing I/F with appendages, equipment, etc. - Classical attachment of equipment/units with bolts screws and specific brackets - I/F between S/C and Ariane-5, Proton, and Soyuz launchers through a dispenser
Thermal control	<ul style="list-style-type: none"> - Mainly passive design supported by a heater system to maintain all equipment - Design based on use of standard technologies: heat pipes, radiators, MLI (Multi Layer Insulation), etc. - Monitoring of temperatures via ICDU (Integrated Control and Data Unit) - Specific accurate thermal control for payload equipment (e.g. clocks)
Platform propulsion	<ul style="list-style-type: none"> - Provides means to perform orbit corrections to: a) reach final orbit position, b) maintain pointing and position on station, c) achieve the graveyard orbit at EOL
Avionics and TT&C	<ul style="list-style-type: none"> - Avionics: a) centralized architecture, b) data transfer: standard serial bus and point-to-point serial link, c) AOCS: Earth pointing and yaw steering capability - TT&C: a) 2 transponders (TM/TC): 2 receivers in hot redundancy and 2 transmitters in cold redundancy, b) 2 integrity receivers in hot redundancy, c) integrity signal directly routed to the payload, d) 2 omnidirectional antennas
Platform power	<ul style="list-style-type: none"> - Standard silicon technology, 1560 W (EOL) of solar array - Lithium-Ion battery with 80 Ah capacity, 12 blocks in series (3400 Wh)
Navigation payload features	<ul style="list-style-type: none"> - Payload provides precise navigation services in L-band - Reception & storage of uplinked navigation data - Decoding & formatting of integrity data from the integrity link - Generation of ranging codes - Provision of messages with error correcting code - Assembly of navigation message in the agreed format - Broadcast of navigation, timing and integrity signals - Navigation payload mass = 80 kg, power = about 900 W
S&R payload	<ul style="list-style-type: none"> - Location of distress beacons (406 MHz legacy and new beacons) with acknowledgement to distress users through the Galileo navigation signal - S&R payload mass = 15 kg, power = 40-60 W

Table 392: Summary of MEO platform design

Spacecraft design overview

- Autonomy (data handling system + clocks)
- Centralized functions such as command/control, power distribution
- Standardized interfaces for ease of testing
- Separate payload for ease of AIT (Assembling, Integration and Test)
- Navigation service (messages, integrity, etc.) driven from ground to simplify S/C design and reduce outage risk
- Reliance on existing designs where possible but taking advantage of emerging technologies such as batteries, clocks, etc.

Figure 222: Schematic configuration of a Galileo spacecraft

H.1.2 System Integrity Concept

The concept is based on a split of integrity between the system and the user

- System provides timely warning if any errors are caused by either a) the satellite, b) the clock, c) the signal, and d) the navigation message - are larger than predicted via a combination of SISA (Signal-In-Space Accuracy) and the IF (Integrity Flag).
- The user has to assess all the hazards on the: a) signal propagation path, and b) all local effects - by using redundant signals and signal quality measures employing RAIM (Receiver Autonomous Integrity Monitoring).
- SISA (Signal-In-Space Accuracy) is a quantitative quality estimation of the orbit and clock prediction by the OSPF (Orbit and Synchronization Processing Facility) updated with every clock update.
- If an error occurs in the satellites, clocks, signal, navigation message or in the OSPF process, it has to be detected by the IPF (Integrity Processing Facility) and a warning (IF) has to be sent to the user.
- The check in the IPF has to be performed nearly instantaneously, with a sufficient number of IMS (Integrity Monitoring Station) reports for a significant statistical test; the option must also exist to exclude an IMS which exhibits a local signal disturbance.

User Integrity Algorithm

- Compute the protection level based on signals from satellites with non-set integrity flags
- If the protection level < alert limit - perform fault detection
- If no fault detected go to first step
- If fault detected, try fault identification

- If no fault isolation possible raise alert - otherwise after fault isolation go to first step
- This approach ensures maximum availability for a navigation solution with integrity for users with a wide range of alert limits, if sufficient satellites are available for RAIM.

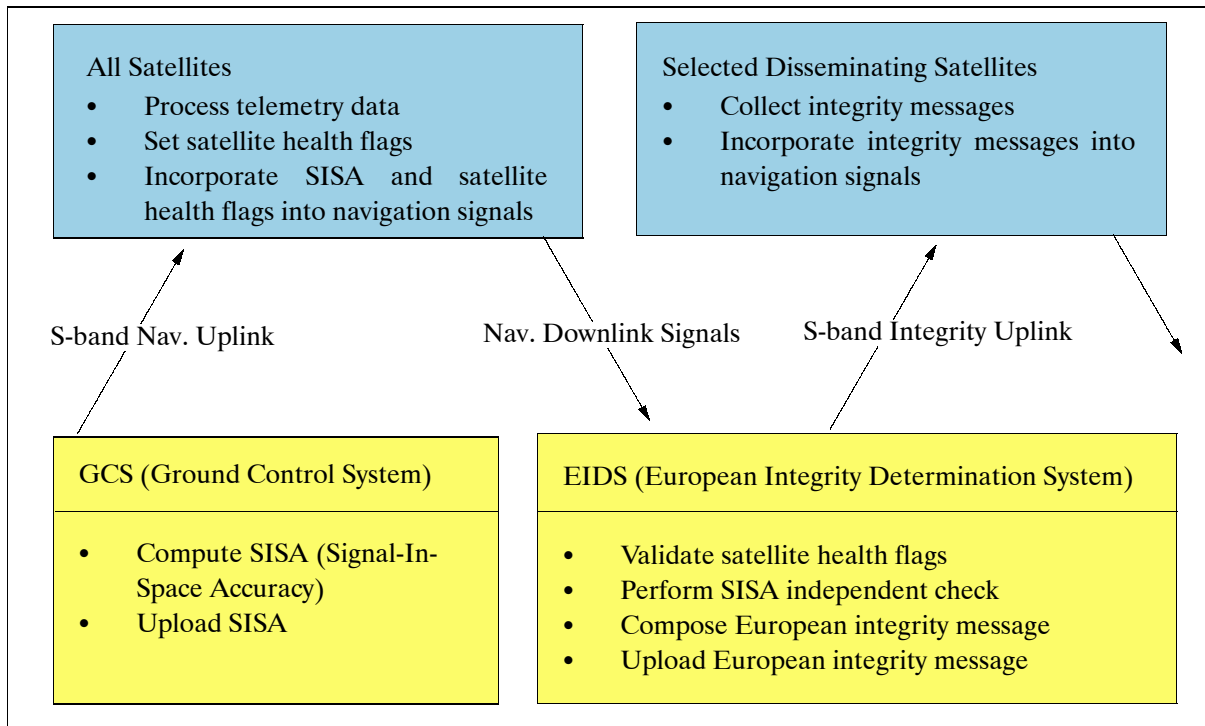

Figure 223: Schematic illustration of the system integrity concept

H.1.3 Signal Baseline

- European stand-alone concept
 - No overlay or bandwidth sharing with GPS and GLONASS
 - Low risk for frequency allocation process
 - Two scenarios considered: L-band only, and combined L- and C-bands
- L-band scenario: without use of C-band

Band	Center Freq. (MHz)	Band-width (MHz)	Service	Modulation Type	Subcarrier	Chip Rate (Mchip/s)	Power ratio	Data Rate (bit/s)	Symbol rate (S/s)
E5	1,202.025	24	OAS, CAS, SAS	QPN	I Q	15.345 15.345	50% 50%	~ 1000 (pilot)	2000 -

E1	1,589.742	4.092	OAS, CAS, SAS	QPN	I Q	3.069 3.069	50% 50%	~ 1000 (pilot)	2000 -

Table 393: Summary of signal configuration

European WRC2000 (World Radiocommunication Conference 2000) scenario. Open, commercial and public services are allocated within E1, E2, E5, and E6 frequency bands.

H.2 GNSS-1 Augmentation Systems

The first generation Global Navigation Satellite System, GNSS-1, is an on-going project for satellite-based navigation, based on the US GPS and the Russian GLONASS satellite

constellations. In addition to the primary constellations, there are regional augmentation systems (all in the development phase starting in 1998), such as WAAS (USA), EGNOS (Europe), and MSAS (Japan), providing enhanced performance services of integrity, availability, and continuity monitoring, to achieve the level of performance needed for civil aviation applications. The space segments of the three augmentation systems are also referred to by their generic name as: SBAS (Satellite-Based Augmentation System). - In addition to the three augmentation systems, Australia is considering the implementation of GRAS (Ground-based Regional Augmentation System) in support of its civil aviation needs.¹²⁶²⁾

The augmentation systems are needed because the current constellations of GPS and GLONASS fail to meet the functional requirements critical to safety of flight. These are:

- **Accuracy.** It refers to the difference between the measured position at any given time to the actual or true position
- **Availability.** It refers to the ability of a system to be used for navigation whenever it is needed by the users, and its ability to provide that service throughout a flight operation
- **Integrity.** It refers to the ability of a system to provide timely warnings to users or to shut itself down when it should not be used for navigation.
- **Continuity of service.** It refers to the ability of a system to provide a service throughout any flight operation.

Obviously, there are also other areas of GPS signal applications outside of the “aviation safety regime” that need (or will need) the infrastructure and service spectrum provided by the augmentation systems.

H.2.1 WAAS (Wide Area Augmentation System)

WAAS is the US FAA (Federal Aviation Agency) program - to improve the accuracy, integrity, and availability of GPS signals for civil aviation to levels that support flight operations in the National Airspace System (NAS) from en route navigation through Category I precision approaches. IOC (Initial Operational Capability) of WAAS is planned for 1998.¹²⁶³⁾

The overall WAAS architecture uses a network of ground-based DGPS stations [24 wide-area reference stations (WRS), two wide-area master stations (WMS), and two satellite uplinks] and several geosynchronous communications satellites to provide nationwide coverage. Differential corrections and integrity data derived from the ground-based network, as well as additional ranging data, are being broadcast to users from the geostationary satellites [Inmarsat-3 constellation, launch of Inmarsat-3 (F1, F2, F3, F4) in 1996 and 1997, Inmarsat-3-F5 launch on Feb. 5, 1998] using an L1-like signal.¹²⁶⁴⁾¹²⁶⁵⁾

Each WRS station in the network collects pseudorange and atmospheric measurements, and pools its data with a WMS (Wide-area Master Station), where estimates for individual corrections are computed for each of the major systematic error types (ionospheric delay, satellite clock and satellite position) for each GPS satellite in view. WAAS corrections are then relayed and broadcast from transponders of geostationary communications satellites to reach all users in a wide area.

The correction message update distinguishes between slow (ephemeris and long-term clock errors) and fast-changing corrections (SA clock errors). The slow correction update is no more often than every 5 minutes, while the faster corrections require a faster update rate. Any GPS receiver in the area of coverage may determine precise orbits from these

1264) G. V. Kinal, O. Razumovsky, “Performance of the Inmarsat-3 Navigation Augmentation Payloads,” Proceedings of ION GPS-97, Sept. 16-19, 1997, Kansas City, MO, pp. 1285-1294

1265) T. Walter, A. Hansen, J. Blanch, et al., “Robust Detection of Ionospheric Irregularities,” ION-2000, Salt Lake City, UT, Sept. 19-22, 2000, pp. 209-218

corrections.¹²⁶⁶⁾ ¹²⁶⁷⁾ WAAS will improve the basic GPS accuracy to approximately 7 meters vertically and horizontally.

LAAS (Local Area Augmentation System)

The second augmentation to the GPS signal is LAAS (also developed by FAA), intended to complement the WAAS and function together to supply users of the US NAS (National Airspace System) with seamless satellite-based navigation for all phases of flight. LAAS applies to locations where the WAAS is unable to meet existing navigation and landing requirements (such as availability).

A primary design goal of WAAS and LAAS is to insure that signal-in-space failures are detected by ground facilities and affected measurements are excluded before differential corrections are broadcast to users. One such failure may be unintentional interference or intentional jamming in the GPS frequency band. To protect integrity, WAAS and LAAS ground facilities must be able to quickly detect the presence of interference that fall within the restricted zone defined by WAAS and LAAS system requirements and thus may be hazardous to users. A system referred to as GIDL (Generalized Interference Detection and Localization System) provides these services.¹²⁶⁸⁾ ¹²⁶⁹⁾

H.2.2 EGNOS (European Geostationary Navigation Overlay System)

EGNOS is the European regional augmentation system to GPS and GLONASS services. A consortium of ESA, EC (European Commission) of the EU, and Eurocontrol (European Organization for the Safety of Air Navigation, Brussels) are jointly developing EGNOS, Europe's regional augmentation system for satellite navigation. The objective is to provide GPS and/or GLONASS users with improved accuracy, integrity and availability, in particular to satisfy civil aviation requirements during all flight phases. Initial operational capability of EGNOS service is planned to start in early 2004 and, ultimately, expanding that system into Galileo, Europe's contribution to the next-generation GNSS-2 (Global Navigation Satellite System-2).¹²⁷⁰⁾ ¹²⁷¹⁾ ¹²⁷²⁾ ¹²⁷³⁾

EGNOS is considered an integral element of GNSS-1 (Global Navigation Satellite System-1) whose main service elements are the GPS and GLONASS constellations. As such, EGNOS must also be interoperable with WAAS-3 (Wide Area Augmentation System) of the FAA in USA, as well as with the Japanese MSAS-4 (Multi-Transport Satellite Augmentation System). MTSAT-1R (Multifunctional Transport Satellite) is the space segment of MSAS.

The EGNOS concept is designed to serve the needs of all modes of transport in the European Region ECAC (European Civil Aviation Conference). A total of 38 states belong to the ECAC service area. The built-in expansion capabilities of EGNOS allow the propagation of the EGNOS technology and service to other regions of the world (Africa, South America, and portions of Asia). EGNOS uses a ground infrastructure and geostationary

¹²⁷³⁾ <http://www.esa.int/EGNOS/>

(GEO) satellites to provide regional coverage with the essential functional augmentations (of accuracy, availability, integrity, and continuity of service) to the GPS and GLONASS systems as outlined under H.2.

The overall functions of EGNOS are: a) to collect raw data from GPS, GLONASS and GEO satellites, b) to compute the augmentation message, and c) to broadcast these messages (differential corrections, etc.) to users via the GEO satellites. In addition, EGNOS also disseminates accurate time to all users in the geostationary broadcast area, synchronized to UTC. EGNOS operates on the GPS L1 frequency; hence, it will be receivable with standard GPS receivers.¹²⁷⁴⁾

The EGNOS system architecture is composed of the following elements:

- 1) The EGNOS space segment consists of navigation transponders, leased on-board two Inmarsat-3 satellites (AOR-E and IOR), which broadcast EGNOS signals to the user community. These satellites are in orbit and positioned at longitudes 65.5° East (IOR) and at 15.5° West (AOR-E). In addition, an EGNOS navigation payload is flown on ARTEMIS (Advanced Relay and Technology Mission Satellite) of ESA (15° W). EGNOS itself relies on the signals of the GPS and GLONASS constellations.
- 2) The EGNOS ground segment is composed of the following elements:
It consists of a number of RIMS (Ranging and Integrity Monitoring Station) which are connected to a set of redundant control and processing facilities called MCCs (Mission Control Center). The system will deploy 34 RIMS and four MCCs, located at Torrejon (Spain), Gatwick (UK), Langen (Germany) and Ciampino (Italy). The MCC determines the integrity, pseudo-range differential corrections for each monitored satellite, and ionospheric delays and generates the GEO satellite ephemeris. The functions of RIMS are to perform one-way ranging of the GEO satellites (3). The RIMS data are transmitted to the MCCs for processing. The calculated positions are then transmitted in the form of messages to the EGNOS NLES (Navigation Land Earth Stations). The NLES uplink these GPS-like signals to the EGNOS transponders for broadcast.
 - MCC (Mission Control Center), consisting of a CPF (Central Processing Facility) and a CCF (Central Control Facility)
 - RIMS (Ranging and Integrity Monitoring Station). There are several RIMS in the system.
 - NLES (Navigation Land Earth Stations). The system will deploy two NILES (one primary and one backup) per GEO navigation transponder as well as a NILES facility for test and validation purposes. The NILES are located in: Torrejon (Spain), Fucino (Italy), Aussaguel (France), Raisting (Germany), Goonhilly (UK), and Sintra (Portugal).
 - EWAN (EGNOS Wide Area Network)
 - EGNOS support facilities [PACF (Performance Assessment and System Checkout Facility), ASQF (Application Specific Qualification Facility), and DVP (Development Verification Platform)].

The functions of RIMS are to perform a) the acquisition of GPS and GLONASS raw data, b) acquisition of weather parameters. The RIMS data are then transmitted to the MCCs for processing (computation, distribution, validation and transmission of GEO ranging, Integrity (GIC) and Wide Area Differential (WAD) data). The calculated positions are then transmitted in the form of messages to the NLES. The NLES uplink these GPS-like signals to the EGNOS transponders (on GEO satellites) for broadcast. NLES also keeps accurate synchronization of GEO message transmission relative to GPS time.

- 3) The user segment consists of EGNOS standard receivers addressing applications in the fields of aeronautical, maritime, and land-mobile navigation.

¹²⁷⁴⁾L Gauthier, P. Michel, J. Ventura-Traveset, J. Benedicto, "EGNOS: The First Step in Europe's Contribution to the Global Navigation Satellite System," ESA Bulletin, No. 105, Feb. 2001, pp. 35-42

The EGNOS space segment is being built by an industrial team led by ASI (Alcatel Space Industries) of France (participation of European and Canadian industry). The Earth stations of France Telecom in Aussaguel and of Deutsche Telecom at Raisting are being used as primary NLES.

The geostationary ranging service requires accurate positioning of the GEO satellites. The integrity monitoring service broadcasts range error estimates for each GPS, GLONASS or EGNOS navigation signal. The wide area differential position service broadcasts correction signals to improve the precision of satellite navigation.

EGNOS System Test Bed (ESTB):

In 1996 an ETS (Early Test System) study/campaign on behalf of ESA was started to investigate the conceptual prototype EGNOS performance at the user level in terms of accuracy and integrity as a functional end-to-end system.¹²⁷⁵⁾ This includes the following elements:

- Software emulation of RIMS with real data of GPS/GLONASS receivers
- Software simulation of different wide area differential algorithms at MCCs, to compute ephemeris and clock corrections and to generate the EGNOS navigation message.
- Analysis of latency effects
- Analysis of the effect of message error rates

ESTB became operational in January/February 2000.¹²⁷⁶⁾ A MOPS (Minimum Operational Performance Standard), compliant with SIS (Signal-In-Space), is available for testing through the Inmarsat AOR-E providing first continuous GPS augmentation services within Europe. It enables users to compute their positions to an accuracy of a few meters (3 m horizontal and 5 m vertical within 95% of the time).

To optimize the overall ESTB effort, existing assets have been taken into account in building the ESTB. These include the SAREF system of NMA (Norwegian Mapping Authority) and the EURIDIS ranging system of CNES. In early 2001, ESTB was connected with the Italian MTB (Mediterranean Test Bed), provided by ENAV (Italian Civil Aviation Authority).

The ESTB architecture is composed of: a) the space segment (comprising two Inmarsat transponders), and b) a ground segment (comprising a number of reference stations across Europe, a processing center and the Inmarsat uplink stations). The ESTB has already supported a number of application demonstrations during 2000. These included the landing of aircraft at several airports, the guiding of ships into harbors, and also the navigation of cars. ESTB will be operational on a 24-hour basis starting in early 2001. The service will embrace applications for service expansion (outside of Europe) and interoperability analysis with WAAS and MSAS. The EGNOS AOC (Advanced Operational Capability) Operational Readiness Review (ORR) is scheduled for December 2003, enabling operations to start in 2004.

H.2.3 MSAS (Multi-Transport Satellite Augmentation System)

The Japanese MSAS is implemented by JCAB (Japan Civil Aviation Bureau) and funded by the Japanese Ministry of Transport. The MSAS space segment is based on MTSAT (Multi-function Transport Satellite) with an aeronautical and a meteorological mission (see F.9 and a description of MSAS under F.9.1.1). MTSAT-1R is scheduled for launch in 2003.

The MSAS ground-based architecture is composed of the following elements: MRS (Monitor and Ranging Stations), GMS (Ground Monitor Stations), and MCS (Master Control

¹²⁷⁵⁾J. Nieto, M. A. Molina, M. L. de Mateo, R. Roman, L. Andrada, "Assessment of EGNOS System and Performance: Early Test System," Proceedings of ION GPS-97, Sept. 16-19, 1997, Kansas City, MO, pp. 1345-1354

Stations). In addition, there are two GES (Ground Earth Station) in the system, namely the Kobe Aeronautical Satellite Center and the Hitachi-Ota Aeronautical Center), providing operational support.

The MSAS user segment consists of receivers addressing the applications in the fields of aeronautical, maritime, and land-mobile navigation. ¹²⁷⁷⁾

H.3 GLONASS

GLONASS ¹²⁷⁸⁾ (Global Orbiting and Navigation Satellite System - Global'naya Navigatsionnaya Sputnikovaya Sistema). GLONASS is a Russian operational satellite navigation system in an experimental phase (designer: NPO-PM, Krasnoyarsk, Siberia; builder: Polet Production Association, Omsk). The system consists of a constellation of satellites capable of providing high-accuracy position information on a global scale for users on sea, land, or in space. Since September 1993 the GLONASS program is operated by VKS (Voenno Kosmicheski Sily), the Russian Military Space Forces, which has responsibility for deployment and on-orbit maintenance and certification of GLONASS user equipment.

The first GLONASS satellite series was launched on Oct. 12, 1982. Further launches were in 1983 (2), 1984 (2), 1985 (2), 1986 (1), 1987 (2), 1988 (1), 1994 (on Aug. 11). Each successful launch has always resulted in positioning of three satellites into orbit. As of November 20, 1995 there were 16 operational GLONASS satellites (full complement of 8 satellites in orbital plane 1) ¹²⁷⁹⁾ in orbit. The GLONASS constellation will eventually be completed with a total of 24 satellites, and three additional spares. Full operational capability of the GLONASS system was expected by 1996, but so far this goal has not been achieved. In Aug. 2001 the Russian government approved funding to upgrade and complete its GLONASS program. ^{1280) 1281) 1282)}

Table 394: GLONASS satellite constellations (May 2001)

A GLONASS S/C has a total mass of 1400 kg. The S/C consists primarily of a cylindrical pressure vessel equipped with a small aft payload platform and two large solar arrays (span of more than 7 m). The electrical power generating capacity is 1.6 kW. Each S/C is three-axis stabilized and equipped with a propulsion system for initial orbit acquisition and positioning.

Parameter	GLONASS	NAVSTAR/GPS
Orbital Parameters		
Period (minutes)	675.73 (~ 11.25 hours)	717.94 (~ 12 hours)
Inclination (degree)	64.8	55.0
Semimajor axis (km)	25,510	26,560
Orbital plane separation (degree)	120 (3 orbital planes)	60 (6 orbital planes)
Ground track repeat (orbits)	17	2
Ground track repeat (days)	8 sidereal days	1 sidereal day
Transmission Signal Parameters		
Signal separation technique	FDMA	CDMA
L-band carrier frequencies (MHz)	L1 = 1602.5625-1615.5 L2 = 1246.4375-1256.5	L1 = 1575.42 L2 = 1227.60
PRS clock rate (MHz)	0.511	1.023
(PRS=Pseudorandom Sequence) C/A code	5.11	10.23
PRS length (chips) P code	511	1.023
C/A code	5.11 x 10 ⁶	6.187104 x 10 ¹²
P code		
Navigation Message		
Superframe duration (minutes)	2.5	12.5
Superframe capacity (bits)	7,500	37,500
Word duration (seconds)	2.0	0.6
Word capacity (bits)	100	30
Number of words per frame	15	50
Satellite ephemeris specification	Geocentric Cartesian coordinates & their derivatives	Kepler elements and perturbation factors
Time reference	UTC (SU)	UTC (USNO)
Position reference	SGS 85	WGS 84

Table 395: Selected NAVSTAR/GLONASS parameters ¹²⁸³⁾

Measurement principle: The user makes range and Doppler measurements to a number of navigation satellites within visibility. Position and velocity are part of the message content from the navigation satellite. **Orbit:** Each GLONASS spacecraft is in a near-circular orbit at an inclination of 64.8° and an altitude of about 19,100 km.

When fully deployed the GLONASS constellation is composed of 24 satellites in three orbital planes whose ascending nodes are 120° apart. Eight satellites are equally spaced in

¹²⁸³⁾ Y. Gouzhva, I. Koudryavtsev, V. Korniyenko, I. Pushkina, "GLONASS Receivers: An Outline," GPS World, January 1994, pp. 30-36

each plane with a 45° argument of latitude displacement. The planes themselves have a 15° argument of latitude displacement.

GLONASS¹²⁸⁴⁾ and NAVSTAR-GPS have a many similarities with respect to: orbits, frequencies, and message formats. GLONASS employs an Earth-centered, Earth-fixed Cartesian coordinate frame of reference different from that used by GPS: GLONASS uses SGS 85 (Soviet Geodetic System); GPS uses WGS84 (World Geodetic System).

Note: GLONASS employed SGS 85 until 1993 when it switched to PZ-90 (also referred to as PE-90). Readers interested in the PE-90 coordinate system and its transformation to WGS84 should consult the MIT/LL GLONASS Group publication.¹²⁸⁵⁾

An improved version called GLONASS-M has been under development since 1990, the first satellite of this class is expected to be launched by 1996. This S/C offers improved timing and frequency accuracies as well as longer lifetimes (5 to 7 years).

Figure 224: The GLONASS S/C model ¹²⁸⁶⁾

GLONASS - GPS Differences:

- While GPS satellites operate with one L1 frequency for the entire constellation, GLONASS satellites each have their own discrete frequency. The frequency allocation scheme for GLONASS, which employs the Frequency Division Multiple Access (FDMA) technique, is $1602 + K(0.5625) \text{ MHz}$, where K = the frequency channel number. Each GLONASS satellite is identified by a unique orbital slot number.
- The Russian government does not implement a policy of signal degradation on the L1 frequency. Hence, the stand alone accuracy of a GLONASS receiver is measurably better than that of a CA Code GPS receiver. L1 GLONASS rms accuracy is about 16 meters; L1 GPS is 100 meters rms with SA on.

H.4 GPS (NAVSTAR-GPS)

NAVSTAR¹²⁸⁷⁾ 1288) 1289) 1290) = NAVigation System with Time And Ranging. GPS = Global Positioning System. The NAVSTAR/GPS program of DoD was formally chartered in 1973 with the designation of the U.S. Air Force as Executive Agent and the establishment of an acquisition agency, the GPS Joint Program Office (JPO),¹²⁹¹⁾ with representation from all the U.S. military services.

GPS is a space-based radio positioning/navigation system that provides three-dimensional position, velocity, and time information to suitably equipped users anywhere on or “near” the surface of the Earth. The total system consists of 21 operational satellites in near-circular orbit in six orbital planes, so that observers anywhere on the surface of the Earth have at least four satellites in view. In addition, there are three backup satellites in orbit. Initially the orbital inclination was defined to be 63° , but this figure has been changed to 55° to allow Shuttle launches. The orbital altitude is 20,200 km.

H.4.1 GPS Space Segment

The space segment consists of the GPS satellites with an operational constellation of 24 satellites: 21 operational satellites plus three active spares. The orbital parameters of GPS are given in Table 395.

As of 1998 there have been three distinct groups of GPS satellites so far, with one subgroup. The groups are designated as ‘blocks.’ The block-I satellites were used for system testing. Functional system capability was achieved with the block II series, featuring cesium clocks for timing, implementation of selective availability (SA), detection of error conditions, and radiation-hardened electronics for longer life times.

H.4.1.1 Block I Satellites

The block I prototype satellites were intended to validate the GPS concept; they were launched in the time frame 1978 to 1985 on Atlas E/F vehicles from VAFB, CA, with the corresponding designation of SVN (Satellite Vehicle Number) 1 through 11. GPS block I satellites were built by Rockwell International, Seal Beach, CA. They were able to sustain on-board operations for up to 3.5 days between navigation message uploads from the ground. Each S/C was capable of storing up to 14 days of navigation messages from the ground. However, the lack of an on-board momentum management required frequent updates from the ground to prevent the satellites from losing attitude determination capability. Some block I satellites operated for more than double their design life.¹²⁹²⁾

The S/C is spin-stabilized (18 hydrazine thrusters in two modules); power:410W from two solar panels (total of 5 m^2) and $3 \times 15 \text{ Ah}$ NiCd batteries; mass=760 kg at launcher separation, 455 kg on-orbit; design life=5 years (propellant for 7 years). Atomic clocks: three rubidium, one caesium. Signal strength: +23.8 dBW for P signal, +26.8 dBW for C/A signal. The last remaining block I type satellite (SVN 10) was deactivated on Nov. 18, 1995.¹²⁹³⁾

Table 396: GPS launch dates and satellite constellations

Navigation payload: (on each block series)

The navigation payload is that part of the satellite which is responsible for the reception of data from the OCS (Operational Control System), intersatellite ranging (only on the block

IIR and block IIF versions) and the transmission of ranging codes and navigation data to the user community. The major elements of the navigation payload are shown in Figure 226. The frequency standards subsystem contains the atomic clocks. The code generator subsystem generates the C/A code and P(Y) codes for modulo-2 addition with the navigation message (sent to the L-band subsystem for transmission to the users). The processor memory also interfaces with the transmitter/receiver for intersatellite ranging (only on block IIR and IIF versions).¹²⁹⁴⁾

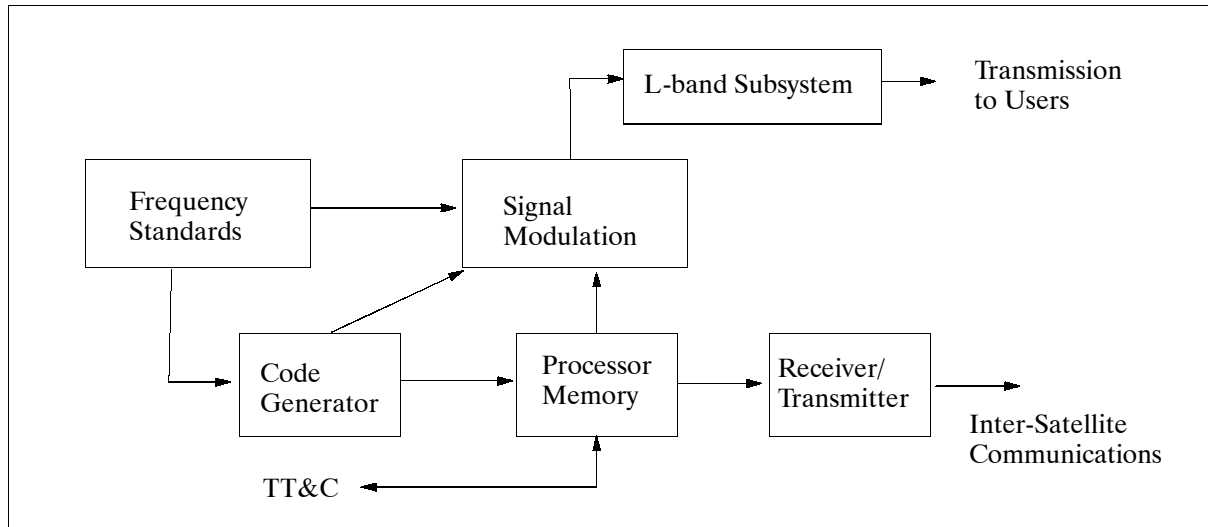

Figure 226: Schematic illustration of the navigation payload

The L-band subsystem contains the L1/L2 synthesizers and the antenna. The L-band antenna array is composed of twelve elements of hollow cylinders arranged in two concentric rings. The inner and outer rings are fed 180° out of phase with each other, with 90% of the power supplied by the outer array. This antenna configuration results in a “dimpled” pattern. The pattern is designed to supply even power across the face of the Earth.

All satellite signal radiation of the GPS constellation (at 20,000 km altitude) is directed toward Earth, providing coverage in particular for “Earth-bound” users, this includes also S/C in the envelope of LEO and MEO orbits. Naturally, coverage will decrease with altitudes approaching those of the GPS constellation and beyond (GEO, etc.).

H.4.1.2 Block II Satellites (NAVSTAR II-1 to II-8)

A total of nine satellites of this series were launched in the time frame April 1989 to Oct. 1990 on Delta 2 expandable launch vehicles from Cape Canaveral, FL. The satellites were built by Rockwell International. The S/C operations layout allows for minimal interaction from the ground without interruption of the signal broadcast. The incorporation of radiation-hardening capabilities is a significant improvement of the block-II design (protection against the harsh radiating environment). In addition, selective availability (SA) and anti-spoofing features are incorporated to enhance security. With no autonomous on-board momentum control, frequent ground contact is needed for for the spacecraft’s momentum management.

The S/C structure is made of aluminum honeycomb panels, the total S/C span is 5.3 m with panels deployed. The S/C is spin-stabilized, with 60 kg hydrazine supply, sufficient for 10 years of normal operations. Power=700 W from two solar panels (total area of 7.26 m²), and 3 x 35 Ah NiCD batteries; S/C mass=1667 kg at launch, 843 kg on-orbit; design life=7.5 years. Atomic clocks: two rubidium, two caesium. Signal strength: -160 dBW for C/A and -163 dBW for P on L₁; -166 dBW for C/A or P on L₂, -165 dBW for C/A on L₃.

¹²⁹⁴⁾L. F. Wiederholt, E. D. Kaplan, “Understanding GPS, Principles and Applications,” Artech House Inc., Boston, 1996, Chapter 3

Sensor complement: (provided by Sandia National Laboratory of DOE)

Note: In addition to the GPS navigation payload, other instruments/experiments have been added to the GPS satellites over the course of time. Examples of the non-GPS-related instruments follow:

The block I satellites (starting with SVN 8) and the follow-up block II satellites incorporate devices by the name of **IONDS** (Integrated Operational Nuclear Detection) that allow monitoring of nuclear explosions either in the atmosphere or in space in support of the Nuclear Non-proliferation Treaty and the Atomic Test Ban (joint program of USAF and DOE). The information is routed via the ring-shaped UHF antennas from satellite to satellite within the GPS constellation. The instrument package includes X-ray sensors, background X-ray sensors, bhangmeters, and radio-wave detectors.

Nuclear explosions emit a very short X-ray flash, in the order of $< 1 \mu\text{s}$. This flash can be seen by the X-ray detectors on several satellites. By measuring the time delay of arrival, the location of the explosion can be determined. The background X-ray sensors monitor the global X-ray environment. The bhangmeters are optical sensors (radiometers) trained of looking for the characteristic double flash of a nuclear explosion by an event trigger mechanism. - Nuclear explosions also emit radio waves which are referred to as EMP (Electromagnetic Pulse). The radio-wave detectors are able to record these EMPs.

H.4.1.3 Block IIA Satellites (NAVSTAR IIA-10 to IIA-27)

A total of 18 satellites of this series were launched in the time frame Dec. 1990 to Sept. 1996 on Delta 2 expandable launcher from Cape Canaveral, FL. The series was designed and built by Rockwell International. An enhanced survivability feature was introduced (storage capability of navigation messages and reference data for up to 180 days). In the event that ground stations are unable to upload navigation information, the satellites will continue to transmit the same navigation message for up to 180 days (graceful degradation). Normal operations were performed on a daily basis to account for orbital perturbations and to provide accurate ephemeris data. - The OCS is limited in its ability to forecast the satellite ephemeris and clock data because of the unpredictable nature of the orbital perturbations. Thus, the accuracy of the navigation message data degrades gracefully over time such that the URE (User Range Error) is bound by 10 km after 180 days. Typically, the URE is 5.5 m (1 sigma) based on fresh uploads of navigation message data on a daily basis. - An autonomous on-board momentum management capability was added to the series, reducing the ground contact requirements.

The S/C structure is made of aluminum honeycomb panels, the total S/C span is 5.3 m with panels deployed. The S/C is spin-stabilized, with 60 kg hydrazine supply, sufficient for 10 years of normal operations. Power=700W from two solar panels (total of 7.26 m^2), and 3 x 35 Ah NiCD batteries; S/C mass=1880 kg at launch, 930 kg on-orbit; design life=7.5 years. Atomic clocks: two rubidium, two caesium. Signal strength: -160 dBW for C/A and -163 dBW for P on L_1 ; - 166 dBW for C/A or P on L_2 , -165 dBW for C/A on L_3 .

H.4.1.4 Block IIR (Replacement Operational Satellites)

The satellite series (with 21 planned launches) is designed and built by Lockheed Martin (formerly GE Astro Space) of Valley Forge, PA; ITT Aerospace/Communications is providing the navigation payload. The contract was awarded in Dec. 1989. The first block IIR satellite experienced a launch failure (booster) on Jan. 17, 1997. The first successful launch of the series occurred on July 22, 1997 (the S/C was declared operational on Jan. 31, 1998 after successful on-orbit testing). The block IIR satellite series features enhanced autonomous satellite operations (AutoNav) for a period of up to six months without ground control corrections (reprogrammable processors that enable problem fixes, upgrades in flight, and increased satellite autonomy and radiation hardness). Orbital position is measured by UHF cross-link ranging between the individual block IIR satellites in the constellation. Orbit es-

timates (ephemeris and clock data) and updates are performed automatically. This Auto-Nav feature allows the system to maintain system accuracy for much longer periods between ground contacts. The atomic clocks, normally updated daily, offer five times the stability of their predecessors. ¹²⁹⁵⁾

Figure 227: GPS Block IIR spacecraft

Each S/C is three-axis stabilized, using momentum wheel, magnetorquing, and 16 hydrazine thrusters (95 kg of total hydrazine); the payload is mounted on six honeycomb structural panels mounted on a central aluminum core; the thermal system: passive and heaters. Power=1136 W (EOL) from two solar panels with a total area of 13.4 m², NiCd batteries provide power during eclipses; S/C mass=2037 kg at launch, 1075 kg on-orbit; design life=10 years.

The new series satellites not only ensures a seamless continuance of service, but also introduces several new features when put into operation. One such feature is the GPS integrity channel (GIC). It is used to broadcast GPS and GLONASS S/C health information to aircraft users. GIC monitors the satellite signals and broadcasts “use/don’t use” signals as well as coarse differential corrections to users. GIC uses geostationary satellites to warn aircraft worldwide in realtime (<10 seconds).

Upgrades to Block IIR spacecraft (for 12 out of 21 in the series): ¹²⁹⁶⁾

Modernized Block IIR (IIR-M) spacecraft feature enhancements in the following areas:

- Software enhancements. The five on-board processors provide a reprogramming capability. The SPU (Spacecraft Processing Unit) supports all bus-related activities such as TT&C attitude control and power management. The MDU (Mission Data Unit) performs functions related to navigation and sensing.
- Hardware enhancements. The upgrades are listed in Table 397. The new L-band HPA (High Power Amplifier) employ the GaAs and FET technologies. The new WGMIC (Waveform Generator/Modulator/IPA/Converter) is programmable using FPGA techniques. The WG supports all generation and routing of the baseband signals (C/A, P(Y), and M-codes). The WG employs a unique ITT proprietary implementation of Interplex modulation which enables the co-existence of three signal components (C/A, P9Y), and M) on a single constant envelope modulated carrier.

¹²⁹⁶⁾T. Hartman, L. R. Boyd, D. Koster, J. A. Rajan, J. Harvey, “Modernizing the GPS Block IIR Spacecraft,” ION GPS 2000, Sept. 19-22, 2000, Salt Lake City, UT, pp. 2115-2121

Component	Magnitude of change	Description of change
Antenna panel	Moderate redesign	Replace L-band elements with broadband proprietary elements
L-band subsystem	Technology upgrade	Replace five separate components with three (L1 and L2 HPAC and WGMIC) multifunction assemblies
L-band structural panel	New design	Higher power dissipation requires integral heat pies in the panel honeycomb structure
PCE (Payload Control Electronics)	Minor modification	Add power switching and fusing to accommodate additional power
PRU (POwer Regulation Unit)	Minor modification	Spare pins connected to additional power and return lines for higher power

Table 397: Block IIR-M hardware upgrades

- Signal enhancements. Block IIR-M spacecraft will support additional military-unique (M-code) signals on L1 and L2. Other capabilities include enhanced navigation software, C/A (Coarse/Acquisition) code on L2 and increased power on the present C/A and P(Y) code signals. In addition, the signal power level output of the Block IIR-M spacecraft can be redistributed on-orbit within C/A, P(Y), and M-code signal components as needed. The Block IIR-M navigation payload design provides the flexibility to support future GPS signal enhancements on-orbit.

Implementation time frame	Activity
May 2000	SA (Selective Availability) removed
2003 - 2006	GPS Block IIR-M enhancements - A civil C/A code is added on L2 - M-code (Military code) on L1 and L2
2005 - 2010	GPS Block IIF enhancements - C/A code on L2 - M-code on L1 and L2 - L5

Table 398: Overview of GPS signal modernization schedule

With the elimination of SA (May 2, 2000), the next largest contributor to the GPS positioning error is the signal delay caused by the Earth's atmosphere. Since the military has full access to two signals and frequencies through the PPS (Precise Positioning Service), military users can correct the ionospheric error by forming a linear combination of L1 and L2 pseudorange measurements to mathematically estimate and remove almost all the ionospheric bias from the L1 measurements.¹²⁹⁷⁾

To compensate for the ionospheric error in limited civilian applications, some receiver manufacturers have developed innovative techniques for using components of the encrypted Y-code signal to calculate the ionospheric effects. However, to function effectively, these so-called "semi-codeless" receivers require an SNR for the L2 signal that is considerably higher than the SNR required by a military dual-frequency PPS receiver.

H.4.1.5 Block IIF Satellites

The 4th generation GPS satellites are referred to as block IIF.^{1298) 1299)} A USAF contract for 33 satellites was awarded to Rockwell International as prime contractor in April 1996 (as of Dec. 1996 part of Boeing North American Inc. of Seal Beach, CA, a subsidiary of The Boeing Company). Block IIF satellites will provide a second civil GPS frequency. First launches are planned to start in 2003 to replace the older block IIA and block IIR satellites.

¹²⁹⁹⁾ K. Ghassemi, S. C. Fisher, "Performance Projections of GPS IIF," Proceedings of ION GPS-97, Sept. 16-19, 1997, Kansas City, MO, pp. 407-415

The Block IIF system allows affordable technology insertion and block upgrades, while emphasizing compatibility and interoperability with the current space vehicles, ground control system, and user equipment.

Performance feature	Block II & IIA	Block IIR	Block IIF (requirements)
Nr. of navigation signals	3 signals	3 signals	up to 5 signals
Signal power to user (combined L1 and L2)	-158.2 dBW L1 -166 dBW L2	-158.2 dBW L1 -166 dBW L2	-156.4 L1 C/A, - 155.7 L1 P (dBW) -152.6 dBW L2
Space & ground URE	2-3 m	1-2 m (AutoNav)	0.75 - 1 m cross-link navigation
Civil performance (2 dRMS)	100 m with SA 25 m w/o SA	100 m with SA 25 m w/o SA	<10 m w/o SA (Selective Availability) and with ionospheric correction
Design life	7.5 years	10 years	15 years
Design flexibility	N/A	Auxiliary payload 45 kg, 90W	Auxiliary payload capacity up to 180 kg and 275 - 1000 W of power

Table 399: Performance parameter comparison of GPS satellite generations

The design features an independent WAAS data uplink and an independent cross-link to update WAAS data between all GPS satellites. Furthermore, the S/C series features advanced atomic clocks to greatly improve performance and give the control segment greater visibility into the health of the units. With four frequency standards composed of both cesium and rubidium technologies, these extremely accurate GPS atomic clocks must keep time to within 8 nanoseconds a day. The improvement involves converting the GPS cesium clocks from analog to digital - the first ever use of the commercially available digital cesium standard technology on spacecraft. The processor-controlled cesium clocks continuously optimize their performance by adjusting internal parameters and compensating for environmental effects. They also perform self-checkout diagnostics.

The block IIF satellite design is of block IIA heritage, consisting of a bus, subsystems, the navigation payload, and other auxiliary payloads. It features a modular design built around a composite “thrust cylinder.” The orbital insertion subsystem, a solid apogee kick motor, is inserted into the thrust cylinder. “Intercostal” panels support the external structure, which in turn supports the electronics packages installed on two modular panels. Forward and aft bulkheads are supported by the trust cylinder and intercostals. The forward bulkhead supports the main L-band antenna array, the UHF crosslink array, the forward telemetry and commanding conical spiral and bicone antennas, and an array of four L-band antennas for auxiliary payload data transmission. The forward bulkhead also contains a combined (spinning and three-axis) Earth sensor and other auxiliary payload sensors.

S/C design life	15 years
L1 link	1575.42 MHz, 29 dBW EIRP
L2 link	1227.6 MHz, 29 dBW EIRP
L5 link (options for L5 civil signal)	1176.45 MHz, for ARNS (Aeronautical Radionavigation Services)
S/C operations	Autonomous operations for up to 60 days
S/C mass	2090 kg with growth potential for new payloads
S/C power	1560 W EOL with growth potential to 2.5 kW
S/C body dimensions	2.4 m x 1.75 m x 1.53 m
S/C data bus	1553B data bus for easy expendability
Uplink frequency, data rate (TT&C)	1783.74 MHz, 1 or 2 kbit/s
Downlink frequency, data rate (TT&C)	2227.5 MHz, up to 32 kbit/s

Table 400: Some S/C parameters of the block IIF series

Payload of Block IIF Satellites:

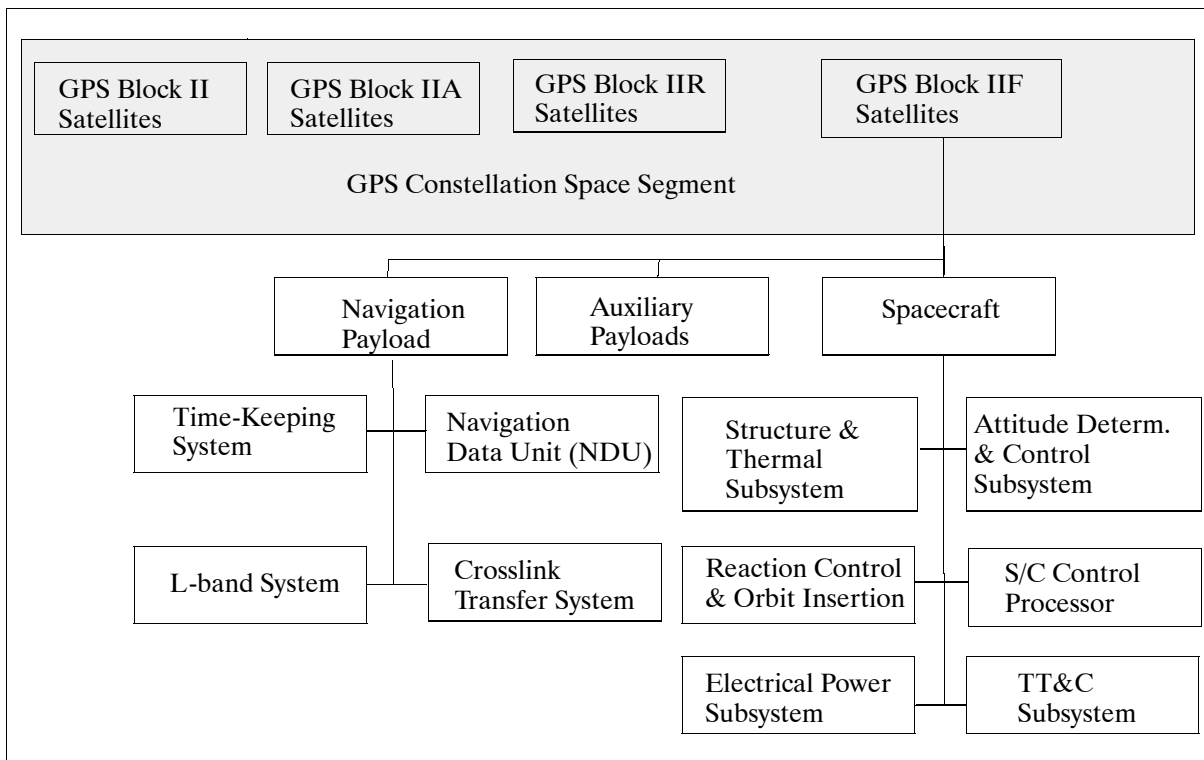

Figure 228: Configuration of the GPS block IIF S/C into the overall GPS constellation

H.4.2 GPS Control Segment

The control segment, called the Operational Control System (OCS), consists of five monitor stations located around the world [Colorado Springs, Hawaii and Kwajalein (Pacific), Ascension Island (Atlantic), and Diego Garcia (Indian Ocean)], and a master control station (MCS), located at Falcon AFB, near Colorado Springs (Note: in 1998, Falcon AFB was renamed to Shriever AFB). Operations are performed by the USAF/SC (Space Command). The monitor stations use a GPS receiver to passively track all satellites in view and thus accumulate ranging data from the satellite signals. The information from the monitor stations is processed at MCS to estimate satellite orbits (ephemeris) and to update the navigation message to each satellite. Updated information (including clock corrections) is transmitted to the satellites via ground antennas, which are also used for transmitting and receiving satellite control information. TT&C functions between MCS and the satellites are transmitted in S-band. ¹³⁰⁰⁾

H.4.3 GPS User Segment

The GPS user segment consists of the global user community with their GPS receivers. A receiver converts the satellite signals into position, velocity, and time estimates. Four satellites are required to compute position and time.

GPS/NAVSTAR is based on direct one-way range measurements with synchronized time references. The satellites share a common time system known as ‘GPS time’ and continuously transmit (broadcast) a precise time reference as a spread spectrum signal at two frequencies in L-band: L1 = 1575.42 MHz, L2 = 1227.6 MHz. Two spread spectrum codes are used: a civil coarse acquisition (C/A) code (1.023 MHz), and a precise (military) protected code (10.23 MHz), referred to as P-code (P). Both carriers, L1 and L2, are phase-modulated with the P-code. The L1 band is, in addition, phase-modulated by the C/A-code. Both signals, L1 and L2, are modulated with a PRN (Pseudo Random Noise) code - a repeated digi-

¹³⁰⁰⁾Ch. Shank, J. W. Lavrakas, “Inside GPS: The Master Control Station,” GPS World, September 1994, pp. 46-54

tal sequence of random bits, that permits a navigation user device to detect a start (i.e., “phase”) of the repeated sequence. The PRN technique is also used for message security. - The GPS signals contain navigation data in the form of time of transmission and satellite position.

The accuracy of both codes is different. The receiver of the civil code cannot decode the military P code when the security status ‘Selective Availability’ in GPS satellites is turned on. [Note: With selective availability (SA) turned on, military users determine their location within 17.8 m, while civilian users determine their position within an accuracy of 100 m; hence, selective availability degrades the navigation information to all civil users]. In March 1990 SA was turned on by DoD, significantly degrading the accuracy of GPS for civilian users of the system.

In the meantime some civil users get centimeter-type accuracy through phase-tracking of the GPS carrier (even with the degraded GPS signals); this is also referred to as “realtime kinematic carrier-phase tracking (RTK)” or CDGPS (Carrier-phase Differential GPS).

Predictable Accuracy	Repeatable Accuracy	Relative Accuracy
PPS = Precise Positioning Service (reserved for military and selected user applications)		
Horizontal = 17.8 m Vertical = 27.8 m Time = 90 ns	Horizontal = 17.8 m Vertical = 27.7 m	Horizontal = 7.6 m Vertical = 11.7 m
SPS = Standard Positioning Service (available to general user community)		
Horizontal = 100 m Vertical = 156 m Time = 175 ns	Horizontal = 100 m Vertical = 156 m	Horizontal = 28.4 m Vertical = 44.5 m

Table 401: GPS accuracy characteristics

Measurement principle: The user makes a range measurement and a range delay measurement, resulting in a three-dimensional position (with four satellites this can be longitude, latitude, and elevation). The visibility of up to three satellites allows two-dimensional position determination (for instance longitude and latitude, which is sufficient for most Earth surface movement). GPS employs the following reference system: DoD World Geodetic System (WGS-84).

Initial Operating Capability (IOC) of the GPS system was declared in December 1993. On February 17, 1995, the FAA announces that GPS is now operational and is an integral part of US air traffic control system. The US Air Force Space Command declared the GPS system operational as of July 17, 1995 for the international user community. An anti-spoofing feature was enacted with the start of the operational period. This means that the P-code is henceforth encrypted (for the Block II configuration satellites) and referred to as Y-code. Any receivers not properly equipped cannot have access to the Y-code. Conventional receivers still have access to the coarse C/A code pseudo-range and L1 carrier phase, but not to the L2 pseudo-range, which is necessary for ionospheric corrections.

H.4.3.1 Fundamental GPS Observables

The full range of signals transmitted by the GPS satellites have expanded the capabilities for positioning moving vehicles, such as aircraft, to the sub-meter level. These applications have extended beyond the initial design of the system which was based principally on the decryption of the two codes. The three fundamental GPS observables used to precisely position a vehicle are: the pseudorange measurements, the carrier phase and the Doppler shift.

- The **pseudorange measurements** are the measured difference between the arrival time of a GPS signal (as measured on the receiver clock) and its transmission time (as deter-

mined by the satellite clock). By simultaneously observing four or more satellites, it is possible to determine the position of the receiver and correct for differences in time between the receiver's clock and the GPS satellite time system. Selective Availability (SA) and the inability for civilian users to access the P-code pseudorange measurements reduce the accuracy of GPS pseudorange positions. The ephemeris error and clock dithering introduced by SA reduces the pseudorange position accuracies to 60 m.

- **Carrier-phase measurements** (short for carrier-frequency phase measurements) are made by reconstructing the carrier signal. All carrier-phase tracking is differential, requiring both a reference and remote receiver tracking carrier phases at the same time (this use of GPS requires specially equipped carrier-tracking receivers). The carrier-phase process includes removing the bi-phase encoding and measuring the phase difference between the reconstructed carrier and a local oscillator within the receiver for both frequencies. As this carrier-beat phase rotates through cycles, the number of cycles is accumulated. The phase measurement is the accumulated phase change from the time the satellite is acquired by a receiver (locked on) until the receiver loses the signal (loss of lock). The carrier phase measurement has a noise level of a few millimeters. The critical parameters for carrier phase measurements are the resolution of the ambiguity and the necessity of maintaining continuous lock on the satellite signal. - Carrier-phase tracking of GPS signals has resulted in a revolution in land surveying and many other applications.

In satellite formation flying applications, the CDGPS (Carrier-phase Differential GPS) technique of relative position measurements is used to provide a high-bandwidth, low-noise measurement of multiple vehicle states (relative position and attitude).¹³⁰¹⁾ Given GPS measurements at two nearby antennas, relative position between these antennas can be estimated to a high degree of accuracy based on tracking the relative phase. GPS transceivers mounted on the vehicles can allow relative positioning in such cases by augmenting the GPS satellite constellation, and can potentially act as a self-constellation when no GPS satellites are available. The same CDGPS technique can also be used for station keeping.

- The **Doppler shift** is most often determined from the time derivative of the carrier phase. The Doppler observable, which is rarely used for geodetic positioning, can be useful for connecting phase measurements across small gaps or cycle slips (<5 s) when the signal from a satellite is lost.

H.4.3.2 Availability of GPS/GLONASS Systems

The GPS system was offered for general civil use, worldwide - with no user fees attached for 10 years - by the FAA administrator James B. Busey at the Air Navigation Conference (ANC) in Montreal in Sept. 1991. This makes the GPS services available to anyone who can live with the 100 m accuracies of the SPS mode. The 10 year period starts at the beginning of 1995 when GPS is fully deployed (21 operational satellites plus three spares).¹³⁰²⁾ GPS can provide a nearly 100% service availability (three-dimensional) with a 21 satellite constellation.

At the same conference, the Soviet Union (now Russia) offered its GLONASS service to the general worldwide civil user community for a period of 15 years after full deployment at no charge. The commitment to the SPS service accuracies of 100 m latitude/longitude and 150 m altitude were matched by Russia. Full GLONASS orbital capability of 24 satellites is expected to be achieved in 1996.

In the meantime the US Government has agreed to give 10 years notice should the US not be able to continue to meet the commitment. The PDD (Presidential Decision Directive) of

¹³⁰¹⁾F. H. Bauer, K. Hartman, J. P. How, et al., "Enabling Spacecraft Formation Flying through Spaceborne GPS and Enhanced Automation Technologies," Proceedings of the ION-GPS Conference, Nashville TN, Sept. 15, 1999

¹³⁰²⁾"GPS - the Next Generation," GPS World, Nov. Dec. 1991, pp. 12-16

March 29, 1996 required a joint military/civil task force, by DoD and DoT respectively, overseeing GPS policies and operations. The PDD also stated also that SA (Selective Availability) would be evaluated annually, starting in 2000. There was an underlying promise that SA would be turned off within a decade (i.e. in 2006). - The Interagency GPS Executive Board (IGEB) was set up as a consequence of PDD, jointly chaired by DoD and DoT, providing some formal civil agency participation in the GPS program.

On May 2, 2000 the SA (Selective Availability) feature was removed for the GPS constellation. The Presidential Directive (of US President Bill Clinton) permits civil users worldwide general access to the highest-possible accuracy of GPS signals. Elimination of SA represents a first step in GPS service modernization to the global user community.

The international community also realizes the need for an integrated long-range Global Navigation Satellite System (GNSS). GNSS has been proposed by the ICAO (International Civil Aviation Organization). GPS and GLONASS will certainly be key elements in this constellation.

In January 1999, US government officials, the Interagency GPS Executive Board, approved the frequencies for two additional civilian GPS signals. The second civilian signal is located at 1227.6 MHz, along with the existing coded military signal L2. It is going to be available starting with the launch of the Block-2F series in 2003. A third civilian signal, exclusively for civil aviation, is at 1176.45 MHz (L5) along with C/A code on L2 and M-code on L1 and L2.

H.4.3.3 GPS Applications

Both GPS and GLONASS provide basic services to large military and civil user communities by supplying instantaneous position, velocity, and time. These parameters are fundamental for navigation in general; they are also implicit to virtually all applications in the field of Earth observation and surveying. Current interest in GPS/GLONASS applications lies in the potential of the system's capabilities; the number of uses will be limited only by the imagination. Only civil applications are considered in this context.

Research Applications

GPS¹³⁰³⁾ lends itself to many different scales of application, from the global level to the most discrete and site-specific. In between are regional and national projects. At the global level GPS applications are planned to help define the dimensions of the planet itself: creating geoidal models, establishing the terrestrial reference frame and Earth rotation parameters, mapping the dynamic topography of the oceans and monitoring plate tectonics. The list of ongoing and possible research applications of GPS services is long. Some examples are:

- Measurement of crustal motion in Central and South America (CASA).
- Tide gauge positioning along the Baltic Sea (unified height system to study the relative land uplift and sea level variations). Poland, Finland, Sweden, etc.
- Development of regional differential GPS (DGPS) systems to aid maritime vessel traffic services along coastlines and in harbors (US Coast Guard and several Scandinavian agencies).¹³⁰⁴⁾
- CNRS of France started a project using GPS positioning to help georeference early photos of glaciers in the French Alps. Growth and recession of ice sheets.
- NASDA is planning to integrate GPS into the navigation system of its H-II orbiting plane.
- Russian scientists use GPS for oceanic work, models for earthquake predictions, etc.
- A new earthquake forecasting research program in the USA is for instance based on GPS technology (1991). The proposed concept uses an array of GPS monitoring sta-

¹³⁰⁴⁾B. Tryggö, R. Bäckström, "Threading the Needle: Differential GPS on the Baltic Sea," in GPS World Sept. 1991, pp. 22-26

tions positioned along a fault; all of these stations are tied into a computer center which calculates Earth movements in the order of 1 cm.¹³⁰⁵⁾

- SCIGN (Southern California Integrated GPS Network) is a collaborative project (NASA/JPL, USGS, UCSD, NSF, etc.) to install 250 permanent, continuously recording GPS receivers in and around the Los Angeles basin to provide accurate deformation information to improve estimates on earthquakes.¹³⁰⁶⁾
- NASA/JPL with its extensive experience in interplanetary navigation and corresponding planet atmosphere interpretation is investigating its occultation techniques to be applied directly to GPS receiver measurements. This allows to determine the Earth's major atmospheric constituents and other parameters. See also GGI sensor definition under EOS sensors, and GPS/MET of Microlab-1.
- There are numerous projects and campaigns in solid Earth research. GIG '91 (GPS Experiment for the International Earth Rotation Service and Geodynamics).
- The Space Shuttle has flown GPS receivers many times.
- In the future GPS will be used for attitude determination on commercial satellites.
- GPS is being used as a precision timing reference in many applications, such as: synchronization of digital telecommunication networks, geodetic positioning, etc.
- There are also numerous questions that involve standards and procedures.
- etc.

Commercial Applications

The potential of GPS is finding its way into the commercial world, which it is just getting to know the technology and gearing up for new navigation and surveying products. The following applications could be supported:¹³⁰⁷⁾

- Civilian air traffic control. GPS will serve as a guidance system for instrument landings. This can be very advantageous to all, especially to Third World Nations who have practically no guidance systems installed at all. The completion of the GPS and GLONASS constellations will be of utmost importance to the civil aviation community.
- Field demonstrations have been conducted of runway and approach guidance of aircraft with carrier-phase DGPS, and precision landing using a DGPS system combined with an inertial navigation system.
- Navigation on the oceans. Marine navigators are asking for a DGPS (see H.4.4 for DGPS) network around coast lines.
- Navigation systems for automobiles such as IVHS (Intelligent Vehicle/Highway Systems).
- Navigation systems for outdoors (tracking, boating, expeditions, etc.)
- Navigation systems for blind people!
- Commercial surveying. We are just beginning to explore the huge potential of the GPS surveying techniques in terms of accuracy, efficiency, and productivity. Example: an integrated GPS tachymeter system is being developed with an on-the-fly datalink and direct output to a Geographic Information System (GIS).
- There is seemingly not a single application in surveying and navigation that cannot be improved using GPS/GLONASS.
- etc.

The market offers a wide variety of GPS receivers/products to serve an increasingly diverse range of GPS applications. The list of manufacturers would be too long to be considered here. In general GPS applications technology is now both operationally capable and also becoming more affordable to the consumer market.

H.4.3.4 Some GPS Orbit and Attitude Instruments

Basic concept of real-time ‘interferometric’ attitude measurements: An array of GPS antennas (e.g. four) are placed on the rigid structure of a spacecraft (fixed baseline configuration - a minimum of only two GPS satellites are required for an attitude fix). Software controlled multiplexing allows for signals being received at all antennas to reach a single receiver, or signals from different antennas are processed by different channels in the receiver. The carrier-phase differences allow the receiver to recover the angle between the antenna baseline and the incident signal direction. Additional on-board code computes attitude from successive carrier phase measurements for real-time determinations. - The accuracy of GPS receiver attitude determination approach is strongly dependent on antenna placement (baseline), the accuracy of the carrier phase measurements, and on-board data-processing techniques. For a 1 m antenna separation, the point solution accuracy is about 0.3° . A Kalman filter can be used to incorporate data about the vehicle dynamics to improve the attitude estimates. ¹³⁰⁸⁾ ¹³⁰⁹⁾ ¹³¹⁰⁾

As of 1999/2000 the phase determination precision is typically 1 mm, so that with an antenna spacing of 1 m an angular accuracy of better than 0.1° can be obtained.

Figure 229: Schematic configuration for GPS interferometry

A great advantage of the GPS-based attitude determination method is its driftless source of attitude, it does not require any calibration. A divers set of applications is possible.

- **TANS Vector** ¹³¹¹⁾ (Trimble Advanced Navigation Sensor Vector - of Trimble Navigation, Sunnyvale, CA). A C/A code, L1, SPS (Standard Positioning Service) receiver with real-time (10 Hz) attitude determination (azimuth, pitch and roll) capability; in addition it provides position, velocity, and time. The TANS Vector system comprises two major sub-assemblies: the RPU (Receiver Processor Unit) with bi-directional interface RS-422, and an array of four low-profile antennas. The nominal measured attitude accuracy is dependent on antenna separation and installation configuration. For a 1m baseline the attitude accuracy is 0.3° (rms), for a 3m baseline the accuracy is 0.10° (rms). The first spaceborne TANS Vector system was flown on the APEX mission of USAF (launch Aug. 3, 1994). The next mission was CRISTA-SPAS-1, which was deployed from the Shuttle Atlantis (SST 66, November 3-14, 1994); the use of the

¹³¹¹⁾ J. K. Brock, R. Fuller, et al., “GPS Attitude Determination and Navigation Flight Experiment,” Proceedings of ION GPS-95, Sept. 12-15, 1995, Palm Springs, CA, Sept. 1995, pp. 545-554

TANS Vector receiver for a 24 hour period produced rms attitude variations around mean motion of 0.19° in roll, 0.15° in pitch and 0.26° in azimuth.

- **GPS Tensor** (a common product of Space Systems/Loral, Palo Alto, CA, and LABEN, Milan, Italy). A sophisticated receiver technology invented at Stanford University, Palo Alto, CA (C. E. Cohen), with licensed technology from Trimble Navigation and Stanford University. The Tensor receiver provides in real-time 13 output states of orbit/attitude data, enough for orbit and attitude determination of any space vehicle. The major instrument parameters provided are: roll, pitch, and yaw angles (and their rates), position, velocity, time **and filtered orbit determination** using a continuous-tracking, L1-, 9-channel C/A code receiver.^{1312) 1313)}

The GPS Tensor instrument adds some advancements to Trimble's TANS Vector receiver. Like TANS Vector, it consists of two modules: the RPU (Receiver Processor Unit) with a dual, full duplex RS-422 interface, and an array of up to four low-profile and lightweight (0.2 kg) antennas. A special purpose ASIC was jointly designed by SS/L and Laben (a subsidiary of Alenia Spazio of Milan, Italy) to process signals of up to nine channels of GPS satellite data, including carrier phase. In addition, the ASIC measures the Doppler frequency of each GPS satellite in view and determines the code phase to form the pseudo-range measurements. An adapted Kalman filter smooths the position readings. A RAIM (Receiver Autonomous Integrity Monitoring) algorithm provides assurance for accuracy and reliability of the navigation system (autonomous detection of large range errors). - GPS Tensor was successfully test flown for the first time on the free-flyer payload ORFEUS-SPAS-2 (see Table 48).

- **GADACS** (GPS Attitude Determination and Control System). A NASA prototype instrument flown on the SPARTAN free-flyer payload of Shuttle flight STS-72 (Jan. 11-20, 1996). The prime objective is to demonstrate GPS attitude measurement technology in LEO. GADACS used two TANS Vector receivers (of Trimble Navigation, Sunnyvale, CA), along with an array of four L-band patch antennas mounted onto a special plate inside of SPARTAN, and DRIRU-II (Dry Rotor Inertial Reference Unit), a high precision gyroscope developed by Teledyne (for proof of GPS measured attitude). GPS data were recorded along with gyro measurements for verification and calibration of the GPS attitude measurements.¹³¹⁴⁾ Note: GADACS was not able to perform attitude determination because it did not lock onto the four GPS signals necessary to obtain a position fix (a required first step to obtain attitude solutions.¹³¹⁵⁾
- **GANES** (GPS Attitude Navigation Experiment). A NASA prototype instrument (developed by: JSC, GSFC, and C. S. Draper Laboratory, Cambridge, MA) flown on Shuttle flight STS-77 (May 19-29, 1996) as a hitchhiker carrier payload on TEAMS (Technology Experiments Advancing Missions in Space). The prime objective was to mitigate the technology risk associated with the use of GPS to determine attitude, position, and velocity for ISS (International Space Station) and to evaluate the accuracy of GPS multipath models. GANES data were used to assess the performance of GPS-based navigation and attitude using an antenna configuration and orientation similar to that planned for ISS. The GANES hardware is comprised of a six-channel, four-antenna (micro pulse choke-ring antennas) system, mounted onto the platform (1.5 m x 3 m) in the cargo bay, and two Trimble TANS Vector receivers. Two instruments were available to calibrate the GPS attitude data: HAINS (High Accuracy Inertial Navigation System) of

the Shuttle which consists of a platform-type inertial measurement units, and a Honeywell ring-laser gyro used as the GANE IRU. - A total of four on-orbit operational test sequences were performed. The GANE requirements called for an attitude accuracy of 0.3° (3 sigma) and attitude rates to within $0.01^\circ/\text{s}$ (3 sigma) per axis at 0.5 Hz. The post flight processing results provided accuracies of 0.1° in yaw and pitch and 0.2° in roll. ¹³¹⁶⁾

- **ARP** (ATV Rendezvous Pre-development). ³³⁸⁾ ARP refers to ESA GPS relative navigation experiments flown on Shuttle flights STS-84 (May 15-24, 1997), STS-86 (Sept. 25 - Oct. 6, 1997) and on the MIR station, in preparation for the rendezvous maneuvers of ATV (Automated Transfer Vehicle) for ISS (International Space Station).
- **GADFLY** (GPS Attitude Determination Flyer). A NASA attitude experiment on the Lewis S/C (launch Aug. 23, 1997, the Lewis S/C could not be operated after launch and reentered the atmosphere on Sept. 28, 1997), consisting of the following hardware: four GPS antennas and pre-amplifiers, cross-strapped to two GPS Tensor (SS/L) receivers. The prime objective was attitude determination, a secondary objective was to demonstrate precise time distribution and to provide real-time navigation solutions to the S/C subsystems and other experiments. To improve the real-time navigation accuracy delivered by the GPS SPS service, the GPS Enhanced Orbit Determination Experiment (GEODE), a navigation filter, was developed for GADFLY. The GEODE algorithm executes a background Kalman filter and a foreground real-time state propagator, outputting position and velocity every second. ¹³¹⁷⁾ ¹³¹⁸⁾ GADFLY was also flown on the NASA SSTI-Clark spacecraft (1998).
- **SIGI** (Space Integrated GPS/INS). SIGI is a NASA instrument (Honeywell Space Systems as prime contractor) with the objective to provide attitude, position and time for ISS. The assembly consists of a GPS receiver and INS (Inertial Navigation System). The INS is a laser ring gyro package needed for sensing accelerations and blending data with GPS solutions to improve accuracy. The SIGI GPS receiver is a 12-channel, C/A code, avionics-grade instrument. Six channels are dedicated to C/A code tracking for navigation. The other six channels are multiplexed across four antenna inputs to provide differential carrier-phase measurements (attitude determination). SIGI combines the GPS attitude measurements in a dynamic filter with measurements from its RGA (Ring Gyro Assembly) to produce an estimate of ISS's attitude. - Russia has its own attitude determination system on its the Russian Service Module. It serves also as backup for SIGI. ¹³¹⁹⁾ ¹³²⁰⁾ ¹³²¹⁾

H.4.3.5 IGS (International GPS Service for Geodynamics)

IGS is an international organization established in 1993 by IAG (International Association of Geodesy) with a central bureau at NASA/JPL for overall management and organization. The primary objective of IGS is to provide a service to support, through GPS products, geodetic and geophysical research activities (broad spectrum of operational activities performed by governmental organizations; services to develop standards and specifications, [and to provide Earth rotation parameters of high resolution for the International Terres-

trial Reference Frame (ITRF) maintained by the International Earth Rotation Service (IERS), and to monitor the global deformations of the Earth's crust]. IGS collects, archives and distributes GPS observation data sets of sufficient accuracy to satisfy the objectives of a wide range of applications and experimentation. These data sets are used by the IGS to generate the following data products:^{1322), 1323) 1324)}

- High accuracy GPS satellite ephemerides
- Earth rotation parameters
- Coordinates and velocities of the IGS tracking stations
- GPS satellite and tracking station clock information
- Ionospheric information

IGS accomplishes its mission through the following components:

- Networks of tracking stations. The networks consists of 30 - 40 core stations and 150 - 200 fiducial stations.
- Data centers. There are operational, regional, and global data centers. The operational data centers are in direct contact with the tracking sites. Their task is to reformat, archive, maintain and download their data to regional or global data centers. The regional data centers collect reformatted tracking data from several operational centers and transmit their data to global data centers. The global data centers are the main interfaces to the analysis centers and the user community.
- Analysis and associate analysis centers. Analysis centers generate IGS data products which are delivered to the global data centers

A number of campaigns (since 1992) by an IAG subgroup (G. Beutler, I. Mueller, etc.) have been conducted to test the feasibility of the program. Initial tracking service products (pilot program) are provided by the following data centers: JPL (central bureau), NASA's Crustal Dynamics Data Information System (CDDIS), Institut Geographique in France, and the Scripps Institution of Oceanography.

H.4.3.6 CIGNET

CIGNET = Cooperative International GPS Network of IAG (International Association of Geodesy). CIGNET continuously tracks the GPS satellites, providing a fiduciary data set that may be used for orbit computation and research. The data from all stations are sent weekly to the National Geodetic Survey (Rockville, MD.) where they are archived. The following SLR (Satellite Laser Ranging) ground stations are participating in the initial CIGNET program.¹³²⁵⁾

- Kokee-Orbit, Hawaii, USA
- Mojave, California, USA
- Onsala, Sweden
- Richmond, Florida, USA
- Tromsø, Norway
- Tsukuba/Kashima, Japan
- Westford, Massachusetts, USA
- Wettzell, Germany
- Yellowknife, Canada

While the current CIGNET provides improved ephemeris data, the more expansive geodetic system would also provide positioning data. As for costs, operating a couple of com-

mercially available GPS/GLONASS receivers at a site that is part of a global CIGNET is orders of magnitude less expensive than building a new laser or VLBI facility.

Note: CIGNET was an important early activity coordinated by USGS for IAG's commission VIII. It became the core of the initial IGS network.

H.4.4 DGPS (Differential GPS)

A DGPS ¹³²⁶⁾ system employs a local reference station, which has a high-quality GPS receiver at a known, surveyed location. The reference station estimates the slowly varying error components of each GPS satellite range measurement and forms a (scalar) correction for each GPS satellite in view. This correction is broadcast to all DGPS users on a convenient communication link. With this concept higher position accuracies are achieved for users in the vicinity (typically up to 150 km) of a DGPS reference station. The differential correction greatly improves the accuracy for all users, regardless of whether selective availability (SA) is activated or not. This improvement arises because the largest GPS errors vary slowly with time, however, they are strongly correlated with distance.

A surveying application: By using GPS equipment on an aircraft—typically dual-frequency, 24 channel receivers with the antenna as close as possible to the camera lens itself—and a DGPS base station on the ground, the position of the plane itself can be recorded to an accuracy level of about two meters (this obviates the need to send in survey crews in advance to set visible ground markers).

Figure 230: Differential operation of GPS with a reference station

In the USA there are plans to modify more than 200 radio beacons to enable broadcasts of DGPS signals along coastal regions. A full DGPS network is planned to be operational by 1997. The network will broadcast corrections to ranging data received from GPS satellites to improve vessel navigation up to a range of a few hundred km (from the reference station).

¹³²⁶⁾ P.K. Enge, R.M. Kalafus, M.F. Ruane, "Differential Operation of the Global Positioning System," IEEE Communications Magazine, July 1988, Vol. 26, No.7, pp. 48-59

Many radio beacon networks of other countries are also being upgraded for the broadcast of differential GPS corrections to marine users. The corrections will improve the accuracy of a mariner's GPS fix to <10 m, which allows harbor and harbor entrance navigation.

A DGPS positioning service was developed by Magnavox and CUE Network in the USA. This positioning service provides real-time, 1-5 m accuracy DGPS corrections, with broadcast over FM subcarriers from selected area radio stations.¹³²⁷⁾ The broadcast standard is referred to as RBDS (Radio Broadcast Data System); RBDS is compatible with the pager-based DGPS service, called ACC-Q-POINT (formerly known as: Pinpoint).

Another commercial service provider company 'Differential Corrections Inc. of Cupertino, CA. has plans to rapidly establish a worldwide network of FM RBDS stations.¹³²⁸⁾

The concept of wide-area DGPS (WADGPS) networks of reference stations is used to form a vector correction for each satellite. These vector corrections are valid over much greater geographical areas, such as continents.

H.5 MTSAT (Multifunction Transport Satellite)

See the MTSAT description under F.9.

H.6 Transit - Navy Navigation Satellite System (NNSS)

A US Navy first generation satellite navigation system (the world's first), designed and built by JHU/APL - the entire development program (S/C hardware, ground support network, user equipment, etc.) was conducted within APL at Laurel, MD, RCA (later named: GE Astro Space, now Lockheed Martin) was the satellite integrator starting with Oscar-18 (Transit-O-18). The program was initiated in the spring of 1958, based on JHU/APL's Doppler tracking discoveries (the Sputnik orbit could be determined from RF Doppler data) and the realization of the "navigation problem" (it states: if the position of the satellite were accurately known, then Doppler data could tell an observer on the ground his unknown position). The Transit program was sponsored by ARPA.^{1329) 272) 1330)}

Orbits: Transit satellite series orbits were generally at altitudes (apogees) of about 1100 km. The initial satellite launches (up to Transit-4B) were from Cape Canaveral, FL. All further launches took place from VAFB, CA, with polar orbit inclinations (Table 402).

The Space Segment: The first satellites (up to and including Transit-3B) were spherical in shape. Transit-1A was completed in seven months after initial program funding. Transit-4A and -4B were drumshaped (almost a cylindrical body with four solar panels) to provide more space for solar cells. In addition, operational frequencies of 150 and 400 MHz were used for the first time. The dual frequency corrected for ionospheric errors. On-board time keeping was done with cesium oscillators. Throughout the Transit system service period (1959 - 1996) four generations of cesium frequency standards and three generations of hydrogen masers were experienced, starting with a stability of 5 parts in 10^{10} to about 2 parts in 10^{15} for the best tuned hydrogen maser.

Transit-1A to -4B were regarded experimental satellites. The mass of each experimental satellite was about 136 kg. The TRAAC (Transit Research And Attitude Control) satellite, also built by APL and launched together with Transit-4B on an Ablestar vehicle (launch

Nov. 15, 1961), flew the first gravity-gradient boom in history. However, stabilization was not demonstrated since only about 1 m of the 18 m boom (total length) deployed. The TRAAC S/C lost signal on Aug. 12, 1963 due to the degradation of solar cells.¹³³¹⁾

The next series of Transit satellites (starting with -5A-1) were regarded as early operational prototype spacecraft. They were launched on a solid-fuel Scout vehicle from VAFB, CA, into polar orbits. The spacecraft mass of the first satellite, Transit-5A-1, was 55 kg. Three-5B series S/C were launched by Thor Ablestar vehicles, each with a piggyback 5E series S/C. The 5E S/C series had a solar power supply, while the 5B series S/C had nuclear power supplies. The Transit-5A series evolved into the Transit-5C-1 satellite with solar power supply.

The Transit Oscar series (Note: the Transit Oscar series should not be confused with the AMSAT Oscar series). The operational series of Transit satellites, more commonly referred to as “Oscar” series [or SOOS (Stacked Oscars on Scout)], closely followed the design of Transit-5C-1 with an important change: Hysteresis rods were installed on the solar panels to dampen the residual motion after the S/C despin maneuver in early orbit. The method of magnetic core storage (30 kbit) was used. Oscar-11 (Transit-O-11) was not used, it was later modified and launched as Transat on Oct. 27, 1977 from VAFB (Scout-D1 vehicle). The design life of the Oscar series was 3 years. Early Oscar series satellites had only short lifetimes. However, beginning with Transit-O-12 (Oscar-12), the satellites demonstrated an average orbital lifetime of more than 14 years. In fact, two S/C, Transit-O-13 and Transit-O-20, operated more than 21 years.

Transit Improvement Program (TIP). TIP was initiated in 1969 with the objective to provide a radiation-hardened satellite. Each TIP satellite was equipped with a minicomputer providing a memory of 64 kbyte. In addition the 150 and 400 MHz transmitters were redesigned, providing an output power of 3 W (150 MHz) and 5 W (400 MHz). A hydrazine thruster system was used to correct for orbital precession. - Each TIP satellite had the requirement to broadcast ephemerides for five days autonomously without input from the ground. This in turn required the development of a drag-free satellite series, referred to as “Triad” (Transit-improved DISCOS).¹³³²⁾ The DISCOS (Disturbance Compensating System) technology was spearheaded by Stanford University (the “ball-in-the-box” concept). Triad uses a three-body system [the actual satellite at bottom facing nadir, DISCOS at the center position, and a nuclear power supply (radioisotope thermal generator) at the top] connected by deployable booms. A major improvement in the TIP-satellite design was the introduction of the quadrifilar helix antenna. All major electronics subsystems were made redundant, radiation-hardened integrated circuits were interconnected on a ceramic substrate to obtain high-density packaging.

Triad-1 (launched Sept. 2, 1972) was the first satellite to fly a completely gravitational orbit, free from all surface forces such as drag and radiation pressure. The orbit could in fact be predicted for up to 60 days.

Triad-2 (TIP-2) and Triad-3 (TIP-3) satellites were each equipped with a redundant pulsed-plasma electric propulsion system ($I_{sp} = 225 \text{ kg s}$) used for drag compensation. The 1 kg Teflon, used for both thrusters, provided a fuel supply for 10 years.

Nova satellites. Three more spacecraft, nearly identical to the TIP series design, were built by RCA on Navy request. Improvements included: the addition of magnetic damping to the DISCOS and a stiffening to the boom assembly, reference clock, computer capacity, 6 m gravity boom, S/C mass was 136 kg. The NOVA satellites used the electric propulsion system (PPT system, $I_{sp} = 543 \text{ seconds}$, total impulse = 2450 Ns) of the TIP series satellites to

¹³³¹⁾ Note: The very first Transit satellites transmitted signals at four frequencies: 54, 162, 216, and 324 MHz. The signals provided experimental data to evaluate ionospheric effects as a function of frequency. The final design is based on a two-frequency method for correcting ionospheric error.

¹³³²⁾ J. Dassoulas, “The TRIAD Spacecraft,” Johns Hopkins APL Technical Digest, Vol. 12, No. 2, pp. 2-13, June 1973

compensate for drag with thruster firings. The NOVA satellites had operational lifetimes of 8 to 9 years. ¹³³³⁾ ¹³³⁴⁾

The Control Segment:

Transit system operations and control are conducted at NAVSOC (Naval Satellite Operations Center, since 1962), Point Mugu, CA - working through tracking stations at Laguna Peak (near Point Mugu, CA), Prospect Harbor, ME, Rosemont, MN, Wahiawa, HI, Finegayan, Guam (since 1993) and at Falcon AFB, Colorado Springs, CO (since 1988). The tracking stations collected Doppler data and transmitted in the uplink the predicted ephemeris to each satellite. This data was stored on-board for continuous rebroadcasts to the user community. ¹³³⁵⁾ ¹³³⁶⁾

When Transit navigation services were terminated/decommissioned on Dec. 31, 1996, NAVSOC retained other mission assignments, among them operations of GFO-1 and NIMS (Navy Ionospheric Monitoring System). On Jan. 1, 1997, the remaining Transit system constellation (of six Oscars in three orbital planes) became NIMS with a new application, namely to utilize the Transit system resources for computerized ionospheric tomography (CIT). In this setup, the NIMS satellites are being used as dual-frequency beacons by ground collection sites to determine the free electron profile of the ionosphere.

Satellite	Launch	Comment
Transit-1A	Sept. 17, 1959, Cape Canaveral (CC), Thor Able-2 launcher	Failed to achieve orbit (final stage failure)
Transit-1B	April 13, 1960, CC, Thor-Ablestar, I= 66.7°, perigee = 626 km, apogee=1078 km	Operation for 89 days, first transmit on 2 frequency pairs to test ionospheric correction technique
Transit-2A Solrad-1	June 22, 1960, Thor Ablestar, I= 66.7°, pe.=626 km, ap.=1078	First dual-payload launch, Transit-2A was operational until Nov. 26, 1962
Transit-3A Solrad-2	Nov. 30, 1960, CC, Thor Ablestar	Failed to achieve orbit
Transit-3B Lofti-1	Feb. 22, 1961, CC, Thor Ablestar	First digital memory in space (384 bits of magnetic core shift register) to store the navigation message
Transit-4A Injun-1 Solrad-3	June 29, 1961, CC, Thor Ablestar	First triple-payload launch. First nuclear power supply tested (RTG). Memory storage capacity (magnetoresistive delay line) is increased to 2048 bits.
Transit-4B TRAAC	Nov. 15, 1961, CC Thor Ablestar I=32.4°, ap.=1100 km, pe.=951	TRAAC flew the first gravity-gradient boom, but only about 1 m of the 18 m long boom deployed
All further launches of Transit series satellites were conducted for VAFB, CA - requiring polar orbits		
Transit-5A-1	Dec. 18, 1962, VAFB, Scout	New technique to deploy solar panels
Transit-5A-2	April-5, 1963, VAFB, Scout	Failed to achieve orbit
Transit-5A-3	June 16, 1963, VAFB, Scout	A malfunction of memory occurred, hence it could not be used for navigation. Transit-5A-3 is the first satellite to achieve gravity-gradient stabilization.
Transit-5BN-1 Transit-5E-1	Sept. 28, 1963, VAFB, Thor Ablestar	Transit-5BN-1 was the first operational navigation satellite used by the Navy (service until Nov. 1964). Transit-5E-1 was operational for 11 years.
Transit-5BN-2 Transit-5E-2	Dec. 5, 1963, VAFB, Thor Ablestar	
Transit-5BN-3 Transit-5E-3	April 12, 1964, VAFB, Thor Ablestar	Failed to achieve orbit
Transit-5C-1	June 4, 1964, VAFB, Scout	Solar power supply
The Oscar (=Operational) satellite series.

Table 402: Overview of Transit program satellites

The User Segment

The Transit navigation operates on the principle that a receiver's position can be determined on a single satellite pass by measuring the Doppler shift for a period of 10 to 15 minutes. A user's receiver on the ground measured the time history of the refraction-corrected Doppler data and recorded the orbital ephemeris as the satellite passed overhead. The user was able to calculate position initially within a few hundred meters, later within 15 to 25 meters. Some limitations: The user had to know his altitude and the satellite ephemeris; an error was introduced for an unknown vessel speed. A position fix with the Transit constellation was only available every 35 to 100 minutes. Navigation information could only be obtained by instruments of slow-moving users (like ships). For stationary users, such as surveying and oil platform location, integration of measurements from several passes yielded rms accuracies in the order of 5 m. Toward the end of Transit system operations in 1995, commercial receiver prices were as low as \$1000. The 2-D system did not permit velocity determination.

In 1967 Transit navigation services were made available to the general public (commercial and private users). Commercial companies were permitted to manufacture and to sell low-cost receiving equipment.¹³³⁷⁾ This action resulted in the use of more than 80,000 privately-owned Transit receivers (in particular in the field of commercial shipping). Also, oil-drilling platforms were among the first to use Transit to determine the boundaries of oil deposits.

During its 32 years of operation, the Transit Navigations System (or NNSS) provided accurate and reliable global navigation for the US Navy and for the civilian community. The system was continuously improved, in addition it contributed to many technology advances (see Table 42).

¹³³⁷⁾ L. J. Rueger, "Development of Receivers to Characterize Transit Time and Frequency Signals, John Hopkins APL Technical Digest, Vol. 19, No. 1, 1998, pp. 53-59

H.7 Summary of Microwave Tracking Systems

There are four spaceborne radiometric tracking systems in use addressing a variety of navigation requirements, among them precision orbit determination. These are: GPS, GLONASS, DORIS and PRARE.¹³³⁸⁾

While these systems differ in the source of the radio signals, they share common characteristics: they operate by determining the signal's "carrier" phase, its time derivative (i.e. Doppler shift) and/or its derivative with frequency (i.e. group delay and range).

GPS and GLONASS (one-way broadcast systems)

GPS and GLONASS are very similar general purpose positioning systems consisting of constellations of 21-24 satellites in roughly 12-hour orbits, continuously broadcasting dual frequency navigation signals. The carriers are modulated with pseudonoise ranging codes to permit both Doppler and one-way range measurements (also known as "pseudorange" measurements). The signals from each satellite blanket the Earth, extending roughly 3000 km beyond the Earth limb. At an altitude below 3000 km, any user of GPS and/or GLONASS will have four or more satellites (transmitters) in view. The combination of dual data types (phase and pseudorange) and continuous three-dimensional coverage makes it possible to employ a quasi-geometric positioning technique.

PRARE and DORIS

PRARE and DORIS are tracking systems requiring a host satellite (for the space segment instrument) and global ground-based tracking networks for precise orbit determination. Both systems (PRARE and DORIS) require an orbit determination process using conventional dynamic techniques (with physical models) whose accuracies depend on the quality of the models.

DORIS is a one-way Doppler system which broadcasts continuously at two frequencies: 401 and 2036 MHz (a two-way upgrade is planned). The DORIS instrument on the host satellite observes individual ground beacons in sequence and measures the Doppler frequency of the received signals.

PRARE is a two-way tracking system, broadcasting dual-frequency signals (2200 and 8500 MHz) from a transmitter on-board the host satellite to receiver-transponders on the ground. The signals are modulated by pseudonoise ranging codes to permit both range and range-rate measurements. The 8500 MHz signal is coherently transponded back to the host satellite (at 7200 MHz) for on-board range and range rate extraction. The 2200 MHz signal is received and tracked on the ground to provide an ionospheric correction.

H.7.1 DORIS Tracking System

See description of DORIS under E.21.1

H.7.2 PRARE Tracking System

PRARE (Precise Range And Range-Rate Equipment) is a microwave tracking system operating at centimeter accuracy levels for the measurement of satellite to ground range and range rate. The concept is based on an autonomous spaceborne two-way, dual frequency microwave tracking system with its own telemetry, telecommand, data storage, timing and data transmission capabilities. - PRARE is a DARA-funded project, defined/designed by

¹³³⁸⁾See "Orbital Analysis" (Chapter 6.4, pp. 205- 212) in 'The Interdisciplinary Role of Space Geodesy,' Springer Verlag, 1989,

Ph. Hartl (University of Stuttgart) and Ch. Reigber (GFZ Potsdam), and built by Kayser Threde of Munich, Time-Tech of Stuttgart, and Dornier of Friedrichshafen. ¹³³⁹⁾ ¹³⁴⁰⁾

PRARE flies on Meteor-3-7 (launch: Jan. 25, 1994) as a passenger payload; as such it is regarded a proof-of-concept mission for all PRARE subsystems. PRARE is also on ERS-2. Applications: PRARE precision orbit data sets can be used in the fields of geodesy, geophysics, and atmospheric sciences, and to supplement orbit-sensitive remote sensing systems for altimetry and SAR interferometry applications.

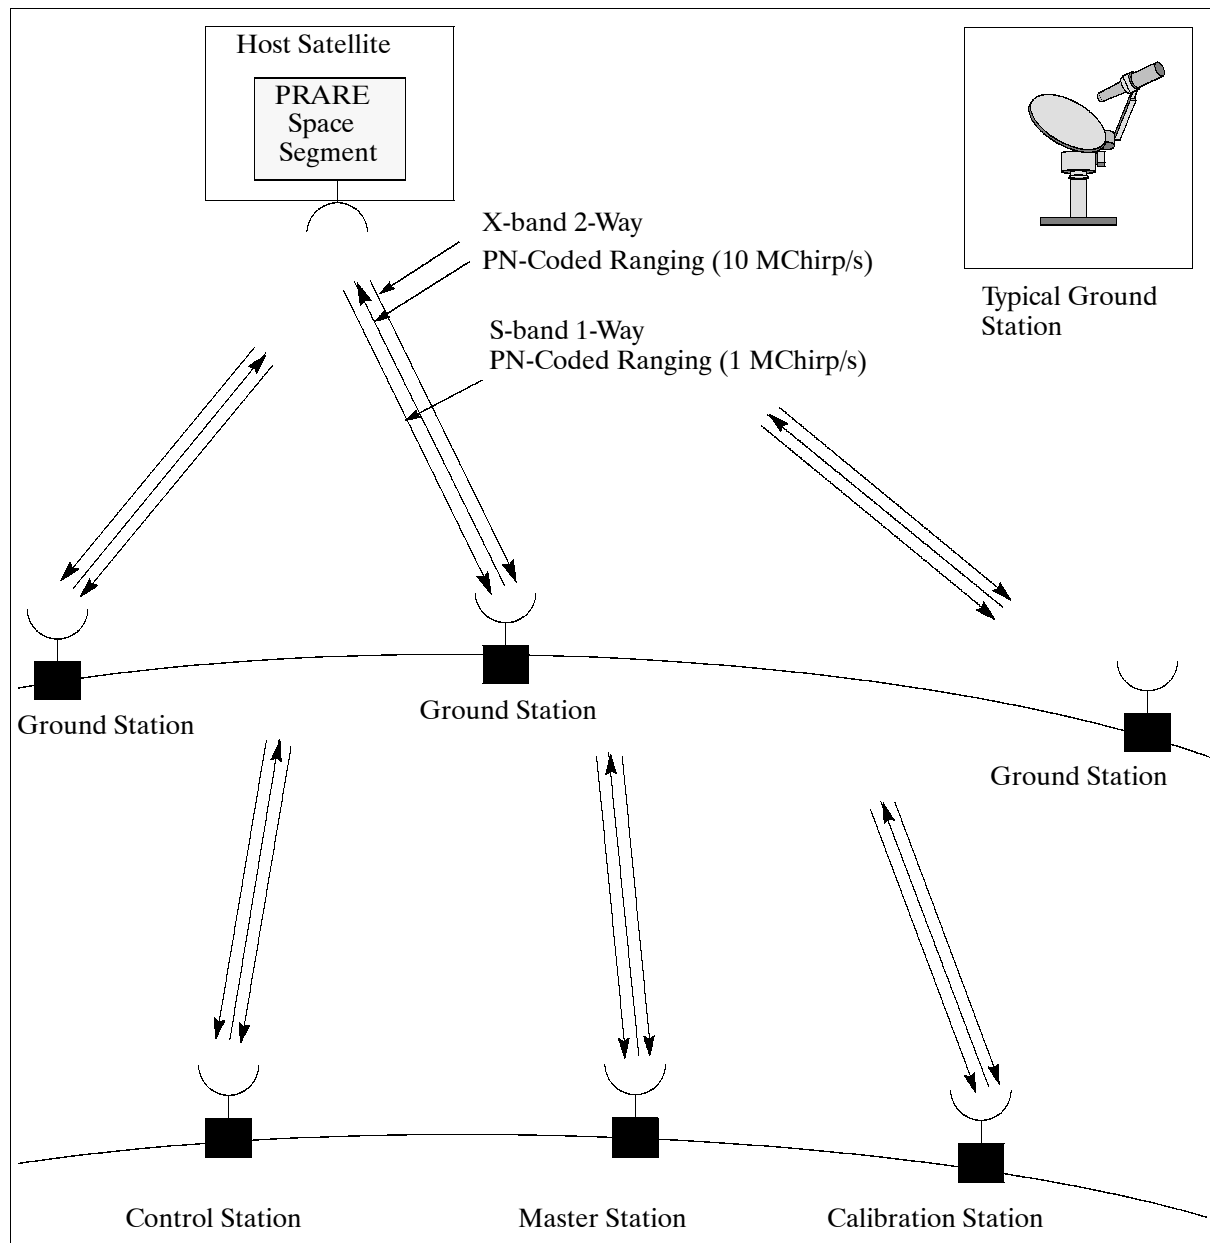

Figure 231: PRARE measurement principle with space and ground segments

PRARE consists of three major components:

1) Space Segment

This is a small self-contained hardware unit with a mass of 19 kg, power consumption of

¹³³⁹⁾ "The Precise Range and Range Rate Equipment PRARE: Status Report on System Development, Preparations for ERS-1 and Future Plans," Submitted by F. Flechtner, K. Kaniuth, Ch. Reigber, H. Wilmes of DGF1, Second International Symposium on Precise Positioning with the Global Positioning System (GPS '90), Sept. '90, Ottawa
¹³⁴⁰⁾ P. Hartl, C. Reigber "Das PRARE-System der ERS-1 Mission," Die Geowissenschaften, 9. Jahrgang, Heft 4-5, April-Mai 1991, pp. 156-162.

39 VA (operational), or 8 VA in standby mode, and communication links independent of the host satellite.

2) Ground Station Network

The network consists of small automated and transportable ground stations (whose positions are known or can be determined from PRARE data to high precision). At X-band a ground station works as a regenerative and coherent transponder, at S-band a station acts as a receiver for the transmitted signals and measures the difference of the time of arrival of both signals.

3) Control Segment (in the case of Meteor-3-7 it consists of:)

- a command station
- a master station (with a time control unit and a preprocessing computer in connection with a user center, eg., DFD). The master station may also command the space segment.
- a station for calibration in collocation with a third-generation laser tracking system.

PRARE Measurement Principle

Two continuous signals are emitted from the space segment to the ground, one of which is in S-band (2.2 GHz), the other in X-band. Both signals are modulated with a PN-code (pseudo random noise, 1 MChirp/s for the S-band and 10 MChirp/s for the X-band) used for the distance measurement and containing data signals (broadcast information) for ground station operation (prediction of orbit visibility, etc.). The time delay in the reception of the two simultaneously emitted signals is measured at the ground stations with an accuracy of better than 1 ns; the result is retransmitted and stored in the on-board memory of PRARE for later ionospheric correction of the data.

In the ground station the received X-band signal is transposed to 7.2 GHz, coherently modulated with the regenerated PN code (or with one of three orthogonal copies for code multiplexing) and including the two-frequency delay data as well as housekeeping and meteorological ground data is retransmitted to the PRARE space segment.

PRARE Control Segment

The PRARE control segment consists of a command station in Stuttgart, a master station at DLR/DFD in Oberpfaffenhofen, and a calibration station in Wetzell.

- Command Station. Controls eventualities and contingency situations. The functions are:
 - Monitoring and commanding the PRARE space segment
 - Simulation capabilities
 - Establishing spacecraft contact in contingency situations during visibility periods.
- Master Station. Functions as a central receiving and preprocessing station for all PRARE tracking data from the global network.
 - Planning and scheduling all tracking activities
 - Updating orbit prediction elements (uplink)
 - Referencing of PRARE space clock time to UTC time standard.
 - Processing of PRARE tracking data, and quality control.
- Calibration Station. Provides the capability to calibrate PRARE in flight with a precise ranging standard (laser station).

PRARE Ground Stations

A PRARE ground station is mobile and consists of the following components:

- an antenna unit with an offset antenna of 60 cm diameter, fronted electronics and tracking system

- an electronics unit including RF-modules, station processor and power supply
- a monitor and test computer (PC) as user interface.

Organizations/Institutions owning/operating a PRARE ground station:

- ASI, Agenzia Spaziale Italiana, Italy (2)
- AWI, Alfred-Wegener-Institut, Germany (1)
- CSR, Center for Space Research, USA (3)
- DGFI, Deutsches Geodätisches Forschungsinstitut, Germany (1)
- DLR, Deutsche Forschungsanstalt für Luft- und Raumfahrt, Germany (1)
- DASA-Dornier, Germany (1)

- NIPR, Nippon Institute for Polar Research, Japan (1)
- Statens Kartverk, Norway (3)
- University of Copenhagen, Denmark, (1)
- POL, Prowdman Oceanographic Laboratories, UK (1)

X-band uplink	7225.296 MHz
Ground transponder power	60 cm parabolic dish, 5 watts transmit
X-band downlink	8489 MHz; 1 Mbit/s BPSK (bandwidth = 1MHz); 1 W transmit power
Satellite antennas	Crossed dipoles at X-band and S-band
Noise values	± 1.5 cm rms for X-band ranging (1 measurement/s) ± 0.05 mm/s rms for X-band Doppler (30 s integration time, 90° elevation)
Bias values	< 1 cm for X-band; < 3 cm for S-band (after post-processing)
Range-error estimation	Tropospheric error: 2-7 cm; ionospheric error < 1 cm; Thermal noise and calibration error: 2-3 cm; Antenna phase center uncertainty < 1 cm
Total ranging accuracy	3-7 cm rms (1 s integration time without postprocessing of filtering)
Total range-rate accuracy	0.05 mm/s rms (30 s integration time and elevation of 90°)

Table 403: PRARE system characteristics and measurement precision parameters

Part I Satellite Emergency Services & Environmental Monitoring

Satellite services for emergency and environmental monitoring support are treated as a new service category. Such services are actually not new, in the past they were provided by a number of operational satellites with imaging instruments (SPOT series, etc.) capable of taking occasional snapshots of a disaster-stricken region.

But there is a general need for better services from space for rapid and frequent disaster monitoring capabilities. On a worldwide scale, natural and human-induced disasters (earthquakes, forest fires, floods, volcanic eruptions, etc.) claim around 100,000 human lives every year, the damages alone are in the order of several hundred billion dollars (or euros). In such extreme situations, emergency managers in the field must have access to information for effective crisis response. The information must be available rapidly and frequently. - The world population more than doubled during the past 40 years of the space-age, reaching 6 billion in 1998, the prediction for 2050 is about 9 billion. It implies that the toll in human lives as well as in total damages will increase in future catastrophes.

Dedicated spaceborne systems (constellations) could be the answer to such services, offering a portion of a global infrastructure for coordinated action. So far, a few space projects have been defined. It will take another decade to reach a certain maturity of services.

I.1 BIRD (Bi-Spectral Infrared Detection)

BIRD is a DLR microsatellite demonstrator mission with the objective to observe fires/hot spots on Earth (caused by lightning, volcanism, oil wells, smoke/water-cloud discrimination, and by man) to permit environmental impact studies. Secondary objectives involve technology demonstrations, namely the operation of a new type of infrared sensor system on a microsatellite and on-board preprocessing techniques.^{1341) 1342) 1343) 1344)}

The S/C structure resembles a compact cube (side length of 62 cm, 1.6 m deployed length), consisting of the following segments: service, electronics, and payload, with one fixed and two deployable solar panels. The bus design is modular using low-mass aluminum and honeycomb structures. BIRD is three-axis stabilized, pointing toward nadir in observation mode with an accuracy requirement of ± 5 arcmin, a pointing knowledge of ± 0.2 arcmin per axis, and a slew rate of $1^\circ/\text{s}$. The S/C attitude is measured by two star sensors, pointing in directions that differ by 30° . The star sensor assembly is referred to as ASTRO-5 (Autonomous Star Sensor), it includes a processor for autonomous attitude determination. In addition, there is a 3-axis laser gyroscope providing a resolution of 2.7 arcsec with a drift rate of $1^\circ/\text{h}$. The actuators of ACS (Attitude Control System) are: magnetorquers (3 pairs) and 4 reaction wheels. The S/C has a command-controlled body-pointing capability ($\pm 30^\circ$) in any direction. A GPS receiver, GEM-S (GPS Embedded Module) of Rockwell-Collins, is used for orbit determination. It is a five-channel C/A- and P-code for L1 signal tracking. The mass of GEM-S is 0.4 kg, power = 6.5 W. An on-board navigation system (ONS) software package uses the GEM-S inputs to provide a) position information (<90 m) for WAOSS imagery, b) orbit information at 2 Hz sampling rates. ONS provides the instantaneous nadir and

1343) K. Brieß, W. Bärwald, T. Gerlach, H. Jahn, F. Laura, H. Studmund, "The DLR Small Satellite Mission BIRD," Acta Astronautica, Vol. 46, No. 2-6, , 2000, pp. 111-120

1344) O. Montenbruck, E. Gill, H. Kayal, "The BIRD Satellite Mission as a Milestone Towards GPS-based Autonomous Navigation," ION GPS-2000, Sept. 19-22, 2000, Salt Lake City, UT, pp. 1968-1975

along-track direction for camera pointing as well as precise position values for real-time geocoding of the imagery. Total S/C mass is 88 kg, average power is 40 W (200 W max), 8 NiH₂ battery cells (12 Ah) provide power during orbit eclipse and peak power phases; the S/C design life is 1 year. The on-board recorder has a capacity of 2 x 1 Gbit.

Figure 232: The BIRD S/C model

A launch of BIRD as a secondary payload is planned on an ISRO PSLV-C3 launcher for Sept. 2001, along with TES (Technology Experiment Satellite) of ISRO as the primary payload and PROBA of ESA as another secondary payload. ¹³⁴⁵⁾

S/C communications are in S-band. The downlink transmitter frequency is 2201,7 MHz, the downlink data rate is 2.2 Mbit/s for recorder dumps during a station pass, and the modulation is: PCM/BI-F-L/BPSK. The uplink frequency is 2032,5 MHz, the data rate is 19.2 kbit/s, and the modulation is PCM/GMSK/PM. - Spacecraft operations are provided by GSOC using one tracking station. A CCSDS protocol suite is used for communications with the ground segment.

S/C operation modes:

- Sun-pointing mode. Most of the time the S/C is operated in sun-pointing mode (solar panels are normal to solar radiation) for energy accumulation.
- Earth-pointing mode G (coarse, downlink of data during station pass)
- Earth-pointing mode F (fine, remote sensing)
- On-board processing (and experimental classification) of sensor data
- Remote sensing or downlink at night-time
- In-flight calibration mode (pointing into deep space or to the moon)

The S/C instrument observations are limited to about 10 minutes per orbit (duty cycle of 0.1). This is estimated to be enough for disaster monitoring coverage. Outside of activity periods (observation and/or communication with the ground segment) the S/C is operated in sun-pointing mode.

¹³⁴⁵⁾ K. Brieß, W. Bärwald, F. Lura, et al., "The BIRD Mission is completed for launch with PSLV-C3 in 2001," Proceedings of the 3rd International Symposium of IAA, Berlin, April 2-6, 2001, pp. 323-326

Orbit: Sun-synchronous circular orbit, altitude = 575 km, inclination = 97.7°, local equatorial crossing time at 10:30 AM.

Sensor complement:

HSRS (Hot Spot Recognition Sensor).¹³⁴⁶⁾ HSRS is a two-channel (MWIR, TIR) infrared imaging instrument, of IRCAM heritage (an airborne prototype imager), with the objective to detect ground surface hot spots. A pushbroom design is employed. The two spectral bands of 3.4-4.2 µm and 8.5-9.3 µm of the system use HgCdTe detector line arrays, each of 2 x 512 pixels. The detector are arrays of HgCdTe (GEC Marconi, UK) loophole diodes hybridized on a silicon CMOS multiplexer chip, both ranges are with an individual layout. The detectors are cooled to 80 K by an integrated cooler-detector unit of Stirling design. The two camera heads are integrated into an optomechanical structure for reasons of co-alignment.

Parameter	HSRS	WAOSS-B
Spectral bands	3.4 - 4.2 µm (MWIR band) 8.5 - 9.3 µm (TIR band)	600 - 670 nm forward 840 - 900 nm, nadir backward
F-number	2.0	2.8
Focal length	46.39 mm	21.65 mm
Pixel element size	30 µm x 30 µm	7 µm x 7 µm
Nr of pixels	2 x 512 staggered	3 x 5184 (2884 illuminated)
IFOV (resolution)	2.22 arcmin	1.11 arcmin
FOV (cross-track)	19°	50°
FOV (along-track)	NA	+25°, 0°, -25°
Ground pixel size	372 m (orbit altitude of 575 km)	185 m
Swath width	190 km (orbit altitude of 575 km)	533 km
Data quantization	14 bit	11 bit
Data rate	957 kbit/s	500 kbit/s
Power consumption	90 W electronics unit inclusive	18 W
Instrument mass	7.3 kg camera head + 6.5 kg electronics unit	8.4 kg

Table 404: Specification of the HSRS and WAOSS-B instrument parameters

WAOSS-B (Wide-Angle Optoelectronic Stereo Scanner, BIRD version). The two-channel VNIR imager is a modified spare model of WAOSS flown on the Russian Mars-96 mission (launch on Nov, 17, 1996 from Baikonur; however, the S/C failed to obtain a Mars orbit). The WAOSS instrument is a compact monoblade device consisting of camera head, electronic modules, and interface boards in one unit. The along-track stereo imaging system is based on 3 CCD-lines (single optics and focal plate), operating in pushbroom mode, and taking images simultaneously in the forward-, nadir- and backward-pointing direction of the orbital ground track. The convergence angle is 25° (angle between forward- and nadir-pointing directions, and angle between nadir and backward-pointing directions). New lenses with integrated filter and wide FOV were introduced. Other modifications pertain to software updates. The main parameters of the instrument are defined in Table 404.

I.2 DEMETER (Detection of Electromagnetic Emissions transmitted from Earthquake Regions)

See the DEMETER description under M.15.1 (Myriade Microsatellite Program of CNES).

I.3 DMC (Disaster Monitoring Constellation)

The Disaster Monitoring Constellation (DMC) is an international project proposed and led by SSTL (Surrey Satellite Technology Ltd), Surrey, UK, to construct a network of five

¹³⁴⁶⁾W. Skrbek, E. Lorenz, “HSRS - An Infrared Sensor for Hot-Spot-Detection,” Proceedings of SPIE, Vol. 3437, 1998, San Diego, CA, pp. 167-176

affordable LEO microsatellites. The objective is to provide a daily global imaging capability at medium resolution (32-36 m) for rapid-response disaster monitoring and mitigation.

Since a microsatellite constellation represents the most affordable and practicable solution to this problem, SSTL proposed in 1999 a five microsatellite constellation to its customers - with a stipulation/agreement by each potential “subscriber” or buyer of a satellite that they work as a constellation in the event of natural or man-made disasters. This innovative proposal provides opportunities, especially to developing countries, to not only own their own satellite, but also to have access to a disaster monitoring and mitigating satellite system. The key to all of this is Surrey’s philosophy of low-cost, rapid access to space.

Parameter	Description
Constellation	
Network	5 spacecraft in a single orbital plane, 5 member ground stations
Constellation orbit	Sun-synchronous circular orbit, altitude = 686 km, inclination = 98°, ascending node at 10:30
Constellation revisit time	Daily revisit (imaging capability) to any point on the equator + more often to higher latitudes
Lifetime	5 years target in orbit operational life
Satellite Payload	
Payload	Two three-band linear array CCD cameras
Payload performance	Swath width of 600 km, Spatial resolution of 32 m at nadir, 34-35 m resolution at the swath edge
Sensor spectral bands	0.52-0.62 μm (green), 0.63-0.69 μm (red), 0.76-0.9 μm (NIR)
Data quantization	8 bit
Optics	Focal length = 150 mm, aperture diameter = 60 mm
On-board data storage	2 x 512 MByte SSDR (Solid-State Data Recorder), providing 1 Gbyte
Satellite Platform	
Platform size	About 60 cm x 60 cm x 60 cm, plus antennas
S/C launch mass, power	<100 kg, 4 GaAs body-mounted solar panels
Battery	NiCd cells, 8 Ah capacity
Orbit determination	GPS receiver
Orbit control	Pressurized cold gas or liquified gas system for constellation phasing maneuvers, 10 m/s delta-v, 0.05 N thrusters
Attitude determination	2 x three axis fluxgate magnetometer; 4 x two-axis sun sensors
Attitude control	3 x orthogonal dual-wound magnetorquers; Momentum wheel (yaw and pitch axis control) Gravity-gradient boom
On-board computer	2 x OBC (providing redundancy)
Communications	
TT&C link	Uplink: omni-directional patch antenna, downlink: monopole antenna S-band, CP-FSK modulation, data rate of 9.6 kbit/s
Payload downlink	Quadrifilar helix antenna, RF power of 4 W S-band link with B/QPSK modulation, data rate of 8 Mbit/s
Ground Segment	
S-band GSN (Ground Station Network)	3.5 m dish antenna, TT&C and payload imagery downlink support (each spacecraft provider is expected to have his own ground station)
Data requests	Via service providers over Internet to CCMPs (Centralized Constellation Mission Planning System)
Data distribution	Between GSNs and service providers via Internet
Data product	Rapid response, intelligible, north-oriented multispectral imagery
Service providers	The Reuter Foundation (to disaster relief agencies); CHEST (to higher education community) ESYS (for commercial evaluation and for data dissemination in schools)
Maximum System Image Capability	
Capacity/day per member	Capacity/day per member >80 images of size: 100 km x 100 km (non-cooperative mode)

Table 405: Technical specification of the DMC microsatellite constellation

As of June 2001, the customers for the first constellation are:

- CNTS (Centre National des Techniques Spatiales) of Algeria. Algerian technicians are currently building their own microsatellite, referred to as AISat-1, at SSTL.
- BNSC (British National Space Centre) is funding its own microsatellite in the constellation.
- The government of Nigeria has signed a contract for a DMC microsatellite. Nigerian engineers are expected to arrive at SSTL and to commence their know-how training program.
- Contract negotiations with two more partners are at the negotiation stage.

The DMC is implemented through international cooperation focused on the Surrey Space Club. It is anticipated that the cooperative use of the constellation will benefit all the members. A launch of DMC is planned for the end of 2002/ start of 2003. ¹³⁴⁷⁾

The constellation has an imaging capability of about 500 images per day. Imagery requests are planned to be coordinated through a centralized mission planning system at SSTL, UK. It is estimated that up to 5% of the imagery will be made freely available to disaster relief organizations. A rapid on-line news and communications service is proposed to make the imagery available to the relief agencies.

Figure 233: Illustration of a DMC spacecraft

I.4 Fuego/FOC (Fire Observation Constellation)

Fuego/FOC is a European program initiative, defined and developed with EC support (within the IV Framework Program of the EC), coordinated by INSA (Ingeniería y Servicios Aeroespaciales) of Madrid, Spain, drawing on support/inputs of many participating institutions across Europe (government and academic). The overall objective is to provide a global capability of early fire detection and high-resolution fire-line monitoring by means of a minisatellite constellation - to be of service to the fire fighter community. Secondary applications include volcano monitoring - for civil protection measures, and general surveillance monitoring.

In Europe, forest fires account for the destruction of 200,000 to 600,000 hectares of forest every year; about 80% of this destruction occurs in the Mediterranean region where fires

¹³⁴⁷⁾Information provided by Audrey Nice and by John Cooksley of SSTL

become increasingly more damaging in dry and hot summers due to the abandonment of traditional agricultural activities. Between 1991 and 2000, 4 million hectares of land were destroyed in France, Greece, Italy, Portugal and Spain, causing enormous damage to the ecosystem, substantial economic losses, and human casualties. A space-based observation system is considered the proper approach to improve the current fire-fighting strategies.

Several studies on Fuego, sponsored by the EC, ESA, and by Spanish national funding have been carried out [The Fuego-1 project (feasibility and definition study) started in late 1996 and was completed in 1998. The Fuego-2 project (design of payloads, platform, ground system) lasted from late 1998 to the beginning of 2001.]. ESA is considering Fuego/FOC within its Earth Watch initiative. A submittal of the program to its member states, covering the development, construction, launch and operations of a demonstration satellite, is expected in 2001. The implementation proposal (2001) of the Fuego concept within ESA's Earth Watch program is taking a two-sliced approach: 1348) 1349) 1350) 1351) 1352)

- 1) FuegoSat. This refers to the Fuego system demonstration and validation phase prior to the deployment of the full constellation (precursor mission). FuegoSat builds on the previous studies of the EC and industry. It comprises the following elements:
 - One demonstration satellite, identical to the full system S/C, to be launched in 2004
 - A ground system (minimum system) to permit satellite operations
 - Ten transportable user stations to permit simultaneous demonstrations of the Fuego service provision to multiple users in Europe and elsewhere
 - Seven years of operation
- 2) The implementation of the full constellation, co-financed by ESA and the industrial team exploiting Fuego, is on a 50-50 basis. The full Fuego system is based on a constellation of 12 minisatellites, with a design life of seven years, and with multiple user stations allowing direct reception of data located at the user control center at a regional level.

Users (fire fighting authorities) have been actively involved in the conception of Fuego since its very start of the program. The identification of user requirements (for fire detection and fire monitoring) has been carried out in successive iterations. This resulted in a corresponding service and data product provision concept proposal. - The user recommendations came up with the following primary objectives of the Fuego Earth Watch Mission:

- Automatic provision of an early fire detection product which identifies the fire outbreaks and their most relevant characteristics like position and intensities.
- Quick delivery of a reliable fire detection product to the user community
- Continuous visualization of the developed fires on request
- The products must be cost effective
- The service of fire detection and monitoring must be provided on a continuous basis, around the clock and throughout mission life.

I.4.1 Fuego System Concept

Each spacecraft of the Fuego series is three-axis stabilized. The total mass of a S/C is limited to 240 kg, including 62 kg of payload mass. The maximum volume limit of a S/C is defined as: 300 cm x 75 cm x 75 cm (the actual dimensions of the bus are: 180 cm x 75 cm x 75 cm without solar panels). The S/C is composed of a lower platform (propulsion and platform interface),

1352) D. Escorial, I. F. Tourne, F. J. Reina, J. Gonzalo, "Fuego: A Dedicated Constellation of Small Satellites to Detect and Monitor Forest Fires," *Proceedings of the 3rd International Symposium of IAA, Berlin, April 2-6, 2001*, pp. 163-166

a middle platform, an upper platform (payload interface), the internal structure, the lateral panels, and the solar panel wings. The power requirements call for 500 W (EOL). A propulsion module ensures the proper constellation deployment and maintenance during the mission. The attitude system requirements for data acquisition call for a pointing accuracy of 0.15° in cross-track and 0.1° in the along-track direction with a stability of 6 arcsec [(1 sigma) from 0.5-2 Hz, and 3 arcsec (1 sigma) from 2-150 Hz]. In addition, each S/C is required to perform pitch maneuvers of 45° in 30 s, to permit extended observation periods onto an area of interest from its orbital path. The on-board data handling requirements call for the MIL-STD-1553B bus standard. The S/C design life is seven years.

A multi-satellite-launch strategy is selected with one launch per orbital plane. The Rockot launch vehicle of Eurockot is the selected baseline (Baikonur launch site). The four S/C will be installed on a single floor of the rocket fairing.

Orbit: Circular (non-sun-synchronous) orbit, altitude = 700 ± 15 km, inclination = $47.5^\circ \pm 0.05^\circ$, period = 98.8 min. The configuration of the constellation consists of three orbital planes with four satellites per plane (Walker configuration of 12/3/2). This arrangement provides a global FOR (Field of Regard) observation capability with a revisit time between 23.8 to 25.8 minutes and a service provision around the clock.

In the general acquisition geometry, the fire detection limit is $\pm 55^\circ$ about nadir, corresponding to a total FOR (Field of Regard) of 2500 km. However, the fire monitoring limit is within $\pm 39^\circ$ about nadir, corresponding to a total FOR of 1250 km. The actual observation swath within each FOR is always $\pm 7.2^\circ$, or 176 km (total) at nadir.

Figure 234: Illustration of a Fuego spacecraft

RF communications: TT&C communications are provided in S-band. The requirements call for an on-board data storage capability and data rates of 16 kbit/s (NRZ-M/PSK/PM modulation) in downlink and 2-4 kbit/s in uplink. The payload data transmission is in L-band at 4 Mbit/s. All communication protocols are in CCSDS standard.

Figure 235: Sketch of the acquisition geometry

Ground segment requirements: The ground segment consists of two main elements:

- The system ground segment consists of a Mission Control Center (MCC) and two ground stations (primary and backup) for the acquisition/transmission of the constellation telemetry and command data (TT&C function). In addition, MCC receives the payload data.
- User ground segment: A distributed network of Primary User Stations (PUS) located at the user premises and operated by the fire-fighting authority of the region. A PUS consists of a PC, a 1.5 m antenna, a front end, and a connection to public networks (also contact with MCC). Each PUS is capable to acquire the real-time payload data.

Sensor complement:

FIS (Fuego Imager Suite). The Fuego instrument package consists of four pushbroom cameras in the four spectral regions: VIS (Visible), NIR (Near Infrared), TIR (Thermal Infrared) and MIR (Medium Infrared), also referred to commonly as MWIR (Mid-Wave Infrared). The cross-track pointing feature is implemented with a scan mirror [a steerable mirror is used to point to the areas of interest within FOR (Field of Regard)] common to all cameras. The WMA (Wide Mirror Assembly) is composed of a mirror, a motor and the driver electronics which deflects the optical axis of the four cameras into the desired direction. The payload power consumption is defined as: 180 W (peak), 140 W (average), and <75 W in standby.

Cross-track pointing capability	$\pm 54.1^\circ$ (for fire detection), $\pm 38.4^\circ$ (for fire monitoring)
Swath width capability	2500 km (for detection), 1250 km (for fire monitoring)
Pointing knowledge	± 20 arcsec (2 pixels)
Pointing stability	0.015°/s
Mirror moment of inertia	0.01 kg m ²
Allowed time for step movement	3 s

Table 406: Requirements of cross-track mirror

The MWIR camera is most appropriate to detect hot spots (mix of solar reflected and thermally emitted radiation), while the TIR camera is used to provide more information on fire presence (background temperature estimation, etc.) and to filter false alarms. The main objectives of the VIS and NIR cameras are to provide rejection of false alarms.

Parameter/Spectral Region	MWIR	TIR	VIS	NIR
Observation geometry				
Swath width FOR (Field of Regard)	2500 km	2500 km	2500 km	2500 km
Monitoring swath width (FOV)	176 km	176 km	176 km	176 km
Detector elements per row	1100 x 2	240 at 45°	8800	8800
Total number of detector elements	2200	480	8800	8800
GSD (Ground Sampling Distance)	80 m	367 m	20 m x 4 m	20 m x 4 m
Optics				
FOV (Field of View)	14.41°	14.41°	14.41°	14.41°
IFOV (Instantaneous Field of View)	0.114 mrad	0.524 mrad	0.0286 mrad	0.0286 mrad
Aperture diameter	54 mm	60 mm	35 mm	35 mm
Focal length	87.5 mm	60.7 mm	227.5 mm	227.5 mm
F-number	f/1.6	f/1.0	f/6.5	f/6.5
MTF (Modulation Transfer Function)	0.28	0.28	0.28	0.28
Radiometry				
Spectral range	3.55 - 4.15 μm	8.0 - 12.0 μm	0.58 - 0.68 μm	0.76 - 0.90 μm
Spectral band center	3.80 μm	10.0 μm	0.63 μm	0.83 μm
Band width	0.70 μm	4.0 μm	0.10 μm	0.14 μm
Sampling time	12.49 ms	57.23 ms	3.122 ms	3.122 ms
NEAT at 300 K	1.7 K	0.5 K	-	-
Data quantization	12 bit	12 bit	9 bit	8 bit
Radiometric accuracy (% reflectance)	-	-	5	5

Table 407: Specification of major FIS instrument parameters

Figure 236: Schematic arrangement of the FIS instrument (two views)

Fire Monitoring Products:

A service subscriber receives a monitoring product with information related to the on-going fire in the specified region., and providing information on the fireline characteristics (geometry, position and intensity).

- Detection product: Provided with a nominal FOR (Field of Regard) of 2500 km. The imagery at the swath edge exhibits pixel distortion; however, this pixel distortion does not prevent from good fire detection.
- Monitoring product: Provided with a nominal FOR of 1250 km. The imagery of half the detection swath width offers a good fireline representation (with only small pixel distortions at the swath edges).

I.4.2 FuegoSat

FuegoSat represents the precursor mission to Fuego/FOC. The primary objective is to provide total confidence in the system prior to embarking on the full program. Its purpose is to demonstrate/validate the critical functionality of the mission. An evaluation of all mission (and economical) aspects resulted finally in a FuegoSat concept consisting of is a single spacecraft.

The FuegoSat spacecraft is identical in design, functionality, and payload configuration to the Fuego/FOC series. The system ground segment consists of MCC and a single ground station. The user ground segment is limited to 10 transportable user stations to permit simultaneous demonstrations of the system.

The implementation and operation of FuegoSat and Fuego/FOC is being managed by an entity referred to as FueCorp (Fuego Corporation). Current plans calls for FueCorp to be established/constituted in February of 2002.

A launch of FuegoSat is planned for 2004 on a Rockot launch vehicle.

I.5 GMES (Global Monitoring for Environment and Security)

GMES is a European initiative put forward by the EC (European Commission) in 1998 with the objective to determine Europe's global monitoring role in the field of the environment and security. The goal of GMES is to develop operational information services on a global scale, using both space- and ground-based monitoring systems, in support of environment and security policy needs. Key issues in this field include the monitoring of: ¹³⁵³⁾

- International environmental conventions (environmental issues of a global nature). The EU has signed more than 40 international treaties to bring forward a more global dimension to environment and security (e.g. biodiversity, global change, desertification). The "Kyoto Protocol" is an example of "treaty monitoring" requirements. NATO and its Member States are increasingly concerned with non-traditional threats to security, including the consequences of environmental change.
- Environmental stress (environmental issues of a regional nature). Environmental stress poses a potential threat to security at all geographic levels. Taking preventative action on environmental stress is the most appropriate approach to preventing environmental conflicts.
- Risks and natural disasters/hazards (including humanitarian help). The major topics of natural hazards are: earthquakes, landslides and avalanches, volcanoes, forest fires, and floods. The service of forest fire detection and monitoring (including risk evaluation) is an important activity in this category.

¹³⁵³⁾ "A European Approach to Global Monitoring for Environment and Security (GMES): Towards Meeting User Needs," ESA/PB-EO (2001) 56, Rev. 1, Annex, June 13, 2001, Version 2.01

The JRC/SAI (Joint Research Center/Space Applications Institute) of the EC in Ispra (Italy) is the main technical support office in charge of the GMES project management and chairs the so-called “GMES Partnership”, a working group bringing together the partners of the project: government agencies, institutional bodies (ESA, EUMETSAT, national space agencies), and the space industry.¹³⁵⁴⁾

The GMES Partnership was formed in late 2000. It involves the member states, the major space agencies, industry representatives and the EC. The mandate is to help formulate the GMES Proposal in response to the council request. GMES seeks to capture and focus existing industrial and political efforts, and thus to provide a common framework to bring activities together and to develop a common ownership and strategy.

The upcoming ESA Earth-Watch missions are an important element in the GMES monitoring strategy, providing long-term monitoring services in various aspects of Earth observation; this includes also long-term data sets.¹³⁵⁵⁾ ¹³⁵⁶⁾

The GMES approach is based on scientific understanding of the whole Earth system. It will benefit from research that links Earth system science to the social sciences in the search for means of measuring and modelling mankind’s impact on the natural environment, and vice versa

Specific implementation proposals for GMES are due in the second half of 2001. The topic of GMES will be addressed at EU Ministerial level in November 2001. By the end of 2001 the EC will have produced a detailed Action Plan for implementing the initial period.

I.6 Search & Rescue (S&R) Satellite Systems

I.6.1 COSPAS-S&RSAT Constellation

COSPAS (Space System for the Search of Distressed Vessels) and **S&RSAT** (Search & Rescue Satellite Aided Tracking System)¹³⁵⁷⁾ payloads are part of an international cooperative satellite-based radiolocation system to support search and rescue operations for aviators, mariners, and land travellers in distress. The COSPAS-S&RSAT system provides distress alert and location data to RCCs (Rescue Coordination Centers) for 121.5 MHz beacons within the coverage area of COSPAS-S&RSAT ground stations, referred to as LUTs (Local User Terminals), and for 406 MHz beacons activated anywhere in the world. The overall system concept is illustrated in Figure 237. The nominal system configuration comprises two COSPAS and two S&RSAT payloads on polar-orbiting satellites. Russia provides two COSPAS satellites in near-polar orbits at an average altitude of 1000 km (83° inclination). The USA supplies two NOAA POES satellites with on-board S&RSAT payloads provided by Canada and France. The orbital period for each satellites is about 100 minutes, the footprint of the COSPAS-S&RSAT visibility is in the order of 4000 km in diameter. The first COSPAS payload was launched on June 29, 1982, while the first S&RSAT equipment was flown on NOAA-8, launched in March 1983.

Background: The satellite system was initially established under a MOU among agencies of the former USSR, USA, Canada and France, signed in 1979. The system was declared operational in 1985. In 1988 the four space segment providers signed an agreement which en-

¹³⁵⁴⁾ <http://gmes.jrc.it>

¹³⁵⁶⁾ “GMES (Global Monitoring for Environment and Security),” Draft by EC and ESA, ESA/PB-EO (2001) 56, April 2001, Version 1.2

¹³⁵⁷⁾ **Note: Although the original acronym for ‘Search and Rescue’ is ‘SAR’ in the context of NOAA missions, it was changed in this book consistently to ‘S&R’ in order to distinguish it from the other widely-used meaning of SAR, namely ‘Synthetic Aperture Radar,’ a sensor type. A consequence is the use of ‘S&RSAT’ (instead of S&RSAT)**

sure service continuity and availability of the system to all States on a non-discriminatory basis. As of 1997, the participants of this program include the four parties to the COSPAS-S&RSAT International Program Agreement [Canada (CRC), France (CNES), Russia (ROSHYDROMET), and the USA (NOAA)], and ground segment providers. About 30 countries have joined the COSPAS-S&RSAT program.

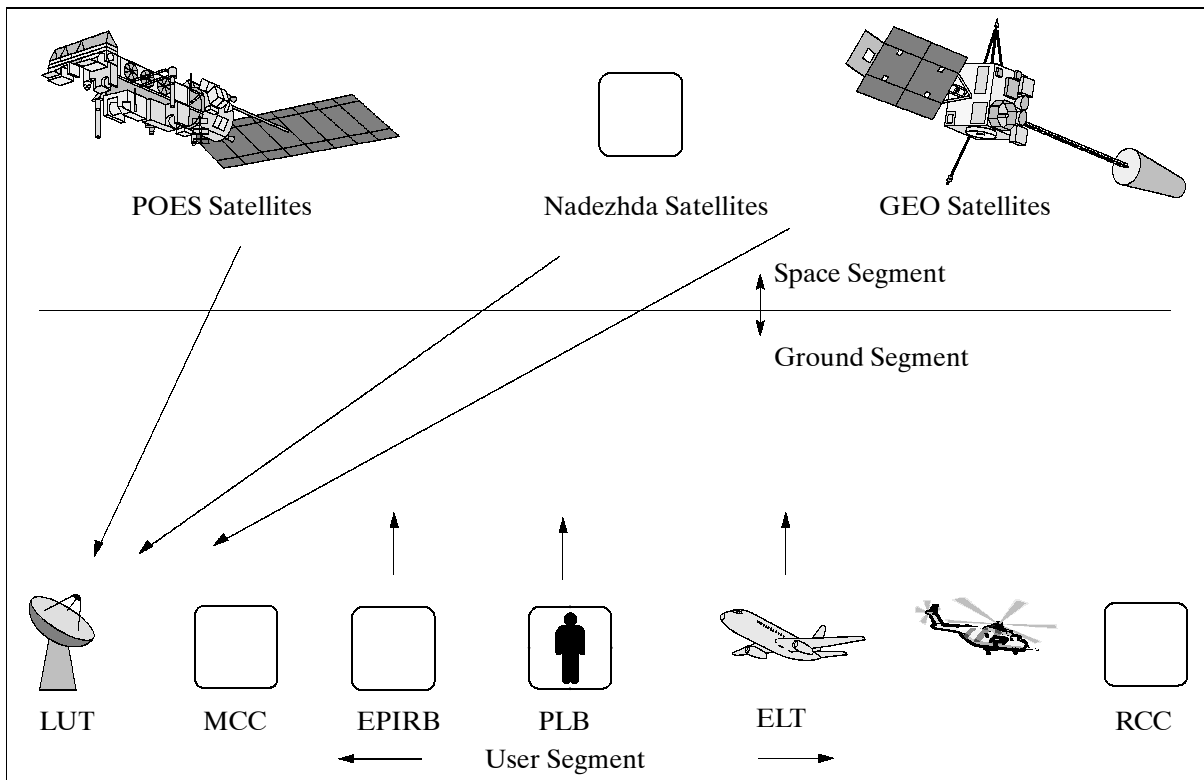

Figure 237: System elements of Search & Rescue Satellites

I.6.1.1 Alert Signal Devices (User Segment)

There are three types of radiobeacon devices (heritage of older rescue services) in use, namely maritime EPIRBs, aviation ELTs, and personal locator beacons (PLBs).¹³⁵⁸⁾

EPIRB (Emergency Position Indicating Radio Beacon). A small battery-powered transmitting device which is carried on vessels (several nations require EPIRB devices on all vessels). It can be activated in times of trouble to send out help signals. EPIRB devices operate on a frequency of 121.5/243 MHz (the 243 MHz frequency is used only in some older beacons), they may also include the 406.025 MHz alert signal for global detection.

ELT (Emergency Locator Transmitter). The 121.5 MHz band service emergency beacons are required on many aircraft, referred to as ELT 121.5, with a smaller number carried on maritime vessels. The 121.5 MHz frequency band is used by an older type of beacons which do not transmit any encoded information. It is also the frequency used for low-power homing transmitters included in most beacons. The more recent ELT devices on aircraft are provided with dual frequency alert systems, 121.5 and 406.025 MHz.

Beacons with the 406.025 MHz signal transmit digitally encoded information which may include beacon identification (which allow S&RSAT services to access registration data bases providing additional information on the unit in distress), and beacon location data (determined by satellite navigation devices such as GPS or GLONASS).

PLB (Personal Locator Beacon). These are handheld or pocket size dual frequency (121.5 and 406 MHz) or single frequency (either 121.5 or 406.025 MHz) devices which transmit distress signals to search and rescue authorities via the COSPAS-S&RSAT satellite system.

Table 408: Overview of S&R payload launches

I.6.1.2 Satellite Payloads (Space Segment)

S&RSAT (Search and Rescue Satellite Payload)

The S&RSAT payload consists of S&RR (S&RSAT Repeater), provided by CRC/Canada; and S&RP (S&RSAT Processor), provided by CNES/France). The S&R problem requires two basic functions for effective S&R operations to take place, namely: 1) **alerting** and 2) **locating**. The alerting function only requires a low-capacity one-way communications system. The locating function, however, places far more demands on the system. The overall system uses low-powered battery-operated distress transmitters that are received by polar orbiting satellites with an S&R subsystem on-board. S&R exploits the Doppler shift resulting from relative motion between the distress transmitter and the polar orbiting satellite. A successful alert requires at least one satellite pass over the distress area to detect a signal and locate the position of the emergency transmitter. In some cases a second pass may be required to resolve ambiguity.

The S&RSAT payload consist of a 2-band (121.5 MHz and 406.05 MHz) repeater S&RR and a 406.025 MHz processor S&RP. The S&RR downlink is at 1544.5 MHz and, besides the two repeated bands, also includes the 2400 bit/s bit stream S&RP output. The 121.5 and 406 MHz bands are also serviced by two Russian COSPAS satellites which, together with the NOAA satellites, provide timeliness of response.

COSPAS (Space System for Search of Vessels in Distress)

The USSR began deploying the space segment with the launch of Cosmos 1383 on June 30, 1982 from Plesetsk into a 989 km x 1028 km, 83° inclination orbit (Tsikada navigational sat-

ellite series). Designated COSPAS-1, the 121.5 MHz band remained operational until December 1987, with 406 MHz utilized primarily for interference monitoring. Cosmos 1447 (launched March 24, 1983) and 1574 (June 21, 1984) adopted the roles of COSPAS 2 and 3, with a third vehicle available as replacement. The COSPAS payload normally shares the Nadezda (Hope) satellite platform with a Doppler navigation payload of the Tsikada system.

I.6.1.3 COSPAS-S&RSAT Ground Segment

The emergency signals are detected by the space segment (such as COSPAS-S&RSAT) and relayed to LUTs which process the signals to determine beacon location. Alerts are then relayed, together with location data, via MCC (Mission Control Center) to the appropriate search and rescue point of contact or to RCC (Rescue Coordination Center).

Doppler location is the means used for signal location. The 406 MHz devices include an identification code in the alert message. Most 406 MHz devices also include a 121.5 MHz homing transmitter to support search and rescue operations. ^{1359) 1360) 1361)}

The 406 MHz emergency beacon signals are immediately processed and stored on-board the satellite and are transmitted to the ground from a continuous memory dump, providing complete worldwide coverage. Around the world, ground station LUTs (Local User Terminal) acquire the processed data and unique beacon identification and send these located and identified alerts to MCCs (Mission Control Centers), which forward the alerts to appropriate Rescue Coordination Centers for action. The 406 MHz beacons are designed to work well with the satellite; the system nominally provides better than 4 km accuracy, 90% ambiguity resolution on first pass, and better than 90% location probability on one pass. Note: the US S&RSAT operational ground system facilities consist of S&RSAT, SOCC at Suitland, MD as the MCC, and three LUTs. In addition to the US facilities, many other cooperating nations operate their own LUTs and MCCs.

The 121.5 MHz emergency beacons, whose use predates the satellite system, have not been specified to work with the satellite; consequently the results are variable, depending on the quality of the beacon. Nominally, location accuracy is about 20 km. All the processing is accomplished within the LUT, and because the satellite does not store these data, only beacons with mutual view of the satellite and LUT will be detected. No identification is included with the 125.5 MHz transmissions. Consequently, many nonbeacon sources are also detected as beacons, increasing the difficulty of using these alerts. Even with these problems, the large number of beacons in the field have provided an impressive performance history. More than 1700 people have been saved by the S&R/COSPAS forces using satellite-derived locations, and for more than 300 of them, the satellite provided the only means of alert.

LUT locations: Goose Bay, Edmonton and Fort Churchill in Canada; Toulouse, France; Tromsø, Norway; Lasham, UK; Kodiak (AK), San Francisco (CA), Hawaii, Texas, Guam, and Puerto Rico, USA; Arkangelsk, Novosibirsk, Nakhodka, and Moscow, Russia; Albany and Bundaberg, Australia; Bangalore, and Lucknow, India; Hong Kong and Beijing, China; Brasilia and Recife, Brazil; Santiago and Punta Arenas, Chile; Lahore, Pakistan; Yokohama, Japan; Wellington, New Zealand; Bari, Italy; Singapore, Singapore; Callao, Peru; Ambon and Jakarta, Indonesia; Maspalomas (Canary Islands), Spain; Quargla, Algeria; Keelung, Taiwan.

I.6.2 GEOS&R (Geostationary Search & Rescue)

With the launch of GOES-H (GOES-7) on Feb. 26 1987, NOAA has started to introduce the S&RSAT payload also on its geostationary satellites. The use of geostationary satellites means that the alert signals can be received almost instantly. However, in order to automatically determine the coordinates of the emergency signal, it is necessary to wait for the system's LEO satellite (position determination can only be provided from a system that moves relative to the Earth). The system thus works in two stages. In the first stage only the emergency signal is received via the geostationary satellite (it is planned to equip GMS and GOMS satellites for this service as well). The received alert signal is transmitted to the search and rescue service to prepare for the operation. In the second stage, the site of the signal origin is determined by the LEO satellite. See also chapter F.4.3 on GEOS&R.

Part J Shuttle - Selected Missions and Payloads

J.1 ASTRO-SPAS (Astronomy Platform - Shuttle Pallet Satellite)

ASTRO-SPAS is the generic name of a reusable platform, designed and built by DASA (formerly MBB, Munich, Germany) under DLR contract, which is used as a self-contained and autonomous free-flyer service structure for special Shuttle payloads with free-flyer requirements for short-duration missions (up to the length of a Shuttle mission). The SPAS structure consists of low-weight, high-stiffness carbon fiber tubes with titanium nodes. Standardized mounting panels are provided for subsystem and payload equipment. The platform is deployed/retrieved by the Shuttle's robot arm RMS (Remote Manipulator System) for a free-flyer mission which may entail separations from the Shuttle up to 100 km. As a service structure, SPAS is particularly suited as a test bed for new science instrumentation and technology demonstrations in space. ¹³⁶²⁾

The platform overall size is 4.5 m x 1.75 m, its empty mass is about 1240 kg (including service subsystems), it can accommodate a payload up to a total satellite mass of 3600 kg. The platform offers the following service subsystems:

- Electrical power: Modular Li-SO₂ battery packs (up to 16), 110 kJh, with 40 kJh of energy available to the payload instruments.
- Thermal control: Passive thermal control via radiation and conduction through the platform surface and multilayer insulation blankets.
- Data management: An on-board computer provides all data management functions such as: telecommanding, storage of source data onto a recorder, telemetry data handling, attitude control, etc.
- Platform stabilization: A three-axis stabilization is provided. A precision star tracker serves as reference for pointing accuracies <3 arcseconds to astronomical targets. A GPS Tensor receiver system provides in addition orbit and attitude. Attitude control (actuator) is provided with a 12-nozzle cold gas thruster system (100 mN thrust).
- Operational modes: Two modes are provided, 'inertial pointing' and 'orbit motion.'
 - The inertial pointing mode serves mainly for astronomical observations. The star tracker (CCD camera) measures the position of three guide stars in its FOV of 4.5° x 6°, the gyro package senses rotations.
 - The orbit motion mode is used for atmospheric research to point into a specific direction. One axis points into a constant, commandable altitude layer (stabilized to ±2 km). The GPS Tensor instrument and the star tracker provide attitude, position and velocity of the platform.
- TT&C: A scheduled communications link via Shuttle is provided by an S-band transponder with uplink data rates of up to 2 kbit/s and downlink rates of up to 16 kbit/s.

The SPAS free-flyer platform concept was first demonstrated for the MOMS-01 imaging payload on two Shuttle missions: STS 7, June 18-24, 1983, and STS-41B, Feb. 3-11, 1984. The current ASTRO-SPAS platform is of SPAS heritage with four flights negotiated between NASA and DLR (DARA).

J.1.1 ORFEUS-SPAS-1

ORFEUS (Orbiting Retrievable Far and Extreme Ultraviolet Spectrograph) was a joint DARA/NASA science mission, flown on the ASTRO-SPAS free-flyer platform of Shuttle flight STS-51 (Sept. 12-22, 1993).

¹³⁶²⁾R. Wattenbach, K. Moritz, "Astronomical Shuttle Pallet Satellite (ASTRO-SPAS)," Acta Astronautica, Vol. 40, No. 10, pp. 723-732, 1997

The ORFEUS instrument payload is an observatory containing three spectrographs to probe the cosmos. Two spectrographs share a single main telescope [1 m mirror, focal length = 2426 mm, mirror micro-roughness < 0.5 nm rms, mirror surface is coated with a layer of iridium]. The telescope tube consists of a carbon fiber compound, the mirror is a light-weight design (70kg). The entire telescope plus spectrograph assembly has a length of 3960 mm, a diameter of 1120 mm, and a total mass of 970 kg.

- **FUV** (Far Ultraviolet) Echelle spectrograph (U. of Tübingen and Landessternwarte Heidelberg, built by Kayser-Threde, Munich). Spectral range = 90 - 125 nm. Two reflection gratings and microchannel plate detectors offer a spectral resolution of $\lambda = 10,000$.¹³⁶³⁾
- **EUV** (Extreme Ultraviolet) spectrograph of UCB. The EUV spectrograph is located at the prime focus of the f/2.4 normal incidence primary mirror with a spectral range of 39 - 120 nm (4-6 cm² effective area). Objective: provision of high-resolution ($\lambda/5000$) spectroscopy of point sources.

IMAPS (Interstellar Medium Profile Spectrometer) Princeton University. IMAPS is an objective grating, Echelle spectrograph in the spectral range of 95 - 115 nm, with the objective to record very high-resolution UV spectra of stars (resolving power of 100,000, detailed observations of the chemical and physical properties of interstellar gas detected around bright, nearby stars). IMAPS does not utilize the main telescope on ORFEUS, but is attached to the side of the platform.

SESAM (Surface Effects Sample Monitor). The objective is to explore the influence of atmospheric atomic oxygen on optical surfaces (used in UV astronomy, tests of “whiteness” samples, etc.). The instrument can accommodate, expose, and test up to 40 samples.

J.1.2 CRISTA-SPAS-1

CRISTA (Cryogenic Infrared Spectrometer and Telescopes for the Atmosphere) is the name of the main payload [STS-66 (Nov. 3-14, 1994)], a mission scientifically combined (co-manifested) with the US ATLAS-3 program (J.2). The orbital altitude was about 300 km at an inclination of 57° of the SPAS free-flyer platform, released and retrieved in an observational orbit between 40 to 70 km behind the Shuttle. As such, it operates independently, except during communication periods with the orbiter. During these periods, the instrument relays status information via the Shuttle to the ground. Dimensions of CRISTA-SPAS: 2 m in length x 4.6 m in height, mass = 3400 kg.

CRISTA is the prime payload of SPAS (PI: D. Offermann, Univ. of Wuppertal, Germany, CRISTA is sponsored by DARA).¹³⁶⁴⁾ It is an infrared instrument with three independent telescopes pointed at the limb (in three directions/dimensions simultaneously). Two telescopes are laterally directed (pointing angles = $\pm 18^\circ$ from center). Objective: analysis of dynamic processes (winds, wave interaction and turbulence) in the middle atmosphere with the detection of trace gases. The four spectrometers provide 26 spectral bands, 21 bands from 4.6 - 14.1 μm , and 5 bands from 15.2 - 71 μm . Each telescope has a short-wavelength spectrometer attached; the center telescope measures the longer wavelengths. The spectrometers take one spectrum per second and measure up to 15 trace gases in 26 channels during this time. The telescopes obtain complete altitude observations of these gases within about one minute as the lines-of-sight are scanned through the atmosphere. The high measurement speed and the sensitivity of the instrument are achieved by cryogenic cooling of the CRISTA optics and detectors with liquid helium. Spectral resolution power ($\lambda/\Delta\lambda$) = 500, spatial resolution: 500 x 650 km in the horizontal direction and 2-3 km in the vertical direction. The CRISTA instrument is contained in a vacuum container cooled.

¹³⁶³⁾ I. Appenzeller, et al., “Medium-Resolution Far-Ultraviolet Spectroscopy of PKS 2155-304,” *The Astrophysical Journal*, 439: L33-L37, Feb. 1, 1995

¹³⁶⁴⁾ P. Barthol, K. U. Grossmann, D. Offermann, “Telescope design of the CRISTA/SPAS experiment aboard the Space Shuttle,” *SPIE*, Vol 1331, Stray Radiation in Optical Systems, 1990, pp. 54-63

Figure 238: Configuration of ASTRO-SPAS platform with its sensors

The SPAS platform was three-axis stabilized to point its telescope near the Earth's horizon using mass expulsion thrusters and aiming at a point 62.9 km above the WGS-84 ellipsoid. Attitude determination was achieved by a star tracker-gyro inertial reference unit (IRU), position data was provided by an Alcatel/SEL GPS receiver. The IRU data determined attitude within 0.05° and served as "truth" reference for a comparison with GPS data. ¹³⁶⁵⁾

Telescope type (total of 3)	Herschel, 120 mm aperture diameter, limb scan
FOV vertical, horizontal	3 arcmin (1.5 km at tangent point) FWHM, 29 arcmin FWHM
Scan range	$\pm 2.25^\circ$ (lateral telescopes), $+2.4^\circ$ to -1.6° (center telescope, short wave)
Vertical resolution	2-3 km
View directions	162° , 180° , 198° with reference to flight vector
Horizontal resolution	200 km x 650 km (maximum at equator)
Pointing accuracy (CRISTA-SPAS included)	less or equal of ± 300 m at tangent point (vertical direction, absolute) ± 80 m at tangent point (vertical direction, relative) ± 1.5 km at tangent point (horizontal direction, absolute)
Spectrometer type (4)	Ebert-Fastie
Spectral range	4-71 μm (26 spectral channels)
Spectral resolution ($\lambda/\Delta\lambda$)	300-600
Integration time	1.2 s (for one spectrum)
Altitude scan	<1 minute
Mass of optics	230 kg
Cryostat, tank 1	Volume of 725 liter of supercritical helium at 5-13 K
Cryostat, tank 2	Volume of 55 liter of subcooled helium at 2.5 - 4.2 K
Electronics mass, power, data	180 kg, 76 W (average power consumption), 123 kbit/s data rate
Instrument mass, size	1350 kg, 2980 mm in length and 1380 mm in diameter

Table 409: Specification of the CRISTA instrument

Definitions for Table 410:

1) The range limit is determined by filter transmission for values marked with a *. 2) The range limit is extended by the Gille and House method for all slashed wavelengths (example: 8.6/9.7). 3) Detector types: SiGa (Silicon Gallium), GeGa (Germanium Gallium), BIB

SCL-6	H ₂ O, HCl	65.0 - 70.91	GeGa

Table 410: CRISTA detector specification

GPS-based attitude determination of SPAS. A TANS Vector (SS/L) receiver, modified by Stanford University software, provided independently attitude and position data. Four GPS patch antennas were mounted on the zenith face of SPAS. The carrier-phase differential GPS (CDGPS) measurements of the TANS Vector receiver served as input for a recursive Kalman filter attitude estimation algorithm. ¹³¹¹⁾

MAHRSI (Middle Atmospheric High Resolution Spectrograph Investigation), Naval Research Lab, PI: R. R. Conway. Measurement of dayglow in the 190 - 320 nm region with a resolution of 0.02 nm. The prime objective is to measure limb intensity profiles of the resonance fluorescent scattering of sunlight, OH and NO, in the mesosphere and thermosphere (40 - 160 km region in total). From these intensity profiles, vertical density profiles of OH and NO are inferred with a vertical resolution of 2 km. By measuring Rayleigh scattering intensity profiles, the experiment provides precise knowledge of the neutral density and temperature in the mesosphere. The MAHRSI instrument consists of four subsystems: the telescope/spectrograph assembly, MECA (MAHRSI Electronics Controller Assembly), MDEA (MAHRSI Detector Electronics Assembly), and HVPS (High Voltage Power Sup-

¹³⁶⁶⁾D. Offermann, et al., "Cryogenic Infrared Spectrometers and Telescopes for the Atmosphere (CRISTA) experiment and middle atmosphere variability," Journal of Geophysical Research, Vol. 104, No D13, July 20, 1999, pp. 16,311-16,325

ply). The telescope/spectrograph assembly employs an f/7.5 Czerny-Turner spectrograph with a 75 cm focal length behind a 50 cm focal length telescope (57 cm² aperture) mounted on CRISTA-SPAS. The wavelength range of sensitivity is from 195-320 nm, the spectral resolution is 0.018 nm at 310 nm and 0.026 nm at 215 nm. A spectral bandwidth of about 4 nm is imaged on the focal plane at a given grating position. The grating can be scanned to cover the entire spectral range of the instrument. A highly polished plane scan mirror at the baffled aperture of the telescope controls the vertical motion of the FOV (0.01° x 1.13°). MDEA provides power distribution, operates the intensified CCD (ICCD) detector, and transfers data from the CCD to the microprocessor after each integration. MAHRSI is operated and controlled by MECA (management of the command data interface, control of the dust door, scanning mirror, rotating polarizing filter, and scanned grating). During observation periods, CRISTA-SPAS holds MAHRSI's FOV parallel to that of CRISTA's center telescope.¹³⁶⁷⁾

SESAM (Surface Effects Sample Monitor). The objective is to explore the influence of atmospheric atomic oxygen on optical surfaces (used in UV astronomy, tests of "whiteness" samples, development stable of surface layers, etc.). The instrument can accommodate, expose, and test up to 40 samples.

J.1.3 ORFEUS-SPAS-2

ORFEUS (Orbiting Retrievable Far and Extreme Ultraviolet Spectrograph) is a joint DARA/NASA science mission, flown on the ASTRO-SPAS free-flyer platform of Shuttle flight STS-80 (Nov. 19 - Dec. 7, 1996). The ORFEUS-SPAS-2 mission is designed to study the spectra that reveal the physical conditions needed to understand the universe.

The ORFEUS-SPAS-2 payload is identical to that of ORFEUS-SPAS-1 with the following addition:

ARP (ATV Rendezvous Predevelopment). Deployment and retrieval maneuvers of SPAS release/approach with Shuttle.¹³⁶⁸⁾¹³⁶⁹⁾ The ORFEUS-SPAS-2 free-flyer on Shuttle flight STS-80 carried, in addition to its prime payload, an ARP secondary payload of ESA/ESTEC, consisting of a GPS Tensor receiver and R-GPS (Relative-GPS) navigation algorithms (referred to as ARP-Kernel, developed by MMS, France). The prime ARP contractor is MMS. ATV is the future Automated Transfer Vehicle, the ESA resupply vehicle for ISS (International Space Station), ARP is considered a prototype system.

[The overall ARP activities are split into two main phases: a) the "long-range" rendezvous leg which demonstrate relative GPS techniques (using Tensor), and b) the "short-range" leg, based on measurements of the Rendezvous Sensor (using a laser sensor of DASA Jena Optronics, Germany). The Rendezvous Sensor (RVS) employs the following principle:

- A laser beam (905 nm wavelength) is emitted from RVS (installed on the forward section of the ATV)
- The beam is reflected by a dedicated target pattern (composed of six retro-reflectors) installed in proximity of the docking port of the ISS Service Module.
- The reflected beam is detected by RVS on ATV, then processed to provide the required data to the on-board navigation function.

RVS is physically composed of two separate units, the sensor head, and the electronic unit.]

The STS-80 ASTRO-SPAS (ORFEUS-SPAS-2) mission is regarded as Flight Demonstration 1 (FD1) in the context of ARP. FD-1 (a joint ESA-NASA experiment) was considering

¹³⁶⁷⁾R. R. Conway, M. H. Stevens, et al., "Middle Atmosphere High Resolution Spectrograph Investigation," Journal of Geophysical Research, Vol. 104, No D13, July 20, 1999, pp. 16,327-16348

¹³⁶⁸⁾M. Cislighi, U. Thomas, M. Lellouch, J. M. Pailot, "Development and Verification of Automated Rendezvous for ATV," Proceedings IAF-96-T.2.08, Oct. 7-11, 1996, Beijing

only the GPS aspects of the ARP-Kernel (ARPK). - The Shuttle orbiter carried also a GPS receiver (TANS Quadrex), implemented on the fixed part of WSF (Wake Shield Facility) within the cargo bay, and an optical sensor TCS (Trajectory Control Sensor). TCS (of NASA, a laser based sensor) verified the R-GPS measurements by tracking a retro-reflector mounted on the x-face of ORFEUS-SPAS.

J.1.4 CRISTA-SPAS-2

A reflight of the CRISTA-SPAS-1 mission and payload took place on STS-85 (Aug. 7-19, 1997), labelled as CRISTA-SPAS-2.

The scientific emphasis was on the study of small-scale tracer “filaments” (long, thin regions of differing composition, including temperatures) in the stratosphere. Data analysis of the two CRISTA-SPAS missions may indicate, how these filaments contribute to the transport of ozone. The STS-85 flight offered an opportunity for increased latitudinal coverage of the atmosphere beyond that of the STS-66 mission (data of summer conditions at northern latitudes and the polar night at high southern latitudes). A CRISTA/MAHRSI campaign (Appendix Q), employing balloons, research aircraft, etc. was conducted in Europe in parallel to the STS-85 mission, in support of CRISTA-SPAS-2.

MAHRSI = Middle Atmospheric High Resolution Spectrograph Investigation (Naval Research Lab, PI: R. Conway). Same instrument as in the STS-66 mission (CRISTA-SPAS-1). During STS-85 flight, MAHRSI gathered new vertical profile data on the distribution of OH in the mesosphere and upper stratosphere under very different conditions (both seasonal and diurnal) from its previous flight on STS-66. Also, more measurements of nitric oxide were conducted. Researchers hope to gain a better understanding of how hydroxyl (OH) behaves during different seasons around the globe and how it interacts with the behavior of ozone and other trace gases.

IPEX-II (Interferometry Program Experiment 2). A NASA/JPL experiment, the prime objective was to monitor on-orbit the microdynamic behavior of space-like booms (to serve as input for future interferometry missions). The IPEX-II boom is a 9-bay expandable ADAM mast (2.35 m x 0.3 m x 0.3 m), developed by AEC-Able, with steel-bracing cables pre-loaded at about 112 kg. The boom was cantilevered to the side of the ASTRO-SPAS platform. The experiment consisted of three phases:

- Investigation of thermal snapping in joint-dominated structures due to temperature gradients. A suite of 24 high sensitivity micro-g accelerometers with collocated temperatures sensors, mounted on the boom, monitored normal operations aboard CRISTA-SPAS in free flight. Data was obtained for five sun-to-shade orbital periods.
- Investigation of structural boom behavior due to induced loads. Two shakers, mounted orthogonally at boom tip, performed random and step-sine tests between 9-300 Hz, with loads from 0.048 to 0.00055 kg to detect any possible nonlinear behavior in the boom.
- Investigation to isolate and to quantify on-board disturbance sources of the CRISTA-SPAS platform and to measure their effect on the boom. This involved gyro and thruster operations and in-between times.

J.2 ATLAS (Atmospheric Laboratory for Application and Science)

The ATLAS program is part of NASA's ‘Mission to Planet Earth’ (MTPE). The ATLAS missions (on the Shuttle) investigate specifically how Earth's atmosphere and climate are affected by the sun and by the products of industrial complexes and agricultural activities. Experiments flown on the three ATLAS missions gathered data throughout the sun's

11-year activity cycle.^{1370),1371)} There is a “core” of instruments which was the same on all ATLAS missions, and additional instruments unique to several of the Shuttle flights. An important goal of the ATLAS program is to provide measurements that relate to and coincide with other instruments that are flying on other satellites. There is a coordinated underflight program for correlative measurements such as: UARS, NOAA-POES, ERBS, EURECA, TOMS (on Nimbus-7 and Meteor-3-6).

ATLAS-1 consists of 12 international experiments and supporting hardware mounted on a two-Spacelab-pallet train in the orbiter payload bay, and one experiment contained in two canisters mounted on one adapter beam assembly (SSBUV). These experiments study the chemical makeup of the atmosphere between approximately 15 and 600 km above the Earth's surface, measure the total energy contained in sunlight and how that energy varies, investigate how Earth's electric and magnetic fields and atmosphere influence one another, and examine sources of ultraviolet light in the universe. Many of the experiments are also scheduled for later ATLAS missions, so the data gathered during ATLAS-1 was the first in a series of long-range studies that measure changes in the atmosphere and the sun.

ATLAS-1 had periods of solar pointing, Earth-limb pointing, and additional special attitudes throughout the mission. The orbiter is the primary experiment pointing system; however, some of the experiments have limited fine-pointing capability for enhanced pointing accuracy.

Orbit: ATLAS-1 was launched March 24, 1992 by STS-45 (Atlantis) to a 296 km orbit, inclination = 57°, 8 day mission. For ATLAS-2 and -3 orbits see O.17 (Space Shuttle Mission Chronology).

Sensors (Core Instruments):

MAS = Millimeter-Wave Atmospheric Sounder (PI: G. Hartmann, MP Ae, Lindau). Measurement of millimeter-wave emission from the atmosphere. As a limb emission instrument, it gets nearly global coverage. Determination of the following parameters:

- Upper troposphere: H₂O, O₃, and CO profiles
- Stratosphere: O₃ for trend analysis, ClO (globally), H₂O
- Mesosphere: O₃, H₂O, and CO
- Temperature and pressure of stratosphere and mesosphere

MAS is the predecessor of AMAS, a Heterodyne Limb Sounder (like MLS), observing in the channels: 61 GHz, 62 GHz, 63 GHz, 183 GHz, 184 GHz and 204 GHz. MAS determines pressure, temperature, ozone, water and ClO profiles (10-100 km altitude). MAS uses a dish-shaped antenna to scan the Earth's limb to collect spectral information at distinct altitudes. The ClO receiver on ATLAS-3 has been upgraded for better sensitivities. The instrument has an antenna aperture of 1 m x 1.3 m; it features 240 channels (12 bit), mass = 200 kg, power = 400 W, data rate = 86.4 kbit/s.

The MAS experiment is a joint project of: University of Bremen (K. Künzi, scientific investigation), University of Bern (hardware), MP Ae Lindau (data processing and scientific investigation) and the Naval Research Lab (Washington).

ATMOS = Atmospheric Trace Molecule Spectrometer (JPL Sensor, PI: M. R. Gunson). This is an infrared absorption instrument which works during occultations (sunrise, sunset) and measures a wide variety of species with good vertical resolution. The ATMOS experiment was already very successful on Spacelab-2 (flown in 1985). It employs a high-resolution FT (Fourier Transform) interferometer and limb viewing in the bands of 2.2-16 μm. During ATLAS-3 the ATMOS instrument also had a video camera to record pictures of the sun during sunrises and sunsets (pointing confirmation).

¹³⁷¹⁾Information provided by the Earth Science Application Division (ESAD Office) at NASA HQ, Washington

Configuration	compensated (cat's-eye) type: continuous scan
Spectral coverage	600 - 4800 cm ⁻¹ (2.2-16 μm)
Maximum resolution	0.013 cm ⁻¹ (unapodized)
Maximum OPD (Optical Path Difference)	±48 cm
Scan time	2.2 s
Detector type	HgCdTe at 77 K
Sensitivity	SNR > 100:1 at 2500 cm ⁻¹ (source-noise limited)
Operating temperature	-5 to + 45 °C
Beamsplitter and compensator	potassium bromide
Beam diameter (internal)	2.5 cm
Telescope diameter	7.5 cm
IFOV	selectable: 1, 2, or 4 mrad
System étendue	≥ 1.39 x 10 ⁻⁴ cm ² sr
Path difference control	stabilized He/Ne laser
Instrument mass, power, data rate	250 kg, 360 W, 16 Mbit/s

Table 411: Parameters of the ATMOS FTS

SUSIM = Solar Ultraviolet Spectral Irradiance Monitor (Naval Research Laboratory, US, PI: G. Brueckner).¹³⁷²⁾ Measures solar UV flux as a function of wavelength from 110 to 410 nm (compatible with SUSIM on UARS (see A.32), also for calibration of UARS instrument). SUSIM can also observe ozone and molecular oxygen profiles by occultation during solar observing orbits. Heritage: SUSIM flew on Spacelab-2 (STS-19), July 29-August 6, 1985.

SOLCON = Solar Constant Sensor (IRMB, Brussels, Belgium, PI: R. Crommelynck). Measurement of the solar constant. The SOLCON instrument is a cooperative effort of IRMB, Space Science Dept. of ESA, and LaRC. Measurement of the absolute value of the total solar irradiance (and long-term variations). The technique used is to compare the heating of a cavity exposed to sunlight with the temperature of another cavity that is not exposed to sunlight. Instrument accuracy to within 0.1% of the solar constant, and about 0.01% precision. SOLCON is a high-resolution, self-calibrating radiometer with a digital processing/converter unit.

ACRIM = Active Cavity Radiometer Irradiance Monitor (JPL, PI: R. C. Willson). See description under ACRIMSAT (A.2) and SMM (K.22). ACRIM is a pyrhelimeter measuring the total solar irradiance (solar constant) with a technique similar to SOLCON's.

SOLSPEC = SOLar SPECtrum Measurement (CNRS, France, PI: G. O. Thuillier). Measures the solar irradiance from 180-3200 nm using three double spectrometers and an on-board calibration device. SOLSPEC can also observe abundances of ozone by measuring the backscatter of specific UV and VIS wavelengths during nadir operations. SOLSPEC heritage: flew on Spacelab-1 in November 1983 (see J.22 on page 853).

SSBUV¹³⁷³⁾ = Shuttle Solar Backscatter Ultraviolet Spectrometer (GSFC, PI: E. Hilsenrath). Uses UV backscatter in nadir to measure vertical profiles of ozone in the stratosphere and in the lower mesosphere from 180 to 450 nm. Note: SSBUV is not a core instrument; it is a separate ATLAS Shuttle payload (co-manifested with ATLAS and integrated into the ATLAS science plan).

SSBUV is a sensor of SBUV/2 heritage (from Nimbus-7 and NOAA-9 satellites onward). Objective: Calibration of long-term satellite ozone data sets with complementary Shuttle flights.

SSBUV is scheduled to fly eight times from 1989 to 1996. The first flight with SSBUV instrumentation occurred on October 19, 1989 on the Shuttle Atlantis. Throughout the

¹³⁷²⁾SUSIM brochure of Naval Research Lab, available at NASA HQ's Document Resource Facility

¹³⁷³⁾"Calibration of Long Term Satellite Ozone Data Sets Using the Space Shuttle," E. Hilsenrath, in Optical Remote Sensing of the Atmosphere, 1990 Technical Digest Series of the Optical Society of America, Vol. 4, pp. 409-412

Shuttle flight period coincident observations were taken with the SBUV on Nimbus-7 and the SBUV/2 on NOAA-9 and NOAA-11 satellites. The SSBUV spectrometer is located in a GAS canister attached to the side of the Shuttle's cargo bay. A motorized door assembly opens up to allow the SSBUV to view the Earth and the sun.

The SSBUV instrument is the SBUV/2 engineering model now flying on NOAA satellites. See also J.26 on page 861 for a description of SSBUV and G.13 (NOAA-POES) for a description of SBUV/2.

The ATLAS Program on Shuttle (about 1 week each time) has the following time schedule:

- ATLAS-1 Mission: March 24 - April 2, 1992 with Atlantis (correlative measurements to UARS). Flown mission on STS-45
- ATLAS-2 Mission: April 8 - 17, 1993 (correlative measurements to UARS). ATLAS-2 payloads gathered data on the relationship between the sun's energy output and the Earth's middle-atmosphere chemical makeup. Study of how these factors affect the Earth's ozone level. Flown mission on STS-56.
- ATLAS-3 Launch: Nov. 3-14, 1994 (with the CRISTA and MAHRSI payload on the ASTRO-SPAS free-flyer, see description under J.1). Flown mission on STS 66.

Additional ATLAS sensors are:

ALAE = Atmospheric Lyman-Alpha Emissions (CNRS, France). Uses on-board hydrogen and deuterium cells to measure thermospheric/exospheric H and D concentrations, as well as Lyman alpha amounts in the interplanetary medium. ALAE will fly on ATLAS-1.

ISO = Imaging Spectrometric Observatory (MSFC). The spectrometer measures 'low light observations' in daylight and on the night-side of the Earth. There are five spectral bands from 30-1300 nm. ISO will fly on ATLAS-1.

ENAP (Energetic Neutral Atom Precipitation), of the University of Texas, Dallas. ENAP is a study which will use data from ISO.

AEPI = Atmospheric Emissions Photometric Imaging (Lockheed, Palo Alto Research Lab). Optical emissions from the upper atmosphere/ionosphere and from the Space Shuttle environment. Images of natural and induced aurora and airglow. AEPI flew on ATLAS-1.

SEPAC = Space Experiments with Particle Accelerators (Southwest Research Institute, US). Uses electron beam accelerator and other instruments to carry out active and interactive experiments on and in the Earth's ionosphere. SEPAC was flown on ATLAS-1.

FAUST = Far Ultraviolet Space Telescope (University of California, Berkeley). Far-ultraviolet images of large-scale phenomena. FAUST flew on ATLAS-1.

J.3 Bitsy-SX (Bitsy-Spacecraft in Future-X)

Bitsy-SX is a Shuttle demonstration payload in NASA's Future-X program, referred to as SPASE (Small Payload Access to Space Experiment), designed and built around AeroAstro's Bitsy-SX spacecraft kernel.

Background: In 1998 NASA announced a new program, Future-X, managed by MSFC, with the aim to support a series of flight demonstrations to validate new technologies. The idea is to prove technologies that improve performance and lower development, production and operating costs of future earth-to-orbit and in-space transportation systems.

Bitsy™ is a trade name, representing a line of spacecraft "kernel" modules, designed and developed by AeroAstro of Herndon, VA. The "Bitsy™ concept" as such is an enabling technology, meaning that one does not fly a Bitsy (though among its design requirements is

that it can behave as a fully functional spacecraft); rather one uses Bitsy as the starting point in the development of a full spacecraft. The kernel approach applies COTS (Commercial-of-the-Shelf) and standardization concepts to the fullest extent to obtain significant cost and turnaround advantages over conventional bus development.¹³⁷⁴⁾

The first Bitsy-SX implementation (the total mass of the Bitsy-SX with a NASA microgravity payload is about 35 kg) will fly on the SPASE vehicle in Nov. 2001 (Shuttle flight STS-108). SPASE uses Bitsy-SX, perched upon an octagonal experiment structure, that fits inside a GAS (Get Away Special) canister on Shuttle. The outside of the experiment housing is covered with solar panels. Bitsy-SX contains lithium-ion batteries, providing 7 Wh of energy (average orbital power is 5 W) during orbital eclipse phases. The ACS (Attitude Control System) of SPASE is passive, using hysteresis rods and permanent magnets to keep the S/C body rates below 10^{-5} g for the crystal growth experiment. The payload interaction consists primarily of keeping the crystal growth cavity within a specified temperature range, commanding a digital camera to take images periodically, and downloading those images when a ground station contact occurs.

Deployment of the SPASE free-flyer vehicle from the GAS canister is attended by the Shuttle crew (Hitchhiker launch). It occurs at an altitude high enough above the atmosphere to remain under the 10^{-5} g requirement for the science experiment. Communications (in UHF at 9.6 kbaud) with SPASE as well as S/C operations are conducted from a ground station at the University of Alabama in Huntsville. SPASE uses internally RS-232 interfaces to communicate with the payload. Simple timed commanding is supported as well as threshold monitoring of all S/C and payload functions. The science mission is designed to last 6 months prior to vehicle reentry into the atmosphere.

J.4 CIRRIS (Cryogenic Infrared Radiance Instrumentation for Shuttle)

CIRRIS is a DoD/USAF instrument, a Michelson FTS (Fourier Transform Spectrometer) interferometer, in a program (AFP-675) of upper atmosphere and space research. The objectives are to develop sensors with the capability to detect and track such targets as aircraft, missiles and satellites against an atmospheric background. The intent is the development of predictive models of atmospheric chemistry and physics under conditions of quiescent and disturbed upper atmospheres by aurora, airglow, rocket fuel injection, and targets of opportunity.

CIRRIS-1A, designed and built by the Center for Space Engineering at USU (Utah State University) for AGFL (Air Force Geophysics Laboratory) of Hanscom AFB, MA, and flown on Shuttle flight STS-39 (Discovery, Apr. 28-May 6, 1991), collected these types of data on the Earth's limb. The orbit of STS-39 provided an altitude of about 260 km with an inclination of 57° . Specific interests were nocturnal, diurnal and latitudinal geomagnetic effects on infrared background radiation. Note: CIRRIS is a predecessor instrument of SPIRIT-III on MSX (see M.14).^{1375) 1376) 1377) 1378)}

The primary CIRRIS-1A experiment assembly consists of an FTS interferometer and a highly sensitive spatial radiometer (length of CIRRIS-1A assembly is 2.8 m, mass = 2000

¹³⁷⁴⁾ S. A. McDermott, D. J. Goldstein, "The Bitsy™ Spacecraft Kernel: Reducing Nanosatellite Mission Cost in the MSFC Future-X Program Through Miniaturized technologies," Proceedings of the 13th AIAA/USU Conference on Small Satellites, Aug. 23-26, 1999, Logan UT, SSC99-IX-8

¹³⁷⁷⁾ G. E. Bingham, et al., "Cryogenic Infrared Radiance Instrumentation for Shuttle (CIRRIS-1A) Earth limb spectral measurements, calibration, and atmospheric O₃, HNO₃, CFC-12, and CFC-11 profile retrieval," Journal of Geophysical Research, Vol. 102, D3, Feb. 20, 1997, pp. 3547-3558

¹³⁷⁸⁾ D. K. Zhou, et al., Stratospheric CH₄, N₂O, H₂O, NO₂, N₂O₅, and ClONO₂ profiles retrieved from Cryogenic Infrared Radiance Instrumentation for Shuttle (CIRRIS-1A)/STS-39 measurements," Journal of Geophysical Research, Vol. 102, D3, Feb. 20, 1997, pp. 3559-3573

kg). These multi-detector instruments share the common collecting optics of a single high off-axis rejection telescope. Mounted on the outside of the telescope heat exchanger are two photometers, two TV cameras, a 16-mm film camera celestial aspect sensor (co-aligned with the primary sensor), and a horizon sensor - to provide position data on the sensor's field of view (FOV).

The interferometer is of standard Michelson design with flat mirrors and reference system path through the center of the infrared beam. Major FTS elements include the optical filter wheel (eight position with seven filters to reduce photon noise), the optical modulator (operating at 20 K contains the optical elements, the translating mirror system, the mirror position reference system, and the remote alignment system), the detectors, internal calibration sources, the FTS control electronics, and the FTS signal conditioning electronics. The spectral range of the system is from 2.5 - 25 μm . The five SiAs detectors provide a resolution of the interferogram ranging between 1-8 cm^{-1} over an eight order dynamic range. The five detectors, with a TFOV of $1.22^\circ \times 1.5^\circ$ (or 21.3 mrad x 26.2 mrad), include one large detector for maximum sensitivity, one detector designed to provide high sensitivity at 1 cm^{-1} resolution, and three small detectors for spatial definition. The interferometer, radiometer, and telescope are cooled by supercritical helium at 20 K to minimize background noise.

CIRRIS-1A calibration sources include wideband sources, a quasi-blackbody source, an alignment source, an off-axis source, photon bias, and detector stimulator sources and passive cold sources.

The sensors are suspended in a two-axis gimbal, mounted in an equipment support system (ESS), to provide the required scanning capability.

Spectral range	2.5 - 25 μm (400 cm^{-1} - 4000 cm^{-1})	
Detectors	SiAs, five element array	
Sensitivity NESR ($\text{Wcm}^{-2} \text{sr}^{-1} \text{cm}^{-1}$ @ 20 μm)	Detector 1: $1.3 \cdot 10^{-14}$	[8 cm^{-1} scan in 1.53 s]
	Detector 3: $2.2 \cdot 10^{-13}$	[8 cm^{-1} scan in 1.53 s]
	Detector 4: $5.0 \cdot 10^{-13}$	[8 cm^{-1} scan in 1.53 s]
	Detector 5: $5.0 \cdot 10^{-13}$	[8 cm^{-1} scan in 1.53 s]
	Detector 2: $1.1 \cdot 10^{-13}$	[1 cm^{-1} scan in 9.75 s]
Dynamic range	8 orders considering the entire array	
Signal bandwidth	DC to 900 Hz (max signal frequency = 450 Hz)	
Focal plane optics	Ritchey-Chretien f/1.6	
Interface optical aperture	4.76 cm	
FOV	Detector 1: 9.6 mrad x 26.2 mrad	$2.50 \cdot 10^{-4}$ sr
	Detector 2: 10.0 mrad x 10.0 mrad	$1.00 \cdot 10^{-4}$ sr
	Detector 3: 2.1 mrad x 7.0 mrad	$1.48 \cdot 10^{-5}$ sr
	Detector 4: 1.6 mrad x 5.0 mrad	$7.77 \cdot 10^{-6}$ sr
	Detector 5: 1.6 mrad x 5.0 mrad	$1.00 \cdot 10^{-6}$ sr
	Overall: 21.3 mrad x 26.2 mrad	

Table 412: Parameters of the CIRRIS-1A instrument

J.5 EURECA (European Retrievable Carrier)

An ESA spacecraft/platform¹³⁷⁹⁾ designed and developed to be recovered from orbit after completion of a particular mission, returned to Earth, refitted with a new sensor complement, and relaunched for another extended/new mission. Typical mission duration is of the order of six months to one year. The concept allows complete payload/sample recovery.

J.5.1 EURECA-1 Mission

Launch of EURECA-1 by Shuttle (Atlantis, STS-46) from KSC on July 31, 1992. Retrieval of EURECA-1 by Shuttle (Endeavour) during the STS-57 mission from June 21 - July 1,

¹³⁷⁹⁾ESA Press Release, ESA/ESTEC, 1991

1993. Mission operations of EURECA-1 was provided by ESOC in Darmstadt; some payload operations were provided by MUSC (Microgravity User Support Center) of DLR in Cologne, Germany. The spacecraft was developed and integrated at DASA/ERNO, Bremen, Germany.^{1380) 1381)}

Figure 239: Illustration of the EURECA platform

The EURECA S/C structure had dimensions of 4.6 m x 2.6 m. The bus structure consisted of carbon fiber struts connected by titanium nodal joints. A grapple fixture permitted deployment/retrieval by the Shuttle Remote Manipulator System. EURECA was three-axis stabilized by magnetorquers, supported by a reaction control assembly of 6 x 21 mN nitrogen thrusters. Orbit transfers between altitudes of 400-500 km were performed by the orbit transfer assembly of redundant 4 x 21 N hydrazine thrusters (the propellant volume was sized for two transfers and 9 months on-orbit stay). The attitude rate was measured by an accelerometer package, gyros and IR Earth and sun sensors. Power was provided by twin deployable/retractable panels of silicon solar cells, generating 5 kW at 28 VDC (providing 1 kW average for payload operations). In addition, 4 NiCd batteries provided energy of 40 Ah. The launch mass of EURECA was 4490 kg (payload capacity of up to 1000 kg). Data was transmitted via S-band downlink at rates up to 256 kbit/s.

Orbit: Low Earth Orbit (LEO) circular; altitude = 502 km, inclination = 28°, retrieval altitude of 476 km.

Sensor Complement

Only those sensors are described and indexed that fit into the scope of this book, namely: "Observation of the Earth and its Environment." The other sensors (in the life and material sciences) are simply listed with a short commentary.

ERA = Exobiology and Radiation Assembly. A multiuser life science facility for experiments on the biological effects of space radiation. PI: H. Bückner, DLR, Germany.

AMF = Automatic Mirror Furnace. Optical radiation furnace for growing single, uniform crystals from the liquid or vapor phases, using the travelling heater or Bridgman methods. PI: K. W. Benz, Universität Freiburg, Germany.

SGF = Solution Growth Facility. A multiuser facility for growing monocrystals from solution. PI: J. C. Legros, Université Libre de Bruxelles, Belgium.

PCF = Protein Crystallisation Facility. A multiuser solution growth facility for protein crystallisation in space. PI: W. Littke, Universität Freiburg, Germany.

¹³⁸⁰⁾ P. Ferri, H. Hübner, S. Kellock, W. Wimmer, "The Joint ESA-NASA Operations for Eureka's Deployment and Retrieval," *ESA Bulletin*, Number 76, November 1993, pp. 81-90

¹³⁸¹⁾ F. Dreger, J. Fertig, D. Gawthrop, S. Martin, et. al., "Eureka: The Flight Dynamics of the Retrieval," *ESA Bulletin*, Number 76, November 1993, pp. 92-99

MFA = Multi-Furnace Assembly. A multiuser facility dedicated to material science experiments. PI: A. Passerone, National Research Council, Genoa, Italy

HPT = High Precision Thermostat. An instrument for long-term experiments requiring microgravity conditions and high precision temperature measurement and control (typical experiments are: 'caloric', 'critical point', and 'phase transitions'). PI: G. Findenegg, Ruhr Universität, Bochum, Germany.

SFA = Surface Forces Adhesion. Study of the dependence of surface forces and interface energies on physical and chemical-physical parameters such as surface topography, surface cleanliness, temperature, and the deformation properties of the contacting bodies. PI: G. Poletti, Università di Milano, Italy.

RITA = Radio-Frequency Ion Thruster Assembly. Study of the use of electric propulsion in space. PI: H. Bassner, DASA-MBB, Munich, Germany.

IOC = Inter-Orbit Communication Instrument. A technological experiment to provide a pre-operational in-flight test and demonstration of all required instrument functions and services. PI: R. Tribes, CNES, France.

ASGA = Advanced Solar Gallium Arsenide Array. A technological experiment for the performance testing of future solar arrays. PI: C. Flores, CISE SPA, Segrate, Italy.

WATCH = Wide Angle Telescope. Objective: detection of celestial gamma-ray burst sources and X-ray sources with photon energies in the range of 5 - 200 keV, measurement of source direction. PI: N. Lund, Danish Space Research Institute, Lyngby, Denmark.

TICCE = Timeband Capture Cell Experiment. Study of microparticle population distributions in near-Earth space, typically Earth debris, meteoroids, and cosmic dust. TICCE captures micron-dimensional particles with velocities in excess of 3 km/s and stores the debris for retrieval and post-mission analysis. PI: J. A. M. McDonnell, University of Kent, UK.

Particles detected by the instrument pass through a front foil and into a debris collection substrate positioned 100 nm behind the foil. Each perforation in the foil has a corresponding debris site on the substrate. The foil is moved during the mission in 50 discrete steps. The phase shift between the debris site and the perforation enables a determination of the impact time. Instrument mass = 8 kg, dimensions: 690 x 690 x 80 mm.

ORA = Occultation Radiometer Instrument. Objective: measurement of aerosols and trace gas densities in the Earth's mesosphere and stratosphere (vertical profiles between 20 -100 km of: ozone, nitrogen dioxide, water vapor, carbon dioxide, and background and volcanic aerosols) . PI: E. Arijs, BIRA (Belgisch Instituut voor Ruimte Aeronomie), Brussels, Belgium.

ORA measures the intensity of solar radiation during the sunrise and sunset phases of each orbit. It uses the SUN pointing capabilities of EURECA and makes measurements in ten narrow wavelength bands (UV/VIS, NIR) in the spectral region 250 - 1100 nm. ORA consists of a UV/VIS unit, an NIR unit and a control/electronics unit. The UV/VIS unit has 8 similar modules which measure the relative solar irradiance in narrow bands. Each module contains a quartz window, an interference window to select the appropriate wavelength, optics to limit the detector viewing angle, and a photodiode.

SOVA = Solar Constant and Variability Instrument (copy of SOLCON). Objective: measurement of the solar constant, its variability and its spectral distribution. PIs: D. Crommelynck, IRMB, Brussels, Belgium; and C. Fröhlich, PMOD/WRC Davos, Switzerland.

The instrument is composed of three boxes, two of which (SOVA1 and SOVA2) house the various devices dedicated to functions such as sun-pointing, sun photometers, and two different types of absolute radiometers. The absolute radiometers are very accurate instru-

ments for the measurement of total irradiance. They are essentially cavities, in which the solar radiation is trapped and absorbed. Heat flux transducers convert the radiative power into electrical power and return a calibrated measurement of the sun's radiation. The high precision radiometer (RELOS) is used to measure solar oscillations in total irradiance. The sun-pointing resolution of SOVA2 is 2 arc seconds. The sun photometers use interference filters to select the wavelength band and silicon diode devices to measure the radiation. The complete set of photometers covers the spectrum from 303 nm to 865 nm.

SOSP = Solar Spectrum Instrument. Objective: study of solar physics and solar-terrestrial relationships in aeronomy and climatology. Measurement of absolute solar irradiance and its variations in the spectral range 170 - 3200 nm (accuracy of 1% in VIS/IR and 5% in UV). PI: G. Thullier, CNRS, Verriers le Buisson, France.

SOSP has three spectrometers, one for each spectral domain (UV/VIS/IR). The spectrometers select the spectral range using a double monochromator; irradiance measurement with a photomultiplier in UV and VIS, in IR with a cooled lead sulfide cell. Spectral resolution: 1 nm in UV/VIS, 20 nm in IR. In-flight calibration is provided.

J.6 IPS (Instrument Pointing System)

IPS is an ESA-sponsored instrument, built by Dornier, and flown on three Spacelab missions with the objective to provide instrument pointing with very high accuracy and stability at stars, the sun, the Earth or other targets of observation. IPS was first flown on Shuttle flight STS-51-F as Spacelab-2 (July 29 - Aug. 6, 1985), then on STS-35 as Astro-1 (Dec. 2-10, 1990), and again on STS-67 as Astro-2 (March 2-18, 1995).¹³⁸²⁾

The IPS provides precision pointing for a wide range of payloads, including large single instruments (telescopes) or a cluster of instruments or a single small-rocket-class instrument. The pointing mechanism can accommodate instruments of diverse sizes and weights (up to 7,000 kg) and can point them to within 2 arcseconds and hold them on target to within 1.2 arcseconds. The IPS accuracy for a 2000 kg payload is 0.4 arcseconds lateral and 11.2 arcseconds for roll under star tracker control (0.5 arcseconds lateral and 41 arcseconds roll in sun mode). The overall mass of IPS is 1,180 kg, power demand of up to 1.25 kW, and a data rate of 16 Mbit/s.

IPS consists of a three-axis gimbal system mounted on a gimbal support structure connected to the pallet at one end and to the aft end of a payload at the other, a payload clamping system to support the mounted experiment elements during launch and landing, and a control system based on the inertial reference of a three-axis gyro package and operated by a gimbal-mounted minicomputer.

The basic structural hardware is the gimbal system, which includes three bearing/drive units, a payload/gimbal separation mechanism, a replaceable extension column, an emergency jettisoning device, a support structure and rails, and a thermal control system. The gimbal structure itself is minimal, consisting only of a yoke, an inner gimbal and an outer gimbal to which the payload is attached by the payload-mounted integration ring.

The three identical drive units are so arranged that their axes intersect at one point. From pallet to payload, the order of the axes is elevation, cross-elevation and azimuth. Each drive assembly includes three wet-lubricated ball bearings, two brushless dc-torquers and two single-speed/multispeed resolvers.

IPS is controlled through the Spacelab subsystem computer and a data display unit and keyboard. It can be operated either automatically or by the Spacelab crew from the pressurized module and also from the payload station on the orbiter aft flight deck. IPS has two operat-

¹³⁸²⁾<http://www.ksc.nasa.gov/shuttle/technology/sts-newsref/spacelab.html>

ing modes, which depend on whether the gimbal resolver or gyro is used for feedback control of attitude. An optical sensor package - consisting of one boresighted fixed-head star tracker and two skewed fixed-head star trackers - is used for attitude correction and also for configuring the IPS for solar, stellar, or Earth viewing.

During a search phase, each star tracker searches a $2^\circ \times 2^\circ$ FOV for one or two star images (stellar or solar missions) appearing in the optics. When a star is detected, the position of the star image on the FOV is determined by a scanning procedure. The tracker delivers this position to the Spacelab Subsystem Computer as electrical coordinates.

Acquisition modes: IPS can obtain optical hold on a specific target in two ways, automatic and manual. The automatic mode uses a procedure known as "Operational Identification" which uses a known set of "guide stars" to identify the star field of each tracker. The manual mode consists of a procedure known as "Manual Target Acquisition" to identify the bore-sight tracker region.

J.7 ISIR (Infrared Spectral Imaging Radiometer)

ISIR is a high precision, multispectral imaging radiometer of NASA/GSFC (built by Space Instruments Inc., Encinitas, CA) flown on STS-85 (Aug. 7-19, 1997) as a hitchhiker payload (ISIR was one of twelve Hitchhiker experiments that were carried in the Shuttle bay on two cross-bay Hitchhiker bridge assemblies).¹³⁸³⁾ ¹³⁸⁴⁾ The objective of ISIR was to demonstrate/validate a new infrared imaging technology with an uncooled detector array for the measurement of the infrared brightness temperature of cloud tops as well as the Earth's surface. The new technology is based on microbolometer focal plane arrays, allowing infrared imaging without external cooling. The ISIR detector is a warm focal plane 327×240 pixel array of silicon micromachined microbolometers. ISIR demonstrated the potential of this new technology for future much more compact, lower cost and more reliable spaceborne infrared imagers. On STS-85, ISIR was operated in conjunction with the Shuttle Laser Altimeter (SLA-2), for a new type of cloud science observation through combined active and passive remote sensing.

ISIR is a compact spectral imager providing radiometrically calibrated infrared imagery in three narrow spectral band centers at 8.55, 10.8 and 11.8 μm , and in a broad-band window from 7 to 13 μm . ISIR's main scientific mission is to image clouds from Shuttle orbit and provide information on cloud-top temperature and classification. A science goal is discrimination of cirrus cloud particle type by split-window analysis. The split-window analysis involves the differential radiance between the 10.8 and 11.8 μm atmospheric window channels. The required NEDT (Noise Equivalent Difference Temperature) system sensitivity performance was 0.1 K. The target spatial resolution was 250 m with a total image swath-width of 85 km from the shuttle altitude.

ISIR is as a pushbroom imager with an MBA (Microbolometer Array) detector. A scene is imaged in a fixed staring mode with the cross-track pixels providing the image swath. Imaging is done with a $f/0.73$ germanium lens of 50.8 mm focal length and 70 mm optical diameter. The cross track full FOV is approximately 15° . A filter wheel between the lens and detector array is driven for spectral selection. In order to obtain the necessary instrument calibration during operation, an on-board blackbody calibration target is included. The blackbody is viewed by swinging in a mirror in front of the lens. A curved focussing mirror is used in order to minimize the size of the blackbody target. The overall instrument includes electronics and tape recorders. Two standard Exabyte-8505c 8mm tape recorders were used for data storage.

¹³⁸³⁾ <http://isir.gsfc.nasa.gov/main.html>

¹³⁸⁴⁾ J. D. Spinhirne, et al., "Preliminary Spaceflight Results from the Uncooled Infrared Spectral Imaging Radiometer (ISIR) on Shuttle Mission STS-85," SPIE, 1998

Spectral bands (4)	8.2 - 9.0 μm ; 10.3 - 11.3 μm ; 11.5 - 12.5 μm ; and 7.0 - 13 μm
Dynamic range	Scene temperatures from 0 K to 400 K
NEDT @ 300 K	0.01 K to 0.06 K
Spatial resolution	1 mrad (250 m on ground from Shuttle @ 250 km)
Field of View (FOV)	19.25°. (81 km swath on ground from shuttle @ 250 km)
Optics	f/0.73, 50 mm focal length, 68 mm diameter
Inflight calibration	Ambient & cold calibration capability
Instrument mass; power	13 kg; 20 W operating, 120 W during cold calibration
Instrument size	45 cm x 35 cm x 30 cm
Data rate	368 kbit/s (with 12 bit encoding)

Table 413: ISIR instrument performance parameters

The primary advantage of the MBA detector (built by Loral with DARPA funding) used in ISIR is that it is a large-format (327 x 240) array providing good sensitivity in the thermal IR at room temperature. A TDI (Time Delay Integration) operating mode was implemented providing a (x 40) cumulative imaging capability. This required a special flight operation mode for high resolution imaging with less than 1/8 pixel smearing. An instrument roll stability of 0.01°/s and a yaw accuracy to the ground velocity vector of $\pm 0.1^\circ$ were provided by the Shuttle.

During the STS-85 mission, three special surface tracking maneuvers were executed by the Shuttle for the ISIR experiment. The goal was to image the thermal emission of cloud tops in high resolution over a large range in angles. The results permit test of angular cloud radiation models that are a key element for cloud retrieval applications of current GOES and LEO satellite data. - There were three aspects of the ISIR experiment that were firsts from space for cloud science.

- The combination with direct laser measurements of cloud height
- A global data set of thermal infrared imagery at near $\frac{1}{4}$ km resolution was acquired
- The additional new observation from space was the use of the 8.5 μm wavelength, which has applications for cloud particle discrimination.

J.8 LDEF (Long Duration Exposure Facility)

LDEF is a NASA/LaRC¹³⁸⁵⁾ freeflying spacecraft which accommodates technology, science, and applications experiments on long-term exposure to the space environment, with the objective to collect small meteoroids and space debris in Low Earth Orbit (LEO) for post-mission impact analysis of surfaces and materials that have been exposed to the space environment. Directional resolution of the flux of meteoroids and space debris particles.

LDEF was deployed on April 7, 1984 on Shuttle flight STS-41 C. Retrieval was planned after 10 months. Due to delays caused by the Challenger accident (STS-25), it was finally recovered 69 months after launch on January 12, 1990 (STS-32). As a consequence of the delay, much more data had been gathered than planned. Post mission deintegration in SAEF-II (Spacecraft Assembly and Encapsulation Facility) at NASA/KSC.

The LDEF spacecraft is an open-grid, 12-sided, cylindrical structure. Length of cylinder = 9.1 m, diameter = 4.3 m. Gravity gradient stabilized spacecraft, with the longitudinal axis pointing toward the center of the Earth. Surface elements are fixed relative to LDEF's velocity vector. Magnetic actuators control the rotation around the longitudinal axis. The LDEF structure is configured with 72 equal-size rectangular openings on the sides and 14 openings on the ends (six on the Earth-facing end, and eight on the space-facing end) for mounting experiment trays. Total mass = 9700 kg.

¹³⁸⁵⁾ A. S. Levine (editor), "LDEF - 69 Months in Space, First Post-Retrieval Symposium," NASA Conference Publication 3134 (Part 1 and Part 2), Proceedings of a symposium sponsored by NASA at Kissimmee, Florida, June 2-8, 1991

Orbit: almost circular orbit, altitude = 477 km, inclination = 28.5°. At the time of retrieval the orbital altitude had decreased to 335 km.

Experiments: All LDEF experiments are self-contained in trays that are clamped to the facility structure. The LDEF has 72 peripheral and 14 end experiment trays. The 12 sides of the LDEF structure are numbered rows 1 through 12 in a clockwise direction when facing the end with the support beam (the Earth-facing end in orbit). The six longitudinal locations are identified alphabetically as Bay A through Bay F, starting at the end with the support beam. A tray location is designated by Bay and Row: A-1, B-5, F-8, etc. The Earth-facing end is designated by a G identifier; the locations have even-number clock-position identifications (G-12, G-2, G-4, G-6, G-8, and G-10). The space-facing end is designated by an H identifier, the locations also following a clock-position convention (H-12, H-1, H-3, H-5, H-6, H-7, H-9, and H-11).

The 57 LDEF experiments are extensively described in the references, only a few experiments follow with short descriptions. ¹³⁸⁶⁾

Table 414: Summary of LDEF experiment complement

Frecopa = French Cooperative Payload (PI: J. C. Mandeville, CERT/ONERA and others). Objective: determination of the number of impacts, and the size and chemical composition of the impacting cosmic dust and debris. A collection area of about 2000 cm² is exposed to the space environment (multilayer thin foil detectors). In addition a large variety of materials placed on the same tray (8500 cm²) is exposed.

SIMS = Chemical and Isotopic Measurements of Micrometeoroids by Secondary Ion Mass Spectrometry (PI's: E. Zinner Washington University, St. Louis, E. K. Jessberger, MPI Heidelberg, and others). Objective: chemical and isotropic measurements of micrometeoroids by secondary ion mass spectrometry. The experiment consists of 237 capture cells, each measuring 8.6 x 9.4 cm, located on three different rows. The target material (germanium wafers) is of very high purity, essential for the determination of the composition of the deposit. The SIMS technique is sufficiently sensitive to allow analysis of deposits that are 0.5 to 5 monolayers thick.

MAP = Multiple-Foil Micro-Abrasion Package (J. A. M. McDonnell, U. of Kent, UK). Objective: measurements of impactor velocity, density, angle of incidence, and chemical composition. A capture cell experiment. Each detector consists of two foils and a pure, polished stop plate to catch fragments of impacting particles. Deployment of MAP detectors on leading and trailing surfaces, and the surfaces normal to them, of LDEF.

UHCRC = A High Resolution Study of Ultra-Heavy Cosmic Ray Nuclei (PI: D. O'Sullivan, Dublin Institute for Advanced Studies, Ireland, and others). The experiment consists of 18 m² of thermal blankets used to collect a large number of meteoroid and debris impact records of various sizes.

J.9 LFC (LARGE FORMAT CAMERA)

Shuttle Missions (STS-2 and STS-41G) Nov. 12, 1981 and Oct. 5-13, 1984 (part of OSTA-3 payload)¹³⁸⁷⁾

Orbit (STS-41G): The Shuttle mission was flown at an inclination of 57° at three different altitudes. Orbits 001 - 022 were flown at an altitude of 352 km; orbits 023 - 036 were flown at an altitude of 272 km; orbits 037 - 128 were flown at an altitude of 225 km.

Application: High-resolution mapping camera. Cartographic mapping to achieve imagery at a scale of 1:50,000. LFC (408 kg) was used at China's request to try to obtain data on geological faults in Asia, among other tasks.

Sensor:

LFC = Large Format Camera (NASA Experiment, built by Itek Optical Systems (Div. of Litton Systems Inc.), Lexington, MA).

¹³⁸⁷⁾B.B. Schardt, B.H. Mollberg, "The Orbiter Camera Payload System's Large-Format Camera and Attitude Reference System," in Monitoring the Earth's Ocean, Land, and Atmosphere from Space, Volume 97, AIAA, 1985, pp. 684 - 709

Spectral range	400 - 900 nm
Focal length	305 mm
Image format	23 x 46 cm
Image scale	1 : 738 000
FOV	73.7° across track; 41.1° along track
Swath width	170 x 340 km (at 225 km altitude)

J.10 LITE (Lidar In-Space Technology Experiment)

LITE¹³⁸⁸) = Lidar In-Space Technology Experiment (NASA/LaRC, PI: M. P. McCormick). The LITE-1 payload was flown on a Shuttle mission (STS-64) from September 9-20, 1994.

Orbit: Altitude = 258 km; inclination = 57°; the orbit allows lidar measurements over both land and water. - Shuttle underflights by aircraft with laser sensors, including the Wallops Electra and P-3 aircraft, are undertaken around the world for LITE data correlation and verification.

Objective: Detection of stratospheric and tropospheric aerosols; measurement of the planetary boundary layer, cloud top heights, atmospheric temperature and density in the range from 10 to 40 km; regional and diurnal studies.

Laser transmitter module:		Telescope	
Output wavelengths	1064, 532 and 355 nm	Primary mirror	0.956 m diameter
Output energy	486, 460 and 196 mJoule	Secondary mirror	0.311 m diameter
Beam divergence	0.9, 0.6 and 0.6 mrad	Focal length	4.825 m
Beam quality	5.0, 4.5, 5.5 X-diff. limit.	Obscuration ratio	f/5.1
Pulse rate frequency	10/s (all wavelengths)		
Pulse width	27, 27, 31 ns		
Aft Optics (Nighttime measurements)		Aft Optics (Daytime measurements)	
Optical throughput	58, 49, 49 %	Interference filter transmission	50, 40, 12 %
Color filter BW	675, 265, 60 nm	Overall optical throughput	29, 20, 6 %
Detector quantum eff.	33, 14, 21 %	Interference filter BW	1, 0.3, 1 nm
		Detector quantum eff.	33, 14, 21 %
		FOV selectable all wavelengths	1.7, 3.4, 5.6 mrad and blocked
Signal Processing Electronics (all channels)			
Baseband amplifier bandwidth	2 MHz		
Filter characteristics	7 pole Bessel lowpass		
Digitizer resolution	12 bits		
Digitizing rate	10 MHz during sampling period		
Data sample period	660 μs		

Table 416: Instrument parameters of LITE

Sensor: The instrument consists of a nominal 1 m diameter telescope receiver, a three-color neodymium YAG laser transmitter, a boresight unit, and the system electronics. LITE makes extensive use of the Shuttle resources for electrical power, thermal control, and command and data handling. The laser transmits energy at three harmonically related wave-

¹³⁸⁸) "Lidar In-Space Technology Experiment (LITE): NASA's first In-Space Lidar System for Atmospheric Research," Optical Engineering, Jan. 1991, Vol. 30 No. 1 pp. 88-95

lengths into the atmosphere. The receiver collects the energy backscattered from the atmosphere and brings it into focus on three detectors.

Some experiments:

- Instrument measurements ‘troposphere’: aerosol backscatter cross-section; aerosol scattering ratio; Planetary Boundary Layer (PBL) height; PBL optical depth.
- Instrument measurements ‘clouds’: height; fractional cloud cover; reflectance/albedo; optical depth.
- Instrument measurements ‘Stratosphere’: density and temperature profiles to 40 km; aerosol backscatter cross-section; aerosol scattering ratio. These measurements were made at 532 nm and 355 nm wavelength only.
- Study of a wide variety of phenomena on regional and global scales.

J.11 MAPS (Measurement of Air Pollution from Satellites)

MAPS is a NASA/LaRC Shuttle payload with the objective to measure (nearly) global tropospheric carbon monoxide (CO) distributions in the middle troposphere in order to evaluate CO sources and chemistry, and to determine the seasonal variations of this key atmospheric trace gas.

The MAPS instrument is a gas filter correlation radiometer consisting of an electro-optical sensor, an electronics module, a digital tape data recorder, and an aerial camera. MAPS is mounted onto MPESS (Multi-Purpose Experiment Support Structure) in the forward end of the Shuttle cargo bay. The instrument makes nadir-viewing measurements from Shuttle orbits of approximately 220 km altitude.¹³⁸⁹⁾

The electro-optical sensor incorporates two gas cells, one containing 350 hPa of CO and another containing 149 hPa of N₂O; their corresponding detectors; a direct radiation detector; an external balance and gain check system, and an internal balance system.

MAPS sensor	Gas filter correlation radiometer
Spectral band	2080 to 2220 cm ⁻¹ (4.5 - 4.8 μm)
Resolution (sensitivity)	1.7 10 ⁻⁷ W cm ⁻² sr ⁻¹ noise-equivalent radiance in the radiometer channel 5.7 10 ⁻⁹ W cm ⁻² sr ⁻¹ noise-equivalent radiance in the difference channel
Swath width	Footprint is 20 km at ground surface (corresponds to spatial resolution)
Data rate	43 bit/s (on-board recorded and downlinked during flight)

Table 417: Specification of some MAPS parameters

MAPS measures the absorption lines of CO and N₂O of incoming radiation. The spectrum is split into three beams; one beam passes through a cell containing CO and falls onto a detector - the CO gas cell acts as a filter. A second beam falls directly onto a detector. The observed signal differences are used for CO determination in the altitude range of 0-18 km. The third beam of the incident radiation passes through a cell containing N₂O and is measured by another detector. Again, the N₂O gas cell acts as a filter for the effects of N₂O present in the atmosphere. Since the global distribution of N₂O is well known, the measured values of N₂O may be used as an indicator for the presence of clouds in the field of view and to correct the simultaneous CO measurement for systematic errors.

The aerial camera mounted next to the MAPS electro-optical head provides information on cloud cover and terrain over which the sensor data are gathered.

MAPS was first flown on STS-2 (November 12.-14, 1981) as part of the OSTS-1 payload, then on STS-13 (October 5 -13, 1984) as part of the OSTA-3 payload. These flights revealed longitudinal variations in CO distributions and identified biomass burning in the Southern

¹³⁸⁹⁾Information provided by V. Connors and D. O. Neil of NASA/LaRC

Hemisphere as a major global CO source (equal in magnitude to the amount of CO generated in the Northern Hemisphere by fossil fuel combustion). MAPS flew on STS-59 (April 1994) and STS-68 (October 1994, see Table in chapter O.17).

J.12 MOMS-01 (Modular Optoelectronic Multispectral Scanner)

MOMS is a German imaging payload/experiment of DLR, University of Munich, and others, built by MBB of Munich). MOMS-01 was a Shuttle payload (mounted on SPAS = Shuttle Pallet Satellite) on two missions (STS 7: June 18, 1983, a 6-day mission; and STS-41B): Feb. 3, 1984, an 8-day mission).

The MOMS-01 instrument consists of five major elements, mounted onto the carbon-fiber structure of the SPAS-01 free-flyer.

- 1) The optical module (scanner head) with four objectives, eight arrays, and associated shutters. Each module, representing one spectral band, consists of filters, dual-lens optics, four CCD detector arrays, and preamplifier electronics.
- 2) A power box for overall power conditioning and thermal and shutter circuitry
- 3) A logic box for all sensor function control (including real-time correction, and formatting of the source data stream from the optical module)
- 4) A HDDT (High Density Digital Tape) recorder (model: Bell&Howell MARS-1428 LT-3B) for digital data storage (72 Gbit capacity/tape)
- 5) A pressurized container for the recording system.

MOMS-01 is a two-channel system which uses the spectral bands of 575 - 625 nm for land observations, and 825 - 975 nm for vegetation detection. A double optical system (focal length = 237.2 mm, relative lens aperture = 1:3.5) is used per band for illuminating the CCD array consisting of four groups with a total length of 6912 pixels (16 μm pixel size). Swath width = 140 km (FOV=26.2°), spatial resolution (pixel size on ground) = 20 x 20 m (IFOV=67.2 μrad).^{1390) 1391) 1392) 1393)}

Application: Observation of the Earth with configurable sensors. Imaging of different ground targets with low-to-high contrast and albedo (arid regions, regions with dense and sparse vegetation coverage, coastal zones, mountainous terrain, open ocean islands) to demonstrate the instrument capabilities for thematic mapping.

Orbit: Shuttle orbit, inclination = 28.5°; STS 7 = 292 km altitude; STS-41B = 289 - 300 km altitude; swath width = 140 km.

MOMS-01 is regarded an early imaging charge-coupled device (CCD) instrument operated in a civilian spaceborne application. CCD pushbroom type: Reticon CCPD 1728 (EG&G Reticon, Sunnyvale CA). Each CCD line array has 1728 detectors. Scan line extension beyond the one CCD array is achieved with a dual-lens configuration, linking all four CCDs to a total scan line of 6912 pixels; data quantization = 7 bits, data rate = 40 Mbit/s; the data were recorded on-board. The MOMS-01 missions yielded 450 individual scenes for thematic evaluation. The total experiment time was 26.5 minutes on STS-7, and 30 minutes on STS-41-B.

Note: Both optical systems observed in reality the entire swath width in parallel (not the split arrangement as shown in Figure 240). This double exposure concept was simply need-

ed to provide a seamless linkage of all four CCD detector arrays for each spectral band across the swath.

Figure 240: MOMS-01 schematic imaging configuration of CCD arrays

J.13 MOMS-02 (Modular Optoelectronic Multispectral Scanner)

MOMS-02 on the Spacelab D-2 Mission (STS-55, 10 day flight). Launch: April 26, 1993. MOMS-2 is an advanced version of MOMS-01 (PIs: F. Lanzl, F. Ackermann, J. Bodechtel). The D-2 orbit had an inclination of 28.5° and an altitude of 296 km (this means: observation of equatorial regions).

The data are used in the following applications: Land cover (vegetated areas: land use, biomass estimation; unvegetated areas: lithology, mineral prospecting, tectonic investigations); geomorphology, ecology, basic research in the spectral signatures of rocks, soil, vegetation, etc. ¹³⁹⁴⁾ ¹³⁹⁵⁾ ¹³⁹⁶⁾

Objectives:

- Stereoscopic visual observation (high degree of interpretability)
- Provision of high-quality topographic regional maps (scale 1:50000) and digital terrain models (<5 m pixel size on ground)
- Test of a digital photogrammetric observation technique and processing system (prototype)
- Correlation of high-resolution panchromatic data with multispectral data.

Experiment: a) triple-stereoscopy, b) along-track-stereoscopy (forward and backward tilt), c) high-resolution imagery, d) multispectral observation (refined modelling of MS classification), e) combination of stereo and multispectral imagery.

The MOMS-02 payload has a total of five optical systems: three are used for stereoscopic imagery, two are employed for multispectral imagery, one is used for high-resolution data. Focal length (f): 220 mm (ch. 1-4); 237.2 mm (ch. 6,7), 660 mm (ch. 5). Quantization: 8 bit with seven gain steps (uncompressed for MS and stereo, 6 bit compressed for stereo). Seven variable observation modes of different band combinations are defined.

Channel	Mode	Orientation	Bandwidth	Ground Pixel	IFOV	Swath Width
1	MS	nadir	449-511 nm	13.5 m x 13.5 m	45.45 μ rad	78/43 km

J.14 SAC (Satélite de Aplicaciones Científicas)

The SAC satellite program of CONAE (Comisión Nacional de Actividades Espaciales), the Space Agency of Argentina, started in 1994 with the approval of the National Space Program by the government of Argentina. CONAE devised a plan, taking into account the available resources, and came up with a policy of international cooperative missions for an optimum in return of the investment. SAC is a key element in this program. ¹³⁹⁸⁾

Satellite	Launch Date	Prime Mission Objective	Partners in Mission
SAC-B	Nov. 4, 1996 (launch failure)	Science	USA, Brazil, Italy
SAC-A	Dec. 4, 1998 (STS-88 launch)	Technology	USA
SAC-C	Nov. 21, 2000 from VAFB (secondary payload to EO-1)	Earth observation	USA, Denmark, Brazil, Italy, France

Table 420: Chronological overview of CONAE's SAC program

J.15 SAC -A (Satélite de Aplicaciones Científicas-A)

The SAC satellite program of CONAE (Comisión Nacional de Actividades Espaciales), the Space Agency of Argentina, started in 1994 with the approval of the National Space Program by the government of Argentina. CONAE devised a plan, taking into account the available resources, and came up with a policy of international cooperative missions for an optimum in return of the investment. SAC is a key element in this program.

¹³⁹⁸⁾D. Caruso, "CONAE's Satellite Missions," IAA 2nd International Symposium on Small Satellites for Earth Observation, Berlin, April 12-16, 1999, pp. 375-381

SAC-A is a CONAE/NASA demonstration mission, an Argentine-built satellite, with the objective to test and characterize the performance of new equipment and technologies which may be used in future operational or scientific missions of CONAE. NASA provides the launch and the Hitchhiker equipment for SAC-A. S/C operations are performed by CONAE from Argentina.¹³⁹⁹⁾

Satellite	Launch Date	Prime Mission Objective	Partners in Mission
SAC-B	Nov. 4, 1996 (launch failure)	Science	USA, Brazil, Italy
SAC-A	Dec. 4, 1998 (STS-88 launch)	Technology	USA
SAC-C	Nov. 21, 2000 from VAFB (secondary payload to EO-1)	Earth observation	USA, Denmark, Brazil, Italy, France

Table 421: Chronological overview of CONAE's SAC program

The SAC-A payload consists of the SAC-A satellite installed in a canister equipped with a Hitchhiker Pallet Ejection System (PES) and Hitchhiker Motorized Door Assembly (HMDA). For the STS-88 mission, SAC-A shared a common Hitchhiker Avionics Unit with MightySat I of AFRL (Kirtland AFB, NM). The SAC-A design life is six months. S/C mass = 64 kg, power = 36 W EOL. SAC-A is three-axis stabilized using momentum wheel, magnetic coils and a three-axis magnetometer. Attitude is measured by a DGPS receiver and an assembly of Si cells as a coarse sun sensor. A launch of STS-88 took place on Dec. 4, 1998. SAC-A was deployed on Dec. 14.

Communications: TT&C via S-band with backup systems for telecommand (TC) in VHF and telemetry (TM) in UHF. Note: The redundant TC/TM system is also being used in a whale tracker experiment.¹⁴⁰⁰⁾

Orbit: near-circular orbit, altitude = 390 km, inclination = 51.6°.

Sensor/experiment complement (technology demonstration):

DGPS (Differential GPS Receiver), PI: R. Alonso. The objective is to provide real-time autonomous attitude measurements for the satellite, ultimately simplifying the amount of ground processing required to control an orbiting satellite. Special algorithms were developed for non-nadir pointing directions of the S/C.

CPC (Commercial Panchromatic Camera), PI: J. Yelos. The objective is to test the performance of a CCD camera for Earth imaging.

Solar cell experiment (PI: J. Duran). Use of an Si cell assembly for power generation and parallel use as a coarse sun sensor. In addition, a CONAE-developed deployment mechanism was tested for the solar panels.

J.16 SHIMMER (Spatial Heterodyne Imager for Mesospheric Radicals)

SHIMMER is a high-resolution UV interferometer, a cooperative development of NRL (Naval Research Laboratory) in Washington DC, UWM (University of Wisconsin at Madison), and St. Cloud State University in St. Cloud, Minnesota. The primary science objective is to acquire global profiles of hydroxyl (OH) in the upper stratosphere and mesosphere by measuring its resonance fluorescence in the UV. The flight of SHIMMER as a Shuttle mid-deck payload will serve as a proof-of-concept of this new and powerful technique, facilitating future high-resolution imaging instruments that are small, rugged, light-weight and

¹³⁹⁹⁾D. Caruso, "CONAE's Satellite Missions," IAA 2nd International Symposium on Small Satellites for Earth Observation, Berlin, April 12-16, 1999, pp. 375-381

¹⁴⁰⁰⁾<http://sspp.gsfc.nasa.gov/current.html>

have no moving parts. SHIMMER is planned to be flown on Shuttle in the time frame of 2002. 1401) 1402) 1403) 1404)

Figure 243: Photo of the SHIMMER instrument assembly

Parameter	Description
Type of measurement	Ultraviolet solar resonance fluorescence
Geophysical parameters observed	OH, Rayleigh scattering, Mie scattering
Viewing geometry	Earth Limb
Time required for a vertical image	2 seconds
Spectral coverage	307-310 nm
Interference filter	2.3 nm FWHM centered at 308.9 nm
Entrance optics	500 mm focal length telescope
Exit optics	7 element relay system
Detector (frame transfer device)	CCD array of 1024 x 1024 pixels at 24 μ m
Gratings: Clear aperture	20 mm x 20 mm
Groove density	1200 lines/mm
Littrow angle	10.7°
Littrow wavelength	307 nm
Field widening prisms: Clear aperture	22 mm x 22 mm
Wedge angle	13.02°
Incident angle	8.73°
Exit angle	10.7°
Beamsplitter: Clear aperture	28 mm x 28 mm

1401) Note: The technology of spatial heterodyne spectroscopy was developed by Fred Roesler and John Harlander of UWM in 1990. SHIMMER observations represent the first spaceborne demonstration of this technology.

1402) Information provided by Robert R. Conway and Christoph R. Englert of NRL

1403) <http://uap-www.nrl.navy.mil/shimmer/shimmer.htm>

1404) J. Harlander, H. T. Tran, F. L. Roesler, K. P. Jaehnig, et al., "Field-Widened Spatial Heterodyne Spectroscopy: correcting for Optical Defects and New Vacuum Ultraviolet Performance Tests," EUV, X-Ray and Gamma-Ray Instrumentation for Astronomy V, SPIE Proceedings 1994, Vol. 2280, p. 310-319

Parameter	Description
FOV (Field of View)	10° at gratings, 2.3° x 2.3° on sky
Spectral resolution	58 MB, or 0.0058 nm (resolving power of 53,000)
Non-aliased spectral range	2.95 nm
Achieved spectral range	Filter limited
Instrument mass, power, size	22 kg, 27 W (with cold finger), 52 cm x 42 cm x 23 cm
Image rate	150-750 images per orbit

Table 422: Summary of basic instrument specifications

The major instrument elements are the telescope, the relay optics, the interferometer, and the CCD camera. The telescope images the sunlit limb scene onto the gratings. The relay optics create an image of the fringe localization plane (gratings) at the CCD. The optical elements of the interferometer are held by a Vascomax steel structure which allows precise positioning of each element. Every pixel row of the CCD, parallel to the horizon, contains the spectral information (interferogram) for the corresponding tangent altitude of the FOV (Field of View). The rows (32 rows) are averaged to yield a vertical resolution of about 2.2 km. The SHIMMER middeck instrument is controlled by a laptop (see also O.11).

J.17 SLA (Shuttle Laser Altimeter)

SLA is a NASA/GSFC designed and developed instrument (within the MTPE program), a pathfinder for future operational space-based laser remote sensing devices and lidar over land surfaces, which is flown as a 'hitchhiker payload' on Shuttle flights. A schedule of 4 flights has been planned for a continuously improving the SLA sensor package. The first flight (SLA-1) took place on STS-72 (January 11-20, 1996). The second flight, SLA-2, was on STS-85 (Aug. 7-19, 1997). There are plans to fly a small-footprint, ultra high pulse repetition rate version of SLA-2 (namely SLA-3) in late December 1998 as part of the STS-96 mission (or on SRTM).

SLA has three major objectives:

- To provide an in-space engineering testbed for future spaceborne laser altimeters
- To acquire samples of land topography and vegetation data
- To measure cloud and aerosol layers in the atmosphere

J.17.1 SLA-1

The SLA instrument package consists of the LAC (Laser Altimeter Canister) and ASC (Altimeter Support Cannister) which are interconnected. The LAC is equipped with an opening motorized door assembly with an optical window. LAC contains a laser transmitter and a concave mirror/detector which collects the reflected laser radiation. The ASC contains control, telemetry, telecommand and power conditioning electronics. The SLA instrument consists of a 38 cm telescope, a diode-pumped Nd:YAG laser transmitter (Q-switched), an altimeter receiver electronics package, and a 250 MHz waveform digitizer coupled to the altimeter receiver for capturing the backscattered echoes from the interaction of short duration laser pulses (about 8 ns duration) with the ground surface.

The SLA altimeter sends out a series of short laser pulses and measures the time-of-flight and the spreading of the laser pulse by the Earth's surface. The pulse time interval measurement is to a precision of about five ns. Recorded is also the temporal shape of the laser echo from the Earth's surface for interpretation of surface height distribution, referred to as TVR (Total Vertical Roughness) within the 100 m diameter footprint. For example, tree heights can be determined by measuring the characteristic double-pulse signature that results from a separation in time of laser backscatter from tree canopies and the underlying ground.

SLA-1 demonstrated the viability of surface lidar sensing from Earth orbit, obtained a high-quality (meter-level accuracy) data set on ocean and land topography, and was a major factor in the selection of VCL (Vegetation Canopy Lidar) for the first ESSP (Earth Systems Science Pathfinder) mission. Tree height data sets obtained on SLA-1 were the first measurements from space that can be tied directly to remote sensing of above ground biomass and forest canopy architecture. Only those echoes that were unsaturated were used to derive TVR values, which represent a total canopy assemblage height in forested areas where the local topography is of low slope ($<3^{\circ}$).

J.17.2 SLA-2

Based on the SL-1 experience (saturation of the link margin over unvegetated areas due to the enormous dynamic range changes of backscattered signal strengths), the SLA-2 instrument was modified to include an innovative VGA (Variable Gain state Amplifier) system in the altimeter receiver chain. This VGA permits the SLA ground operator to control the signal intensity from the silicon avalanche diode detector to the waveform digitizer to preclude saturation.

SLA-2 provided direct measurements of the height of clouds, and acquired profiles of land and surface vegetation canopies over continental and island targets with a 1-10 m rms surface elevation accuracy and sub-kilometer spatial resolution. SLA-2 also measured the complex shape of laser pulse echoes from land and vegetation with sub-meter vertical resolution and obtained grids of altimetry data for major topography study regions, including the continental United States. Other primary targets for SLA-2 surface research included: the Amazon Basin in Brazil; the Canadian Boreal Forest; the Kamchatka Peninsula; the Patagonian ice fields; West Africa Tropical Forests; high latitude steppe deserts in China; large inland seas including the Caspian and Aral Seas; large oceanic islands, including Tasmania, the Falkland islands, and Madagascar; the Northern Sahara Sand Seas (Grand Ergs) and the Mississippi Delta region of the U.S.

J.18 SPARTAN (Shuttle Pointed Autonomous Research Tool for Astronomy)

A continuous NASA/GSFC program which started in the early 1980s. SPARTAN is a Shuttle-deployed retrievable free-flyer platform (an autonomous sub-satellite, three-axis stabilized) providing short-term LEO observation opportunities for instrumentation in various disciplines and fields of applications, such as astronomy, remote sensing, and technology demonstrations. ¹⁴⁰⁵⁾ ¹⁴⁰⁶⁾

The Spartan spacecraft is a small, rectangular, free-flying vehicle, measuring roughly 1 m x 1.25 m x 1.5 m. It is released from the shuttle and picked up after several days of conducting its experiments. Several SPARTAN platform configurations have been built so far.

Mission duration	2-5 days, depending on mission requirements
Deployed mass	up to 1400 kg
Platform dimensions	Mission dependent (up to a length of 2.3 m) a rectangular pallet
Power	Self-contained subsystem, 28±5 VDC, 3 A max, 7 kWh available
Instruments	Mission-dependent
Attitude control	Three-axis stabilized with cold gas thrusters, max slew rate : 1°/s ²
Thermal control	Active and passive, SPARTAN electronics limited to 0° - 50°C
Data rates	Mission dependent
Data storage	Onboard recorder

Table 423: Some characteristics of the SPARTAN platform series 200

¹⁴⁰⁵⁾ SPARTAN Capabilities Statement, SP515, 1993, NASA/GSFC

Shuttle Flight	Payload	Comments
STS-51G, June 17 - 24, 1985	2 X-ray proportional counters	SP-A (mass of 1100 kg)
STS-51L, Jan. 28, 1986	Challenger accident	SP-Halley, 203, (UV-spectrometer)
STS-56, April 8 -17, 1993	UVCS, WLC, solar physics	SP-201-1, (mass of 1360 kg)
STS-64, Sept. 9 - 20, 1994	UVCS, WLC, solar physics	SP-201-2, reflight of SP-201-1 timed to coincide with Ulysses south polar pass
STS-63, Feb. 3 - 11, 1995	Far UV imaging spectrograph (FUVIS) of NRL	SP-204, galactic dust clouds
STS-69, Sept. 7-18, 1995	UVCS, WLC, solar physics	SP-201-3, mass = 1136 kg, reflight of SP-201-1 timed to coincide with Ulysses north polar pass
STS-72, Jan. 11 - 20, 1996	REFLEX, GADACS, SE-LODE, SPRE	SP-206 OAST flyer, technology experiments
STS-77, May 19 - 29, 1996	Inflatable Antenna Experiment	SP-207/IAE
STS-87, Nov 19 - Dec. 5, 1997	UVCS, WLC, TEXAS, VGS, solar physics	SP-201-4, reflight of SP-201-1
STS-95, Oct. 29 - Nov. 7, 1998	UVCS, WLC, TEXAS, VGS, solar physics	SP-201-5

Table 424: Overview of SPARTAN flights on Shuttle

J.18.1 SPARTAN-1

Spartan-1 (also referred to as Spartan-101), as the first of the series (launch June 17, 1985 on STS-51G), was intended to demonstrate the low-cost approach and its ability to achieve the desired technical performance in the STS environment. Pointing and stabilization were achieved by an attitude control system capable of three-axis stabilized pointing to any target within ± 3 arcmin. The scientific objective of the spacecraft was to investigate the photon emission processes in clusters of galaxies and to explore the center of our galaxy. The X-ray detector had an energy range of 1 to 12 keV, scanning its targets (various cosmic sources) with narrowly collimated ($5 \text{ arcmin} \times 3^\circ$) gas scintillation proportional counters (two identical counters, each with an effective area of 660 cm^2). Counts were accumulated for 0.812 s into 128 energy channels. The energy resolution was 16% at 6 keV. - Total mass = 1,100 kg.

J.18.2 SPARTAN-Halley

This spacecraft failed when Space Shuttle Challenger exploded on launch (Jan. 28, 1986, STS-51L). Same platform and capabilities as SPARTAN-1. The main objective of this spacecraft was to obtain UV spectra of the coma and tail of Comet Halley in January 1986 shortly before its perihelion.

J.18.3 SPARTAN-201

The SPARTAN-201 series (five missions) is dedicated to NASA's solar physics program. Scientific data are collected during each mission using a tape recorder and, in many cases, film cameras. There is no command and control capability after deployment. Power during the deployed phase of the mission is provided by on-board batteries, and attitude control is accomplished with pneumatic gas jets. Retrieval of the SPARTAN platform at the end of each mission by the Shuttle.

- SPARTAN-201-1 (STS-56, April 8 -17, 1993, mass of 1360 kg). Objective: monitoring of solar-wind acceleration by observing the hydrogen, proton and electron temperatures and densities, and the solar-wind velocities in a variety of coronal structures at locations from 1.5 to 3.5 solar radii from the sun.
UVCS (Ultraviolet Coronal Spectrometer) of SAO (Smithsonian Astrophysical Laboratory, Cambridge, MA). Measurement of line profiles/intensities of Lyman-alpha

(1215 Å) and intensities of the Oxygen VI lines (1031.9 and 1037.6 Å). The measurements are used to determine velocities, temperatures and densities of the coronal plasma in the regions observed.

WLC (White-light Coronagraph) of GSFC, built by NCAR. Measurement of polarization/ intensity of white-light corona. The measurements allow determination of electron densities in the coronal features observed. The WLC instrument is the most recent version of the spaceborne externally occulted Lyot coronagraph. WLC uses a rotating half-wave plate, a linear polarizer, a serrated occulting disk for occulting the disk at 1.25 solar radius, and a linear, wide dynamic range detector CCD camera to measure the intensity and polarization of broad band visible coronal radiation. The distance between pixel centers of the CCD camera is 22.5 arcseconds. Observations out to 6 solar radii from sun-center were obtained within a sector of 60° in width centered on the UVCS radial scan capability.

- SPARTAN-201-2 (STS-64, Sept. 9-20, 1994). Reflight of UVCS and WLC to study the solar wind. The SPARTAN platform flew about 80 km behind the Shuttle orbit for its measurement mission..
- SPARTAN-201-3 (STS-69, Sept. 7-18, 1995, mass = 1136 kg). Reflight of UVCS, WLC and an X-Ray instrument to study corona and galactic clusters during its two-day mission.
- SPARTAN-201-4 (STS-87, Nov 19 - Dec. 5, 1997) S/C mass = 1350 kg. The 201-4 mission was coordinated with the SOHO mission. Instruments: UVCS, WLC, TEXAS, VGS. All S/C operations were preprogrammed. No RF links until addition of TEXAS on SP201-04. Power supplied by Silver-Zinc batteries, 18 kWh/ 28 VDC.
TEXAS (Technology Experiment Augmenting Spartan). TEXAS is an S-band communication system baselined for future Advanced Spartans. The system is used to allow real-time downlink of solar images and uplink of pointing corrections. The WLC instrument was modified for solar image downlink and pointing command uplink via interface to TEXAS.
VGS (Video Guidance Sensor), an MSFC experiment with the objective to test the ranging and attitude measurement system being developed for the RLV automated docking system.
- SPARTAN-201-5 (STS-95, Oct. 29 - Nov. 7, 1998). Reflight of UVCS.

J.18.4 SPARTAN-204

SPARTAN-204 (STS-63, Feb. 3 - 11, 1995). Objective: observations of galactic dust clouds using **FUVIS** (Far UV Imaging Spectrograph), of NRL in the DoD Space Test Program (STP). FUVIS obtained far ultraviolet spectroscopy of diffuse sources, both natural and man-made [Shuttle surface glow and plume emissions from the RCS (Reaction Control System) thrusters]. - In addition to the FUVIS operations, Spartan 204 supported two space station Detailed Test Objectives (DTO). For the first DTO, Spartan 204 was fitted with six laser retro-reflectors to aid in testing the tracking control system.

J.18.5 SPARTAN-206

SPARTAN-206 (STS-72, Jan. 11 - 20, 1996). OAST (Office of Aeronautics and Space Technology) free-flyer with REFLEX, GADACS, SELODE and SPRE.

REFLEX (Return Flux Experiment). A technology experiment designed to verify computer generated contamination models used during design, fabrication, and operation of payloads. The primary objective of REFLEX is to investigate one important mechanism, referred to as molecular backscattering or “return flux,” associated with on-orbit molecular

contaminant transport (study of mixing contaminants with residual molecules of the atmosphere that are reflect back onto the S/C surface).

REFLEX consists of the following equipment: a mass spectrometer; three Temperature-Controlled, Quartz Crystal Microbalances (TQCMs); two electronics boxes; a pneumatics system; and a support structure. The spectrometer, built by the Physics Department at the University of Minnesota, is a Mattauch-Herzog type, and is equipped with an energy analyzer. It will measure the species, velocities, and densities of molecules in the Earth's residual atmosphere as well as return flux molecules from the onboard inert gas sources of Argon and Krypton. The shuttle's Low Earth Orbit (LEO) ensures that the atmospheric density is ample to provide sufficient backscattering of the molecules. The three TQCMs are placed on the exterior of the experiment to study contamination buildup and atomic oxygen erosion; one of the TQCMs is uncoated and the other two are coated, one with a film of carbon and one with a material called Kapton.

GADACS (GPS Attitude Determination and Control System).¹⁴⁰⁷⁾ A NASA/GSFC prototype instrument. The prime objective is to demonstrate GPS attitude measurement technology in LEO (derivation of position, velocity, time, and attitude). GADACS used two TANS Vector GPS receivers (of Trimble Navigation, Sunnyvale, CA), along with an array of four L-band patch antennas (and pre-amplifiers) mounted onto a special plate inside of SPARTAN, and DRIRU-II (Dry Rotor Inertial Reference Unit), a high precision gyroscope developed by Teledyne (for proof of GPS measured attitude). GPS data were recorded along with gyro measurements for verification and calibration of the GPS attitude measurements.¹⁴⁰⁸⁾ Note: GADACS was not able to perform attitude determination because it did not lock onto the four GPS signals necessary to obtain a position fix (a required first step to obtain attitude solutions).

SELODE (Solar Exposure to Laser Ordnance Device). The major objectives of SELODE are to verify if natural, low-orbit, solar energy can inadvertently fire laser pyrotechnics, and characterize how the LEO environments effect the reliability and/or performance of the pyrotechnics after flight. SELODE is the first experiment to test these devices on a shuttle mission. SELODE consists of four different Laser Initiators (LI), one kind of laser detonator (LD), and two Laser Diode Firing Units (LDFU). The initiators and detonators are exposed to sunlight three different ways: magnified solar exposure, direct solar exposure, and no solar exposure at all.

SPRE (SPARTAN Packet Radio Experiment), developed by the University of Maryland. Objectives: Test of GPS and packet radio based tracking system using a LEO satellite. Provision of an educational tool. SPRE is an amateur radio communications experiment. SPRE relays ground station positions and transmits telemetry containing the GPS location of the spacecraft and housekeeping data. The GPS data is generated by another Spartan experiment and sent to SPRE via a serial connection. Special software called APRtrak is used at SPRE ground stations to provide a mechanism to plot the positions of stations and objects world-wide using SPRE transmissions.

The SPRE experiment is constructed by integrating several specific subsystems. Some of these subsystems were designed and built by students, while other subsystems were purchased as a unit (such as the radios). The SPRE hardware consists of an electronics box and two antenna arrays. The electronics box contains the SPRE computer, packet terminal node controller (TNC - radio modem), and two radios. The computer receives GPS data from GADACS and communicates with the REFLEX mass spectrometer. The two antennas arrays are mounted on opposite sides of the spacecraft above the thermal louvers.

J.18.6 SPARTAN-207

SPARTAN-207/IAE (Inflatable Antenna Experiment) on STS-77, May 19 - 29, 1996. The objective was to validate and characterize the mechanical function and performance of a 14 m diameter inflatable deployable antenna reflector structure in orbit. The payload consisted of two main pieces of hardware: the SP207/IAE (Spartan free flyer and experiment) and the Spartan Flight Support Structure (SFSS), which held the Spartan S/C in the Space Shuttle Cargo Bay. The struts are attached to the Spartan spacecraft, and the entire assembly was deployed and then recovered by the Space Shuttle. Once in low-Earth orbit, the Spartan became a platform for the antenna that, when inflated in space, was roughly the size of a tennis court. After inflation, an optical system surveyed the antenna and measured the accuracy of the surface at a variety of internal pressures and thermal conditions.

The antenna experiment was conducted in order to gather more definite information on other galaxies and on Earth's environment, there is a need for larger and more reliable space antennas.

J.18.7 SPARTAN-250 Carrier System

The Spartan 250 platform is an upgrade to the existing Spartan 200 series carrier. It is (Spartan 250) a medium sized, low cost, reusable, 3-axis stabilized, freeflying carrier that provides extended mission flight opportunities for a variety of scientific studies in low Earth orbit. Spartan 250 is designed to be a multipurpose carrier system which evolves in response to each mission. Spartan 250 is taken into orbit by the Shuttle, deployed, operated via ground commands as a sub-satellite, retrieved on the same mission, and returned to the ground for subsequent reuse. Because of the absolute necessity to recover the hardware, redundancy and back-up systems have been incorporated to assure this recovery.

Experiment mass	Up to 450 kg
Experiment power	Up to 175 W (orbital average), 245 W (peak)
Experiment power voltage	Unregulated +7/-6 VDC
Guidance, navigation, control	Three-axis stabilized (solar, stellar, nadir, zenith, and limb)
Experiment data storage	Up to 3 GByte
Data interfaces (experiment-S/C)	MIL-Std-1553, Up to 200 kbit/s for total experiment complement
Data RF communications	Up to 2.25 Mbit/s downlink in S-band, 30 Mbit/s in X-band

Table 425: Some characteristics of the SPARTAN platform series 250

J.18.8 SPARTAN-251

The XSS-10 (Experimental Spacecraft System) mission is a joint effort between AFRL and NASA (GSFC, JSC, KSC) in pursuit of space operations.

The SPARTAN 251 carrier for the XSS-10 mission consists of the carrier previously flown on the SPARTAN-204 and -207/IAE missions with significant enhancements. The SPARTAN carrier is upgraded from the 200-series carrier to the SPARTAN-250 series configuration with the addition of an RF command and telemetry link and an on-board computer.

J.18.9 SPARTAN-401

The SPARTAN-400 is design concept for a standardized, reusable bus that may be deployed from the Shuttle cargo bay and retrieved on a later Shuttle flight. The carrier itself is focused on providing experimenters with standard interfaces, capabilities, services and physical accommodations satisfying a wide range of requirements. The spacecraft provides a three-axis stabilized platform that supports solar or stellar inertial fine pointing, as well as nadir, offset nadir, and ground track.

As an option, the Spartan 400 spacecraft has the capability of incorporating a propulsion system. This system widens the range of mission orbit altitudes available from the Shuttle launch from 300 km to over 600 km. Higher apogee altitudes are possible with eccentric orbits.

J.19 SIR-A (Shuttle Imaging Radar)

SIR-A = Shuttle Imaging Radar with Payload A. A JPL payload on the Shuttle. Launch: Nov. 12, 1981 (duration: 3 days, second orbital test flight of the Shuttle Columbia, STS-2). The science payload aboard this Shuttle flight was referred to as OSTA-1 (Office of Space and Terrestrial Applications).

The success of the Seasat SAR prompted the first flight of a SAR on the Shuttle. The Shuttle was seen as an opportunity to progressively develop and fly increasingly more complex radar systems for short missions, allowing the hardware to be returned to Earth for reuse on follow-on missions.

SAR Application: Land use, geology, hydrology, forestry, and mapping.

Orbit: Shuttle orbit, 38° inclination, 257 km altitude, SAR swath width: 50 km.

Sensor complement:

SAR = Synthetic Aperture Radar in HH Polarization; L-band (freq. = 1.28 GHz); fixed look angle (incidence angle) = 47 degrees; pixel size = 40 x 40 m; optical data only.

Note: The system characteristics for SIR-A, were defined primarily by the spare parts available from the Seasat SAR. SIR-A, therefore, had essentially the same design as Seasat: L-band wavelength and HH polarization. The antenna look angle was fixed at 47° in order to optimize geologic mapping in topographically rough terrain. From the shuttle altitude, the 2.16 m x 9.4 m antenna (spare Seasat SAR antenna panels were used) provided a 50 km swath. The antenna was mounted in a fixed open position on the starboard side of the payload bay, with the long axis parallel to the velocity vector when the shuttle was flying nose-forward. This allowed imaging only on the northern side of the shuttle nadir track. Because simplicity was a requirement for SIR-A, the data were recorded optically in the payload bay and were not accessed until the film was off-loaded after landing. The optical recorder on which the data for SIR-A were recorded was a spare from the Apollo 17 Lunar Sounder Experiment and was 14 years old when flown on SIR-A. ¹⁴⁰⁹⁾

Data: Image size: 50 km x length of active orbit. Optical image correlation, transparencies and photos available. Transmission: no transmission, optical recording on-board.

The SIR-A mission provided much improved image data for geologic analyses, since they are relatively free of the layover distortion that accompanied Seasat images of high-relief regions. SIR-A SAR data also led to the discovery of buried and previously uncharted dry river beds beneath the Sahara Desert in Sudan and Egypt. This demonstrated the ability of a L-band radar to penetrate up to several meters in hyper-arid sand sheets.

Other remote sensing instruments of the OSTA-1 payload were: (see also LFC in J.9)

SMIRR¹⁴¹⁰⁾ = Shuttle Multispectral Infrared Reflectance Radiometer (NASA/JPL experimental instrument). SMIRR was also part of the science payload (OSTA-1)

Objectives of SMIRR: a) obtain radiometric measurements from orbit of land surfaces in 10 wavelength channels (rock and mineral identification). b) determine the spectral re-

¹⁴⁰⁹⁾J. Way, "Spaceborne Imaging Radar – From Remote Sensing Science to Earth Science Questions," Launchspace Magazine, Volume 3.04, Aug/Sep 1998

¹⁴¹⁰⁾Manual of Remote Sensing, Second Edition, American Society of Photogrammetry, 1983, pp. 1707-1710

sponse of known rock types under different climatic conditions worldwide; c) establish the utility of orbital narrow-band radiometry in the 2.0 to 2.5 μm region; d) establish the requirements for future narrow-band imaging systems.

OCE = Ocean Color Experiment.¹⁴¹¹⁾

The experiment consists of a multispectral image scanner of high sensitivity, dedicated to the measurements of water color and its interpretation in terms of major water constituents (chlorophyll, sediments, pollutants, etc.). The instrument is an 8-channel optomechanical image scanner. Total wavelength range from 464 - 773 nm. FOV = $\pm 45^\circ$. IFOV = 3.5 milliradian.

Prior to and during the Shuttle mission with the OSTA-1 payload, various OCE-related experiments took place. The main objective of these activities was to perform comparative measurements from aircraft, ship and ground for correlation and verification of the Shuttle OCE data. A duplicate instrument, referred to as **OCS** (=Ocean Color Scanner) was shipped from GSFC to DLR and installed in aircraft for pre-Shuttle test flights in various regions of Europe.

The following organizations participated in OSTA-1/OCE related activities: GSFC (USA), DLR (Germany), University of Lisbon (Portugal), Hydrologic Institute of the Navy (Portugal), University of Lille (France), GKSS (Germany), INTA Madrid (Spain), IIP Barcelona (Spain).

J.20 SIR-B

SIR-B = Shuttle Imaging Radar with Payload B. A JPL payload on the Shuttle as part of the OSTA-3 payload. Launch: Oct. 5, 1984 (duration: 1 week). Application: Land use, geology, hydrology, forestry, mapping.

Orbit: Shuttle orbit, 57° inclination, 225 km altitude, swath width: 30 - 60 km

Sensor: **SAR** = Synthetic Aperture Radar in HH Polarization; L-band (freq. = 1.28 GHz); look angle = variable from $15 - 55^\circ$. SIR-B provided for the first time the ability to mechanically tilt the antenna over a range ($15 - 55^\circ$) so that radar imagery from multiple angles of incidence could be obtained. Pixel size = 25m azimuth; radiometric resolution = 3-6 bit raw data. - The SIR-B radar was significantly upgraded. It had the additional flexibility of imaging geometry, particularly the effect of incidence angle on radar backscatter. One additional panel was added to the SIR-B antenna, bringing its total length to 10.7 m; again the antenna was mounted on the starboard side of the payload bay. The southern side of the track was also imaged during the SIR-B flight by rolling the shuttle 75° or yawing it 180° . A final improvement to the antenna was the ability to fold for launch in order to accommodate an additional deployable payload.

Data: Image size: 30 - 60 km x length of active radar. A digital data handling assembly (DDHA) converted the analog signal to a digital signal on-board the Shuttle. Data transmission: Shuttle downlink via TDRSS in Ku-band; data rate: 40 Mbit/s.

J.21 SIR-C/X-SAR

Shuttle Imaging Radar with Payload C (SIR-C).^{1412) 1413) 1414) 1415)} A NASA/JPL, DARA/DLR, and ASI payload on the Shuttle. This payload is also known under the name SRL (Space Radar Laboratory). Total payload mass = 11,000 kg, power consumption of payload sensors = 3 - 8.5 kW. Two Shuttle missions were conducted, each of 10 days duration.

¹⁴¹¹⁾H. v.d. Piepen, V. Amann, H. Helbig, HH. Kim, W. Hart, et al. "The Promise of Remote Sensing," IEEE paper presented at IGARSS '82, June 1-4, Munich

The SIR-C/X-SAR is the first spaceborne radar system capable of obtaining simultaneous multifrequency and multipolarization radar imagery. - A multipolarization, distributed C-band system was added along with a more powerful multipolarization distributed L-band system. Instead of using a single, high-power transmitter, the distributed SIR-C radars consisted of numerous low-power solid-state transmitters distributed across the antenna aperture. Large power losses were avoided and as much as an eight-fold improvement in efficiency was possible. The distributed C- and L-band SIR-C radars allowed electronic beam steering in the range direction (123°) from a fixed antenna position of 38° (look angle), thus making it possible to acquire multi-incidence angle data without tilting the entire antenna.

1) SRL-1 (STS-59): April 9 - 20, 1994

2) SRL-2 (STS-68): September 30 - October 11, 1994

Application: Land use, geology, hydrology, oceanography, snow and ice, vegetation, calibration, and technological experiments.

Objectives:

- Conduct geoscience investigations that require the observational capabilities of orbiting radar sensors, alone or in conjunction with other sensors, that will lead to a better understanding of the surface conditions and processes on the Earth.
- Explore regions of the Earth's surface that are not well characterized because of vegetation, cloud, or sediment cover in order to better understand land and ocean surface conditions and processes on a global scale.
- Incorporate this new knowledge into global models of surface and subsurface processes.

Orbit: Shuttle orbit, 57° inclination, 225 km altitude.

Sensor complement: All three SAR instruments were flown on each mission. Microwave sensors are independent of the day/night cycle and mostly independent of the weather. - The SRL-2 orbit was nearly identical to that of SRL-1 permitting repeat cross-track interferometric SAR processing for measuring elevation as well as to detect change in the radar direction (a significant amount of data was collected at all three frequencies). - The total instrument/antenna mass of SIR-C/X-SAR is 11,000 kg, power consumption = 3 - 7.5 kW.

The dedicated payload filled the entire Shuttle cargo bay. The antenna was mounted in a tilted position and the shuttle rolled to a nominal 38° look angle. In order to acquire data at look angles other than 38° with the conventional X-band system, the X-band antenna, which was mounted along the upper portion of the array, was mechanically tilted. ¹⁴¹⁶⁾

1) **L-band SAR** (1.250 GHz, wavelength = 23.5 cm), JPL. The L-band antenna is a planar array (12 m x 2.95 m in size) composed of a uniform grid of dual-polarized microstrip antenna radiators, active phased arrays. Further details are given in Table 426.

2) **C-band SAR** (5.3 GHz, wavelength = 5.8 cm), JPL.

The SIR-C payload comprised the L-band and C-band SAR antenna plus instrumentation. The SIR-C antenna boresights were steered electronically to provide coverage at varying distances from the Shuttle ground track. The SIR-C phased array also provided for broadening of the beam in the elevation direction from its minimum value of 5° to

1415) R.L. Jordan, B. L. Huneycutt, M. Werner, "The SIR-C/X-SAR Synthetic Aperture Radar System," Proceedings of the IEEE, Vol. 79, No. 6, June 1991, pp. 827-838

1416) F. V. Stuhr, R. L. Jordan, M. U. Werner, "SIR-C/X-SAR A Multifaceted Radar," IEEE Aerospace and Electronic Systems Magazine, Vol. 10, No. 10, Oct. 1995, pp. 15-25

16° (selection of seven values). The SIR-C phased array enabled the operational modes of **ScanSAR** and **Spotlight**. In ScanSAR, the antenna pattern coverage on the ground was stepped in the cross-track direction during the synthetic aperture period to allow coverage over a wider swath, however, at the expense of azimuth resolution. The swath width ranged from 15 to 65 km for calibrated images and 40 to 90 km for mapping mode (ScanSAR) images. For the Spotlight mode, the boresight was positioned in azimuth to dwell on a particular area as the Shuttle flew by. This permitted an increase in azimuth resolution to a value of 7 m for the selected area, at the expense of the along-track swath.

- 3) **X-SAR** (SAR for X-band Measurement (9.6 GHz, wavelength = 3.1 cm), provided by DARA/DLR and ASI, built by Dornier and Alenia). X-SAR uses only vertical polarization (VV). The X-SAR instrument uses a passive slotted-waveguide antenna (12 m x 0.4 m) which is tilted mechanically to align the X-band beam with the SIR-C C-band and L-band beams. The X-SAR antenna has a fixed beamwidth of 5.5° in elevation and 0.14° in azimuth as opposed to the phased array, multi-polarization antenna of SIR-C. The instantaneous area illuminated by the antenna on the ground (footprint) is an ellipse of size 60 km x 0.8 km from an orbital altitude of 225 km. The electronics part of X-SAR is mounted on a cold plate structure and positioned underneath the antenna structure. A TWT amplifier is transmitting up to 1736 pulses/s at a peak transmit power of 3.35 kW. The pulses are frequency-modulated with a pulse length of 40 μs and a programmable bandwidth of 10 or 20 MHz.

Parameter	L-band Antenna	C-band Antenna	X-band Antenna
Frequency	1.25 GHz	5.3 GHz	9.6 GHz
Antenna aperture length	12.0 m	12.0 m	12.0 m
Antenna aperture width	2.95 m	0.7 m	0.4 m
Architecture	Active Phased Array		Slotted waveguide
Phase control	4 bits	4 bits	N/A
Polarization	HH and VV	HH and VV	VV
Polarization isolation	>25 dB	>25 dB	39 dB
Antenna gain	36.4 dB	42.8 dB	43.5 dB
Mechanical steering range	N/A	N/A	±23°
Electronic steering range	±20°	±20°	N/A
Elevation beamwidth	5-16°	5-16°	5.5°
Azimuth beamwidth	1.0°	0.25°	0.14°
Transmit pulse length	33.8 μs	8.5 μs	40 μs
Radiometric resolution	1.5 dB	1.5 dB	2.5 dB
Peak radiated power	3200 W	1700 W	1500 W
System noise temperature	450 K	550 K	551 K
Mass of antenna structure	3300 kg		49 kg
Look angle (adjustable off-nadir angle)	15° - 55°	15° - 55°	15° - 55°
Swath width	10 km - 70 km	10 km - 70 km	15 km - 45 km
Azimuth resolution (4 look)	30 m	30 m	25 m
Range resolution with 10/20 MHz bandwidth	25 m/13 m	25 m/13 m	20 m/10 m
Data rate per channel	45 Mbit/s Total of 90 Mbit/s	45 Mbit/s Total of 90 Mbit/s	45 Mbit/s

Table 426: SIR-C/X-SAR instrument parameters

Data:

- The source data are digitally coded and recorded on-board.
- Transmission: only one SAR data stream at a time is possible. Ku-band via TDRSS to White Sands, NM, etc.
- Image size: 100 km (flight direction) x 50 km

- A SIR-C/X-SAR POCC was operated at NASA/JSC (Houston, TX).

Figure 244: Configuration of the SIR-C/X-SAR antenna payload in the Shuttle bay

Nominally, 50 hours of SIR-C data (on each of the four channels) and 50 hours of X-SAR data were recorded by on-board tape recorders. In addition, a limited amount of SIR-C/X-SAR data was transmitted to the ground (via TDRSS Ku-band 50 Mbit/s data link). for real-time digital processing during the mission. Data “takes” were largely over experiment sites selected prior to launch, with some in-flight “targets of opportunity.” The orbital altitude was trimmed for the last days of the second flight (SRL-2) to provide a repeat-track interferometric observation geometry. See also the campaign description of SRL-1 and -2 in Appendix Q.

The intent was to provide data calibrated in such a way as to allow comparisons with other spaceborne SAR data (eg., ERS-1, JERS-1, Radarsat, etc.) so that a time-series view of key geophysical parameters may be realized.

MAPS (Measurement of Air Pollution from Satellites). See description under J.11.

Also, on-board the SRL flights, was an ocean wave spectra processor, designed and built by Johns Hopkins Applied Physics Laboratory, which collected data on ocean surface wave length, direction, and height.

J.22 Spacelab-1

Shuttle Mission (STS-9, Columbia) Nov. 28, 1983 - Dec. 8, 1983 (10 day flight). Orbit: 240 - 257 km, inclination = 57°. NASA-ESA mission.

Sensor complement:

Metric Camera (German/ESA experiment; the camera was a slightly modified aerial survey camera of the Zeiss RMK A 30/23 type). Objective: to test the mapping capabilities of high-resolution space photography on a large film format.

Application: Topographic and thematic mapping. The metric camera provided high-resolution photographs and experimental results on planimetric and topographic mapping from outer space. ¹⁴¹⁷⁾

Spectral range	535 - 900 nm
Focal length	305 mm
Image size, Image scale	23 cm x 23 cm, 1:820,000
Image overlapping	60-80%
FOV (Field of View), Swath width	41.2°, 189 km
B/W film	Kodak Double-X Aerographic film 2045; pixel size = 12 x 12 m
Color film	Kodak Aerochrome infrared film 2443; pixel size = 12 x 12 m
Data rate	550 frames per film

Table 427: Some instrument parameters of the Metric Camera

For metric camera operations, the Shuttle flew with the open cargo bay oriented towards the Earth. In this flight attitude, the camera's optical axis looked vertically down to the Earth's surface. A total of 21 camera operations (exposure series) were taken which varied in duration from 2 to 18 minutes.

MRSE = Microwave Remote Sensing Experiment. MRSE operates in two modes, the scatterometer mode or the thermal radiometer mode. The two frequency scatterometer measured backscatter from the ocean surface at two adjacent frequencies. The thermal radiometer measured surface temperature.

GRILLE = Infrared spectrometer (French/Belgian sensor). GRILLE has a high resolution in the infrared region (2 µm); it measures vertical profiles of: CO, CO₂, NO, H₂O, CH₄, H₂O and HCl.

SOLSPEC = SOLar SPECTrum Measurement (CNES). Measures the solar irradiance from 180 - 3200 nm using three double spectrometers and an on-board calibration device.

SOLCON = Solar Constant Sensor (IRMB, Brussels, Belgium, PI: R. Crommelynck). Measurement of the solar constant. The SOLCON instrument is a cooperative effort of IRMB, Space Science Dept. of ESA, and LaRC. Measurement of the absolute value of the total solar irradiance (and long-term variations).

¹⁴¹⁷⁾ "Spacelab-1 Metric Camera, User Handbook and Data Catalogue," compiled by M. Schroeder, E Suckfüll, G. Todd, and P. Lohmann of DLR, Oberpfaffenhofen, Dec. 1986

J.23 Spacelab-3

Shuttle (Challenger, STS-17) mission between April 29 and May 6, 1985.¹⁴¹⁸⁾

A total of 15 experiments on-board, most of them on microgravity (crystal growth).

Orbit: 352 km altitude, 57° inclination

Sensor:

ATMOS = Atmospheric Trace Molecule Spectrometer (JPL sensor). Same instrument as on ATLAS. Objective: Investigation of the distribution of neutral constituents in the Earth's atmosphere. The ATMOS sensor is a Michelson interferometer, with a response to radiation in the NIR to IR regions, designed to make observations from on board the Shuttle in the solar occultation mode.

ATMOS gathered data during 20 occultation events; 13 sunset occultations located between 26° - 34° N latitudes and 7 sunsets around 48° S.

ATMOS employs high-resolution FT (Fourier Transform) interferometry and limb viewing in the of 2.2 µm to 16 µm bands.

J.24 Shuttle EO Imaging Cameras

A special camera system was developed for Shuttle flights with the objective to obtain high-resolution images of special areas of interest from piloted space systems.

Applications: spot target observations.

ESC - Electronic Still Camera¹⁴¹⁹⁾

The system consists of the following components:

- a hand-held battery-operated high-resolution camera (fully digital and programmable)
- a lap-top computer-based playback/downlink unit for on-board image processing
- a ground station capable of receiving Shuttle data, processing images, producing hard copies, and distributing the data and hard copies to end users.

The camera is designed and built with astronomical-grade CCDs, which resulted in near-film-quality imaging. The downlink capability provides the means of investigator ground inspection and interaction during Shuttle flights. This interaction capability optimizes the yield of experiments and observations. The Orbiter's Ku-band downlink scheme permits image transmission within 15 seconds; however, ESC images may also be downlinked through any channel, regardless of bandwidth and bit rate. As of 1992 the Naval Research Laboratory is developing a latitude-longitude locating system, which when used with the ESC will identify the location of the Earth target imaged within 1 nautical mile. The camera flown on STS-48 was set up for a 1000 x 1000 CCD array.

ESC specifications:

- ESC spectral range: 0.4 - 1.1 µm; the spectral response allows for multispectral imaging. Human interaction on-board permits quick decisions: for instance on the best way to photograph a scene, (lenses may be exchanged, filters may be selected for multispectral imaging, a new data storage cartridge may be loaded, etc.).
- Ground resolution of about 40 m (at 470 km orbit with 180 mm lens); or of = 15 m (at 290 km orbit with 300 mm lens, theoretical limit)
- ESC is fully programmable to support a variety of sensors: 1000 x 1000, 2000 x 2000, and 1000 x 1000 color (note: a 2000 x 2000 array is planned)
- Dynamic range = 60 dB; sensor dynamic range = 80 dB

¹⁴¹⁸⁾ "Overview of ATMOS Results from Spacelab-3," Optical Remote Sensing of the Atmosphere, 1990 Technical Digest Series of the Optical Society of America, Volume 4, pp. 64-66

¹⁴¹⁹⁾ S. D. Holland, "The NASA Electronic Still Camera System," IEEE IGARSS '92 Volume I, pp. 149-151

- Removable image storage media for unlimited storage capability
- Adaptable to all Nikon lenses or any instrument that uses a Nikon mount
- Retains the functions of a Nikon F4, such as autofocus, autoexposure, and manual override.

The ESC was first used on mission STS-48 in September 1991. Since then, ESC has flown on STS-42 and is planned to fly on STS-45, STS-49, and STS-53.

Playback/downlink capabilities:

- Employs virtual imaging, which allows the user to display ESC images on a variety of monitors with a variety of solutions
- Provides standard and nonstandard image processing
- Allows the user to select and deselect desired images for downlinking
- Allows notes to be included with each downlinked image.

Ground station capabilities:

- Compatible with Shuttle digital downlink
- Primary image processing performed with Sun 3/470 and PIXAR imaging computers
- Capability of processing 4000 x 4000 true color images
- Data can be networked anywhere in the world
- Hardcopy capability for ground crew

J.24.1 Shuttle Film Camera Systems

Earth photographs are collected using 35 mm, 70 mm, and 5 inch (12.7 cm) format still cameras, equipped with a variety of lenses and film types.

- Modified Hasselblad single-lens reflex camera, model 500 ELX (prior to Jan. 1990 ELM).^{1420),1421)} A 70 mm- format hand-held camera for photography by astronauts. An important accessory is the data recording module for the film magazine, which records the exact time when the photograph was taken (for post-flight identification of the scene). Data Recording Modules (DRMs) were installed on Hasselblad cameras in April 1985 with STS-51-B. Before DRMs were installed, determining the location of ocean features required identifying geographic references in the photograph, eg., coastlines or islands.
- Rolleiflex single-lens reflex camera, model 6008 (was flown several times during 1990-92, first flight on STS-32 in Jan. 1990). A 60-frame, 70 mm film magazine was devised. The camera features automatic exposure control.
- Linhof Aero Technika 5-inch (12.7 cm) format camera system. The camera is flown on a space-available basis. First flight on STS-41G in Oct. 1984. Lens focal lengths: 90 mm or 250 mm. Time and date recording of Linhof photographs began in Dec. 1988 with STS-27.
- Nikon camera systems F3 and F4. These cameras are being used primarily to document the Shuttle interior, they have also been used for Earth observation photography. Telephoto lenses of 180 mm and 300 mm focal lengths. Cataloging of these 35 mm Earth images has been instituted since STS-37 (April 1991).

Postflight Support:

A catalog is published after each Shuttle flight supplying for each frame the geographic location, geographical name, flight ephemeris data, and some descriptive feature information. A typical Shuttle flight produces 3000-6000 pictures.

Electronic Database:

The Space Shuttle Earth Observations Project (SSEOP) Photography Database,¹⁴²²⁾ containing geographical references to more than 90,000 space photographs (over 26,000 from Shuttle flights up to 1991) is operational at NASA/JSC, Houston, TX. Access to this database is free-of-charge and available 24 hours a day.

J.24.2 IMAX Space Cameras

IMAX Corporation of Mississauga (Toronto), Canada, is the pioneer of large-format film and giant-screen projection technology. IMAX was created after Montreal's Expo 1967, when Canadian film makers Graeme Ferguson, Robert Kerr and Roman Kroitor impressed audiences with their multi-screen films. Aside from the entertainment business activities, there is also an engagement in the documentation of significant space activities, to promote NASA's educational goals using the IMAX film medium.¹⁴²³⁾

Background: The IMAX space camera project is a collaboration between IMAX Corporation, NASA, the Smithsonian Institution's National Air and Space Museum, and Lockheed Martin Corporation. The system, developed by IMAX Corporation of Toronto, Canada, uses specially designed 65 mm cameras and projectors to record and display very high definition color motion pictures which, accompanied by six-channel high-fidelity sound, are displayed on screens in IMAX and OMNIMAX (dome projection) theaters that are up to ten times larger than a conventional screen, producing a feeling of "being there."

IMAX space cameras have been flown on Shuttle missions STS-41-C (launch April 1984), 41-D, 41-G, -29, -34, -32, -31, -42, -46, -51, -61, -63, -71, -74, -88, etc. - to document crew operations in the payload bay and the orbiter's middeck and flight deck as well as to film spectacular views of space and Earth. Film from those missions was used as the basis for the IMAX productions "The Dream Is Alive," "The Blue Planet," and "Destiny in Space."

The STS-88 mission was the first space station assembly flight of the Shuttle to ISS (International Space Station) which took place from Dec. 4 to 15, 1998. The primary objectives of ICBC (IMAX Cargo Bay Camera) on STS-88 were to film the Node 1 installation onto the orbiter docking system (ODS), the functional cargo block (FCB) rendezvous, FCB docking, extravehicular activity (EVA) tasks, separation burn, and fly-around. ICBC is a space-qualified, 65 mm color motion picture camera system consisting of a camera, lens assembly, and a film supply magazine containing approximately 1100 m (3,500 feet) of film and an empty take-up magazine.¹⁴²⁴⁾

The 65 mm film from STS-88 was transferred to 70 mm motion picture film for use in a large-format feature film. An audio tape recorder with microphones in the crew compartment recorded middeck sounds and crew comments during camera operations. The audio was transferred to tapes and compact disks to accompany the motion picture.

J.24.3 IMAX-3D Space Cameras

In 1997, IMAX Corporation in association with NASA and Lockheed Martin, started a program to develop new IMAX-3D space cameras.

J.24.4 ICBC (IMAX Cargo Bay Camera)

The primary objectives of ICBC (IMAX Cargo Bay Camera) on STS-88 are to film the Node 1 installation onto the orbiter docking system (ODS), the functional cargo block

¹⁴²²⁾ R. M. Nelson, K. J. Willis, W. J. Daley, F. R. Brumbaugh, J. M. Bremer, "Cataloging and Indexing - The Development of the Space Shuttle Mission Data Base and Catalogs from Earth Observations hand-held Photography," IEEE IGARSS '92 Volume I, pp. 155-157

¹⁴²³⁾ <http://www.imax.com/>

¹⁴²⁴⁾ <http://www.shuttlepresskit.com/STS-88/payload19.htm>

(FGB) rendezvous, FGB docking, extravehicular activity (EVA) tasks, separation burn, and fly-around.

The ICBC is a space-qualified, 65 mm color motion picture camera system consisting of a camera, lens assembly, and a film supply magazine containing approximately 3,500 feet of film and an empty take-up magazine. The camera is housed in an insulated, pressurized enclosure with a movable lens window cover. The optical center line of the 30 mm camera lens is fixed and points directly out of the payload bay along the orbiter Z-axis with a 23-degree rotation toward the orbiter nose. Heaters and thermal blankets provide proper thermal conditioning for the camera electronics, camera window, and film magazines.

For STS-88, the delivery reel is loaded with 3,500 feet of film (nominally), enough for approximately 10.5 minutes of filming at normal camera speed (24 frames per second, fps). On this flight, the camera speed can be changed to 6 fps for photographing slower moving objects. The ICBC can also be loaded with a 2,200-foot film magazine. A single 30 mm wide-angle lens is mounted on the camera; lenses and film cannot be changed during the flight. ICBC operations are terminated when all film is exposed.

The ICBC is controlled from the aft flight deck with the enhanced GAS autonomous payload controller (GAPC) and uses orbiter dc power. A crew member can command the ICBC to turn main power on, go to a standby mode, adjust f-stop and focus, and film a scene. A spotmeter will be used by the crew to aid in setting the IMAX camera f-stops. By using the GAPC, the crew member can also determine the status of the camera, such as the current f-stop and the amount of film exposed. A light level measurement unit is used to set the lens aperture. A fixed focus zone and seven aperture settings are available for this flight. A tape recorder is also provided for crew documentation. All the GAS hardware, such as the GAS control decoders, status responder units, GAPCs, and the GAS signal and control cable, are owned, serviced, and certified by NASA's Goddard Space Flight Center.

The basic operational profile of the ICBC is as follows: enable the heaters within seven hours of launch or approximately 30 minutes before a planned payload activity to be filmed, maintain thermal conditioning of the camera and film magazine, perform a typical filming sequence, and return to thermal conditioning.

A typical filming sequence begins with powering the camera in standby mode. This consists of powering up the internal camera electronics, feed magazine and drive, take-up magazine and drive, IMAX interface electronics, and the lens drive to a standby mode. The f-stop, focus, and frame rate are adjusted to the desired settings. Actual filming occurs when the door motor and camera drive motor are operated. The camera then returns to standby until the end of the filming sequence.

Background: The IMAX space camera project is a collaboration between IMAX Corporation, NASA, the Smithsonian Institution's National Air and Space Museum, and Lockheed Martin Corporation. The system, developed by IMAX Corporation of Toronto, Canada, uses specially designed 65 mm cameras and projectors to record and display very high definition color motion pictures which, accompanied by six-channel high-fidelity sound, are displayed on screens in IMAX and OMNIMAX theaters that are up to ten times larger than a conventional screen, producing a feeling of "being there."

The 65 mm film from STS-88 will be transferred to 70 mm motion picture film for use in a future large-format feature film. An audio tape recorder with microphones in the crew compartment will record middeck sounds and crew comments during camera operations. The audio will then be transferred to tapes or compact disks to accompany the motion picture.

IMAX cameras have been flown on Shuttle missions STS-41-C (launch April 1984), 41-D, 41-G, -29, -34, -32, -31, -42, -46, -51, -61, -63, -71, -74, -88, etc. - to document crew operations in the payload bay and the orbiter's middeck and flight deck as well as to film spectacular

views of space and Earth. Film from those missions was used as the basis for the IMAX productions “The Dream Is Alive,” “The Blue Planet,” and “Destiny in Space.” The STS-88 mission was the first space station assembly flight of the Shuttle to ISS (International Space Station) which took place from Dec. 4 to 15, 1998.

The IMAX project is designed to document significant space activities and promote NASA’s educational goals using the IMAX film medium.

J.25 SRTM (Shuttle Radar Topography Mission)

SRTM is a joint Shuttle mission on STS-99 (Atlantis) between NASA, DoD/NIMA (National Imagery and Mapping Agency), DLR (Deutsches Zentrum für Luft- und Raumfahrt, Germany), and ASI (Agenzia Spaziale Italiana). Funding for SRTM is from NIMA, while NASA is supplying the SIR-C hardware, Shuttle launch, ground systems, mission operations and data processing support. DLR and ASI are supplying the X-SAR hardware, ground systems, mission operations and data processing support. - SRTM represents a re-flight of the basic SIR-C/X-SAR payload instruments on the SRL-1 (STS-59, April 9 - 20, 1994) and SRL-2 (STS-68, Sept. 30 to Oct. 11, 1994) missions (J.21). However, the SRTM configuration considers only two independent SAR systems, one in C-band (JPL instrument), the other in X-band (DLR/ASI). Both SAR systems operate with the main antenna of each instrument located in the open cargo bay of the Shuttle, and a second receive antenna mounted on a deployable outboard mast, respectively. The configuration (a bistatic system) for both radar systems represents a single-pass interferometer, also referred to as IFSAR, with a baseline of 60 m (separation of the two antenna systems). The mission is managed by JPL. SRTM represents the first fixed baseline single-pass spaceborne IFSAR technology with wide-swath scanning SAR and dual-frequency (C-band and X-band) coverage. The 11-day STS-99 Shuttle mission took place Feb. 11-22, 2000. 1425) 1426) 1427) 1428) 1429)

The mission objective is to obtain single-pass interferometric SAR imagery to be used for DEM (Digital Elevation Model, also referred to as DTM = Digital Terrain Model) generation, i.e. topographic maps. Coverage of the Earth’s land surfaces is provided between latitudes of -54° and $+60^{\circ}$, representing nearly 80% of the land masses. The digital topographic map production objective (C-RADAR) calls for requirements which meet ITHD-2 (Interferometric Terrain Height Data -2) specifications, i.e., a spatial pixel (30 m x 30 m) posting with a 16 m absolute vertical linear accuracy and 20 m absolute horizontal radial accuracy at 90%. On-board data storage uses high-rate data recorders (300 cartridges each of 40 GByte capacity). - Applications: the topographic data are being used for such studies as: flooding, erosion, landslide hazards, earthquakes, weather forecasts, climate zones, etc.

Orbit: circular exact repeat orbit, altitude = 233 km, inclination = 57° . The Shuttle flies upside down and tail forward for simultaneous radar observations.

The look angle for the C-RADAR antenna system is 45° , for the X-RADAR antenna system = 52° . A nominal data collection period of 80 hours is assigned for both radars.

The on-board AODA (Attitude and Orbit Determination Avionics) consists of a suite of sensors (target tracker, a new GPS receiver system configuration, called BlackJack for orbit

1425) Note: While the L-band radar/antenna is flown as part of the overall structure, there is no interferometric L-band capability due to the large antenna dimensions needed at the outboard location. The L-band radar is not being operated, however, some of its electronic capabilities are used for the C-RADAR.

1429) P. Chien, “Around the World in 11 Days,” Launchspace Magazine, Vol. 3.06, Dec. 1998

and attitude determination, distance meters, inertial reference units, and star tracker) to collect attitude and position information. The AODA data rate is 8.192 kbit/s. The baseline knowledge of the two inboard and outboard antenna pairs is known within 3mm, the angular alignment knowledge is better than 9 arcsec. The stiff and rigid mast (or boom) can experience length variations of up to 10 mm (thermal distortion) and bending/twist up to 0.1° during radar data acquisition. The mast itself consists of 87 cubical sections (referred to as bays) with a total mass of 360 kg. The total mast plus outboard antenna system has a mass of 1700 kg (AEC-Able Engineering is the manufacturer of the extendible boom). Since the long boom tends to drift into a gravity-gradient attitude (where one end of the S/C points toward Earth), this has to be counteracted by a thruster system mounted on the boom structure.

Figure 245: Configuration of the SRTM/X-SAR payload

Sensor complement: It consists of modified SIR-C/X-SAR instruments (plus added on structures) flown on SRL-1 and SRL-2 in April and October 1994, respectively. The two single-pass interferometric SAR systems, namely **C-RADAR** and **X-RADAR**, are

configured in such a way that each radar is operating a transmit/receive antenna system inside the Shuttle cargo bay (primary or inboard system) and a receive-only antenna system at the boom tip (secondary or outboard system). The boom structure is oriented in the cross-track direction, perpendicular to the velocity vector of the Shuttle, with tip-mounted antennas, forming a parallel antenna system with the inboard system. Single-pass interferometry observation requires a beam overlap geometry of the primary and secondary antenna systems. This implies alignment measures for each antenna system to compensate for possible misalignments during the mission.¹⁴³⁰⁾

- The X-RADAR system provides a two-axis alignment capability. The inboard antenna can be steered mechanically (tilt of $\pm 1.5^\circ$) in the cross-range direction to fine-tune the footprint of the outboard antenna. In addition, the outboard antenna can be steered electronically ($\pm 1^\circ$) in the azimuth direction to match the footprint of the inboard antenna.

Figure 246: Illustration of SRTM observation geometries

- The phased array antenna system of C-RADAR provides 2-D electronic steering of the inboard and outboard systems for beam alignment. Four C-band subswaths of the inboard system are generated sequentially in ScanSAR mode, where two beams are forming an instantaneous ScanSAR pair, each pair producing a subswath with V and one with H polarization. Two parallel transmit/receiver channels are employed for this

¹⁴³⁰⁾ M. U. Werner, J. Heinstadt, "A Spaceborne X-band Single Pass Interferometric SAR Antenna System," ESTEC Workshop on Large Antennas for Radio Astronomy, Noordwijk, NL, Feb. 28-29, 1996

purpose, one is of the C-band system, the other channel is “borrowed” from the otherwise dormant L-band system.

C-RADAR (C-band Radar Instrument). C-RADAR (5.3 GHz, wavelength = 5.6 cm, bandwidth = 10 MHz) is provided by JPL, it offers a dual-polarization capability. The peak radiation power is 1.2 kW/polarization. In ScanSAR mode, C-RADAR employs two simultaneous beam pairs, as shown in Figure 246, which switch back and forth within the full swath width, creating a contiguous and overlapping SAR imagery pattern. The total swath width is 225 km providing a pixel size (resolution) of about 30 m (data point spacing of one arcsec). Instrument source data are collected at 180 Mbit/s (in four channels) and stored on the on-board recorders. Instrument telemetry data at 15.12 kbit/s is downlinked continuously.

X-RADAR (X-band Radar Instrument). ¹⁴³¹⁾ X-RADAR (9.6 GHz, wavelength = 3.1 cm) is provided by DLR and ASI, it offers fixed beam (52° look angle) single polarization (VV inboard and V outboard antenna). The peak radiation power is 1.7 kW at a PRF of 1674 pulses/s. X-RADAR operates in a wide-swath mode of 50 km, the horizontal pixel resolution is 30 m x 30 m with a vertical height resolution of 6m relative and 10 m absolute. The X-SAR swath is positioned in the middle of the two outer subswaths of C-RADAR. The instrument science data rate is 90 Mbit/s and stored on the on-board recorder. Instrument telemetry data at 9.6 kbit/s is downlinked continuously.

Parameter	L-band Antenna	C-band Antenna	X-band Antenna
Frequency	1.25 GHz	5.3 GHz	9.6 GHz
Bandwidth		10 MHz	9.5 MHz
Inboard antenna: Aperture length x width	12.0 m x 2.9 m	transmit/receive 12.0 m x 0.75 m	transmit/receive 12.0 m x 0.4 m
Outboard antenna: Aperture length x width		receive only 8.0 m x 0.75 m	receive only 6.0 m x 0.4 m
Architecture	Active Phased Array Patch-type planar antenna with 2-D steering		Slotted waveguide array
Phase control	4 bits	4 bits	N/A
Polarization	4 subswaths transmit/receive H,V,V,H, inboard 4 subswaths receive only H,V,V, H, outboard		VV inboard antenna, (V outboard antenna)
Polarization isolation	25 dB	25 dB	39 dB
Antenna gain	36.4 dB	42.7 dB	44.5 dB
Mechanical steering range	N/A	N/A	±23°, fixed at 7° SRTM
Electronic steering range	±20°	±20°	±0.9°
Elevation beamwidth	5-16°	5-16°	5.5°
Azimuth beamwidth	1.0°	0.25°	0.14° (0.28°)
Transmit pulse width		34 μs	40 μs
Look angle (adjustable off-nadir angle)	15° - 55°	15° - 55°	52°, 17° - 60° possible
Peak radiated power	4400 W	1.2 kW/polarization	1.7 kW
System noise temperature	450 K	550 K	551 K
PRF		1344-1550 Hz	1440-1674 Hz
Swath width		225 km	50 km
Ground resolution		30 m x 30 m	30 m x 30 m
Height resolution relative		10 m	6 m
Quantization		8 bit (equivalent)	6 bits I and 6 bits Q
Data rate		180 Mbit/s(4x45 Mbit/s)	90 Mbit/s (2x45 Mbit/s)

Table 428: SRTM/X-SAR instrument parameters

J.26 SSBUV (Shuttle Solar Backscatter Ultraviolet Spectrometer)

SSBUV is a NASA/GSFC instrument (PI: E. Hilsenrath) using UV backscatter in nadir to measure vertical profiles of ozone in the stratosphere and in the lower mesosphere in the

¹⁴³¹⁾K. B. Klein, M. U. Werner, “System Performance Monitoring for X-SAR/SRTM,” EUSAR’98, VDE-Verlag, May 25-27, 1998, Friedrichshafen, Germany, pp. 383-386

spectral range from 200 to 405 nm. The objective is to fly the SSBUV payload on numerous Shuttle missions to provide complementary calibration data for long-term satellite ozone data sets. The first flight with SSBUV instrumentation occurred on October 19, 1989 on the Shuttle Atlantis (STS-34). Throughout this Shuttle flight coincident observations were taken with the SBUV on Nimbus-7 and the SBUV/2 on NOAA-9 and NOAA-11 satellites.

The SSBUV instrument and its flight support electronics, power, data and command systems are mounted in the Shuttle's payload bay in two flight canisters (total mass of 410 kg). The instrument canister holds the SSBUV instrument, its aspect sensors and inflight calibration system. Once in orbit, a motorized door assembly opens the canister, allowing the SSBUV to view the sun and the Earth. The canister closes, providing contamination protection, while SSBUV performs inflight calibrations. ¹⁴³²⁾

The SSBUV instrument is the SBUV/2 engineering model now flying on NOAA satellites - see G.13 (NOAA-POES). The SBUV/2 sensor is a spectrally scanning UV radiometer (nadir-viewing sensor) measuring solar irradiance and scene radiance (backscattered solar energy) over a spectral range from 200 to 405 nm (note: SSBUV actually measures from 160-405 nm; however, there is no calibration below 200 nm because a vacuum is needed for this region). Resolution = 50 km.

The SSBUV program has pursued a vigorous laboratory calibration effort using NIST-traceable standards. Of particular importance are the direct comparisons conducted with the instruments for the TOMS-EP (TOMS), ERS-2 (GOME), and NOAA-14 (SBUV/2) missions. These instruments were calibrated using SSBUV standards. The SSBUV flight on STS-72 provided a first opportunity to compare space observation from instruments which have been intercalibrated on the ground.

Monochromator	0.25 cm diameter double Ebert Fastie design, F5
Detector	Biakali photomultiplier tube (PMT)
Grating	Holographic, 2400 lines/mm
Wavelength	160-405 nm continuous for solar radiance, 12 steps programmable for ozone measurements
Bandwidth	1.1 nm
Dynamic range	10 ⁶
Linearity	< 1%
FOV	11.3°

Table 429: Specification of the SSBUV instrument ¹⁴³³⁾

Shuttle Flight	Date	SSBUV coincident ozone observations with instruments on the following satellites
STS-34, Atlantis	Oct. 18-23, 1989	Nimbus-7 (SBUV/TOMS), NOAA-9, -11 (SBUV/2)
STS-41, Discovery	Oct. 6-10, 1990	NOAA-9 and -11 (SBUV/2)
STS-43, Atlantis	August 2-11, 1991	Meteor-3-6/TOMS, NOAA-9 and -11 (SBUV/2)
STS-45, Atlantis (ATLAS-1),	Mar. 24, to April 2, 1992	NOAA-11, Meteor-3-6/TOMS, UARS (CLAES, ISAMS, HALOE)

¹⁴³³⁾ Information provided by E. Hilsenrath of NASA/GSFC, Greenbelt, MD

Part K Space Science/Solar-Terrestrial Missions

K.1 ACE (Advanced Composition Explorer)

A NASA/GSFC solar-terrestrial mission in the Explorer Program (Explorer-71) with the objectives to determine: the elemental and isotopic composition of matter, the origin of the elements, the formation of the solar corona and acceleration of the solar wind. S/C designer and builder: JHU/APL. The S/C structure has two octagonal decks, 1.6 m across and 1 m high; the S/C is spin stabilized with the spin axis Earth/sun pointing (star and sun sensors). Mission launch occurred on August 25, 1997 with a Delta II launch vehicle from Cape Canaveral, Florida. S/C mass = 785 kg (includes 189 kg of hydrazine fuel for orbit insertion and maintenance), power=443 W (EOL) from four fixed solar arrays, nominal life of the mission is 2 years with a five-year goal.¹⁴³⁴

Orbit: Halo orbit about the Lagrangian (or libration) point L_1 (250 Earth radii toward the sun, or about 1.5 million km from Earth).

Figure 247: The ACE S/C model

Sensor complement: (PI for mission: E. C. Stone, Caltech/JPL).

- **SWIMS** = Solar Wind Ion Mass Spectrometer (PI: G. Gloeckler, U. of Maryland). Objectives: Measurement of solar wind composition data over a wide range of solar wind bulk speeds and for all solar wind conditions. Abundances of most of the elements and several isotopes in the mass range from 4 - 60 amu (atomic mass unit) every few minutes. SWIMS uses a time-of-flight (TOF) measurement technique to determine the mass of a solar wind ion with high accuracy. SWIMS consists of the Wide-Angle, Variable Energy/charge (WAVE) three chamber parallel-plate electrostatic analyzer, the time-of flight High-Mass Resolution Spectrometer (HMRS), high-voltage supplies, and analog and digital electronics.

- **SWICS** = Solar Wind Ion Composition Spectrometer (PI: G. Gloeckler, U. of Maryland). Objective: measurement of the elemental and ionic-charge composition and the temperature and mean speeds of all major solar wind ions from H through Fe at solar wind speeds ranging from 145 km/s (for protons) to 1532 km/s (for Fe⁺⁸). The instrument, which covers an energy per charge range from 16 - 60 keV/Q, combines an electrostatic analyzer with post-acceleration, followed by a time-of-flight (TOF) and energy measurements.
- **ULEIS** = Ultra-low Energy Isotope Spectrometer (PI: G. Mason, U. of Maryland, R. Gold, APL). Objective: measurement of ion fluxes over the charge range from He through Ni from about 20 keV/n to 10 MeV/n (superthermal and energetic particle ranges). ULEIS is a time-of-flight (TOF) mass spectrometer which identifies incident ion mass and energy by simultaneously measuring the time-of-flight, τ , and residual kinetic energy, E , of particles which enter the telescope cone and stop in one of the six detectors in the telescope.
- **SEPICA** = Solar Energetic Particle Ionic Charge Analyzer (PI: E. Möbius, U. of New Hampshire and MPE Garching; D. Hovestadt, MPE Garching). Objective: measurement of the ionic charge state, Q , the energy, E , and the nuclear charge, Z , above 0.2 MeV/n. - Energetic particles entering the multi-slit collimator will be electrostatically deflected between the six sets of electrode plates which are supplied with variable high voltages up to 30 kV. The deflection, which is inversely proportional to energy per charge, E/Q , is determined in the back portion of the instrument (dE/dX device and a position-sensitive silicon solid-state detector). The residual energy of the particle, E_{res} , and the amount of electrostatic deflection is directly determined in the detector, thus yielding the energy per ionic charge, E/Q , of the incoming particle, and its energy, E .
- **SIS** = Solar Isotope Spectrometer (PI: A. Cummings, California Institute of Technology). Objective: measurement of elemental and isotopic composition of solar energetic particles, anomalous cosmic rays, and interplanetary particles from He to Zn over the energy range from 10 - 100 MeV/nucleon. Measurements by a technique considering a particle's energy loss ΔE in a detector (multiple ΔE versus residual energy E).
- **CRIS** = Cosmic Ray Isotope Spectrometer (PI: A. Cummings, California Institute of Technology; T. von Rosenvinge, GSFC; R. Binns, Washington U.; M. Wiedenbeck, JPL). Objective: measurements of all stable and long-lived isotopes of galactic cosmic ray nuclei from He to Zn over the energy range from ~ 100 to 600 MeV/nucleon. CRIS also provides limited measurements of low energy H isotopes and data for exploratory studies of the isotopes of "ultra-heavy" (UH) nuclei. Measurements by a technique considering a particle's energy loss ΔE in a detector (multiple ΔE versus residual energy E). CRIS is of CRRES, ISEE-3 and SAMPEX heritage.
- **EPAM** = Electron, Proton, and Alpha-particle Monitor (PI: R. Gold, JHU/APL). Objective: measurement of solar and interplanetary particle fluxes with a wide dynamic range and a directional coverage of nearly a full unit sphere. EPAM consists of five apertures in two telescope assemblies. It measures ions ($E_i \geq 50$ keV) and electrons ($E_e > 30$ keV) with essentially complete pitch angle coverage from the spinning ACE spacecraft. It also has an ion elemental abundance aperture using a ΔE versus E technique in a three-element telescope.
- **SWEPAM** = Solar Wind Electron, Proton, and Alpha Monitor (PI: D. McComas, LANL). Objective: high quality measurements of electron and ion fluxes in the low energy solar wind range (electrons: 1 - 1240 eV; ions: 0.26 - 35 keV). SWEPAM is of Ulysses mission heritage. SWEPAM makes simultaneous and independent electron and ion measurements with two separate sensors. Both sensors make use of curved-plate electrostatic analyzers which are spherical sections cut off in the form of a sector.

- **MAG** = Magnetic Field Monitor (triaxial fluxgate; PI: N. Ness, U. of Delaware). Objective: measurement of the three components of the magnetic field. MAG is boom-mounted.

Instrument	Mass (kg)	Power (W)	Data rate (bit/s)	Measurement Technique	Type. Energy (MeV/nucleon)
CRIS	29.3	22	462	dE/dX x E	~300
SIS	20.6	21.5	2000	dE/dX x E	~50
ULEIS	18	30.5	1000	TOF x E	~5
SEPICA	28.6	16	600	$\Delta E \times E \times E/Q$	~1
SWICS	6.3	9	500	TOF x E x E/Q	~0.001
SWIMS	8.3	19.4	505	TOF thru special E-field	~0.001
SWEPAM	6.7	6.4	1000	Electrostatic Analyzer	~0.001
EPAM	6.4	6.5	160	dE/dX x E	~0.3
MAG	4.3	4.4	300	Triaxial Fluxgate	

Table 431: ACE instrument summary

Communications with ACE are at S-band. Science and engineering data are collected during one 3-4 hour pass per day. Real-time data is transmitted at a data rate of 6.9 kbit/s or 434 bit/s. Data may be recorded onto a 2 Gbit solid-state recorder (two recorders available) and played back at a rate of 78 kbit/s.

K.2 ACTIVE (AKTIVNY-IK)

Russian (IKI) solar-terrestrial mission within the Intercosmos program (International Space Plasma-Waves Laboratory, Intercosmos 24). Objectives: comprehensive study of VLF-wave (Very Low Frequency) propagation phenomena in the Earth's magnetosphere and wave interaction with the energetic particles of the radiation belts.^{1435),1436)}

Mother-daughter pair of spacecraft. The mother craft is also designated as Intercosmos 24, the daughter spacecraft is provided by the Czech Republic and is designated 'C2-AK' or 'Magion-2'. Mother craft: three-axis spin-stabilized; S/C diameter = 2 m; S/C height = 3 m; mass = 270 kg; power = 270 W;

Launch on Sept. 28, 1989 with a Cyclone launch vehicle from Plesetsk, releasing the Magion-2 subsatellite. Magion-2 orbits around the mother in a controlled mode. Magion-2 separation from mother satellite was on October 3, 1989. Magion-2 began its science program in January 1991. ACTIVE is an operational mission as of 1993. Scientific program leader (since 1993): G. L. Gdalevich, (IKI, Moscow).

Orbit: apogee = 2500 km, perigee = 500 km, inclination = 82.5°, period = 116 minutes.

Sensors of mother S/C:

The mother craft carried a plasma generator for a modulated plasma environment around the antenna. A neutral xenon injector injected xenon around the S/C for monitoring the ionization of neutral gas flow and its propagation effects.

VLF = Very-Low Frequency Generator [PI: O. A. Molchanov, IFZ RAN (Institute of Earth Physics) and Yu. N. Agafonov, IFZ RAN]. Objectives: generation of VLF waves in the range 9-11 kHz via a 20 m diameter ORA-20 loop antenna (current about 10A). Note: ORA = O-formed loop antenna.

¹⁴³⁵⁾ "The ACTIVE International Space Plasma-Wave Laboratory," The Solar-Terrestrial Science Project of the Inter-Agency Consultative Group for Space Science, ESA SP-1107, November 1990, pp. 45-49

¹⁴³⁶⁾ Aktivny-IK, Interavia Space Directory, 1992-93, pp. 149

ORA-20 (transforms oscillations from the generator to electromagnetic emission). The tube from soft ductile aluminum alloy, with a wall thickness of about 1 mm, is used for the build-up of the antenna loop. The tube is tightly rolled up at launch and slowly unfolds in orbit (by its spring-load) on command into a loop antenna of 20 m diameter.

PVP = Generator of Electric Oscillations (PI: Yu. M. Mikhailov, IZMIRAN). Objectives: generation of VLF waves in the range 1.5 - 20.5 kHz. The PVP sensor consists of a self-opening band-type cylindrical dipole antenna of 15 m length and 25 mm diameter.

- Output voltage: 50 - 300 V
- Time of impulse: 0.25 s
- Time of pause: 0.75 s

NVK-ONCH = VLF Analyzer (PI: Yu. M. Mikhailov, IZMIRAN). Objective: measurement of magnetic and electric field components in the range from 8 Hz - 20 kHz, three magnetic and two electric components.

Sensitivity of electric components	$10^{-7} \text{ V m}^{-1} \text{ Hz}^{-1/2}$
Sensitivity of magnetic components	$10^{-5} \text{ nT Hz}^{-1/2}$
Dynamic range	80 dB
Sensors for magnetic components	coil-type magnetic antenna with ferrite
Sensors for electric components	double spherical sondes with a diameter of 100 mm and with distances of 2.5 m between the sondes

Table 432: NVK-ONCH parameters

Figure 248: The ACTIVE S/C model

SHASH = VLF Spectroanalyzer (PI: J. Tarchai, Eötvös U. of Budapest). Objective: digital analysis of VLF signals and noise levels from the NVK-ONCH instruments in the range of 20 Hz - 20 kHz. Independent transmission of the analyzed information is provided by a transmitter (frequency = 460 MHz, transmission rate = 100 kbit/s).

VLF-2 = Very-Low Frequency Generator 2. (PI: Z. Klos, Center of Cosmic Research, Polish Academy of Sciences, Warsaw). Objective: provision of a parallel analysis of VLF spectra (one electric component with the use of 12 filters); measurement range = 20 Hz - 20 kHz. The VLF-2 sensor uses the same equipment as NVK-ONCH.

PRS = Plasma Wave Spectrometer (PI: Z. Klos, Center of Cosmic Research, Polish Academy of Sciences, Warsaw); Objective: measurements of HF-noise spectra in the range from 0.1 - 10 Hz; data rate = 10 kbit/s; mass = 5.1 kg. The sensor consists of a self-opening band-type antenna of 15 m length.

ZL-A = Langmuir Probe Experiment (PI: J. Rustenbach, MPE, Berlin). Objective: measurement of plasma electron/ion temperature and densities. Electron temperature range = 10^3 - 10^4 K, electron density range = 10^2 - 10^8 cm⁻³. The sensor is a cylindrical sonde.

KM-6 = Cold Plasma Analyzer (PI: J. Shmilauer, Geophysical Institute, Prague). Objective: measurement of plasma density and temperature, electron distribution and drift velocity; data rate = 23 kbit/s; mass = 5.7 kg; electron temperature range = 10^3 - 10^4 K; ion density 10^2 - 5×10^6 cm⁻³. The sensor is a plane sonde that is made up of 4 electrodes.

NAM-5 = Radiofrequency Mass-Spectrometer (PI: J. Shmilauer, Geophysical Institute, Prague). Objective: measurement of ions and neutral plasma composition. Range of mass = 1-60 amu; data rate = 29 kbit/s; mass = 6.1 kg

DME = Soft Electron Detector (PI: A. Melentiev, IKI). Objective: flux measurement of soft electrons in the energy spectrum of 0.01 - 10 keV; data rate = 6 kbit/s; mass = 6.1 kg.

ANAPURNA = Energy and Pitch Distribution Experiment (PI: A. Melentiev, IKI). Objective: measurement of energy and angular distributions of electrons in the range: 0.2 - 40 keV; data rate = 4 kbit/s; mass = 11 kg

SPE-1 = High Energy Particles Experiment (PI: K. Kudela, Institute of Exp. Physics, Kosice, CSFR). Objective: measurement of spectra and anisotropy of electrons and protons; E_e = 30-600 keV; E_p = 15-600 keV; data rate = 14 kbit/s; mass = 4.5 kg.

K.2.1 Subsatellite Magion-2 (C2-AK)

Magion = **M**agnetospheric and **I**onospheric research satellite (built by the Academy of Sciences of the Czech Republic, Geophysical Institute, Prague) with spring separation on command from mother craft. Objectives: monitoring of propagation VLF waves from the mother spacecraft. Magion 2 introduced the current Magion base configuration with a mass of about 52 kg and a diameter of 0.6 m. The octagonal bus is equipped with four small solar arrays as well as body-mounted solar panels.

Full deployment of booms and four solar panels was confirmed on Dec. 24. 1989. The science program began on January 21, 1990. Magion-2 was operational until November 20, 1990. Magion-2 mass = 51.7 kg (11.4 kg of scientific instruments); 26 face polyhydron; 560 mm diagonal (see Figure 249 for Magion S/C). Data: Downlink transmission in VHF-band (frequencies of 137 and 400 MHz). Selectable digital data rates of 5, 10, 20, and 41 kbit/s.

Orbit: perigee = 507 km, apogee = 2491 km, inclination = 82.59°

Sensors for the measurement of the electric and magnetic fields; VLF waves, plasma and energetic particles.

SGR-7 = 3-axis Fluxgate Magnetometer (PI: M. Ciobanu, IKI, Romania). Measurement range of ± 50048 nT or 6256 nT, resolution = 16 nT or 2 nT, frequency range = 0 - 20 Hz. Measures magnetic field vector and serves as an attitude sensor.

- **SGR6** = 1-component Fluxgate Variometer; dynamic range = ± 156 nT; resolution = 50 nT; frequency range = 0.1 - 20 Hz.

KEM-1 = Magnetic and Electric Field Analyzer (PI: P. Triska, GFU, Czech Republic);

- ULF = Electric Field Experiment (three components of the quasi-static electric field); dynamic range = 0.005 - 8000 mV, frequency range = 0.1 - 20 Hz.
- VLF Wave Experiment (2-axis electric and 1-component magnet ELF-VLF field measurements, broadband waveforms, spectrum analyzer, filter bank;
 $E_{x,y,z}$: 0.1 Hz - 120 kHz, sensitivity of $10^{-7} \text{V/mHz}^{1/2}$, 120 dB dynamic range.
 B_x : 10Hz - 40 kHz, sensitivity of $5 \times 10^{-6} \text{nT/Hz}^{1/2}$ at 2 kHz and $10^{-4} \text{nT/Hz}^{1/2}$ at 100 Hz, dynamic range 120 dB.
- Data transmission modes selectable: broadband analog data 10 Hz - 60 kHz one channel, 10 Hz - 20 kHz broadband three channels, subcarriers of 1 kHz bandwidth four channels.
- Filter bank; 17 Hz - 15 kHz, eight filters, four independent sets
- Frequency analyzer: range of 1 - 220 kHz, 32 frequency steps, full spectrum/2s, selection of any frequency.

KM-12 = Cold Plasma Analyzer (PI: J. Shmilauer, GFU, Czech Republic); HF probe measures two components of the electron temperature in the range: $T_e = 10^3 - 10^5 \text{ K}$, spacecraft potential from -2 to +2V; Spherical ion trap measures ion density (N_i) in the range: $10^8 - 10^{13} / \text{m}^3$, $\Delta N_i / N_i$ fluctuations $f_{\text{max}} = 50 \text{ Hz}$.

Figure 249: The Magion-2 S/C model

ZL-A-S = Langmuir Probe (PI: K. Sauer, MPE, Germany); measurement of electron and ion density in the range: $500 - 10^8 \text{ cm}^{-3}$; electron temperature: 0.05 - 3 eV; current range:

10^{-10} - 10^{-3} A; in the current-mode density fluctuations $f = < 200$ Hz, $\Delta N_e/N_e$ resolution 10^{-3} .

PRS-2-C = Radiowave Spectrometer (PI: Z. Kloss, CBK PAN, Poland). Measurement of HF wave spectra. Frequency range = 0.1 - 10 MHz, dynamic range = 1 μ V - 10 mV, 0.2 s/spectrum using $\Delta f = 50$ kHz or 2s/spectrum using $\Delta f = 15$ kHz; field fluctuations at fixed frequency (selectable), $\Delta t = 1$ ms.

DOK-A-S = Silicon Detector Spectrometer (PI: K. Kudela, UEF SAV, Slovakia); two sensors (parallel and perpendicular to the magnetic field vector), measurement of electrons and ions (20 keV - 1 MeV, eight energy levels, geometric factor 10^{-2} cm² sr).

MPS SEA = Energetic Particle Spectrometer (PI: Z. Nemecek, Prague University, Czech Republic); electrostatic analyzers, measurement of electrons and positive ions: 0.2 - 20 keV in 16 energy levels, pitch angle resolution 30°, geometric factor is $\sim 10^{-3}$ cm² sr.

FDS = Photometer (PI: N. Petkov, IKI, Bulgaria); measurement of optical ionospheric plasma emissions (630 and 577.7 nm).

K.3 ALEXIS (Array of Low-Energy X-Ray Imaging Sensors)

ALEXIS ¹⁴³⁷⁾ is a sophisticated ‘minisatellite technology demonstration mission’ of Los Alamos National Laboratory, (LANL) Los Alamos, New Mexico, funded by DOE and built by AeroAstro Inc., Herndon, VA. Sandia National Laboratory, UCB/SSL (UC Berkeley/Space Sciences Laboratory) are partners of LANL in the mission. The spacecraft was launched by a Pegasus air-launched booster (of OSC) on April 25, 1993. During powered flight a solar paddle was damaged; initial attempts to contact ALEXIS were unsuccessful. The satellite responded in June 1993 and soon was brought under control. By late July 1993, full satellite operations had been restored through implementation of new procedures for attitude control. S/C operations are performed from LANL. ^{1438) 1439) 1440)}

The S/C bus is a complex, robust, and flexible structure comprised of communications, power, and control subsystems. The bus processor comprises redundant 80C86-based CPUs and six on-board mass memory boards with 96 MByte (SRAM) total storage capacity. This bus assembly occupies less than 25% of the S/C volume with a mass of 45 kg. The S/C is spin-stabilized and uses solar pointing for orientation (fine and coarse sun sensors) and magnetic torque coils for attitude reconstitution. The bus points the payload in the anti-sun direction and rotates once per about 50 seconds about that sun-line. Sun sensors and a limb sensor provide attitude knowledge of 0.1°. Attitude is controlled using magnetic torque coils. Total S/C mass = 113 kg, power = 60 W. Power is produced by four deployable solar panels and a fifth fixed disk which also serves as a sun shield. Power is distributed to four 1.2 Ah NiCd 28V batteries.

The ALEXIS payload consists of an ultrasoft X-ray telescope array and a high-speed VHF receiver/digitizer with the name of Blackbeard.

S-band data transmission (uplink/downlink). Downlink data rate = 750 kbit/s, uplink data rate = 9.6 kbit/s.

Orbit: Apogee = 844 km, perigee = 749 km, inclination = 70°

¹⁴⁴⁰⁾ <http://nis-www.lanl.gov/nis-projects/alexis/>

Figure 250: The ALEXIS S/C model

Status of S/C mission: Up to 1999 the ALEXIS mission was operating nominally, it has exceeded all expectations in spite of the serious launch incident with the solar panel array. A completely new software system (on the ground) is in place to calculate S/C attitude, critical to the on-board operation of the X-ray telescopes. Over 80 GByte of mission data have been received thus far. The design life of one year has been exceeded by far.¹⁴⁴¹⁾

Dual-ported RAM failures in the fall of 1999 have resulted in data only available from telescope pairs #1 & #2 and from the Blackbeard experiment. Data quality in the telescopes has been degrading as solar maximum approached due to increased particle backgrounds.

Sensor complement:

ALEXIS = Array of Low Energy X-Ray Imaging Sensors (instrument has the same name as the S/C). Alexis is an outward-looking instrument for the detection of astrophysical signals. The instrument is an ultrasoft X-ray monitor, consisting of six compact normal-incidence telescopes tuned to narrow bands centered on 66, 71 and 93 eV. The 66 and 71 eV band-passes are centered on a cluster of emission lines from Fe IX-XII. The 93 eV band, although designed as a continuum channel, includes Fe XXIII line characteristics of 10^7 K plasma.

The six ALEXIS EUV telescopes are arranged in pairs covering three overlapping 33° FOVs. During each 45-second spin of the S/C, ALEXIS monitors the entire antisolar hemisphere. Each telescope consists of a spherical mirror with a Mo-Si layered synthetic microstructure (LSM) or multilayer coating, a curved profile microchannel plate detector located at the telescope's prime focus, a UV background-rejecting filter, electron rejecting magnets at the telescope aperture, and image processing readout electronics. The geometric collecting area of each telescope is about 25 cm², with spherical aberration-limiting resolution to about $0.25''$. The resolution of each telescope is limited to about 0.5° diameter. The ALEXIS detectors are double plate, curved front faced, microchannel plates (MCP) paired with wedge and strip-resistive anodes. The two MCPs, of 46 mm in diameter, are single photon imaging detectors, each with 12.5 μ m diameter channels.

¹⁴⁴¹⁾Information provided by J. Bloch of LANL, Los Alamos, NM

The mass of the ALEXIS instrument is 45 kg, power = 45 W; the average data rate is 10 kbit/s of event data. Position and time of arrival are recorded for each event (detected photon, etc.). Measurement objectives: mapping the diffuse background in three bands, performing a narrow-band survey of point sources, searching for transient phenomena, and monitoring variable ultrasoft X-ray sources.^{1442), 1443)}

Blackbeard. The instrument looks at signals emitted near the Earth. Blackbeard is a radio frequency (RF) experiment with the objective to study distortion and interference effects on transient transionospheric VHF signals, such as lightning and artificial pulses. The instrument senses perturbations to the ionosphere; it can make a distinction between multipath distortions resulting from large-scale coherent perturbations and from small-scale random perturbations to the ionosphere. The specific experiments of Blackbeard include:

- Broadband VHF measurements of transient signals originating from a controlled pulsed ground beacon, to characterize broadband ionospheric distortion.
- Narrowband VHF measurements of CW-signals from a multichord interferometry ground beacon array, to characterize the ionospheric structure contributing to transmission distortion.
- Surveying power envelopes of lightning and man-made interference in selectable VHF bands, for background rejection purposes.

Blackbeard operation consists of on-board 150 MHz digitization for 0.1 s in a broadband reception mode; or 50 kHz digitization for 320 s in a narrow-band reception mode; or 120 kHz effective digitization for 130 s in a power-envelope survey mode. - The broadband mode has selectable bandwidths up to 65 MHz within the ranges 25-100 MHz and 100-175 MHz, with a maximum of 30 dB SNR. The narrow-band mode has eight selectable 4 kHz bands between 32 and 36 MHz, with a maximum 40 dB SNR and 0.1 Hz Doppler resolution. Mixed-mode operation is available in which broadband and narrowband data are collected to allow correlated RF distortion and ionospheric structure analysis.

The Blackbeard instrument observed strange radio bursts called TIPPes (Trans-Ionospheric Pulse Pairs). These strange signals are the most intense radio sources from Earth which can be much stronger than typical lightning. Then in 1996, LANL researches reported the first simultaneous Blackbeard observations and multiple ground station measurements of TIPPes. The new evidence suggests that TIPPes come from thunderstorms and probably comprise an atmospheric event and its reflections off Earth. ^{1444) 1445)}

K.4 AMPTE (Active Magnetosphere Tracer Explorers)

AMPTE^{1446),1447),1448)} is a three satellite cooperative mission of the United States, Germany and the United Kingdom. Objectives: studies of solar-terrestrial interactions, in particular the interaction processes between two cosmic plasmas. Further aims of this mission are a systematic exploration of the highly variable mass and charge composition of the natural plasma population and a detailed investigation of the magnetospheric boundaries.

AMPTE uses artificial injection of rare ionic species for long-range tracing of mass transport into and through the magnetosphere system. Injection of lithium, barium and europium ions into the solar wind and magnetotail.

The AMPTE program consists of three spacecraft - the Ion Release Module (IRM) provided by Germany, the United Kingdom Subsatellite (UKS), and the US/NASA Charge Composition Explorer (CCE). All S/C were launched in a stack on a single Delta vehicle on Aug. 16, 1984 from Cape Canaveral.

The IRM S/C has a mass of 705 kg. It carries scientific instruments and 16 canisters, 8 of which are filled with 5.8 kg of a copper-oxide-lithium mixture, the remaining eight are filled with a copper-oxide-barium mixture. The canisters are released in pairs by ground command, and the copper-oxide thermite reactions, which vaporize the tracer elements, are initiated by internal timers triggered during the release. A total of seven releases were planned over a period of 8 months which could be monitored by the maneuverable UKS following 3 minutes behind IRM and by CCE in a much lower orbit.

The IRM S/C was developed and built by MPE Garching and operated by GSOC (of DFVLR, now DLR) at Oberpfaffenhofen. IRM failed in eclipse on Aug. 12, 1986.

Figure 251: Orbital plane constellations at major events in the AMPTE mission

The UKS spacecraft has a mass of 78 kg. It is intended to detect and measure ion releases in the vicinity of the IRM S/C. The UKS spacecraft was developed and built by RAL and operated by SERC. UKS failed unexpectedly on Jan. 16, 1985.

Figure 252: The AMPTE mission S/C models (launch stack configuration)

Final Orbits	CCE	IRM	UKS
Apogee (geocentric)	8.8 R _E	18.7 R _E	18.7 R _E
Perigee (height)	1113 km	552 km	552 km
Period	15.6 hrs	44.3 hrs	44.3 hrs
Inclination	4.82°	28.68°	28.68°
Releases (active injections)		7	
1st releases (Sept. 1984) of lithium tracer ions into the solar wind near the ‘nose’ of the magnetosphere and close to the Earth/sun line.			
2nd release (Dec. 27, 1984) called ‘artificial comet’ with IRM located in the dawn magnetosheath			
3rd and 4th releases (March and May 1985) with IRM located in the Earth’s magnetotail region			

Table 433: Orbit parameters and major release periods of the AMPTE spacecraft

The CCE spacecraft weighs 240 kg. Its function is to detect and measure trace quantities of injected ion releases at far distances. APL of Johns Hopkins developed and built the CCE spacecraft under NASA/GSFC contract, JPL provided tracking and S/C operations support. CCE operated fully until Jan. 10, 1989 and then intermittently until July 17, 1989 when the mission was terminated.

In September 1984, lithium was released into the solar wind by IRM; preliminary results indicated that less than 1% of the solar wind gained access to the Earth’s magnetosphere. On December 27, 1984, IRM released two barium canisters; they were observed to explode 10 minutes later by UKS, CCE, two high-flying aircraft and ground stations in the Pacific. The expanding cloud of the barium mixture (in a position about 103,000 km above the Pacific ocean) ionized within seconds by solar UV radiation, fluorescing in the dawn sky as seen from the western US. After about 12 minutes an ‘artificial comet’ of about 225 km diameter had formed, developing a tail longer than 9000 km.¹⁴⁴⁹⁾

K.4.1 IRM Instrumentation (Sensors)

IPIP = IRM Plasma Instrument Package (3-D Plasma Analyzer). The instrument package consists of three sensors. Two of them measure the 3-D velocity distribution of ions and electrons. The third sensor is a retarding potential analyzer (RPA) for low-energy electron measurements; symmetrical quadrispheres. Energy ranges: ~0 eV - 25 eV, and 15 eV - 30 keV.

MSIS = Mass-Separating Ion Spectrometer. Objective: good mass-imaging characteristics and a wide fan-shaped angle of acceptance such that all ion species of interest can be measured simultaneously. Measurement technique: quadrispherical E/q analysis, magnetic analysis. Coverage: 0.01 - 12 keV/q.

SULEICA = Suprathermal Energy Ionic Charge Analyzer. Measurement of the ionic charge state and mass composition of all major ions from H through Fe for energies of the suprathermal plasma (~5 - 270 keV/q) by the use of electrostatic deflection, time-of-flight (TOF) measurement, and energy analysis in solid-state detectors. Measurement technique: electrostatic analyzer, time-of-flight and total E. Coverage: 10 - 300 keV/q. The data contain counting rate information for evaluating absolute particle fluxes, live pulse-height events, and matrix rates for selected ions.

Magnetometer. Measurement technique: vector fluxgate (triaxial). Objective: measurement of the magnetic variations during artificial plasma-cloud injections and study of magnetospheric boundary layers and the ring-current region. Coverage: DC - 50 Hz. Dynamic range = 0.1 - 60000 nT; resolution = 16 bit analog to digital conversion.

PWI = Plasma Wave Instrumentation (spectrometer). Measurement of plasma wave activity in the magnetosphere/solar wind environment and inside artificial plasma clouds. Mea-

¹⁴⁴⁹⁾“AMPTE,” Interavia Space Directory 1992-93, p. 149

surement technique: 42 m tip-to-tip dipole antenna, boom-mounted search coils. Coverage: E-field: DC - 5 Hz; B-field: 30 Hz - 1 MHz.

Lithium/Barium Experiments. Measurement technique: Copper-oxide thermite reaction. The injection of lithium and barium plasmas into the solar wind and geomagnetic tail constitute the active element of the AMPTE mission. The objective of the releases is ion tracing and the study of the interaction of two vastly different plasmas in space.

- 8 lithium release canisters (52 kg)
- 8 barium release canisters (108 kg)

K.4.2 UKS Instrumentation (Sensors)

3D-Ion Analyzer. Objective: measurement of the 3-D distribution function of positive ions. Measurement technique: electrostatic analyzer. Coverage: 10 eV/q - 20 keV/q.

3D-Electron Analyzer. Objective: measurement of electrons (count rates). Measurement technique: electrostatic analyzer. Coverage: 6 eV - 25 keV.

SPACE = S/C Particle Correlator Experiment. Objective: Measurement of particle modulations (ions and electrons) resulting from local wave-particle interactions. Measurement technique: electron and ion signal processing. Coverage: ~ 1 Hz - ~ 1 MHz.

Magnetometer (of ISEE1/2 heritage). Measurement technique: vector fluxgate (triaxial), boom-mounted about 1 m from the S/C body. Coverage: DC - 10 Hz.

Plasma Wave Spectrometer. Objective: Measurement of the electric and magnetic field components. Measurement technique: 7 m tip-to-tip probe. Coverage: E-field: 30 Hz - 132 kHz, 4 spot frequencies to 2 MHz; B-Field: 30 Hz - 50 kHz (boom-mounted search coil).

K.4.3 CCE Instrumentation (Sensors)

HPCE = Hot Plasma Composition Spectrometer (energetic ion-mass spectrometer and an electron background-environment monitor). Heritage of GEOS-1/2, ISEE-1 and DE-1 missions. Measurement technique: retarding potential electrostatic analyzer, ExB analyzer. Coverage of ion composition: 0 eV/q - 17 keV/q. Measurement technique of electrons: magnetic analyzers. Coverage: 50 eV - 25 keV.

CHEM = Charge-Energy-Mass Spectrometer. Measurement of energy spectra, pitch angle distributions, and ionization states. Measurement technique: electrostatic analyzer, time-of-flight and total E. Coverage: ion composition in the range from ~ 1 keV/q - 300 keV/q.

MEPA = Medium Energy Particle Analyzer. Measurement technique: time-of-flight and total E. Coverage: ion composition in the range of 10 keV/nucleon - > 1.0 MeV/nucleon.

Magnetometer. Measurement technique: vector fluxgate (triaxial). Coverage: DC - 50 Hz.

Plasma Wave Spectrometer. Objective: provision of first-order correlative information for studies of strong wave-particle interactions that develop close to the magnetic equator or have maximum effectiveness there. Measurement technique: electric dipole. Coverage: AC E-fields. 5 Hz - 178 kHz.

K.5 APEX (Active Plasma Experiment)

APEX^{1450) 1451)} is a cooperative solar-terrestrial mission within the Intercosmos program (Russia/CSFR/Hungary/Germany/Poland/Bulgaria/Romania). Objectives: study of terres-

trial magnetospheric and auroral ionospheric relationships by the injection and monitoring of electron and ion beams by a parent/subsatellite pair. The injection of electron and ion beams into the magnetosphere is accomplished by the parent craft.

- Simulation and initiation of aurora and radio frequency radiation in an auroral region.
- Study of the dynamics of modulated beams and plasmoids in the near-Earth plasma.
- Study of the nature of electrodynamic relationships of electromagnetic waves in the magnetosphere and ionosphere.
- Determination of radio emission characteristics of modulated beams of charged particles and plasmoids.
- Search for nonlinear wave structures of the electromagnetic soliton type in a disturbed environment.

Launch: December 18, 1991 by SL-14 from Plesetsk. APEX mass = 1350 kg, payload mass = 340 kg (parent satellite), Magion-3 (subsatellite) = 52 kg. Science program leader: V. N. Oraevski (IZMIRAN). APEX is an operational mission as of 1993.

Orbit: apogee = 3071 km, perigee = 438 km, inclination = 82.56°.

Sensor complement:

UEM-2 = Electron Accelerator (PI: V. Dokukin, IZMIRAN). Objective: Injection of a modulated electron beam with an energy of 10 keV. The beam current is in the range from 10^{-2} A to 15 A. The frequency modulation is in the range from 10 Hz - 2.5×10^5 Hz.

UPM = Neutral Plasma Accelerator (PI: V. Dokukin, IZMIRAN). Objective: injection of xenon ions. The beam has an energy of 300 eV, the beam current is 2A; the frequency modulation range is from 60 - 1000 Hz.

PEAS = Electron and Ion Analyzer (PI: N. M. Shutte, IKI). Objective: measurement of the energetic and pitch-angle distributions of electrons and ions with energies in the range from 30 eV to 30 keV. The sensor is a toroidal electrostatic analyser.

DEP-2E = Electric Field Instrument (V. Chmirev, IZMIRAN, G. Stanev, IKI, Bulgaria). Objective: measurement of quasi-static electric fields. Sensor: three-component double-spheric sonde.

DEP-2R = AC Field Analyzer (V. Chmirev, IZMIRAN, G. Stanev, IKI, Bulgaria). Objective: measurement of the quasi-static electric field. The signals of DEP-2R are analyzed by DEP-2E.

DANI = Potential and Soft Particle Analyzer (PI: Tc. Dachev, IKI, Bulgaria; V. Temnyi, IZMIRAN). Objective: measurements of energetic and pitch-angle distributions of electron and ions in the range from 0.1 - 30 keV as well as the potential of the satellite and the electron density. Sensors: toroidal analyser, parabolic analyser (Rogoski belt).

KM-10 = Cold Plasma Measurements (PI: V. Afonin, IKI; J. Shmilauer, GFI CSAN, former CSFR now CR). Objective: measurement of the temperature distribution of electrons, the anisotropy of the temperature, the energetic distribution in a range from 0.1 - 10 eV, the density of ions, and the potential of the satellite. The sensor is a plane sonde with four electrodes.

NVK-ONCH = VLF Analyzer (PI: Ya. Sobolev, IZMIRAN). Same instrument as in ACTIVE mission.

UF-3K = Photometer (PI: Yu. Ruzhin, IZMIRAN). Objective: observation of optical effects at the injection time of the electron and ion beams. Working wavelengths: 3914 Å, 5577 Å, and 6300 Å. The dynamic range is 80 dB and the look angle is 8° (from nadir).

1450) "The Active Plasma Experiments in the Earth's Magnetometers," The Solar-Terrestrial Science Project of the Inter-Agency Consultative Group, ESA SP-1107, November 1990, pp. 55-60

1451) Information provided by Yu. M. Mikhailov, IZMIRAN

FS = Photometer (PI: Yu. Ruzhin, IZMIRAN). Objective: measurement of the illumination intensity (at the injection of the electron and ion beams) in the range from 3914-6563 Å.

SGR-5 = Fluxgate Magnetometer (PI: L. Zhusgov, IZMIRAN). Objective: measurement of the three components of the magnetic field in the range of $\pm 64,000$ nT with an accuracy of 1 nT.

MNCH = Search-Coil Magnetometer (PI: V. Chmirev, IZMIRAN). Objective: measurement of the magnetic field variations in the frequency range from 0.1 - 10 Hz and an amplitude range of 40 - 400 nT. The information transfer is provided on the DEP-2E sensor.

NAM-5 = Radiofrequency Mass-Spectrometer (PI: V. Istomin, IKI, J. Shmilauer, GFI CSAN, CSFR). Same instrument and same objectives as on ACTIVE mission.

AVCH-2T = HF-Field Analyzer (PI: Z. Klos, Center of Cosmic Research, Polish Academy of Sciences, Warsaw; S. A. Pulinets, IZMIRAN). Objective: Spectrum analysis of high-frequency electromagnetic radiation in the range of 0.1 to 15.1 MHz. The sensor is a self-opening band-type antenna of 15 m length.

K.5.1 APEX Subsatellite (Magion-3) Scientific Payload

Objective: monitoring the propagation of electron beams and plasma injected by the parent spacecraft as well as monitoring plasma of natural origin. Magion-3 was separated from its parent on December 28, 1991; the experiments are almost identical to those of Magion-2 (ACTIVE mission).

Orbit: perigee = 500 km, apogee = 3200 km, inclination = 83°

SGR-7 = 3-axis Fluxgate Magnetometer (PI: M. Ciobanu, IKI, Romania). Measurement range of ± 50048 nT or 6256 nT, resolution = 16 nT or 2 nT, frequency range = 0 - 20 Hz. Measurement of magnetic field vector and serving as attitude sensor.

- **SGR6** = one-component Fluxgate Variometer; dynamic range = ± 156 nT; resolution = 50 nT; frequency range = 0.1 - 20 Hz.

KEM-1 = Magnetic and Electric Field Analyzer (PI: P. Triska, GFU, Czech Republic);

- **ULF** = Electric Field Experiment (three components of the quasi-static electric field); dynamic range = 0.005 - 8000 mV, frequency range = 0.1 - 20 Hz.
- **VLF Wave Experiment** (three-axis electric and one-component magnet ELF-VLF field measurements, broadband waveforms, spectrum analyzer, filter bank;
 $E_{x,y,z}$: 0.1 Hz - 120 kHz, sensitivity of 10^{-7} V/mHz^{1/2}, 120 dB dynamic range.
 B_x : 10 Hz - 40 kHz, sensitivity of 5×10^{-6} nT/Hz^{1/2} at 2 kHz and 10^{-4} nT/Hz^{1/2} at 100 Hz, dynamic range 120 dB.
- Data transmission modes selectable: broadband analog data 10 Hz - 60 kHz one channel, 10 Hz - 20 kHz broadband three channels, subcarriers of 1 kHz bandwidth four channels.
- Filter bank; 17 Hz - 15 kHz, eight filters, four independent sets
- Frequency analyzer: range of 1 - 220 kHz, 32 frequency steps, full spectrum/2s, selection of any frequency.

KM-12 = Cold Plasma Analyzer (PI: J. Shmilauer, GFU, Czech Republic); HF probe measures two components of electron temperature in the range: $T_e = 10^3 - 10^5$ K, spacecraft potential from -2 to +2V; spherical ion-trap measures the ion density (N_i) in the range: $10^8 - 10^{13}$ /m³. $\Delta N_i/N_i$ fluctuations $f_{\max} = 50$ Hz.

ZL-A-S = Langmuir Probe (PI: K. Sauer, MPE, Germany); measurement of electron and ion density, range: $500 - 10^8$ cm⁻³; electron temperature: 0.05 - 3 eV; current range: $10^{-10} - 10^{-3}$ A; in the current-mode density fluctuations $f < 200$ Hz, $\Delta N_e/N_e$ resolution 10^{-3} .

PRS-2-C = Radiowave Spectrometer (PI: Z. Kloss, CBK PAN, Poland). Measurement of the HF wave spectra. Frequency range = 0.1-10 MHz, dynamic range = 1 μ V-10 mV, 0.2 s/spectrum using $\Delta f = 50$ kHz or 2 s/spectrum using $\Delta f = 15$ kHz; field fluctuations at fixed frequency (selectable), $\Delta t = 1$ ms.

DOK-A-S = Silicon Detector Spectrometer (PI: K. Kudela, UEF SAV, Slovakia); two sensors (parallel and perpendicular to the magnetic field vector), measurement of electrons and ions (20 keV - 1 MeV, 8 energy levels, geometric factor 10^{-2} cm² sr).

MPS SEA = Energetic Particle Spectrometer (PI: Z. Nemecek, Prague University, Czech Republic); electrostatic analyzers, measurement of electrons and positive ions: 0.2 - 20 keV in 16 energy levels, pitch angle resolution 30°, geometric factor is $\sim 10^{-3}$ cm² sr.

K.6 ASTRID

ASTRID is a spin-stabilized microsatellite series designed and built by SSC (Swedish Space Corporation) of Solna, Sweden; the payload design is by the Swedish Institute of Space Physics in Kiruna (IRF-K).

Figure 253: ASTRID-1 S/C Model

K.6.1 ASTRID-1

ASTRID-1 is a research mission in the field of solar-terrestrial energy transport physics and has the objective to investigate the Earth's near-space plasma with emphasis on neutral particle phenomena with high-resolution observations in the upper ionosphere and the lower magnetosphere.¹⁴⁵²⁾

The S/C design marks the first use of the Freja-C compact satellite platform featuring a generic bus. The S/C structure consists of a perforated, corrosion-resistant Al-honeycomb

¹⁴⁵²⁾Information provided by S. Grahn of SSC

core; it is a box-like structure (420 x 420 x 290 mm) with four solar panels. ASTRID-1 is spin-stabilized; attitude determination and control of the S/C is provided by a sun sensor, by two 2-axis flux-gate magnetometers, and two magnetotorquers. Antennas: S-band transmit and UHF transmit & command receive. RF transmitters: S-band frequency = 2200-2300 MHz, RF output power = 2 W, phase modulation; UHF: frequency = 400.15-401 MHz, RF output power = 2W, frequency modulation. Command receivers: frequency = 449.95 MHz, FM modulation. Power: solar array output = 42 W at 29.8 V plus battery. S/C mass = 27 kg (payload mass=4.5 kg).

ASTRID-1 was launched piggyback, together with FAISAT-1, on a Russian launch vehicle (Kosmos-3M rocket) from Plesetsk on January 24, 1995. Design life of S/C = 6 months. Mission control performed by the Swedish Institute of Space Physics in Kiruna via Esrange. Data rates: 131 kbit/s (S-band) and 8 kbit/s (UHF). Status: The ASTRID-1 payload was operational until March 1, 1995. The S/C platform worked until September 1995.

Orbit: Circular orbit, altitude = 1000 km (apogee=1026 km, perigee=966 km, inclination = 83°, nodal period = 105.07 minutes.

Sensors: all instruments are built by IRF (Swedish Institute of Space Physics, Kiruna.¹⁴⁵³⁾

PIPPI = Prelude in Planetary Particle Imaging (PI: O. Norberg, IRF, Kiruna)

A neutral particle imager (main sensor of ASTRID-1) with the objective to measure energetic neutral particles in the Earth's magnetosphere. The instrument consists of two cameras: an SSD (Solid State Detector) camera which resolves the energy of detected particles; and the MCP (Microchannel Plate) camera which uses a technique whereby incoming neutrals cause charged secondary particles to be emitted from a graphite target; the secondaries are then detected by MCP. Both cameras have deflection systems which can reject charged particles up to an energy of 140 keV. The sensor aperture plane is perpendicular to the spin plane; all directions are thus covered in half a spin period or ~1.5 s. PIPPI also serves as the data processing unit for EMIL and MIO.

Parameter	SSD Camera	MCP Camera
Energy range	13-140 keV	0.1-70 keV
Energy resolution	8 levels	-
Sampling time	31.25 ms	31.25 ms
Number of apertures	14	31
Angular resolution	23° x 5°	11° x 9°
Geometric factor	0.035 cm ² steradian	0.08 cm ² steradian
Bit rate	60.5 kbit/s	16 kbit/s
Mass, Power	3.1 kg, 4.0 W	

Table 434: PIPPI instrument characteristics

EMIL = Electron Measurements, In-situ and Lightweight

The electron spectrometer consists of a swept-energy toroidal electrostatic analyzer and a microchannel plate (MCP) detector with six angular channels in the satellite spin plane. The sensor measures the electron distribution in the magnetosphere at 62.5 ms or 125 ms resolution.

Energy range	50 eV - 40 keV, resolution ($\Delta E/E$) = 0.10
Energy steps	32 or 64
Sampling time per step	2 ms
Total geometric factor	4 x 10 ⁻⁴ cm ² steradian keV/keV
Bit rate	24 kbit/s
Mass, Power	0.9 kg, 0.9 W

Table 435: EMIL instrument characteristics

¹⁴⁵³⁾Information provided by O. Norberg of IRF, Kiruna

MIO =Miniature Imaging Optics

The instrument consists of two UV-photometers mounted in the satellite spin plane. MIO-1 measures the Lyman- α emission from the Earth's geo-corona; MIO-2 observes auroral emissions. Each photometer consists of optics mounted in a stainless steel tube with a ceramic channel electron multiplier at the opposite end.

Spectral passbands	MIO-1 (Lyman- α): 121 nm (MgF2 + oxygen gas filter + KBr) MIO-2 (oxygen): 125-160 nm (CaF2 + KBr)
Focal width, FOV, sampling time	255 mm, 1°, 2 ms
Geometric factor	2×10^{-4} cm ² steradian
Bit rate, Mass, Power	8 kbit/s, 0.3 kg, 0.16 W

Table 436: MIO instrument characteristics

K.6.2 ASTRID-2

ASTRID-2 is also a research mission in the field of solar-terrestrial energy transport physics with the objective to perform a) high-resolution E-field and B-field measurements in the auroral region, b) electron density measurements, c) high-resolution measurements of electron and ion distributions functions, and d) UV auroral imaging and atmospheric UV-absorption measurements. The S/C structural design and stabilization is identical to that of ASTRID-1 (spin-stabilized sun-pointing platform) Attitude is sensed by ASC (Advanced Stellar Compass). The total S/C mass is 30 kg with a payload mass of about 10kg. The down-link is in S-band, data rate of 128 kbit/s, BPSK modulation (convolutional encoded). The uplink is in S-band at 10 kbit/s, FSK modulation. A launch took place on a Russian vehicle (KOSMOS-3M, ASTRID-2 was a secondary payload to a Russian navigation satellite, named Nadezhda-5) from Plesetsk on Dec. 10, 1998.

Orbit: Circular orbit, altitude = 1000 km, inclination = 83°.

Figure 254: The ASTRID-2 spacecraft

Sensor complement:

EMMA (Electrical and Magnetic field Monitoring of the Aurora). The objective is to measure both the electrical and magnetic fields.

LINDA (Langmuir Interferometer and Density experiment for Astrid-2). The objective is to measure the fine structure of the plasma density irregularities down to 1 m scales and, by using two probes, distinguish between temporal and spatial effects. LINDA consists of two 10 mm diameter spherical probes mounted on two light-weight booms. The booms are 61 cm long and mounted on the outer tips of the solar panels giving a probe-to-probe separation distance of 2.9 m. The sampling rate is 32 k-samples/s by using the snapshot technique. The measured quantities are the plasma density (derived from the probe current) and the relative density variations, derived from the variations in probe current.

MEDUSA (Miniaturized Electrostatic Dual-tophat Spherical Analyzer), a joint instrument provided by Southwest Research Institute, San Antonio, TX, and IRF-K. The objective is to measure simultaneously electrons and ions with energies up to 18 keV/q. The resolution is 16 energy sweeps/s for electrons, and 8 seconds for ions. Particles are measured in 16 sectors in the plane of acceptance, which is almost parallel to the satellite spin plane. MEDUSA includes a CPU for instrument control and data compression; instrument mass=1.5 kg, power = 5.3 W, data rate = 32 kbit/s (includes PIA photometers).

PIA (Photometers for Imaging the Aurora), provided by MP Ae, Katlenburg-Lindau, Germany, and by IRF-K. PIA consists of two spin-scanning photometers (PIA-1/2) for auroral imaging and one sunward-looking photometer (PIA-3) for atmospheric absorption measurements. PIA-3 is located under the sunward-facing platform and views the sun in Lyman-alpha (121 nm) via a diffuse reflector. PIA-1 and PIA-2 have four pixels each and a focal width of 250 mm. All photometers are sampled at 256/s. Instrument mass = 0.6 kg.

K.7 CLuster (Four S/C Mission in Concert with SOHO)

Cluster is a collaborative ESA/NASA mission within ESA's 'Solar Terrestrial Science Program' (STSP), part of ISTP (International Solar Terrestrial Physics Programme). Study of key interaction processes between two cosmic plasmas [study of small-scale structures (from a few to a few tens of ion Larmor radii) in the Earth's plasma environment].^{1454),1455)} The goal is to study the physical processes involved in the interaction between the solar wind and the magnetosphere by visiting key regions like the polar cusps and the magnetotail (mapping in three dimensions the plasma structures contained in these regions). Other regions of measurement are: a) solar wind and bow shock, b) magnetopause, and c) auroral zone. The simultaneous four-point measurements (with four S/C) also allow the derivation of differential plasma quantities for the first time.

K.7.1 Cluster-I

Note: The launch failure of Ariane-5 on June 4, 1996 with the Cluster satellites onboard and the ESA decision of a recovery program - are the reasons for a division into Cluster-I and Cluster-II programs.

The four identical Cluster S/C are spin-stabilized (15 rpm, stringent requirements on electromagnetic cleanliness). Conductive surfaces and an extremely low S/C-generated electromagnetic background noise are mandatory for accurate electric field and cold plasma measurements.

¹⁴⁵⁴⁾ISTP Global GEOSPACE Science - Energy Transfer in Geospace, ESA/NASA/ISAS brochure, 1992

¹⁴⁵⁵⁾J. Credland, G. Mecke, J. Ellwood, F. Drigani, P. Ferri, et al., Special Section of the Cluster mission, spacecraft, payload, data, and mission operations, ESA Bulletin, No. 84, Nov. 1995, pp. 113-150

Figure 255: The Cluster S/C model

Each S/C is cylindrical in shape with a diameter of 2.9 m and a height of 1.3 m with conductive surfaces. The S/C structure is based on a central CFRP cylinder supporting the main equipment platform (an aluminum-skinned honeycomb panel reinforced by an outer aluminum ring). The solar array power is 224 W (47 W are allocated to the payload), the five AgCd batteries have a capacity of 80 Ah. The solar arrays consist of BSR (Back-Surface-Reflection) cells, arranged in self-compensating formations to minimize the generation of DC magnetic fields. The conductive coating on the cell cover glass minimizes the build-up of differential charge potentials. - S/C attitude and spin data are provided by an internally redundant star mapper and an internally redundant X-beam sun sensor. On-board attitude determination is better than 0.25° by the star mapper and the sun sensor. The reconstitution of attitude data, such as inertial attitude, spin rate and spin phase, is performed on the ground. Orbit and attitude maintenance are performed by using control thrusters, both semi-radial and axial, together with the main engine, which are used to perform the large orbital change maneuvers required to reach the polar mission orbit from geostationary transfer orbit. Launch masses: No 1 = 1183 kg; No 2 = 1169 kg; No 3 = 1171 kg; No 4 = 1184 kg. Each S/C has 650 kg of propellant and 72 kg of payload mass.

The platform accommodates on one side the instruments. Each satellite carries two high capacity redundant tape recorders (data return of 50% per orbit). Two rigid booms, each 5 m, carry the magnetometers. Two pairs of wire booms, each with a tip-to-tip length of 100 m, permit electric field measurements (background magnetic field of about 0.25 nT is aim). - Cluster operations are performed by ESA/ESOC with support provided by NASA's DSN (Deep Space Network). The telemetry downlink of each S/C supports the following data rates: a) 2 kbit/s of TT&C data, b) 22 kbit/s for nominal science data, c) 131 kbit/s for burst science data, and d) 262 kbit/s for the WBD (Wide Band Data) experiment.

Orbit: Near-polar elliptical orbits of the spacecraft with an apogee of $20 R_E$ (127,000 km) into the solar wind, and a perigee of $4 R_E$ (25,500 km), inclination of 90° . Six months later the apogee swings through the geotail. The inter-spacecraft distances are smaller ($< R_E$) on the dayside orbital phase, eg., when the apogee is turned into the solar wind, and up to $4 R_E$ in the nightside orbit phase, eg., when the apogee swings through the geotail.

The Cluster launch on June 4, 1996 with the first Ariane-5 flight from Kourou turned out to be a failure. Ariane-5 rose flawlessly to an altitude of 3.5 km, at which point a sudden swiveling of both solid-booster nozzles caused the vehicle to tilt sharply. The resulting intense aerodynamic structural loads caused the rocket vehicle to break up, prompting the onboard safety systems to initiate self-destruction. The entire four-spacecraft mission was lost.

Sensor complement: (each payload consists of 11 instruments)¹⁴⁵⁶⁾ ¹⁴⁵⁷⁾ ¹⁴⁵⁸⁾

A Wave Experiment Consortium (WEC) was formed to get maximum scientific return from the available spacecraft instruments. WEC comprises five coordinated experiments designed for measuring electric and magnetic fluctuations, and small-scale structures within critical layers in the Earth's magnetosphere. These WEC experiments are: STAFF, EFW, WHISPER, DWP, and WBD.

FGM = Fluxgate Magnetometer. (PI: A. Balogh, Imperial College, London, UK)

Study of small-scale structures and processes in the Earth's environment. Objective: Provision of intercalibrated measurements of the magnetic field vector **B** at the four Cluster S/C. Identical instrumentation on all S/C (two triaxial fluxgate sensors and a data processing unit). Measurement of **B** wave from DC to 10 Hz, resolution ≥ 6 pT. Four magnetometer ranges:

- ± 256 nT resolution = ± 0.015 nT
- ± 1024 nT resolution = ± 0.061 nT
- ± 8192 nT resolution = ± 0.5 nT
- ± 65536 nT resolution = ± 4 nT

STAFF = Spatio-Temporal Analysis of Field Fluctuations (N. Cornilleau-Wehrin, CRPE/CNET, France)

Objectives: Study of wave-particle interaction in the region where the solar wind meets the Earth's magnetosphere. Measurement of **B** wave from up to 10 Hz, compressed data up to 4 kHz, cross-correlator for $\langle \underline{E}, \underline{B} \rangle$. A STAFF instrument is provided on all four S/C; it consists of a three-axis search coil magnetometer (measurement up to 4 kHz), and a spectrum analyzer to perform the auto and cross correlations between electric and magnetic components on board each satellite. STAFF is one of the five complementary experiments which form the Wave Experiment Consortium (WEC).

EFW = Electric Fields and Waves [G. Gustavson, IRF-U (Swedish Institute of Space Physics), Uppsala, Sweden]

Objectives: measurement of electric field and density fluctuations, determination of electron density and temperature, study of nonlinear processes that result in acceleration of the plasma, study of large-scale phenomena of data from all four S/C. The instrument consists of double probes, mounted on two pairs of wire booms, each 100 m tip-to-tip. Measurement of **E** wave from 10 Hz, compressed data up to 100 kHz, sensitivity < 50 nV/m (Hz)^{1/2}. EFW measurement modes:

- Instantaneous spin plane components of the electric field vector, over a dynamic range of 0.1 - 700 mV/m, and with variable time resolution down to 0.1 ms.
- Low energy plasma density, over a dynamic range at least 1 to 100 cm⁻³
- Electric field and density fluctuations in double layers of small amplitude, over dynamic ranges of 0.1 to 50 mV/m for the fields, and 1 - 50% for the relative density fluctuations, time resolution of 0.1 ms on some occasions
- Waves, ranging from electrostatic ion cyclotron emissions having amplitudes as large as 60 mV/m at frequencies as low as 50 mHz, to lower hybrid emissions at several hundred Hz and with amplitudes as small as a few μ V/m.

¹⁴⁵⁸⁾ "The Cluster Mission - Scientific and Technical Aspects of the Instruments," ESA SP-1103, ISSN 0379-6566, Oct. 1988

- Time delays between signals from up to four different antenna elements on the same S/C, with a time resolution of 25 μ s on some occasions.
- S/C potential

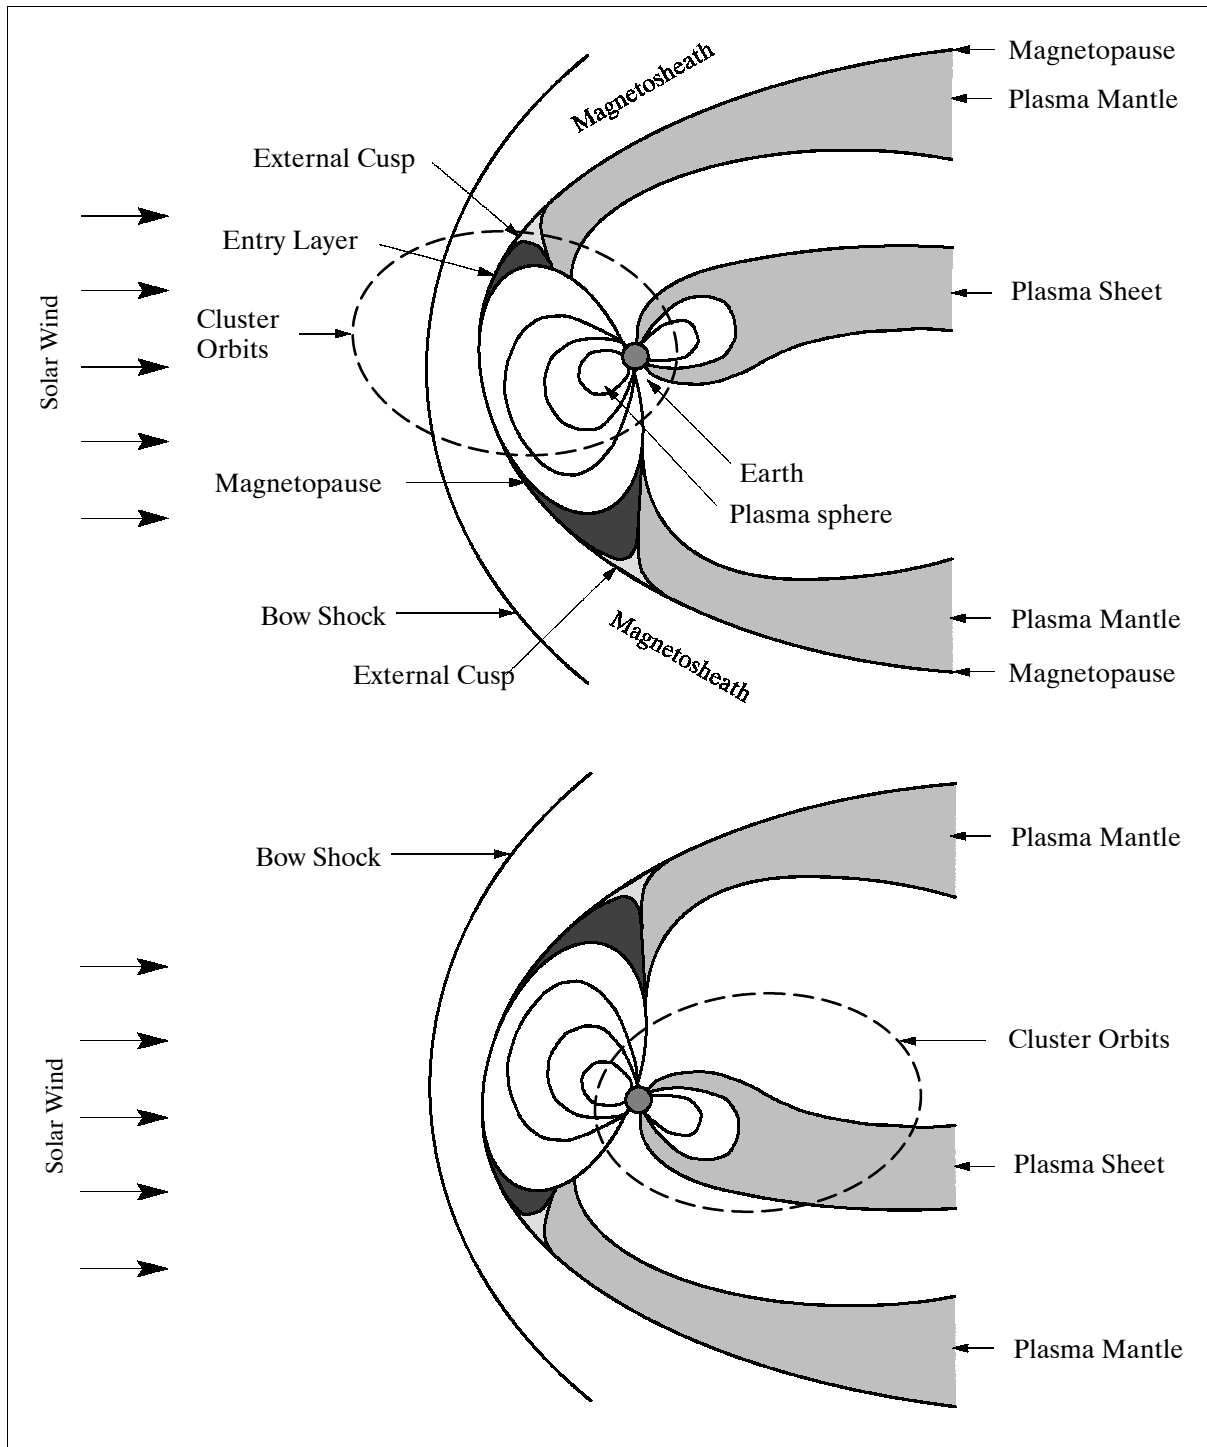

Figure 256: Cluster orbits in relation to the magnetosphere at six month intervals

WHISPER = Waves of High Frequency and Sounder for Probing of Density by Relaxation [P. M. E. Décréau, LPCE (Laboratoire de Physique et Chimie de l'Environnement), Orléans, France]. Objectives: accurate measurement of total plasma density within the range from 0.2 - 80 cm^{-3} (prime objective), continuous survey of one electric component of plasma waves in the frequency range from 4 - 80 kHz with an accuracy of about 160 Hz (secondary objective).

WHISPER employs the method of relaxation sounding (using parts of the EFW wire booms). The analysis of density variations is performed via active sounding of plasma resonances. Expected measurement results:

- identification of regions in space and mass transport
- spatial extension and drift speed
- density fluctuations
- wave mode identification
- coldest component of the electron density

Passive measurements of natural plasma waves up to 400 kHz.

WBD = Wide Band Data (D. A. Gurnett, University of Iowa, USA)

Objectives: Study of E-field wave form up to ~ 100 kHz in the Earth's magnetosphere. A wideband receiver system measures electric and magnetic fields over a frequency range from 25 Hz to 577 kHz. The Cluster wideband receiver is similar to the instruments flown on ISEE-1 and DE-1. WBD makes use of the EFW sensors (two electric dipole antennas, two search coil magnetometers); conversion frequencies: 0, 125 kHz, 250 kHz, 500 kHz; band-pass filter ranges: 1 kHz-100 kHz, 50 Hz-25 kHz, 10 Hz-10 kHz; frequency resolution: limited by FFT (75 Hz typical); time resolution: 10-20 ms (per FFT spectrum); The WBD measurements complement those of the other WEC instruments and also provide a unique new capability to perform very-long baseline interferometry (VLBI) measurements. - The wideband technique involves transmitting band-limited waveform data to a ground station using a high-rate data link (262 kbit/s R/T or 131 kbit/s in burst mode).

DWP = Digital Wave Processor (PI: H. Alleyne, University of Sheffield, UK)

Objectives: Correlation of wave/particle phenomena and wave/particle interactions. DWP is the on-board control system (multiprocessor unit based on the use of transputers with parallel processing and re-allocatable tasks to provide a high-reliability system.) of all WEC instruments performing data compaction and compression, event selection, particle/wave correlation, and control of WHISPER.

EDI = Electron Drift Instrument (Pi: G. Paschmann, MPE, Garching, Germany)

Objectives: accurate and highly sensitive measurements of the electric field. EDI measures the drift of a weak beam of test electrons which for certain emission directions return to the S/C after one gyration (the drift is related to the electric field and to the gradient in the magnetic field). EDI consists of two emitter/detector assemblies, each with a 2π FOV. $E = (0.1 - 10 \text{ mV/m}, < 100 \text{ Hz})$, ∇B , $|B| = 5-1000 \text{ nT}$, emission and tracking of two electron beams.

CIS = Cluster Ion Spectrometry [Pi: H. Rème, CESR (Centre d'Etudes Spatial des Rayonnement), Toulouse, France]. Objectives: Study of the dynamics of magnetized plasma structures in the vicinity of the Earth's magnetosphere (physics of the bow shock, the magnetopause boundary, the polar cusp, the geomagnetic tail, and the plasma sheet). CIS is a comprehensive ionic plasma spectrometry package on-board the four Cluster spacecraft capable of obtaining full 3-D ion distributions with good time resolution (one spacecraft spin) with mass per charge composition determination.

CIS consists of two instruments, CODIF and HIA to measure both the cold and hot ions from the solar wind, the magnetosheath, and the magnetosphere (including the ionosphere) with sufficient angular, energy, and mass resolution.

CODIF = Composition and Distribution Functions analyzer (energy range = 0.02 - 40 keV/q) to measure the 3-D distribution of major ion species (H^+ , He^{2+} , He^+ , and O^+). The instrument is a symmetrical hemispherical analyzer with RPA (Retarding Potential Analyzer) and TOF (Time-of-Flight) electronics, FOV = $2\pi \times 8^\circ$; split geometric factor.

HIA = Hot Ion Analyzer for high time resolution of the solar wind (energy range = 3 eV/q - 40 keV/q). The instrument is a symmetric quadri-spherical analyzer; FOV = $2\pi \times 8^\circ$ with high resolution. ($\geq 2.8^\circ$).

PEACE = Plasma Electron and Current Analyzer [Pi: A Fazakerley, MSSL (Mullard Space Science Laboratory), University College, London, UK]. Objectives: Study of the 3-D veloc-

ity distribution of electrons. PEACE consists of two electron sensor devices. LEFA = Low Energy Electron Analyzer (energy range = 0 - 100 eV). The instrument is a spherical electrostatic analyzer with a FOV of $\pi \times 3.8^\circ$. HEFA = High Energy Electron Analyzer (energy range = 0.1 - 30 keV). The instrument is a toroidal electrostatic analyzer with a FOV = $2\pi \times 4.6^\circ$.

RAPID = Research with Adaptive Particle Imaging Detectors [PI: B. Wilken, MPAe (MPI für Aeronomie), Lindau/Harz, Germany]. Objectives: Study of suprathermal plasma distributions in the energy range from 20 - 400 keV and 2 keV/n - 1500 keV for electrons and ions, respectively.

RAPID provides complete coverage of the unit sphere in phase space. It is made up of two instruments, the IIMS and IES. IIMS = Imaging Ion Mass Spectrometer for ion distribution. IIMS is a position-sensitive instrument with solid state detectors and TOF (Time-of-Flight) electronics. IES = Imaging Electron Spectrometer for measuring energetic electrons. IES has a position-sensitive solid state detector.

ASPOC = Active S/C Potential Control [PI: W. Riedler, IWF (Institut für Weltraumforschung), Graz, Austria]. Objective: control of the S/C charge potential to insure effective, complete measurement of the ambient plasma distribution functions. The basic approach involves the emission of charges from the S/C sufficient to balance the excess of charge accumulating on the satellite by the environment (photo emission of electrons drives the S/C potential positive relative to the plasma potential). - The method employed is field ionization with a Liquid Metal Ion Source (LMIS) of the "solid needle" type. LMIS uses Indium as charged material. The instrument consists of an electronics box and two cylindrical emitter modules with five needles each.

K.7.2 Cluster-II

In April 1997 ESA decided to go ahead with a recovery program, a new four-spacecraft mission, called Cluster-II, retaining all of the critical mission parameters. The Cluster-II mission comprises the Phoenix ¹⁴⁵⁹⁾ spacecraft (built with spares from the four original Cluster satellites) and three identical new satellites (construction and test of four S/C in 18 months, the industrial consortium is led by Astrium GmbH of Friedrichshafen, Germany). The overall objective is to investigate the physical interaction between the sun and the Earth, with four spacecraft flying in tetrahedral formation. ¹⁴⁶⁰⁾ ¹⁴⁶¹⁾ ¹⁴⁶²⁾ ¹⁴⁶³⁾ ¹⁴⁶⁴⁾ ¹⁴⁶⁵⁾

Like their predecessor of Cluster-I, each Cluster-II S/C is cylindrical in shape with a diameter of 2.9 m and a height of 1.3 m (launch mass = 1200 kg, payload = 72 kg, S/C (dry) = 550 kg, propellant = 650 kg), solar array power = 224 W (payload power 47 W), battery capacity = 80 Ah.. Each Cluster-II S/C has a single main thruster (400 N) and eight smaller (10 N) thrusters. All thrusters use mono-ethyl hydrazine and mixed oxides of nitrogen for propellant. The large propellant mass is needed for an extensive series of maneuvers to reach the operational orbit and, during the course of the mission, to change the relative spacing of the

¹⁴⁵⁹⁾ Note: The new S/C was named after the mythical bird "Phoenix." In ancient Egypt and in classical antiquity, phoenix is a fabulous long-lived bird associated with the worship of the sun. As its end approached, the phoenix fashioned a nest of aromatic boughs and spices, set it on fire, and was consumed in the flames. From the pyre miraculously sprang a new phoenix, which, after embalming its father's ashes in an egg of myrrh, flew with the ashes to Heliopolis ("City of the Sun") in Egypt, where it deposited them on the altar in the temple of the Egyptian god of the sun, Re.

¹⁴⁶³⁾ J. Credland, R. Schmidt, "The Resurrection of the Cluster Scientific Mission," ESA Bulletin, No. 91, August 1997, pp. 5-10

¹⁴⁶⁴⁾ <http://sci.esa.int/cluster/>

¹⁴⁶⁵⁾ The Cluster mission is covered in considerable detail in Space Science Reviews, Vol. 79, pages 11-658. (Jan. 1997)

S/C. The four spacecraft are spin-stabilized at 15 rpm. The in-orbit configuration is characterized by two 5 m experiment radial booms, four 50 m experiment wire booms and two axial telecommunications antenna booms. The S/C attitudes ensure a solar aspect angle of about 90°.

More detailed objectives call for the mapping of plasma structures and current densities at:

- The solar wind bow shock: Study of the propagation of electric waves through the bow shock and magnetosheath
- The magnetopause, characterizing the motion and local geometry of the magnetopause, and identify the mechanism whereby plasma infiltrates the magnetopause
- The polar cusps, studying the behavior of postulated plasma vortices
- The magnetotail: observation of ion beams, and calculation of the magnitude of field aligned currents, in the plasma sheet boundary layer. Studies of the disruption of cross-tail currents during substorms, and the consequences for the plasma sheet
- The auroral zones. Determination of the sources of magnetospheric plasma, such as the polar wind, the cleft ion fountain, and nightside auroral zone.

The Cluster S/C are described under K.7.1.

The launch of the Cluster-II mission uses two Soyuz launch vehicles (with two S/C at a time) from Baikonur. The launch of the first mission took place on July 16, 2000. The second pair of S/C was launched on Aug. 9, 2000. The launch sequence called first for the injection of the S/C into an intermediate transfer orbit in pairs of two. Then, a series of propulsive maneuvers brought the four S/C from their initial transfer orbits into their mission orbits.

On launch day (Aug.9, 2000), the four Cluster spacecraft were named by ESA as: Rumba, Salsa, Samba, and Tango. The names of the dances were suggested by Raymond Cotton of Bristol, UK (the winner of a naming competition); they are supposed to reflect the way in which the four satellites are dancing in formation around the heavens during their mission. The two S/C of the first launch carry the names Salsa and Samba; the spacecraft of second launch have the names Rumba and Tango.

Orbit: Polar elliptical orbits, nominal apogee = 19.6 R_E (125,000 km), perigee = 4 R_E (25,000 km). The orbit for each S/C is selected so that each is located at a vertex of a predetermined tetrahedron when crossing the regions of interest within the magnetosphere. The size of this tetrahedron is varied from 200 km up to about 19,000 km during the course of the mission. The S/C, after release, use their own on-board propulsion systems to reach the final operational orbit. Since the Cluster-II orbit is fixed in the inertial system, the rotation of the Earth around the sun causes the S/C to cross the various near-Earth plasma regions, such as the Earth magnetotail soon after launch and the polar cusp and solar wind six months later.

Sensor complement:

The instrument complement remains identical to the original version of Cluster-I. Each of the four Cluster-II spacecraft carries an identical set of 11 scientific instruments as defined in K.7.1.

Ground Segment:

Operations of four S/C are provided by two centers: ESA/ESOC in Darmstadt, Germany for mission operations, and JSOC (Joint Science Operations Center, located at the Rutherford Appleton Laboratory, Didcot, UK. The function of JSOC is the coordination of science operations. Its main task is to merge the input from the PI teams into a command schedule. In addition, JSOC monitors the health of the payload instruments and disseminates information of the mission.

Communications: Science data are downlinked at a rate of 16.9 kbit/s real-time (105 kbit/s burst mode) or stored on one 2.25 Gbit solid-state recorder for replay (Note: the original

two solid-state recorders were replaced by a single recorder of a new design). The S-band system operates at 2025-2110/2200-2290 MHz (up/down) at 10 W. Data from the four S/C is synchronized via a highly stable on-board clock. - The Villafranca ground station (Spain) of ESA is the prime station for all TT&C functions. Further support is provided by NASA's Deep Space Network (as well as other ground stations) during critical initial mission phases. About 1 GByte of science data per day is downlinked.

In the ground segment, the Cluster science data are available to the scientific community through CSDS (Cluster Science Data System). The CSDS consists of eight nationally funded and operated data centers. These are:

- Austrian Cluster Data Center, IWF, Graz (ASPOC)
- Chinese Cluster Data Center, Beijing (ASPOC)
- French Cluster Center, CNES, Toulouse (CIS, STAFF, WHISPER)
- German Cluster Data Center, MPE, Garching (EDI, RAPID)
- Scandinavian Data Center, KTH (Royal Institute of Technology), Stockholm (EFW)
- Hungarian Data Center, KFKI, Budapest
- UK Cluster Data Center, RAL, Didcot and QMW, London (DWP, FGM, PEACE)
- US Cluster Data Center, GSFC, Greenbelt, MD (WBD)

K.8 CORONAS-I

Coronas [Complex of Orbital (Near-Earth) Observations of the Activity of the Sun]^{1466,1467} is a Russian Intercosmos project with the cooperation of several international partners [Ukraine (Dnepropetrovsk) for satellite construction, Poland and CSFR for sensor development, Germany for science data reception and data interpretation (DLR/DFD, and Astrophysikalisches Institut Potsdam (AIP)].

Figure 257: The CORONAS-I spacecraft model

¹⁴⁶⁶) V. N. Oraevsky, Yu. D. Zhugzhda, "Project CORONAS-I - Orbital Observations of the Solar Activity and Oscillations, 1991," Coronas Information Series, paper by AIP, DLR/DFD and IZMIRAN, K Pflug (editor)

¹⁴⁶⁷) I. Sobelman, I. Zhitnik et al., "XUV and Optical Observations of the Sun by Means of the TEREK-C Telescope/Coronagraph and the RES-C Spectroheliometer aboard the CORONAS-I satellite," 1992, Coronas Information Series, paper by AIP, DLR/DFD and IZMIRAN, K Pflug (editor)

Main objectives: study of the internal structure of the sun and the different processes of solar flares. Coronas-I (with IZMIRAN as project coordinator) is the first of three spacecraft (CORONAS-I launch: March 2, 1994 from Plesetsk); satellite mass= 2200 kg, diameter= 2 m, height= 6 m. There are a total of 10 scientific instruments on-board. The lifetime of a mission is expected to be 1.5 years. The CORONAS project is viewed as an important successor mission to NASA's most successful Solar Maximum Mission (SMM). The CORONAS-I mission provides observations during minimum solar cycle, while the -F mission will mostly be for maximum solar cycle observations.

Note: In July 1994 the sun sensor of the attitude system experienced a malfunction which resulted in permanent orientation problems of the S/C (all of the gas for the AOCS was consumed within the first six months of operation). This in turn made the data of a number of instruments useless that depended on proper sun orientation.

Status: The CORONAS-I mission was completed in late 2000. Sensor measurements were still being collected in the un-oriented mode of CORONAS-I to study the background radiation.

Data from the solar flare observations is considered for the study of:

- energy transfer from the solar interior to the surface and its subsequent release in solar flare events,
- explosive flare processes on the sun,
- the characteristics of solar cosmic rays, exit conditions, their propagation in the IMF and subsequent influence on the magnetosphere of the Earth,
- development of a theory of flares and techniques for forecasting their geophysical effects.

Orbit: Circular polar orbit, altitude of 500 km, inclination = 82.5°; quasi-synchronous orbit to assure 20 day observation periods in which the satellite will be outside the Earth's shadow.

Sensor complement:

Table 437: Overview of CORONAS-I scientific payload

TEREK-C = Solar X-Ray Telescope/Coronagraph. PIs: I. A. Zhitnik, I. Sobelman. Instrument is of TEREK heritage flown on PHOBOS-1 in 1988.

Objectives: studies of large and fine structures in the solar atmosphere, determining the characteristics of hot solar plasma in active regions, studies of coronal holes, etc. TEREK records images of the solar corona in the spectral ranges as defined in Table 438.

The detectors in all channels are CCD frame transfer image sensors with a dynamic range of $\sim 10^5$. Spatial resolution of ~ 7 seconds.

Spectral range	Description
5 - 25 Å, X-ray channel	Lines of ions: O VII-VIII, Mg XI, Fe XVII, Si XIII (Wolter-1 type grazing incidence objective with filters mounted on a 4-position wheel for subchannel selection)
170 - 180 Å	Lines of ions: Fe IX-XI
290 - 320 Å	Lines of ions: He II and Si XII
Near 52 Å	Lines of: Si XII
Near 130 Å	Lines of: Fe XXIII-XXIV
4000 - 6000 Å, channel K	Optical coronagraph

Table 438: Spectral ranges of TEREK-C

RES-C = Solar X-Ray Spectral Polarimeter. Objective: Study of hot solar plasma structures in the range of $1-3 \times 10^7$ K. RES-C provides monochromatic images of the sun's X-ray radiation and linear polarization simultaneously in three spectral ranges:

- 180 - 205 Å (XUV channel) consisting of two subchannels with perpendicular dispersion planes. Each channel contains a grazing incidence plane grating (2400 lines) with multilayer coating, spherical mirrors working at normal incidence and intensified cooled CCD frame transfer image sensors. The spectral resolution is 0.03 Å, the angular resolution $6'' \times 90''$.
- 8.41 - 8.43 Å (Mg XII channel). The Mg XII channel comprises the bent quartz ($d=4.25$ Å; 5 cm) and crystal spectrometer with CCD image sensor. The spectral resolution is about 7×10^{-4} Å; the angular resolution is $6'' \times 6''$.
- 1.85 - 1.87 Å (Fe XXV channel). This channel contains the bent spherical quartz ($d=1.18$ Å, $R=30$ cm) crystal with CCD image sensor. The spectral resolution is 2×10^{-4} Å; the angular resolution is $2'$.

DIOGENESS = Diagnostic of Energy Sources and Sinks in Flares. Spectrometer and Photometer within the soft X-ray region. Objectives: provision of energy source and sink measurements that enable a study of the balance of the solar flare energy contained in its main thermal reservoir.

The DIOGENESS instrument consists of three independent units: a Bragg high-resolution spectrometer (BS), an X-ray spectrophotometer (BF), and a microcomputer for the control of BS and BF.

BS spectral range: 2.835 - 3.356 Å. The most important lines are CaXVIII, CaXIX and CaXX. The BS time resolution is 0.1 - 10 s.

BF spectral range: 2 - 160 keV. The energy channels are: 2-4, 4-8, 10-20, 20-40, 4-80, and 80-160 keV. The time resolution is 1 second in the range of 2-8 keV and 0.1 second in the range of 10-160 keV.

HELICON = Solar X-ray and γ -ray Scintillation Spectrometer. Helicon has the following characteristics:

- number of detectors: 2 (solar and antisolar directions)
- energy range: 10 keV - 8 MeV
- energy windows for the investigation of time histories: 10-50 keV, 50-250 keV, 250-800 keV
- sensitive area of each detector: 314 cm^2 which corresponds to a sensitivity for flares with fluencies $> 10^{-7} \text{ erg cm}^{-2} \text{ s}^{-1}$
- statistical criterion for identification of flare: G_0 above the background
- number of PHA (Pulse Height Analyzer) channels: 64 for each detector
- number of spectra registered during one flare: up to 64 (depending on flare power)
- accumulation time for single spectra: 2 ms to 8 s (depending on the magnitude of the flare)
- number of time analysis channels: 4096
- time resolution: from 2 ms to 0.25 s
- background spectrum control: 2 minutes each

- duration of time history recording: up to 4 minutes

IRIS = Solar Burst Spectrometer. Objective: provision of measurements for the study of integral intensities and X-ray spectra with the following characteristics:

- energy channels: 2-4, 4-8, 8-12, 12-20, 20-30, 30-40, 40-60, 60-90, 90-120, 120-150, 150-200, and 200-300 keV
- studies of X-ray precursors of solar flares in the range of 2-20 keV with a sensitivity of $10 \text{ erg cm}^{-2} \text{ s}^{-1}$
- studies of the dynamics of hard X-ray spectra during flare impulse phases in the range of 30-120 keV with a time resolution of about 0.01 s

SUFR-Sp-C = Solar UV Radiometer. Objectives: measurement of the solar radiation intensity in the UV range of $\lambda < 130 \text{ nm}$. SUFR records the solar EUV radiation with the use of thermoluminescent material (24 specimens arranged on a rotating wheel). The thermoluminescent material $\text{CaSO}_4 (\text{Mn})$ is practically insensitive to radiation in the range of $\lambda > 130 \text{ nm}$. Dynamic range of the SUFR-Sp-C measurements: $0.1\text{-}30 \text{ erg cm}^{-2} \text{ s}^{-1}$

The instrument contains 24 screens: one without filters measuring the total EUV radiation flux for $\lambda < 130 \text{ nm}$, others with different filters (MgF, Al foil, Mylarfilm). The filters isolate the wave bands of soft X-rays (0.3-12 nm) and the Lyman alpha hydrogen line (121.6 nm). The absolute error does not exceed 15%. The exposure time for one screen and measuring time of its thermoluminescent signal is $18.5 \pm 0.5 \text{ s}$. The total measurement cycle last 8 minutes.

VUSS = Vacuum UV Solar Spectrometer. Objective: long-term measurements of the solar EUV radiation. The instrument performs absolute measurements of solar line intensities in the wavelength region of 20-58 nm. Its operation is based on the concept of collision photoionization spectroscopy. The maximal spectral resolution is $\lambda/\Delta\lambda \approx 400$. The threshold sensitivity is $5 \times 10^6 \text{ quants x cm}^{-2} \text{ s}^{-1}$.

DIFOS = Solar Flux Optical Photometer (PI: Yu. D. Zhugzhda). Objective: observation of global solar oscillations in the spectral range of 0.4-1.0 μm . A three-channel instrument at 0.550 μm (.1 μm band), 0.750 μm (0.10 μm band), and 0.4-1.1 μm range. Intensity measurements with a relative accuracy of about 10^{-5} . The time resolution is 16 seconds.

SORS = Solar Radiospectrometer. Objectives: investigation of solar radio bursts, diagnosis of surrounding ionospheric plasma near the satellite.

SORS works with two sweeping receivers in the frequency ranges of 50 kHz - 30 MHz, and 25 MHz - 300 MHz. A wide-band channel ($\Delta f = 4 \text{ MHz}$) is used to study the detailed structures of radio bursts in time scales of ms.

The SORS measurements of solar radio-emission in the low frequency range $< 25 \text{ MHz}$ will complement the ground-based radioastronomical measurements with high time resolution. Direct measurements of UV emission and of local plasma density on the same satellite will improve ionospheric modelling and forecasting.

SKL = Solar Cosmic Ray Spectrometer Complex (PI: S. N. Kuznetsov). Objectives: measurement of charged and neutral components of energetic particle fluxes (energy spectra and elemental, isotopic and charge composition). SKL consists of three devices: SKE-3, MKL, and SONG.

- SKE-3 measures the fluxes of nuclei with charges ranging from $z=1$ to 10, and with energies from 1.5-19 MeV / nucl for ^4He and 3.7-4.6 MeV / nucl for ^{20}Ne .
- MKL is a cosmic ray monitor for measuring the spectra of electrons (0.5 - 12.0 MeV), protons (1 - 200 MeV), and alpha-particle fluxes (120 - 240 MeV), which includes five detectors.
- SONG measures the solar neutrons, gamma rays (continuum and lines) and detects charged particles, mainly electrons and protons. A Cs (Te) detector (200 mm diameter, $h = 100 \text{ mm}$) surrounded by a 4π anticoincidence shielding of a plastic scintillator is used. The SONG instrument permits the detection of:

- neutrons with $E \geq 30$ MeV (5 channels)
 - gamma rays in the range of 0.1-100 MeV (9 chan.) and 0.3 - 16 MeV (236 chan.)
 - high-energy protons in the ranges 200 - 500 MeV and 11 - 108 MeV (6 chan.).
- SONG operates in two modes (“flare” and “monitoring”) with a time resolution of 0.04 s, 2.5 s, or 120 s.

Data Transmission Parameters:

- Transmission power +9 dBW
- Antenna 2 V-dipole
- Antenna gain +0.5 dB
- Polarization right circular
- EIRP +5.5 dBW
- Carrier frequency 136.35 MHz / 137.45 MHz (VHF)
- Bandwidth 120 Hz
- Modulation BPSK, bi-phase
- Data rate 32 kbit/s / 64 kbit/s
- Word length 8 bit
- Frame length 128 byte

Coronas-I has an on-board data recording capability. The ground segment consists of Russian S/C control (TT&C function) and science data reception by the DLR/DFD ground station Neustrelitz (only science data reception station in the project). Neustrelitz is responsible for all science data reception, for intermediate archiving of all data, and for science data distribution to all parties involved. DLR/DFD Neustrelitz also processes/evaluates data from the SUFR and VUSS sensors. The AIP (Astrophysikalisches Institut Potsdam) receives data of the following sensors for evaluation: DIFOS, HELICON, SORS, and SKL.

IZMIRAN	Institute of Terrestrial Magnetism, Ionosphere and Propagation of Radio Wave Propagation -Russian Academy of Sciences, Troitsk (Moscow region)
FTI	Ioffe Physical Technical Institute (St. Petersburg)
GAO	Main Astronomical Observatory of the Ukrainian Academy of Sciences, Kiev
IKI - RAN	Space Research Institute - Russian Academy of Sciences, Moscow
OKB MEI	Special Research Bureau of Moscow, Power Engineering Institute
MEPhI	Moscow Engineering Physics Institute
MIFI	Moscow Institute of Physical Engineers (note: MIFI and MEPhI are the same things)
NIIYaF	Institute of Nuclear Research of Moscow State University (MGU)

IEP Kosice	Institute of Experimental Physics of the Slovak Academy of Sciences
CBK	Space Research Center of the Polish Academy of Sciences, Poland (also referred to as SRC)
DLR/DFD	Germany, Neustrelitz Station - reception of all science data
AIP	Astrophysikalisches Institut, Potsdam, Germany - processing of some sensor data

Table 439: Principal institutes involved in the cooperative project CORONAS

K.8.1 CORONAS-F

CORONAS-F is the second satellite of the international series with IZMIRAN as the prime lead and coordinator of the mission (V. N. Oraevsky). The Southern Design Office, Dnepropetrovsk, Ukraine [also referred to as YUZHNOYE (Research and Production Association)], as the spacecraft builder and integrator. The overall objective of CORONAS-F is

the study of active sun and its neighborhood (small and large scale processes) by observations in the spectral range from gamma rays to radio waves. Specific science objectives are: 1468)

- To study the energy transport from the solar interior to the surface, its build-up in the upper atmosphere and subsequent release in non-stationary solar events (includes measurements of electrons, protons, and neutrons)
- The study of major dynamic phenomena of the active sun (sunspots, flares, plasma ejection's) in order to develop their theoretical interpretation and prediction methods
- The study of cosmic rays, accelerated in solar flares, as well as of other active phenomena, their escape, interplanetary propagation, and geophysical effect
- Seismological studies of the solar interior based on observed global oscillations

The CORONAS-F spacecraft is spin-stabilized and sun-pointed. The pointing accuracy of the longitudinal S/C axis to the sun is 10 arcsec, the pointing knowledge is 5 arcsec. The projection of the angular speed relative to the S/C coordinate system is known to 0.005°/s. The S/C has a total mass of 2260 kg, the payload mass is 395 kg, the design life is >1 year.

A launch of CORONAS-F took place on July 31, 2001 (launch site: Plesetsk, Russia).

Orbit: Circular orbit, altitude = 500 km, inclination = 82.5°. The orbit ensures continuous observations of the sun in recurrent intervals of about 20 days.

Instrument	Objectives
DIFOS (Solar Photometer), IZMIRAN	Investigation of the global oscillations of the solar irradiance
SORS (Solar Radiospectrometer), IZMIRAN	Registration of the radio emission of the solar active regions and flares
HELICON (Solar X-ray and γ -ray Scintillation Spectrometer), FTI	Study of the solar flare processes in ranges of soft X-ray to γ -ray region
IRIS (Solar Burst Spectrometer), FTI	Study of the solar flare processes in the X-ray range
TEREK-C (Solar X-Ray Telescope/Coronagraph), FIAN	Provision of solar imagery (and solar corona) in UV and soft X-ray ranges
RES-C (Solar X-Ray Spectral Polarimeter), FIAN	Measurement of monochromatic solar imagery in UV and soft X-ray ranges
SPR-N (Solar X-Ray Polarimeter), FIAN	Summary polarization measurement of the solar X-ray radiation
SCR (Cosmic Ray Spectrometer), NIIYaF MGU	Measurement of energetic particle fluxes
SUFR-Sp-C (Solar UV Radiometer), IPG	Measurement of the solar radiation intensity in the vacuum UV range
VUSS (Vacuum UV Solar Spectrometer), IPG	
DIOGENESS (X-Ray Photometer Spectrometer), SRC, Poland	Diagnostic of the energetic characteristics of the solar flares
RESIK (X-Ray Spectrometer), SRC	Spectral observations of the solar X-ray radiation
AVS (Amplitude-Time Spectrum Analyzer), MIFI	Investigation of the solar flare spectrum in the γ -ray region
RPS-1 (X-Ray Semiconductor Spectrometer), IKI	Registration and spectrometry of the X-ray solar flare radiation and its forerunners
IMAP-5 (Three-Axis Magnetometer), IZMIRAN	Registration of the Earth's magnetic field components
SSNI (Data Collection System), IZMIRAN	High-speed data collection from instruments in the ground segment

Table 440: Sensor complement of CORONAS-F

K.8.2 PHOTON

PHOTON is a Russian solar mission (third satellite in the CORONAS program) with the following objectives:

- Study of the temporal variations in the energy spectra of hard radiation in the energy band from 15 keV to 2000 MeV
- Fast timing of the hard X-radiation in flares
- Measurement of the linear polarization of hard X-radiation fluxes
- Observation of neutrons with energies $E > 5$ MeV and measurement of their spectrum in the region of 5 - 300 MeV
- Study of energy spectra (charge and mass composition of ions accelerated in flares)
- Observation of energetic electrons, electrical fields and magnetic fields.¹⁴⁶⁹⁾

The PHOTON mission is a cooperative project of FIRAS (P. N. Lebedev Physical Institute, Moscow), MEPhI (Moscow Engineering Physics Institute), YUZHNOE (Ukraine), TATA (Bombay), FTI (Ioffe Physical Technical Institute, St. Petersburg), AIP (Astrophysikalisches Institut Potsdam), FhG/IPM (Fraunhofer Gesellschaft/Institut für Physikalische Meßtechnik, Freiburg), and DLR/DFD (Neustrelitz). It uses the same S/C structure as for the CORONAS-I and -F missions. The PHOTON S/C is three-axis stabilized; the pointing accuracy to the sun is within 10 arcmin; payload mass = 650 kg; S/C mass = 2500 kg; payload power = 400 W (average); on-board data recorder, science data in S-band.

A launch of PHOTON is TBD (a new launch date of the mission will occur in the summer 2001).

Orbit: Circular high-inclination orbit, altitude = 500 km, inclination = 82.5°.

Sensor complement: [Sensors NATALYA-2M, RT-2, PENGUIN and FXM have two modes of operation, a routine mode and a flare mode (the flare mode exhibits higher activity levels, higher readout frequencies, and a higher number of energy channels)]

NATALYA-2M (Gamma-ray Spectrometer, FIRAS and MEPhI). The objective is the measurement of gamma rays in the energy range of 0.3 - 2000 MeV and of neutrons in the range of 10 - 300 MeV. The instrument consists of two spectrometers (upper and lower). The upper spectrometer is surrounded by a scintillation dome. Both spectrometers employ identical detectors, eight CsI (TI) blocks and PMTs. Measurement of gamma rays in four energy bands (0.3 - 2 MeV, 1 - 10 MeV, 7 - 200 MeV, 0.1 - 2 GeV), and neutron-type events. The energy resolution for gamma rays is 14% ($E = 0.660$ MeV), 6.0% ($E = 10$ MeV), and 12% ($E = 100$ MeV). An α -source is used for absolute instrument calibration. Instrument mass = 530 kg.

RT-2 (X-ray Telescope), TATA Institute of Fundamental Research, Bombay, India). Objective: Measurement of hard X-rays in the energy range of 15 - 150 keV, hard X-rays and low-energy fluxes in the range of 150 - 10,000 keV, and gamma rays. RT-2 employs three identical detector units with three different FOVs (2°, 3°, and 5° respectively). NaI (TI)/CsI (Na) detectors are used for the registration of X-rays. Both scintillators and collimators are surrounded by shielding. Instrument mass = 6 kg.

PENGUIN (Hard X-ray Polarimeter and Neutron Detector, FTI and MEPhI). Objective: Measurement of hard X-ray fluxes in the energy range of 20 - 150 keV (fast timing, energy spectra and linear polarization), of hard X-ray and low energy particles in the range of 20 - 1000 keV, and of neutrons in the range of 5 - 50 MeV (energy of recoil protons). Two types of scintillators are used for the registration of neutrons and photons, namely high-Z CsI (TI) and low-Z monocrystal p-terfinil (p-TF, an organic scintillator). The assembly is covered by two plastic counters for rejection of incoming charged particles. Linear polarization measurements are based on analysis of the Compton scattering asymmetry. Instrument mass = 17.5 kg.

FXM (Fast X-ray Monitor, MEPhI). Objective: Measurement of X-ray radiation in six energy levels covering the region between 20 - 600 keV (20 - 30, 30 - 40, 40 - 50, 50 - 70, 70 - 130,

¹⁴⁶⁹⁾ Yu. D. Kotov, S. I. Nikolsky, V. I. Dranovsky, "Satellite Project PHOTON for the study of solar hard radiation," paper provided by Yu. Kotov

130 - 600 keV). FXM is a scintillation counter using a monocrystal of YAlO_3 (Ce) as scintillator with a fast readout capability. The minimum time (24 ns) interval for averaging the counting rate depends on the flare intensity (3 ms for large flares). The time resolution may be changed via telecommand. Instrument mass = 6 kg.

ELECTRON-5 (Charged Particle Spectrometer), MEPhI. Objective: measurement of charged particles in the following energy ranges: [electrons: 0.04 - 2 MeV, protons: 0.5 - 60 MeV, α -particles: 3 - 120 MeV, nuclei $Z < 8$: 1.2 - 20 MeV/nucleon]. The instrument includes a dE/dx semiconductor telescope and two Geiger counters. The geometrical factor of the telescope is $\sim 0.2 \text{ cm}^2 \text{ sr}$. FOV = 20° for the spectrometer, FOV = 46° for the Geiger counters. Instrument mass = 15 kg.

REIS (Complex for the Measurement of Electromagnetic Fields, IZMIRAN). The complex consists of three instruments: FM-2, DMP-1, and DEP-1. The magnetometer FM-2 measures the magnetic field in the range $\pm 65.5 \mu\text{T}$ with an accuracy of 15 nT. Complex mass = 30 kg.

Sensor	Type of Field	Components	Frequency Band	No. of Sensors
Magnetometer FM-2	magnetic	H_x, H_y, H_z	0 - 4 Hz	one
DMP-1	magnetic	H_x, H_y, H_z	5 - 1000 Hz	one
DEP-1	electric	E_x, E_y	0.1 - 1000 Hz	four

Table 441: Sensors in the REIS complex

DMP-1 Sensor		DEP-1 Sensor	
Frequency (Hz)	Sensitivity (A/m $\text{Hz}^{0.5}$)	Frequency (Hz)	Sensitivity (A/m $\text{Hz}^{0.5}$)
20	3×10^{-7}	0.1 - 10	10^{-4}
120	4×10^{-8}	20	10^{-6}
700	6×10^{-9}	200	10^{-7}
1000	5×10^{-9}	1000	10^{-8}

Table 442: Sensitivities of DMP-1 and DEP-1 sensors

EUV-PHOKA (EUV Photocathode Experiment), MEPhI, AIP, FhG/IPM. Objectives: Measurement of the solar EUV and X-ray spectrum (whole solar disk intensity variation in seven spectral bands). The instrument consists of the following elements:¹⁴⁷⁰⁾

- Detector module: photodiodes (XUV silicon photodiode detectors), collimators, filters; preamplifiers, electrometers and logarithmic amplifiers in each channel; thermosensors)
- Electronic module: (input amplifiers, 12 bit A/D converter, processor unit, etc.)

Modes of operation: 1) Normal mode with a time resolution of 10 s allows an estimation of long-term variations (days, solar rotations and longer) and flare processes, 2) Flare mode with time resolution of 1 second, 3) Occultation mode with a time resolution of 0.2 s (scan of the Earth's atmosphere during the orbital exit from its shadow). Instrument data volume is 1024 - 1408 kbit/day depending on operational mode. Instrument mass = 2.5 kg

Channel No.	Wavelength (nm)	Emission Line
1	< 10	
2	30.4	He II
3	58.4	He I
4	80	O II - O IV
5	102.6	Lyman- β
6	121.6	Lyman- α
7	VIS

K.9 Equator-S

Equator-S ('small') is a solar-terrestrial energy transport mission of MPE-Garching (DARA sponsored) for plasma and field measurements in several regions not covered by any of the ISTP missions, namely the low-latitude dayside magnetopause and its boundary layer, the magnetospheric boundary regions, the auroral source region, the equatorial ring current region, and the near-Earth equatorial plasma sheet. Equator - S is considered a complement to the 'Global Geospace Science (GGS) Program.' EQUATOR-S was launched from Kourou on an Ariane 44P vehicle on December 2, 1997, together with JCSAT-5. The S/C and payload are provided by Germany (PI for mission: G. Haerendel, MPE).¹⁴⁷¹⁾

Within the GGS/ISTP context, simultaneous measurements in the solar wind (WIND and SOHO) and in the magnetospheric boundary regions (CLUSTER and EQUATOR-S) will allow a more quantitative understanding between input parameters and transfer efficiencies. Simultaneous measurements at equatorial (EQUATOR-S) and polar latitudes (POLAR and CLUSTER) at distances of 10 R_E will provide clues about the origin and low-latitude connection of entry layer and mantle, on the dayside, and between plasma injections from the tail and large-scale morphology and dynamics of auroral sheet currents, Alfvén waves, particle beams and plasma flows, on the night side. The energy flow from the deeper tail as well as the sequence of events constituting a magnetospheric substorm can only be assessed with simultaneous measurements in the near-Earth plasma sheet (EQUATOR-S) and tail (GEOTAIL and INTERBALL).^{1472) 1473)}

Figure 258: The Equator-S S/C model

The Equator-S spacecraft is spin-stabilized (attitude control with a magnetorquer, S/C attitude is determined from magnetometer and sun sensor data), with its spin axis oriented at

¹⁴⁷¹⁾ "A Small Equatorial Satellite to Complement the Global Geospace Science Program - Equator - S," MPE Equator-S proposal, Sept. 30, 1991

¹⁴⁷²⁾ "EQUATOR-S - A Contribution to the Interagency Solar-Terrestrial Physics Programme," MPE paper provided by H. Höfner

¹⁴⁷³⁾ G. Haerendel, "Equator-S: The Mission and first Coordinated Measurements with GEOTAIL," *Advances in Space Research*, Vol. 25, No 7-8, 2000, pp. 1277-1286

right angles to the Earth-sun line, and with a spin rate of 60 rpm to allow for high temporal resolutions for the measurement of the particle distributions functions. Total S/C mass=235 kg, S/C power=70 W (16 planar solar cells mounted around the circumference); four NiCd batteries, 1 Ah each (power during eclipses); S/C design life = 2 years; payload mass = 48 kg, power = 46 W; downlink data transmission rates vary between 32 and 262 kbit/s, uplink data rate at 500 bit/s, a CRC code is used for error detection, 1.5 GByte of on-board memory storage for flexible data acquisition. RF systems: two redundant RF transmitters, S-band (2284.5 MHz); RF power=1W; two redundant RF receivers, S-band (2103.6 MHz); five switchable antennas with 4π steradians coverage, gain ≥ 3 dB.

Orbit: A near-equatorial orbit with a $10 R_E$ distance apogee and low perigee at 500 km altitude, inclination = 7° . Equator-S was launched into a geostationary transfer orbit (perigee=200 km, apogee=35,975 km, inclination= 7°). Insertion into the final orbit with a one-impulse maneuver (perigee=500 km, apogee=65,600 km, inclination= 7°). Equator-S has its own solid-propellant kick-motor (Thiokol Star 13A).

The S/C was designed, built and tested by MPE. Some assistance and in-kind contributions are received from ESA and NASA. Mission operations are provided by DLR/GSOC.

A spacecraft failure occurred on May 1, 1998, terminating all operations. The evidence indicates that the May 1 failure of the redundant processor system was caused by a latch-up in one of the memory chips of the processor system, as was the failure of the prime processor system on December 17 1997.

Sensor complement:

- **MAM** (Magnetic Field Instrument), Lead investigator: W. Baumjohann, MPE. The instrument consists of three-axes fluxgate magnetometers, one mounted at the end of a 1.8 m boom, the other 50 cm further inward, to reduce (and determine) the amount of interference from the S/C.
The sampling rate is 128 vectors/s when only one of the magnetometers is used, and 64 vectors/s when both are utilized. The resolution is 16 bits, and ranges can be selected in steps of 4, between 250 and 64,000 nT.
- **EDI** (Electron Drift Instrument), Lead investigator: G. Paschmann, MPE. This instrument is identical in concept and design to the EDI sensor on CLUSTER. EDI measures the drift of a weak beam ($<1 \mu\text{A}$) of test electrons which is related to the ambient electric field and the gradient in the magnetic field. EDI is capable of measuring the electric field, local gradients in the magnetic field, and the magnetic field itself. EDI consists of two emitter/detector assemblies, each with a 2π FOV. $E = (0.1 - 10 \text{ mV/m}, <100 \text{ Hz})$, $|B| = 5\text{-}1000 \text{ nT}$, emission and tracking of two electron beams.
 - Sample rate: 32 vectors/s
 - Mass: 10.8 kg
 - Power consumption: 10.3 W
 - Data rate: 4 (16) kbit/s
- **3D-Plasma Analyzer** (also referred to as 3D-A. The instrument is of WIND 3-D Plasma instrument heritage; lead investigator: G. K. Parks, U. of Washington, Seattle). The instrument consists of an electron electrostatic analyzer (EESA) and an ion electrostatic analyzer (PESA).
Measurement of ion and electron distribution functions in 192 angle- and 56 energy-channels, in the energy-per-charge range from 10 eV to 25 keV; $\Delta E/E = 0.2$; geometric factor = $10^{-3} \text{ cm}^2 \text{ sr}$; FOV = $180^\circ \times 12^\circ$; angular resolution = $5.6^\circ \times 5.6^\circ$. Instrument mass = 8.6 kg, power = 7.1 W, data rate = 8 (36) kbit/s.
- **EPI**=Energetic Particle Instrument (EPI is physically part of 3D-Plasma Analyzer). Lead investigator: T. Sanderson, ESA/ESTEC. The instrument consists of a pair of double-ended semiconductor detector telescopes providing 3-D measurements of

electrons and ions with high sensitivity and high energy resolution. Measurement ranges: electrons from 20 keV to 226 keV; ions from 20 keV to 400 keV; instrument mass = 5.1 kg, power = 4.5 W, data rate = 2 (9) kbit/s.

- **ESIC** (Ion Composition Instrument). Lead investigator: L. Kistler, UNH, Durham, USA. This instrument is essentially a copy of CODIF (Composition and Distribution Functions Analyzer) on the CLUSTER mission (heritage of SULEICA and the 3-D Plasma Instrument flown on AMPTE). ESIC consists of a retarding-potential analyzer (RPA), followed by a toroidal energy-per-charge (E/q) analyzer with disk-shaped field of view, followed by a 20 keV post-acceleration into a time-of-flight analysis section. ESIC measures the 3-D distribution function of the major ion species (H^+ , He^+ , He^{2+} , O^+ and a combination of O_2^+ and NO^+). CODIF covers the energy range from about 15 eV to 40 keV/q. Instrument mass = 8.2 kg; power = 7.6 W, data rate = 6 (53) kbit/s.
- **PCD** (Potential Control Device). Lead investigator: K. Torkar, Space Research Institute, Graz. The instrument reduces the S/C potential (caused by the ambient plasma charging of the outer surfaces) to acceptable levels. The method employs beams of 6 keV indium ions to neutralize the S/C charging (see also 'ASPOC' of the CLUSTER mission). Instrument mass = 2.6 kg, power = 2.8 W, data rate = 128 bit/s.
- **SFD** (Scintillating Fiber Detector). Lead investigator: L. Adams, ESA/ESTEC. Measurement of the omnidirectional energy flux of protons and electrons. SFD makes use of the light emission property of some materials when hit by ionizing radiation. Optical fibers guide the emitted light to a photodiode operated in current mode. A logarithmic amplifier converts this detector current to an analog output voltage. Energy discrimination is achieved by using three differently shielded channels. This way electrons above 0.26, 0.4, and 1.9 MeV are measured, and photons above 6.3, 9.5, and 35 MeV, with a time resolution of 64 s. Mass = 0.4 kg, power=0.4 W, data rate= 128 bit/s.
- **GPS receiver** (Motorola Viceroy GPS receiver capable of L_1 band C/A code reception). Lead investigator: B. Eisfeller, Bundeswehr Universität, Neubiberg. A prime objective is to investigate the conditions of GPS reception above the GPS satellite constellation. Determination of S/C position. Mass=2.6 kg, power=8.3 W, data rate=512 bit/s.
- **Solar Cell Diagnostic** (ESTEC, NASA). Measurements of temperature, current/voltage characteristics (degradation by radiation). Mass=0.4 kg, data rate=128 bit/s.

K.10 EXOS (Exospheric Observations)

Japanese (ISAS) solar-terrestrial interaction program with a series of four satellites for the study of the magnetosphere and auroral phenomena.

K.10.1 EXOS-A (Kyokko)

ISAS mission with the objective to study the magnetosphere (auroral activity), plasma environment and VLF (Very Low Frequency) emissions. S/C mass = 126 kg. Launch: Feb. 4, 1978 by M-3H-2 vehicle from Kagoshima. End of EXOS-A mission in November 1979 due to the degradation of solar cells by radiation belt particle bombardment.

Orbit: apogee = 3970 km, perigee = 630 km, inclination = 65°.

Sensors:

UV-TV Camera. This wide-angle TV camera took an instantaneous auroral picture that covered almost the entire polar region, every 128 seconds during its operation over the north-

ern polar region. About 10 to 20 pictures were obtained during one pass. More than 20,000 pictures of aurorae in UV were obtained in all.

UV Glow Spectrophotometer. Spectrophotometry of ultraviolet glows from the thermosphere, magnetosphere, and interplanetary space in the spectral range of 300 - 1300 Å.

Electron Spectrometer. Measurement of upward and downward electron fluxes along the magnetic field line of force in the energy range from several eV up to around 10 keV. Measured data show precipitation patterns with longitudinal as well as latitudinal variations.

Ion Mass Spectrometer. Objective: study of the light ion trough, atmospheric composition of ionized species of H, He, and O atoms in the thermosphere.

Ionospheric Plasma Probes. Measurements of density and temperature of ambient electrons by plasma probes, and plasma waves especially with reference to the emission associated with auroral phenomena.

ISAS also cooperated with Kyokko in an international experiment with a Scandinavian group during rocket and balloon campaigns at Kiruna, Sweden.

K.10.2 EXOS-B (Jikiken)

ISAS mission with the objective to explore geomagnetic field, plasma density, and wave particle interaction as part of the IMS (International Magnetosphere Study) program.¹⁴⁷⁴⁾ Launch of EXOS-B on Sept. 16, 1978. The mission lasted over 3 years.

Orbit: quasi-equatorial orbit, apogee = 30,100 km, perigee = 220 km, inclination = 31°, period = 524 minutes. Within three years the apogee gradually changed from the initial value of 30,100 km to 28,000 km, while the perigee oscillated in the range from 220 to 290 km.

Sensor complement:

SPW = Stimulated Plasma Wave Experiment (H. Oya, Tohoku University) in the plasmasphere and magnetosphere across the plasmopause.

Objective: study of plasma wave resonance mechanisms (upper hybrid resonance, plasma resonance, harmonics of electron cyclotron resonance, electrostatic resonance, sequence of diffuse resonance). Plasma waves are excited by RF pulses transmitted from the S/C to study nonlinear wave-plasma interactions.

SPW instrumentation consists of four systems: the signal generation system (high power RF transmitter for the stimulation of plasma waves in the frequency range from 10 kHz to 3 MHz), the power amplifier, the antenna system, and the receiver. The signal generator can produce two types of frequency variations that are swept frequency mode: Tx sweep, and the fixed frequency mode: Tx-Fix-n (Tx-Fix-1 = 21 kHz, Tx-Fix-2 = 90 kHz, Tx-Fix-3 = 390 kHz, and Tx-Fix-4 = 1.7 MHz).

NPW-A = Natural Plasma Wave Astronomy Mode (H. Oya, Tohoku University). Objective: observation of planetary (terrestrial kilometric radiation) and solar radio waves in the frequency range from 10 kHz - 3 MHz.

Instrumentation: the satellite is equipped with two sets of long dipole antennas arranged orthogonally to each other in the perpendicular plane of the S/C spin axis (length = 102 m tip-to-tip and 72 m tip-to-tip). The 102 m antenna is mainly used for plasma and radio wave reception, while the 72 m antenna is used for the plasma relaxation sounder and the impedance probe.

VLF = Very Low Frequency Wave Detectors (I. Kimura, Kyoto University). Objective: observation of wave particle interactions in the magnetosphere (electromagnetic and electro-

¹⁴⁷⁴⁾Journal of Geomagnetism and Geoelectricity including Space Physics, Volume 33, No. 1, 1981, featuring EXOS-B, pp. 1-160

static waves in a frequency range between 150 Hz and 9.5 kHz, the measured range of electron is from 5 eV to 11 keV). The VLF receiver is normally connected to the 102 m dipole antenna.

DPL = Doppler Shift Measurement. Objective: detection of ionization ducts in the magnetosphere. DPL observes the Doppler shift (intensity, phase shift, and antenna capacitance at the same frequency) of an NWC (22.3 kHz) signal transmitted from North West Cape in Australia.

IEF = Impedance and Electric Field Measurement. Objectives: measurement of antenna impedance, DC electric field and AC electric field (low frequency) using a long cylindrical antenna system. Study of electron density and wave phenomena in the frequency range from 1 Hz to 450 Hz.

IEF has a cross-dipole antenna system with an originally designed length of 120 m; these antenna elements were not fully deployed due to an unstable satellite attitude. The actual length of each antenna element is as follows: A1 = 33.4 m, A2 = 36.2 m, B1 = 51.7 m, B2 = 51.3 m. IEF consists of four instruments:

- IEF-1 is a frequency swept impedance probe using the A1 antenna and a frequency range from 10 kHz to 3 MHz with a swept period of 2 seconds or 8 seconds. An equivalent capacitance range measured is from 0.5 pF to 5000 pF.
- IEF-S and D are single and double Langmuir probes using A1 and A2 antennas, respectively.
- IEF-C is an electric field detector using A1 and A2 or B1 and B2 antennas with 1 Hz to 450 Hz electric field measurements.

MGF = Triaxial Fluxgate Magnetometer. Objective: measurement of the geomagnetic vector field. Study of relation between field-aligned currents and dynamics of the magnetosphere, and the generation and propagation mechanisms of hydromagnetic waves near the plasmapause. Resolution from 2 nT to 380 nT in four ranges. Sampling rate of either 1 second or 4 seconds. The dynamic range of MGF covers 247 nT to 46,840 nT.

ESP = Charged Particle Detectors. Objectives:

- investigate the dynamics of electrons and ions in the inner magnetosphere
- study wave-particle interaction in the inner magnetosphere together with wave measurements
- observe the response of magnetospheric plasma when an active experiment, that is SPW (high power radio wave emission) and/or CBE, is performed.

ESP is composed of an electron sensor, an ion sensor and electronic circuits. Measurements of electron and ion fluxes in the energy ranges from a few eV up to 10 keV and of ion fluxes from 10 eV up to 30 keV, respectively, in the magnetosphere of L-shells from $L \approx 2.5$ to $L \approx 8$. Energy resolution $\Delta E/E = 3\%$ for electrons and 5% for ions.

CBE = Controlled Beam Experiment. Objectives: control of satellite potential by electron beam emission. Study of wave excitation (linear and nonlinear wave phenomena caused by beam-plasma interaction).

K.10.3 EXOS-C (Ohzora = Sky)

ISAS mission with the objective of upper-atmosphere exploration. Launch: Feb. 14, 1984 by a M-3S-4 vehicle from Kagoshima, Japan. S/C mass = 208 kg. The S/C is stabilized with the aid of a momentum wheel, whose spin axis is automatically controlled so that one side of the S/C faces the solar disk. Power = 160 W. The mission ended in 1987.

Orbit: apogee = 865 km, perigee = 354 km, inclination = 75°, period = 97 min.

Sensor complement:

- LAS=Limb Scanning Spectrometer (passive device) for the 1.27 μm infrared atmospheric band airglow to deduce ozone density in the altitude range of 70 - 90 km.
- UV Spectrometer for nadir observation of backscattered UV radiation (2500 - 3500 Å) to obtain ozone profiles in the altitude range of 25 - 60 km.
- Solar Image Radiometer. Measurements in several visible and near-infrared bands to detect limb absorption by stratospheric aerosols and ozone.
- IR Solar Spectrometer. Monitors stratospheric water vapor, methane, carbon dioxide, and ozone by the limb absorption technique.
- Topside Ionospheric Plasma Sounder (including a receiver). Measurement of plasma waves caused by plasma turbulence associated with precipitating particles.
- Receiver for global monitoring of electromagnetic waves radiated from power line networks and high-power electric equipment on the ground.
- Electron Temperature Probe¹⁴⁷⁵⁾ (for electron density and temperature measurements), consisting of four sensor electrodes (S1, S3, S5, S7) mounted at the ends of the solar cell paddles. The electrode plane is parallel to the satellite spin axis. Dayside cusp observation. Characteristics: frequency of the oscillator = 30 kHz; amplitude of the signal = 500 mV, 250 mV, 0 mV; input impedance of DC amplifiers = 110 M Ω
- Energy spectrum analyzer for precipitating particles.

K.10.4 EXOS-D (Akebono)

ISAS mission for 'exospheric observations' with the objective to study the generation mechanism of auroral charged particle precipitation in the polar cusp region in comparison with the simultaneously observed electric field. The S/C is spin-stabilized at 7.5 rpm; the spin axis points toward the sun; attitude control is by magnetic torquing. Payload mass = 295.4 kg, science instruments = 97 kg (including antennas and booms). Surface conductivity: 98.9% of the S/C surface, including the solar cells, is made conductive so as to minimize electrostatic disturbances around the satellite.^{1476), 1477)}

Launch: Feb. 22, 1989 with M-3SII-4 vehicle from Kagoshima, Japan. EXOS-D is operational as of the end of 1995 and is expected to continue operations for a few more years.

Orbit: elliptical polar orbit with an initial apogee into the southern hemisphere, apogee = 10,500 km, perigee = 275 km, inclination = 75°, period = 212 minutes.

Sensor complement:

EFD = Electric Field Detector (PI: H. Hayakawa, ISAS)

Objective: study of the quasi-static vector electric field along the spacecraft orbit, in particular: a) the electric field structure in the auroral ionosphere and its relationship to ion dynamics and auroral ion acceleration, b) global dynamics of the polar ionosphere, c) plasma wave instability, d) electric field in the "plasma bubble."

EFD measures the electric field by two techniques: namely the double probe and the ion beam technique. Double probe measurement from DC to 10 Hz; the ion beam measures the electric field twice per spin period.

¹⁴⁷⁵⁾K. I. Oyama et al, "Electron Temperature Probe on Board Japan's 9th Scientific Satellite Ohzora," J. Geomagnetism and Geoelectricity, Volume 37, 1985, pp. 413-430

¹⁴⁷⁶⁾EXOS-D (Akebono) - Japan's 12th Scientific Satellite - A Study of auroral particle acceleration processes, ISAS brochure

¹⁴⁷⁷⁾Selected papers on EXOS-D (Akebono) Observations in Geophysical Research Letters, Volume 18, No. 2, Feb. 1991, pp. 293-352

Ion beam technique: the instrument consists of four lithium ion guns, four lithium ion detectors, a data control unit, an ion beam direction control unit, and a peripheral interface module.

Double probe technique: measurement of the electric field in the plane perpendicular to the satellite spin axis using two pairs of wire antennas (30 m). The sampling rates are 32, 8, and 2 samples per second.

MGF = Magnetic Field Detectors (PI: H. Fukunishi, Tohoku University) Objectives:

- study the relationship between fine structures of field-aligned currents and auroral forms by comparing magnetometer data with ATV data and ground-based auroral TV data.
- determine the current carriers using simultaneous magnetic field and particle data
- study the driving mechanism of field-aligned currents from simultaneous measurements of magnetic fields and electric fields
- identify plasma wave modes in the frequency range < 100 Hz

MGF is a triaxial fluxgate magnetometer (mounted at the tip of a 5 m mast) and a triaxial search coil magnetometer (mounted at the tip of a 3 m mast). The fluxgate magnetometer measures within four ranges: $\pm 65,536$ nT, $\pm 16,384$ nT, $\pm 4,096$ nT, and ± 1024 nT with resolutions of: 2 nT, 0.5 nT, 0.125 nT, and 0.031 nT, respectively. Sensor drive frequency = 15 kHz; frequency response = DC to 50 Hz. Search coil magnetometer: triaxial search coil with 10^5 turns and permalloy cores, frequency response = 1-1000 Hz; sensitivity = 1 pT at 10 Hz.

Figure 259: The Exos-D (Akebono) S/C Model

VLF = Very Low Frequency Wave Detectors (PI: I. Kimura, Kyoto University)

Objectives: study of the behavior of plasma waves associated with auroral particles, wave particles interaction mechanisms, and propagation characteristics of whistler mode and electrostatic mode waves in the magnetospheric plasma.

The instrument, consisting of the following subsystems, uses a pair of dipole wire antennas, 60 m tip-to-tip.

- WBA (wide band receiver for observation of VLF spectra), 50 Hz - 5 kHz E or B component
- MCA (multichannel analyzers), 16 channels for E, 16 channels for B
- PFX (step frequency receiver for the measurement of wave normal direction and pointing flux), band width = 50 Hz
- ELF (ELF band receiver, 4 channels), 100 Hz, 50 Hz (upper cut-off frequency)
- VIP (vector impedance measurement of the wire antennas)
- DUP (data processing unit)

Joint experiments with VLF and the HIPAS (High Power Active Stimulation) facility located in Fairbanks, Alaska, were undertaken in 1989. The ground VLF observations were successful in the sense that the VLF signals associated with the amplitude modulated HF HIPAS transmissions were clearly detected.

PWS = Plasma Wave Detectors and Sounder (PI: H. Oya, Tohoku University)

Objectives: measure high frequency plasma waves (observe naturally occurring plasma and electromagnetic waves), conduct stimulated plasma wave experiments.

The instrument consists of:

- a dynamic spectrum analyzer (frequency range from 10 kHz to 5 MHz, frequency resolution = 1 kHz, dynamic range is about 100 dB)
- a polarization measurement system (frequency range from 20 kHz to 5 MHz)
- a pointing vector measurement system (measurement of wave amplitudes and phases of two electric field components and three magnetic field components, the analyzed wave frequency is stepped in frequency from 60 kHz to 1.3 MHz)
- a high power transmitter/sounder (coverage of a wide frequency range at high power from 20 kHz to 12 MHz, also operational modes to detect plasma density with high spectral resolution)
- an impedance measuring system (swept frequency impedance of the antenna in the plasma is measured in the same frequency range as the sounder)

The PWS sensors employ two sets of 60 m tip-to-tip antennas and a 70 cm diameter three dimensional loop antenna.

LEP = Low Energy Particle Detectors (PI: T. Mukai, ISAS). Objectives: comprehensive observations of energy and pitch angle distributions of electrons, ions, and mass per unit charge of the ions in the auroral magnetosphere. In particular:

- study of the characteristics of charged particles associated with various types of auroras
- study of particle acceleration due to electrostatic potential drops along magnetic field lines
- identification of charge carriers of the field-aligned currents
- study of wave-particle interactions
- study of particle modulations (<16 Hz) and determination of source locations
- direct detection of flux modulations of electrons and ions in the VLF and HF ranges
- study of the plasma transport between the polar ionosphere and the distant magnetosphere

LEP-S1 instrument (3-D energy/charge analyzer). Energy range = 10 eV - 16 keV for electron measurement and 13 eV/Q -20 keV/Q for ion measurement; scanning rate = 32 steps/second; energy resolution $\Delta E/E = 12\%$; FOV = $8^\circ \times 10^\circ$ centered at $180^\circ, 150^\circ, 120^\circ, 90^\circ, 60^\circ$ with respect to the solar direction.

LEP-S2 (3-D energy/charge analyzer). Identical to the LEP-S1. The view directions of LEP-S1 and LEP-S2 are symmetrical with respect to the spin axis of the satellite.

LEP-M (3-D energetic ion-mass spectrometer). Energy range = 1 - 25 keV/Q. Type of measurement = 135° spherical electrostatic analyzer, 40° magnetic analyzer and MCP; simultaneous measurements of mass and pitch angle distributions, differential energy spectra (32

steps) for ion species H^+ , He^{++} , He^+ , O^{++} , and O . Scanning rate = 16 steps/second for energy scanning; FOV = $3^\circ \times 34^\circ$ with the longer dimension parallel to the spin axis of the satellite.

SMS = Suprathermal Ion Mass Spectrometer (PI: B. Wahlen, NCR, Canada)

Objectives: measurement of the distribution functions of the major as well as the minor ion constituents of the magnetospheric ion population.

SMS is a radio-frequency-type ion mass spectrometer measuring mass, energy and angular distributions of positively charged ions species. The instrument uses a time-of-flight technique to measure ion velocities and electrostatic deflection to define the ion energy per unit charge, thereby determining the ion mass per unit charge. Instrument characteristics:

- energy/unit charge (E/Q) range: $-0 < E/Q < 4$ kV
- mass/unit charge (m/Q) range: $-0.8 < m/Q < 60$ AMU/Q
- energy resolution (ΔE): $-0.05 < \Delta E < 0.2$ kV (programmable)
- mass resolution ($\Delta m/m$): $-0.05 < \Delta m/m < 0.2$ (programmable)
- angular resolution in plane to S/C spin axis ($\Delta\theta$): $-3^\circ < \Delta\theta < 90^\circ$ (FWHM, programmable and dependent on energy and geometric factor)
- angular resolution in plane to the scan ($\Delta\theta$): $-3^\circ < \Delta\theta < 90^\circ$ (FWHM, programmable and only available for low energy $E/Q < 0.1$ kV ions)

TED = Thermal Electron Detectors (PI: K. Oyama, ISAS). Objective: to measure the behavior of background plasma electrons associated with auroral phenomena. In particular:

- Detection of the field-aligned current carriers responsible for the downward current in the auroral region.
- Observation of the behavior of thermal electrons in the trough region and their relationship to double layers or to V-shaped electric fields.
- Observation of the velocity distribution function anisotropies of thermal electrons in the polar region.
- Study of the heating mechanism of thermal electrons due to wave-particle interaction.
- Observation of the behavior of thermal electrons at low altitudes in the South Atlantic geomagnetic anomaly.
- Observation of the equatorial “plasma bubble” and study of the nonthermal properties associated with this phenomenon.

TED-1 instrument characteristics (electron temperature T_e and floating point potential V_f): energy range: $T_e = 0 - 1.0$ eV, $-5V < V_f < 5V$; type of measurement: two planar probes with a shape of two semicircular disks, each mounted on the tip of a solar paddle. The surfaces of the two probes are arranged to be perpendicular to each other. Superposition of AC signal of 1 kHz.

TED-2 instrument characteristics (velocity distribution and electron density): energy range: $0 - 2.5$ eV, $0 - 5$ eV; density range: $10^2 - 10^6$ cm^{-3} ; type of measurement: two planar probes of circular shape with their surfaces mutually perpendicular.

ATV = Visible and UV Auroral Television (PI: T. Oguti, University of Tokyo)

Objective: imaging the global aurora through two spectral windows in the VIS and UV ranges with highly sensitive devices which are essential to the observation of faint polar cusp auroras.

ATV produces auroral images in the VIS (557.7 nm) and UV (115-160 nm) spectral ranges using a despun mirror system. ATV uses a CCD imaging system of 488 (vertical) x 376 (horizontal) pixels with a FOV of 30° (vertical) x 40° (horizontal) for VIS, and 36° (vertical) x 36° (horizontal) for UV, respectively. The integration time of the CCDs may be set to 100 ms, 200 ms, 400 ms, or 600 ms.

Data:

On-board storage capability of 67 Mbit (bubble recorder). Data transmission in S-band

PCM at 65, 16, and 4 kbit/s; and UHF analog data transmission at 10 kHz and at 5 kHz. The EXOS-D (Akebono) science data will be placed in the public domain some years after acquisition.

K.11 FREJA

Swedish/German small-satellite mission with international cooperation in the instrumentation (follow-up to Viking, see K.29). The objective is: magnetospheric research, to make high-resolution measurements in the upper ionosphere and lower magnetosphere (auroral phenomena). The satellite features a magnesium structure, it was built by SSC (project management: Swedish Board of Space Activities) and weighs 256 kg (spinning disk with a diameter of 2.2 m and with a spin axis solar-oriented, spin rate = 10 rpm). An attitude knowledge of 0.5° is provided. Nominal lifetime = 2 years. Project scientists: R. Lundin of Swedish Institute of Space Physics, and G. Haerendel, MPE Garching.

Piggyback launch of Freja on Oct. 6, 1992 with a Long March (CZ-2C) vehicle from Jiuquan Spacecraft Launch Center, China. Operational mission until June 1995. FREJA was put into a standby mode as of June 30, 1995 (to be used for future special campaigns).

Orbit: apogee = 1790 km, perigee = 650 km, inclination = 65°

Sensor complement: The science payload includes six radial wire booms (1 < 15 m) and two stiff radial booms (1m and 2m).

F1: Electric Field Experiment (PI: Göran Marklund, Royal Institute of Technology, Stockholm). The objective is to further explore (and estimate the relative roles of) various suggested mechanisms for particle acceleration either by quasi-DC parallel electric fields (eg., double layers, anomalous resistivity and magnetic mirror effects) or by wave-resonance. Measurement of the electric field as potential difference between opposite probes. Two components can be measured since the probes are all in the spin axis of the satellite (the third component is deduced). The measurement parameters are as follows: maximum field = 1 V/m; minimum field = 0.03 mV/m; accuracy ≈ 0.5 mV/m; sampling rate (normal mode) = 768 s^{-1} ; sampling rate (burst mode) = 6144 s^{-1} . F1 measures in addition the satellite potential. The electric field is measured with the double probe technique. Six spherical probes are used, extended on three wire boom pairs in the spin plane. ¹⁴⁷⁸⁾ ¹⁴⁷⁹⁾

F2: Magnetic Field Experiment (PI: L. Zanetti, APL, Johns Hopkins University, MD, USA). Objectives: static DC structure measurements of large and small scale current with full orbit data and 50 m resolution; vector wave measurements up to Nyquist frequencies of 64 Hz and spin axis measurements up to 256 Hz in the normal 256 kbit/s telemetry mode. Instrument characteristics:

- Triaxial ring core fluxgate sensor, 2m boom mounted
- Low noise (10 μV) analog, 16 bit A/D, S/C mounted
- Internal 1.3 Mbit RAM, event trigger, FFT S/W, oversampling
- Real-time data output: 14.3 kbit/s for 256 kbit/s TM rate, and 28.6 kbit/s for 512 kbit/s TM rate
- DC - B: 128 vector samples/s (vs/s), range $\pm 65,000$ nT, ± 1 nT
- AC - B: 128 vs/s, bandpassed 1.5-128 Hz, range ± 500 nT
- Spin axis: 1.5 - 256 Hz FFT, 2 Hz resolution
- Instrument mass: 3.5 kg (excluding boom and mount)
- Instrument power: 3.7 W (including DC/DC)

¹⁴⁷⁹⁾ "The Freja Scientific Satellite," brochure of Swedish Space Corporation

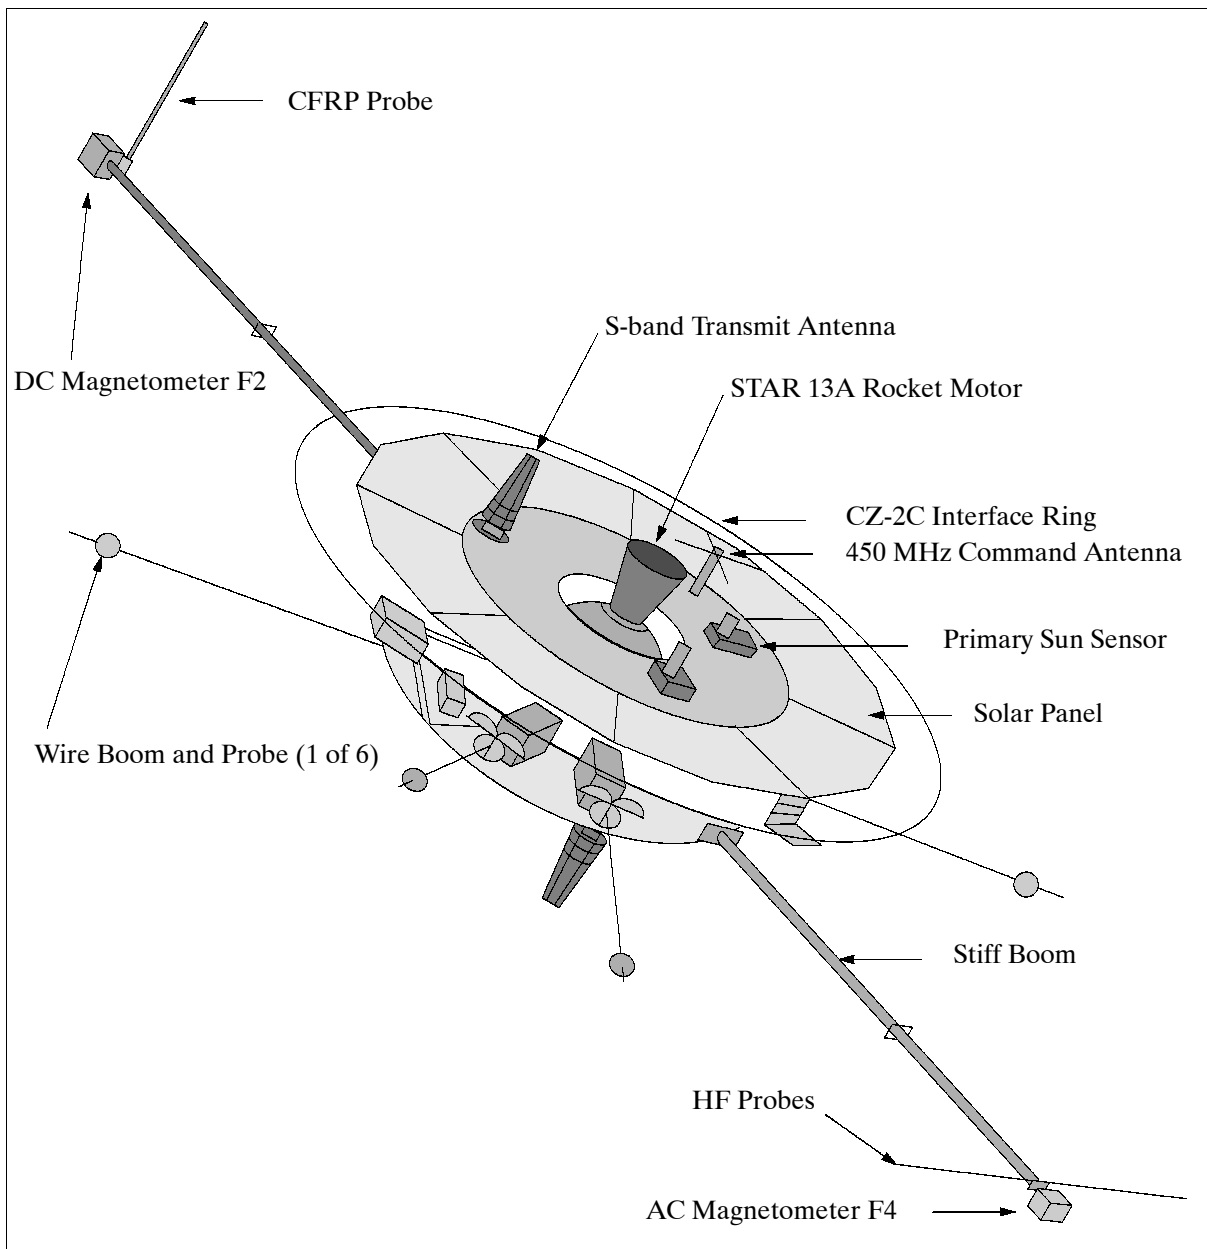

Figure 260: The Freja S/C model

F3C: Particles Experiment - Cold Plasma Analyzer (PI: B. A. Wahlen, NRC, Canada). Objectives: quantitative measurements of cold ionospheric plasma distribution; small scale auroral plasma structure investigation; identification of the plasma wave mode; investigation of low-altitude energization mechanisms; direct observation of the cloud plasma drift velocity; coordinated ground-based observations.

Instrument characteristics: boom-mounted sensor; technique: electrostatic analyzer;

- Species detected: negatively and positively charged particles (electrons and ions)
- Energy range: $0 \leq E/Q \leq 300$ eV
- Dynamic range: $10^2 \leq n \leq 10^5$ cm⁻³
- Energy resolution: $0.05 \leq \Delta E/E \leq 0.20$ (programmable)
- Angular resolution: azimuth, $10^\circ \leq \Delta\phi \leq 90^\circ$ (programmable)
- Angular resolution: elevation, $5^\circ \leq \Delta\alpha \leq 90^\circ$ (programmable)
- Temporal resolution: ~ 10 ms (typical), maximum ~ 0.1 ms (on one selected parameter)
- Instrument mass: 5.5 kg (including boom)
- Instrument power: 8.4 W (normal)

- Telemetry rates: 16.384 kbit/s (nominal); 32.768 kbit/s (maximum)

F3H: Particles Experiment - Hot Plasma Analyzer (PI: L. Eliasson, Swedish Institute of Space Physics, Kiruna). Objectives: study of ion distributions of ionospheric origin (mainly H^+ and O^+) in the energy range from a few eV up to several keV transverse to the geomagnetic field, of electron distributions observed on auroral field lines, and study of auroral acceleration mechanisms. The instrument consists of three units: MATE (an electron spectrometer), TICS (a 3-D ion composition spectrometer, and DPU (data processing unit).

- **MATE** characteristics: Measurement of the angular and energy distributions of electrons with high temporal and spatial resolution; energy range: 0.1 keV - 120 keV; angular segments: 32; energy levels: 16; FOV/sensor head: $2^\circ \times 10^\circ$; energy resolution: 15-30% FWHM; minimum sampling time: 10 ms/energy-angle matrix; maximum data rate: 51.2 kByte/s (no data compression); normal data rate: ≈ 20 kbit/s; mass = 2.7 kg; power = 3.8 W.
- **TICS** characteristics: Measurement of 'hot' magnetospheric and 'cold' ionospheric ion distributions, study of the heating/acceleration of ions perpendicular to the magnetic field lines. TICS consists of a 90° spherical 'top hat' electrostatic analyzer with 360° FOV followed by a cylindrical sector magnet momentum analyzer. Energy range: 0.5-15000 eV/q; mass range: 1-40 AMu/q; angular segments: 32; energy levels: 32; energy resolution: 10% FWHM, FOV/sector head: $5^\circ \times 10^\circ$; sampling time: 10 ms/mass-angle matrix (32 x 32); FOV: 360° ; geometric factor: $1 - 10^4$ (cm² s sr keV/keV) per 11° opening; time resolution: 0.5 spin period; maximum data rate: 102.4 kByte/s (no data compression); normal data rate: ≈ 20 kbit/s; mass: ≈ 3.3 kg; power: 4.5 W.

F4: Waves Experiment (PI: B. Holback, Swedish Institute of Space Physics, Uppsala). Objectives: study of wave modes and energy; measurement of electric, magnetic, density and electron temperature wave fields and turbulence; background plasma density and electron temperature.

The F4 instrument utilizes a number of sensors mounted on booms in the satellite spin plane. Three pairs of spherical probes (P1-P4 and P8-P9) are mounted on three wire boom pairs (switchable for electric field and plasma density measurements). A Cylindrical Langmuir Probe (CYLP) is mounted at the outer end of a stiff boom. The High Frequency (HF) experiment uses the P1 and P2 signals or the dedicated HF probes (HFa, HFb). The Search Coil Magnetometer (SCM) assembly consists of three search coils mounted at the end of a stiff boom. Measured quantities of F4 instrument:

- Electric wave fields (ΔE)
- Magnetic wave fields (ΔB)
- Plasma density ($\Delta n/n$) and temperature ($\Delta T_e/T_e$) variations
- Langmuir (DC) current to provide the cold plasma characteristics (N_e and T_e)

F5: Auroral UV Imager (PI: J. S. Murphree, University of Calgary, Canada). Objectives:

- Determination of the growth rate of distortions in discrete arcs
- Determination of the local time extent of optical substorm onsets
- Characteristics of discrete arcs from Maxwellian and non-Maxwellian source distributions (in conjunction with the particle observations)
- Determine whether episodic expansion or continuous propagation is the dominant form of substorm spiral motion
- Characterize substorm onset precursor activity.

F5 is of Viking mission heritage (see V5 in chapter K.29). F5 is an inverted Cassegrain Burch type camera [mass = 10.8 kg; power = 8.4 W (high); TM rate = 88.064 kbit/s or 44.032 kbit/s; image storage capability: 952 kByte]. F5 measurement characteristics:

- Camera optics: inverse Cassegrain, speed F/1; focal length = 22.4 mm; FOV = $25^\circ \times 20^\circ$; optical axes are 90° from spin axis.
- Spectral passband: camera 0: 134 nm - 180 nm (BaF₂ + CsI); camera 1: 125 nm - 160 nm (CaF₂ + KBr);

- Detector: intensified CCD; image size (max) 385 x 4598 pixels; pixel size = 22 μm x 22 μm ; full well potential: $3 \times 10^5 \text{ e}^-$
- Resolution: angular = $0.0783^\circ \times 0.0783^\circ$; spatial (from apogee with 2 x 2 pixels) $\sim 5 \text{ km}$
- Exposure: 0.37 s (for 6 second spin period)

Branch	Sensor Signal	Sampling rate k-samples/s	Word (bits)	Telemetry (Word/s)	Duty Cycle (%)
HF 1 channel	HF Probes $e_1 - e_2$	8,000,000	8	1024	0.01
MF 1 channel	$e_{i,k}$ $b_{x,y,z}$	32.768	16	512	1.6
LF 4 channels	$e_{i,k}$ $b_{x,y,z}; \Delta n/n_{1,2,3,4}$	4.096	16	768	18.8
n up to 4 probes	$n_{1,2,3,4}$	0.128	16	128	100

Table 444: Summary of key parameters for the F4 wave analyzer

F6: Electron Beam Experiment (PI: G. Paschmann, MPE, Garching). Objectives: measurement of electric fields associated with the auroral acceleration region (method based on sensing the drift of weak electron beams). F6 is of GEOS heritage, see also EDI instrument on Cluster missions (K.7). F6 has three electron guns (three components of E-field, up to 700 samples/s) consisting of the following components:

- an electron gun with a magnetic deflection system
- a position-sensing detector
- the analog detection electronics
- the gun and deflector supplies
- interfaces with the electronics box

F7: Particle Correlator Experiment (PI: M. H. Boehm, MPE, Garching). Objectives: measurement of electron distributions, electron-electric field correlations, particle-particle correlations.

The F7 TESP/correlator instrument consists of a swept-energy electrostatic analyzer to measure the full electron distribution function at 64 ms time resolution, and wave/particle and particle/particle correlations (correlation with F4) measuring variations in the distribution function at frequencies up to several MHz. TESP measurement parameters:

- Angular channels: 32, evenly spaced
- Energy range: $\sim 10 \text{ eV} - \sim 30 \text{ keV}$
- Typical number of energy steps: 32 or 64
- Typical sampling time per step: 1 ms
- Sweep retrace time: $< 1 \text{ ms}$
- Maximum entrance aperture deflection angle: $\sim 30^\circ$, partially blocked by the satellite
- Total geometric factor (numerically calculated): $0.025 \text{ cm}^2 \text{ ster keV/keV}$
- Approximate energy width (retarding grid off): 15% FWHM
- Approximate energy width (retarding grid on): $\sim 7\%$ FWHM at $\sim 0.006 \text{ cm}^2 \text{ ster keV/keV}$.

Freja Data:

On-board data storage capability. S-band downlink with data stream phase-modulated onto the carrier, data rates (direct transmission) = 262 kbit/s or 524 kbit/s, $> 2 \text{ Mbit/s}$ (burst memory mode). Esrange ground station at Kiruna for S/C control and science data reception, Prince Albert station in Saskatchewan also for data reception.

Temporal resolution of Freja data:

- Fields: $\leq 0.1 \text{ ms}$
- Particles: $\approx 10 \text{ ms}$
- Images: $\approx 6 \text{ s}$

Spatial resolution of Freja data:

- Fields: ≤ 1 m
- Particles: ≈ 100 m
- Images: ≈ 2 km

K.12 Genesis (Solar-Wind Sample Return Mission)

A NASA mission into a halo orbit around the Lagrangian point L1 (outside of the Earth's magnetosphere) with the objective to monitor the solar wind and to collect particles of the solar wind by ion implantation into the collector materials for a duration of two years, and to return these samples for isotopic and chemical analysis in terrestrial laboratories. - The outer portion of the sun is believed to reflect the bulk composition of the original solar nebula. One way to measure the composition of the outer portion of the sun is to analyze the solar wind. The science objectives are:

- To obtain precise measures of solar isotopic abundances. Measurement of isotopic compositions of oxygen, nitrogen, and noble gases. These data enable scientists to better understand the isotopic variations in meteorites, comets, lunar samples, and planetary atmospheres.
- To obtain greatly improved measures of solar elemental abundances
- To provide a reservoir of solar matter for 21st century science research, eliminating the need for future solar wind sample return missions.

Overall mission scenario: At L1, Genesis unfurls its collector arrays and begins collecting particles of the solar wind that imbed themselves in specially designed high purity wafers. After two years, the sample collectors will be re-stowed and returned to Earth for a mid-air recovery of the sample return capsule. The samples will be stored and cataloged under ultra-pure clean room conditions and made available to the world scientific community for study.¹⁴⁸⁰⁾

The Genesis mission is managed by JPL. The S/C and the SRC (Sample Return Capsule) were developed and built at LMA (Lockheed Martin Astronautics), Denver, CO. Other project partners are: LANL (Los Alamos National Laboratory - development of the sample concentrator and two solar wind monitors); NASA/MSFC [with AAIF (Advanced Analytical Instrument Facility)]; JSC (Johnson Space Center) - providing the class 10 cleanroom for assembly and post-flight disassembly of the solar wind collectors, as well as curation of the returned samples (Note: "class 10" refers to the fact that only 10 particles of contaminant per cubic meter are allowed). The head of the project is Principal Investigator Donald Burnett of the California Institute of Technology. Approximately 18 science co-investigators are from various institutions and countries, including Japan, Switzerland, and the U.K.

The Genesis S/C is sun-oriented and spin-stabilized with two fixed solar arrays. The spin rate on station is one revolution in 37.5 seconds. The S/C has three major components: the platform, the SRC (Sample Return Capsule), and the payload. The platform structure employs a truss of graphite-polycyanate composite tubes with titanium end-fittings. The truss supports a composite honeycomb-reinforced deck that forms a platform for equipment mounting. The SRC is attached to the platform via three bipod struts. The size of the platform, 1.7 m diameter x 0.5 m height, is dictated by the SRC diameter of 1.4 m, selected in turn to maximize the payload collector area. Attitude control is provided by thrusters; the attitude is sensed by redundant star sensors. The deployed length of the S/C is 7.9 m. Power of 202 W (EOL) is provided by two non-articulated solar arrays (each of 1 m²); in addition, two batteries provide energy during trajectory correction maneuvers. The C&DH (Command and Data Handling) subsystem uses a RAD 6000 processor (redundant processors, uplink/downlink, I/O and payload/attitude control functions. A propulsion subsystem with

¹⁴⁸⁰⁾Note: In the initial project phase (1995) the solar-wind sample return mission was called "Suess-Urey." It was renamed to "Genesis" in 1996 after the completion of Phase A.

monopropellant hydrazine thrusters (78 kg of propellant) is used for the cruise phase from Earth to the halo orbit. The S/C mass is 494 kg, the launch mass (including propellant) is 636 kg.

Figure 261: Illustration of the Genesis spacecraft

Communications: An on-board recorder of 1 Gbit storage capacity is provided. The uplink and downlink is in S-band at 15 kbit/s 120 bit/s during cruise phase). The low data rate of the solar wind monitors at <1 kbit/s allows infrequent (weekly) contacts with the S/C via DSN.

Figure 262: The Genesis trajectory

A launch of Genesis took place Aug. 8, 2001 on a Delta-7326 vehicle from Cape Canaveral Air Station, FLA.

Orbit: A halo orbit into the Lagrangian point L1, balanced gravitationally between the sun and the Earth. L1 is located about 1.5 million km from Earth, amounting to 1/100 the distance from Earth to the sun. The S/C takes approximately 3 months to arrive at the halo orbit insertion, after which it makes 4 orbits about the L1 point over a period of about 2 years. The spacecraft then moves out of the halo orbit on a trajectory taking it through the L2 point on the anti-sunward side of the Earth in order to position it for a daytime reentry. Reentry is currently scheduled for September, 2004 over the Utah Test and Training Range (UTTR), where the S/C can be tracked by the High Altitude Multiple Object Tracking System (HAMOTS). Two helicopters will be vectored to the spacecraft location and will catch the capsule as it descends on a parachute, thus avoiding a hard ground-landing. An optional three-day parking orbit allows alternate reentry dates if conditions prove to be poor for the initial reentry date. ¹⁴⁸¹⁾ ¹⁴⁸²⁾ ¹⁴⁸³⁾

Instrument/Payload Complement:

The Genesis mission has two primary instruments, a) collector arrays which passively collect solar wind samples and b) the concentrator. Both the collector arrays and the concentrator contain suites of ultra-high purity target materials, each of which is tailored to enable the analysis of a different element family. In addition, there are two solar wind monitors (electron and ion spectrometers) to measure and classify the solar wind. ¹⁴⁸⁴⁾

Collector Arrays: A set of four panels (comprised of individual hexagon collectors), each capable of separate deployment to sample the different kinds of solar wind.

Each collector has the form of a flat pan with a diameter of 73 cm. In L1 halo orbit, after the canister lid opens, the stack of four arrays is rotated away from the canister, exposing the concentrator inside the canister. The topmost two of the four collector arrays, along with the array and the canister lid, are always exposed to the solar wind flux. The two lower collectors in the stack are exposed one at a time, depending on which of the solar wind regimes is being detected by the solar wind monitors. The collector retraction mechanism is inertial to the canister, consisting of a set of motors driving concentric cylindrical actuators which rotate the arrays individually about a common axis. - Each of the four collector arrays is composed of 55 hexagonal collector wafers, made of different materials and of ultra-high purity. The majority of the wafers are made of silicon; they are about 0.5 mm thick and 10 cm (point-to-point) hexagonal shape. Other wafer materials are aluminum and gold foils. The temperature of all collector arrays is kept at < 200 K.

Solar Wind Concentrator: The assembly consists of an electrostatic mirror which enhances the density of C, N and O ions from the solar wind to provide better signal-to-background ratios for these elements. An ion concentration by a factor of >20 is achieved, focusing them onto a target of 6 cm in diameter. The basic design is illustrated in Figure 263. Solar wind ions enter from the top through a series of three high transmission grids. The topmost grid is maintained at ground potential so that potentials inside the concentrator do not extend outside of it or affect the trajectories of particles prior to their entry. The next grid is biased at a variable positive high voltage. This voltage is set such that the bulk of the solar wind protons are rejected while essentially all of the heavier ions are transmitted. The third grid is mounted to a metal structure which completely encapsulates the inner region of the concentrator and is maintained at a constant negative high voltage of -8 kV. The target is a

six centimeter disk mounted onto a structural spider that is in the plane of, and supports, the third (-8 kV) grid. ¹⁴⁸⁵⁾

Heavy ions enter through the grounded grid, pass through the proton suppression grid, and are accelerated into the interior region by -8 kV on the accelerator grid. They are then reflected between the mirror grid and the solid electrode, and embedded deep into the target. The inset shows micro-machined steps in the electrode which serve to reflect light and heat back out into space rather than concentrating it also onto the target. Energetic ions from the sun penetrate into the collector materials and remain implanted.

Figure 263: Schematic illustration of the solar wind concentrator

The solar wind collection system is built around collector arrays which are deployed from the SRC (Sample Return Capsule) which faces the sun.

Solar-Wind Monitors: A pair of solar wind monitor instruments (electron spectrometer and ion spectrometer) are used to detect the solar wind regime. These monitors determine the type of prevalent solar wind being measured [types: a) fast solar wind from coronal holes, b) slow interstream solar wind, and c) coronal mass ejections (CMEs)], to document the solar wind properties, and to determine the solar-wind speed. The information is needed to control the deployment of collectors and voltages on the solar wind concentrator. These monitors measure properties such as: 1) the H/He ratio, 2) the bulk wind velocity, 3) ion and electron temperatures, and 4) the angular distribution of super-thermal electrons. These data are fed into an on-board computer algorithm which determines in real-time the occurrence of a solar wind change.

- The **electron spectrometer** is a spherical-section electrostatic analyzer which uses an array of 7 channel electron multipliers, plus the spacecraft spin, to map out nearly the entire unit sphere in velocity space. The instrument has a FOV of 10°-170° with respect to the spin axis by 30° in azimuth. There are 24 available energy steps (analyzer plate

¹⁴⁸⁵⁾D. J. McComas, B. L. Barraclough, R. C. Wiens, et al., "Solar Wind Concentrator," Measurement Techniques in Space Plasmas: Particles, Geophysical Monograph 102, AGU, 1998

voltages), logarithmically spaced from 1.5 eV to 1000 eV. Four energies are sampled per spin.

- The **ion spectrometer** is a spherical-section electrostatic analyzer which uses a Z-stack MCP (Micro Channel Plate) detector, plus the spacecraft spin, to ensure capture of the solar wind beam over a wide range of solar wind conditions. The FOV is 20° starting along the spin axis by <10° in azimuth. There are 40 energy steps per spectrum, chosen from an array of 180 available steps spanning 200 eV/q to 25 keV/q.

Sample Canister Assembly: The collector arrays and the solar wind concentrator are mounted within the sample canister. The overall configuration of the instruments has been designed to achieve this ultra-clean environment within the canister by the exclusion of practically all sources of outgassing. While the solar wind collectors reside within the canister, the mechanisms and electronics mount on the outside of the canister. The only exception to this is the collector array deployment mechanism, which by necessity must be attached to the deployable arrays within the canister. - The canister structure consists of a base and cover, each machined out of a billet of aluminum alloy. The canister measures 78 cm in outside diameter and 38 cm in height. This structure supports the collectors, mechanisms and electronic boxes for the launch and recovery loads, and transfer them to the SRC through six interface struts.

K.13 GEOTAIL

GEOTAIL is Japanese/USA (ISAS)/NASA) collaborative mission within ISTP (S/C built by ISAS, launch by NASA/GSFC). GEOTAIL inaugurates the Collaborative Solar-Terrestrial Research Program (COSTR). COSTR defines the NASA contributions to the GEOTAIL, SOHO, and Cluster missions. GEOTAIL objectives: study of the structure and dynamics of the geomagnetic tail. In particular:

- Determine the overall plasma, electric and magnetic field characteristics of the distant and geomagnetic tail.
- Determine the role of the distant and near-Earth tail in substorm phenomena and in the overall magnetospheric energy balance and relate these phenomena to external triggering mechanisms.
- Study the processes that initiate magnetic field reconnection in the near-Earth tail and observe the microscopic nature of the energy conversion mechanism in the reconnection region.
- Study plasma entry, energization, and transport processes in interaction regions such as the inner edge of the plasma sheet, the magnetopause and the bow shock, and investigate associated boundary layer regions.¹⁴⁸⁶⁾

GEOTAIL launch on July 24, 1992 from Cape Canaveral with a Delta 2 vehicle.¹⁴⁸⁷⁾ S/C mass = 970 kg (330 kg propellant, 105 kg science payload). There is a pair of 100 m tip-to-tip antennas and two 6 m long masts. The S/C is a 20 rpm spin-stabilized cylinder of 2.2 m diameter and 1.6 m in height. Data are received at a rate of 64 kbit/s in the real time mode, and at the same time they are recorded on board at a rate of 16 kbit/s. GEOTAIL is operational as of the end of 1999.¹⁴⁸⁸⁾

Orbit: GEOTAIL objectives require spacecraft measurement in two orbits: a nightside double lunar swingby GeoTail orbit to distances of 220 R_E , and a low inclination orbit at geocentric distances of about 8 to 30 R_E . GEOTAIL uses the gravity of the moon to assist its orbit on the night side of the Earth, where the magnetotail is stretched out as a result of the impact of the solar wind encountering the Earth. In this phase, GEOTAIL's orbit extends from 220 R_E (1,401,620 km) at its farthest point to 8 R_E (50,960 km) at its nearest point.

¹⁴⁸⁶⁾ "The GEOTAIL Mission," in NASA Facts, GSFC, June, 1992

¹⁴⁸⁷⁾ "Delta Launches GEOTAIL," Space News, July 27-Aug. 9, 1992, p. 12

¹⁴⁸⁸⁾ <http://www.isas.ac.jp/e/enterp/missions/index.html>

- Distant tail orbit: 1.75 years in distant tail configuration (double lunar swingby to an $8 \times 220 R_E$ orbit). This orbit also allows us to study the boundary region of the magnetosphere as it skims the magnetopause at perigees. In the first two years the double lunar swing-by technique was used to keep apogees in the distant magnetotail.
- Near tail orbit: 1.45 years in near tail configuration (reduced to an $8 \times 30 R_E$ orbit, 7.5° inclination).

The apogee was lowered down to $50 R_E$ in mid November 1994 and then to $30 R_E$ in February 1995 in order to study substorm processes in the near-Earth tail region. The present orbit is $9 R_E \times 30 R_E$ with an inclination of -7° to the ecliptic plane.

Figure 264: The GEOTAIL S/C model

Science background: The solar wind, emanating from the sun, injects plasma into the magnetosphere and transfers energy to it. Several times a day the magnetosphere undergoes a disturbance called a substorm. As the substorm grows, most of the solar energy is dissipated within the magnetosphere, ionosphere and upper atmosphere. This disturbance ultimately causes auroral displays, the acceleration of charged particles to high energies, the emission

of intense plasma waves, and the generation of strong ionospheric currents that produce significant changes in the upper atmosphere. These waves and currents often result in severe problems on Earth with regard to communications, power supplies, and spacecraft electronics.

Sensor complement: ¹⁴⁸⁹⁾

- **EFD** = Electric Field Detector (PI: K. Tsuruda, ISAS). Objectives: study of the coupling of the E-Field in the near-Earth magnetosphere and in the ionosphere (in particular during substorms). EFD uses electric-field antenna sampling at 64 samples per second, and an electron beam technique at 2 samples per spin.
- **MGF** = Magnetic Fields Measurement (PI: S. Kokubun, U. of Tokyo, R. Lepping, GSFC, instrument sponsored by ISAS). Objectives: study of the transport dynamics of mass, momentum, and energy between the magnetospheric and ionospheric plasma. Study of merging in the magnetotail. Instrument: MGF also contains the GEOTAIL Inboard Magnetometer provided by the US.
- **HEP** = High Energy Particles Experiment (T. Doke, Waseda University, Tokyo, instrument sponsored by ISAS). Objectives: measurement of high energy particles up to 25 MeV for electrons, 35 MeV for protons, and 210 MeV/charge for ions. Measurements may indicate the plasma boundary surfaces and reflect whether magnetic field lines are open or closed.
- **LEP** = Low Energy Particles Experiment (PI: T. Mukai, ISAS). Objectives: study of the dynamics of the magnetotail plasmas, plasma circulation and its variability in response to fluctuations in the solar wind and in the interplanetary magnetic field. Measurement of electrons from 6 eV to 36 keV, and ions from 7 eV to 42 keV/ charge.
- **PWI** = Plasma Waves Investigation (PI: H. Matsumoto, Kyoto University, instrument sponsored by ISAS). Objectives: study of the wave phenomena related to plasma dynamics in the different regions on various scales (phenomena include magnetic-field-line merging, moving plasmoids, and particle acceleration). Measurement of plasma waves in the frequency range of 5 Hz - 800 kHz. PWI contains also the Multi-Channel Analyzer provided by the US.
- **EPIC** = Energetic Particle and Ion Composition Experiment (PI: D. J. Williams, APL, John Hopkins University, instrument sponsored by NASA). Objectives: measurement of the charge, mass, and energy of ions. Study of the relative importance of ion sources and mechanisms for acceleration, transport and loss of particles, the formation and dynamics of magnetospheric boundary layers. - The EPIC instrument is actually composed of two separate sensor and processing assemblies:
 - **STICS** (Supra-Thermal Ion Composition Spectrometer). Objective: Measurement of ions. STICS uses a quadrispherical electrostatic analyzer followed by a foil/solid state detector time-of-flight (TOF) telescope to measure charge state, mass and energy of ions with energies of 30 - 230 keV/charge. It uses an electrostatic analyzer with a geometry factor of 0.05 cm² sr, time of flight and energy analysis.
 - **ICS** (Ion Composition Subsystem). The objective is to measure mass and energy properties of energetic ions with energies of less than 50 keV to 3 MeV. ICS uses a pair of collimators with sweeping magnets to reject electrons, followed by TOF and energy analysis, with a geometry factor of 0.2 cm² sr. A thin foil/solid state detector electron telescope measures electrons higher than 30 keV.
- **CPI** = Comprehensive Plasma Investigation (PI: L. A. Frank, U. of Iowa, instrument sponsored by NASA). Objectives: measurement of the 3-D plasma in the Earth's mag-

¹⁴⁸⁹⁾ "GEOTAIL Instruments and Initial Results," Foreword by A. Nishida, Journal of Geomagnetism and Geoelectricity, ISSN 0022-1392, Vol. 46, 1994,

netotail. The plasma data will be correlated with the magnetic field, plasma waves, electric particles, and auroral imaging data to determine magnetotail plasma dynamics. Instrument: measurement range of 1 eV - 50 keV for the Hot Plasma and Ion Composition Analyzer, and 150 eV - 7 keV energy /unit charge for the Solar Wind Analyzer. Plasma parameters, including heat flux and field-aligned current density, are measured.

Data: Two on-board recorders at 450 Mbit each. Real-time/playback transmission rates at 16.384 kbit/s, 65.536 kbit/s, or 131.072 kbit/s. Ground data reception at Usuda and Kagoshima stations (Japan) and NASA DSN.

K.14 HESSI (High Energy Solar Spectroscopic Imager)

A NASA SMEX mission, selected in Oct. 1997, and managed for NASA/GSFC by the Space Science Laboratory at UCB (University of California, Berkeley). The overall objective is to explore the basic physics of particle acceleration and energy release in solar flares. The prime observations performed are simultaneous, high resolution imaging and spectroscopy of solar flares from 3 keV X-rays to 20 MeV gamma rays with high time resolution. HESSI is a collaboration between the following institutions: GSFC, UCB (PI: Robert Lin), PSI (Paul Scherrer Institute, Villigen, Switzerland), and ETH Zürich (HESSI Experimental Data Center - HEDC). The S/C bus is designed and built by Spectrum Astro of Gilbert, AZ.¹⁴⁹⁰

Figure 265: The HESSI S/C model

HESSI is a sun-pointing and spin-stabilized S/C spinning at 12-20 rpm. The S/C structure is 1.1 m in diameter (at base) and 2.1 m in length. Its attitude and control subsystem employs sun sensors (fine and coarse) and a magnetometer for attitude sensing and magnetic torque rods as actuators. The S/C is capable of performing autonomous sun acquisition and spin-up from any orientation. Sun pointing (precession) control is $<0.2^\circ$ provided by SAS (Sun Aspect System). The on-orbit mass properties adjustment direct the sun pointing error measurement to about 0.05° . The S/C mass is 280 kg, power = 400 W. The power is provided

¹⁴⁹⁰<http://hessi.ssl.berkeley.edu>

by four deployable solar wings; in addition there is an NiH_2 battery energy of 15 Ah. The S/C design life is two years with a goal of three years. ¹⁴⁹¹⁾ ¹⁴⁹²⁾

S/C communication is in S-band. The downlink frequency is at 2215 MHz with selectable data rates of 4 Mbit/s, 1 Mbit/s or 125 kbit/s, with NRZ-M and BPSK data modulation. The uplink frequency is 2039.6458 MHz, the data rate is 2 kbit/s. Continuous S/C operations are supported through a UCB ground station and Mission/Science Operations Center. The data are distributed to SDAC (Solar Data Analysis Center) at GSFC and to HEDC at Zürich. There is also a complementary ground-based program supported by observatories throughout the world.

A launch on a Pegasus XL vehicle is planned for 2001 from Cape Canaveral, FL.

Orbit: circular orbit, altitude = 600 km, inclination = 38°

Sensor complement: (the instrument name is identical to the S/C name)

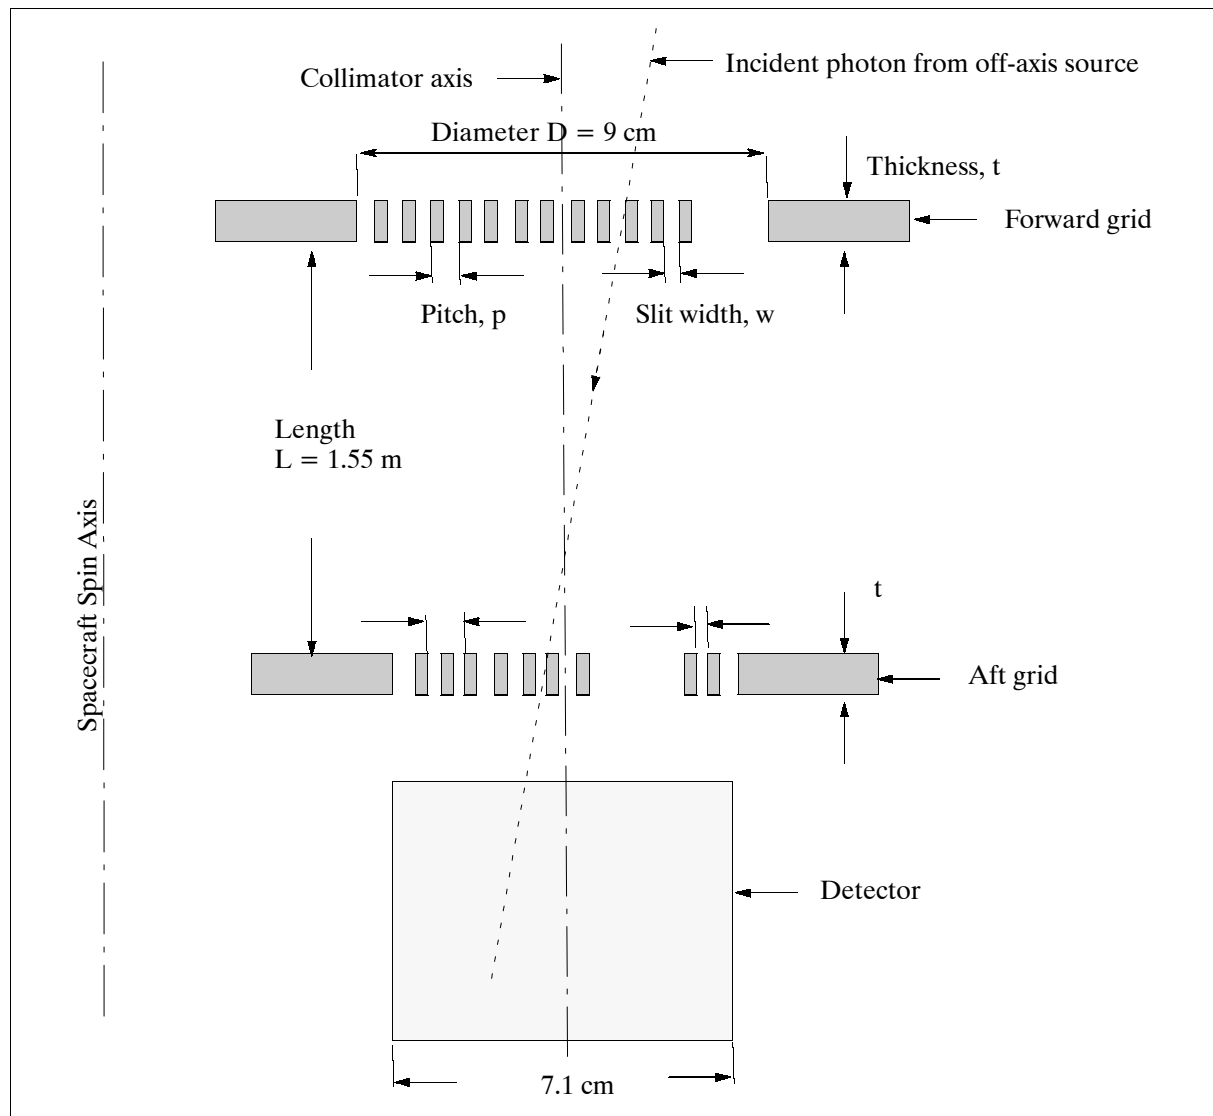

Figure 266: Schematic illustration of the HESSI grid pair parameters

HESSI (High Energy Solar Spectroscopic Imager). The objective is to obtain high fidelity color movies of solar flares in X-rays and gamma rays [imaging of solar flares in energetic

¹⁴⁹¹⁾ <http://hesperia.gsfc.nasa.gov/hessi/>

¹⁴⁹²⁾ Information provided by Brian R. Dennis of NASA/GSFC

photons from soft X-rays (about 3 keV) to gamma-rays (up to about 20 MeV) and to provide high resolution spectroscopy up to gamma-ray energies of about 20 MeV]. The instrument employs two new complementary technologies: fine grids (molybdenum and tungsten grids with slits as fine as 20 μm wide) to modulate the solar radiation, and germanium detectors to measure the energy of each photon very precisely (about 1 keV FWHM). HESSI is an FTS (Fourier Transform Spectrometer) device using a set of nine RMCs (Rotational Modulation Collimators). Each RMC consists of two widely-spaced, fine-scale linear grids, which temporally modulate the photon signal from sources in the field of view as the S/C rotates about an axis parallel to the long axis of the RMC. The modulation can be measured with a detector having no spatial resolution placed behind the RMC. The modulation pattern over half a rotation for a single RMC provides the amplitude and phase of many spatial Fourier components over a full range of angular orientations but for a small range of spatial source dimensions. Multiple RMCs, each with different slit widths, can provide coverage over a full range of flare source sizes. An image is reconstructed from the set of measured Fourier components in exact mathematical analogy to multi-baseline radio interferometry.

Energy range	3 keV to 20 MeV
Energy resolution	<2 keV below 1 MeV to 5 keV at 20 MeV
Angular resolution	2.3 arcseconds from 3 to 100 keV, 7 arcseconds to 400 keV, 36 arcseconds above 1 MeV
Instrument mass, power	130 kg, 148 W
Instrument size	Grid support structure: 45 cm diameter, 1.7 m long Detector/cooler enclosure: 1 m diameter x 30 cm deep
Data storage capability	16 Gbit in 10 minutes (solid-state on-board recorder)

Table 445: HESSI instrument specification

The detectors are the largest currently available hyperpure (n-type) germanium detectors of size: 7.1 cm in diameter and 8.5 cm in length. They are cooled to 77 K by a single stage electro-mechanical cryocooler (an integral counterbalanced Stirling cycle cooler which provides up to 4 W of cooling at 77 K, with an input of 100 W). The detectors cover the entire X-ray to gamma-ray energy range from 3 keV to 20 MeV. The keV spectral resolution of germanium detectors is necessary to resolve all of the solar gamma-ray lines (with the exception of the neutron deuterium line, which has an expected FWHM of only 0.1 keV).

K.15 IMAGE (Imager for Magnetopause-to-Aurora Global Exploration)

The first MIDEX (Medium-class Explorer) mission of NASA/GSFC with the overall objective to study the global response of the Earth’s magnetosphere to changes in the solar wind. Observations of high spatial and temporal resolution 3-D imagery of magnetospheric plasma motions. IMAGE uses ENA (Energetic Neutral Atom), ultraviolet, and radio imaging techniques to: ¹⁴⁹³⁾

- Identify the dominant mechanisms for injecting plasma into the magnetosphere on substorm and magnetic storm time scales
- Determine the directly driven response of the magnetosphere to solar wind changes
- Discover how and where magnetospheric plasmas are energized, transported, and subsequently lost during substorms and magnetic storms.

SwRI (Southwest Research Institute, PI: J. L. Burch,) of San Antonio Texas is the prime partner of NASA in this project. The S/C, built by LMMS (Lockheed Martin Missiles & Space), employs a spin-stabilized platform. It has the form of a regular octagon and measures 2.25 m in diameter and 1.52 m in height. Surface-mounted solar cells (high-efficiency, dual-junction GaInP₂/GaAs/Ge cells) provide an efficiency of 20-21.5% with average pow-

¹⁴⁹³⁾ W. C. Gibson, et al., “IMAGE, the First of the New MIDEX Missions,” Proceedings of the 13th AIAA/USU Conference on Small Satellites, Logan, UT, Aug. 23-26, 1999, SSC99-VII-2

er of 250 W (21 Ah NiCd batteries for eclipse operation). S/C mass = 496 kg. - IMAGE has a nominal spin period of 2 minutes (or a spin rate of 0.5 ± 0.01 rpm); its spin axis is perpendicular to the orbital plane. The AD&C (Attitude Determination & Control) subsystem consists of the following actuators/sensors: a magnetic torque rod, a passive nutation damper, a three-axis magnetometer for magnetic aspect information, an enhanced sun sensor, and AST (Autonomous Star Tracker) developed by LMMS. AST is mounted with its boresight 10° from the spin axis. The two-axis sun sensor provides spin rate and sun aspect angle information. MCS (Magnetic Control System) controls both spin axis orientation and spin rate. Attitude knowledge is accurate to within 0.1° . The C&DH (Command & Data Handling) subsystem design employs the MIL-STD-1553B bus which communicates with the instrument controllers over RS-422 interfaces. The CCSDS protocol is used for all internal and external communication. The 1553/CCSDS protocol design provides substantial advantages in terms of spacecraft/payload decoupling (the S/C serves mainly as a “bent pipe” for science data produced by the payload). All time synchronization between S/C and payload is accomplished exclusively over the 1553 bus. ¹⁴⁹⁴⁾ ¹⁴⁹⁵⁾

Mechanical subsystem	Aluminum honeycomb side panels (8), forward and aft panels, payload deck, and interior shear walls; two central load-bearing aluminum cylinders (forward and aft)
Mass	Spacecraft: 340 kg, Instrument Payload: 196 kg, Total: 536 kg
Thermal subsystem	Heat pipes in payload deck connected to radiators on S/Ct side panels; MLI blankets; thermostat- and CIDP/PDU-controlled electrical resistance heaters for payload and spacecraft operations and survival
Command & data handling subsystem	System Control Unit (SCU) consisting of RAD6000 flight computer plus modules for I/O, mass memory, command & telemetry, communications & memory, and power supply; VME backplane; 4.096 Gbit DRAM in mass memory module; Mil-Std-1553B interfaces to other observatory systems
Communications subsystem	S-band transponder; 1 medium-gain helix antenna; 2 low-gain omni-directional antennas; uplink data rate: 2 kbit/s; downlink data rate: 38 kbit/s (real-time mode); 2.28 Mbit/s (stored data playback mode)
Attitude determination & control subsystem	Spin-stabilized; closed-loop spin-rate control Sensors: Adcole 44690 sun sensor; Lockheed Martin ATC AST-201R autonomous star tracker; MEDA TAM-2A 3-axis magnetometer Actuator: 1 Ithaco magnetic torque rod
Solar arrays	Body-mounted dual-junction gallium indium phosphide/gallium-arsenide/germanium solar cell arrays
Battery	21 Ah super NiCd battery; operating range: 22-34 VDC

Table 446: Overview of S/C design features

Communication: three antennas for S-band communication with the ground. A medium-gain helix antenna and two low-gain omni-directional antennas. One of the omni antennas is mounted on the aft end panel of the spacecraft; the other is mounted together with the helix antenna on the forward panel. The helix antenna is used to transmit data from the spacecraft to the ground; the co-mounted omni antenna is used to receive uplinked commands and data. Uplink data rate = 2 kbit/s. Downlink of stored science, engineering, and housekeeping data at a rate of 2.28 Mbit/s. In addition to the playback of stored data, the S/C also continuously transmits real-time data at a nominal rate of 38 kbit/s. The real-time data is mainly for CRL of Tokyo, Japan and for NOAA (space environment weather forecasts).

A launch on a Delta II 7623-9.5 ELV vehicle took place from VAFB on March 25, 2000.

Orbit: HEO (Highly-elliptical Earth Orbit), a polar orbit, perigee = 1000 km, apogee = $7.2 R_E$ (45,922 km). The location of the apogee changes during the course of the two-year mission, both in latitude and, because of the Earth’s revolution about the sun, in local time. At the beginning of the mission, apogee is at approximately 40° north geographic latitude and

¹⁴⁹⁴⁾ <http://image.gsfc.nasa.gov/>

¹⁴⁹⁵⁾ <http://pluto.space.swri.edu/IMAGE/>

at dusk local time. As the Earth moves around the sun, the plane of the orbit shifts relative to the Earth-sun line (by 30° of longitude each month). During IMAGE's two-year nominal mission, the line of apsides will precess over the pole and return to 40° north geographic latitude. This type of orbit permits the IMAGE instruments to image the inner magnetosphere on nearly a continuous basis. ¹⁴⁹⁶⁾

Figure 267: The IMAGE S/C model

Sensor complement:

The IMAGE S/C carries three ENA (Energetic Neutral Atom) imagers whose combined energy coverage permits the detection of ENAs with energies ranging from 1 eV to 500 keV per atomic mass unit (amu). Each neutral atom instrument generates images showing the intensity and spatial distribution of ENA emissions produced in the inner magnetosphere through charge-exchange reactions between geocoronal neutral hydrogen and various magnetospheric ion populations. Neutral atom imaging of the ionosphere and magnetosphere is possible because the Earth's geocorona acts like an imaging screen for magnetospheric and ionospheric ions. The interpretation and quantification of observed ENA signals depend upon the knowledge of the energy dependence and magnitude of the appropriate charge-exchange cross sections.

LENA (Low-Energy Neutral-Atom Imager), PI: T. E. Moore of GSFC (collaboration of GSFC, University of Maryland, University of New Hampshire, University of Denver, University of Bern, Lockheed Martin Co.). The objective is to detect ENAs in the energy range from 10-500 eV. LENA's primary role is to image the outflow of low-energy ions from the polar ionosphere. The specific objectives are to: ¹⁴⁹⁷⁾

- Measure neutrals without interference from electrons, ions, or UV
- Distinguish neutral protons from oxygen
- Determine ion outflow on five minute time scales over broad range of local times
- Measure energies as low as 10 eV with high counting statistics

¹⁴⁹⁶⁾J. L. Burch, J. L. Green, S. A. Fuselier, "Mission Allows Magnetospheric Physicists to "See" the Invisible," EOS Transactions of AGU, Vol. 82, No 22, May 29, 2001, pp. 241 and 245

¹⁴⁹⁷⁾T. E. Moore, et al., "The Low Energy Neutral Atom Imager for IMAGE," Kluwer Academic Publishers, 1999

The LENA instrument consists of a collimator, a conversion unit, an extraction lens, a dispersive energy analyzer, and time-of-flight mass analyzer with position-sensitive particle detection. LENA is specifically designed of looking at and in the direction of the sun. Principle of operation: Neutral particles enter the instrument through a collimator which filters charged particles. LENA converts neutrals to negative ions through a near specular glancing reflection from a tungsten surface. Negative ions from the surface are then collected by the extraction lens which focuses all negative ions with the same energy to a fixed location. In the extraction lens, the ions are accelerated by 20 kV prior to entering the electrostatic analyzer (they are detected as they pass through a thin foil and strike an image plane detector). Finally, the ions pass into a time-of-flight/position sensing section where ion mass, energy, and angle are determined.

LENA uses electrostatic optics techniques for energy (per charge) discrimination and carbon foil time-of-flight techniques for mass discrimination. The instrument has a $90^\circ \times 8^\circ$ FOV in 12 pixels, each nominally $8^\circ \times 8^\circ$. The S/C spin provides a TFOV of $90^\circ \times 360^\circ$, comprised of 12 x 45 pixels.

Energy range (incident neutral atom)	15-1250 eV
Energy resolution	$E/\Delta E = 1$ at FWHM
Mass range	1-20 amu (H^+ and O^+)
Mass resolution	$M/\Delta M = 4$ at FWHM
Angular coverage	Sampling: $8^\circ \times 8^\circ \times 12$ sectors per spin: $360^\circ \times 90^\circ$ in 45 x 12 samples
Angular resolution/response	$8^\circ \times 8^\circ = 12$ steradians (sr)
TFOV (Total Field of View)	2.8π sr
Pixels per image	$3.2 k = 3$ energy x 45 Az x 12 polar x 2 mass
Pixel physical aperture	1.0 cm^2 ($A_{\text{eff}} < 1 \times 10^{-3} \text{ cm}^2$)
Pixel solid angle	0.02 sr per pixel x 12 pixels
Time resolution 1D polar x energy	2.7 s
Time resolution 2D (Az x polar) x energy	120 s
Time resolution 3D (Az x polar x energy)	1 spin period (120 s)
Dynamic range	10^4
Instrument mass, power, data rate	20.75 kg, 13.1 W (orbit averaged), 0.5 kbit/s

Table 447: Overview of LENA instrument parameters

MENA (Medium-Energy Neutral-Atom Imager), PI: C. J. Pollock of Southwest Research Institute (collaboration of SwRI, LANL, RAL, USC, UCB, University of West Virginia). Objective: Detection of ENAs in the energy range 1-30 keV. Provision of images of the ring current, near-Earth plasma sheet, and the nightside injection boundary. In addition, MENA images the ion populations of the cusp. The instrument determines the time of flight and incidence angle of the incoming ENAs; from these raw data it calculates their trajectory and velocity and generates images of the magnetospheric regions from which they are emitted. The MENA instrument (a slit-type imager) is composed of three identical sensors, mounted to a common DPU (Data Processing Unit) assembly. Each sensor is supported by two dedicated FFE (Front End Electronics) cards, time of flight (FEETO), a pulse height analyzer (FEPPHA), and a triple-function (+10 kV, +4 kV, -1kV) high-voltage power supply. Each of the three sensors provides 1-D imaging of incident ENAs in the polar angle direction based on a spherical coordinate system. The second imaging dimension (azimuth) is obtained using collimation and S/C spin. The sensors are mounted to provide look directions that view a common azimuth (spin) angle, but are offset from one another in their polar angle field of view. The center of the sensor 2 look direction is perpendicular to the spin axis, at a polar angle of 90° . - ENAs, charged particles and photons incident from within the sensor's FOV enter through the collimator, where charged particles with energies up to 13 times the adjustable applied voltage are removed by electrostatic deflection. The remaining particles and photons must pass through a free-standing UV blocking grating, where the UV photons are removed around a very wide stop band by the optical proper-

ties of the grating. The grating structure eliminates the solar hydrogen Lyman- α (121.6 nm) light reflected from the geocorona. The detector system uses MCP detector arrays (The detector assembly consists of a Hamamatsu MCP and an anode that employs a novel "capacitive charge division" technique to determine the position of the ENA impacts on the MCP).¹⁴⁹⁸⁾

The TOF for each ENA detected is determined by the FEE from the start and stop pulses triggered in the MCP. This value, together with the positions of the start and stop pulses on the MCP, is processed by the look-up tables to compute the incidence angle of an incoming ENA, the length of its path through the detector, and its velocity. The amplitude of the start and stop pulses i.e. their "pulse height," is also measured. Knowledge of both the spin phase and the incidence angle is needed to determine the position in the sky from which the detected ENAs are emitted and to produce the image of the ENA emission region.

HENA (High-Energy Neutral-Atom Imager), PI: D. G. Mitchell of JHU/APL [collaboration of APL, University of Maryland, University of Arizona, MPAe (Katlenburg-Lindau, Germany)]. Detection of ENAs in the 10-500 keV energy range. HENA imaging is focused principally on the ring current, inner plasma sheet, and substorm injection boundary. HENA is a modified version of the Cassini INCA instrument, it provides global images of ENA emissions from Saturn's magnetospheric ion populations. The two main HENA components are the sensor and the main electronics unit (MEU) The HENA sensor consists of alternately charged deflection plates mounted in a fan configuration in front of the entrance slit; three microchannel plate (MCP) detectors; a solid-state detector (SSD); two carbon-silicon-polyimide foils, one at the entrance slit, the other placed just in front of the back MCP; and a series of wires and electrodes to steer secondary electrons ejected from the foils (or the SSD) to the MCPs.¹⁴⁹⁹⁾

HENA determines the velocity of the ENAs that it detects by measuring their time of flight (TOF) and trajectory through the sensor, i.e., from the entrance slit either to the back foil and 2-D imaging MCP detector or to the SSD.

Wavelength, bandpass	30.4 nm, 5 nm
Sensitivity	0.2 counts/s per Rayleigh per pixel
Field of View (FOV)	30° by 84° (instantaneous), 84° by 360° (total)
Spatial resolution	640 km x 640 km at apogee (8 Earth radii)
Imaging frequency	1 image accumulated every 10 min (= 5 S/C rolls)
Instrument mass, power	15.6 kg, 15.5 W
Thermal range	-25 to +40° C (operating), -50° to +60° C (non-operating)

Table 448: EUV instrument parameters

EUV (Extreme Ultraviolet Imager), PI: B. R. Sandel, University of Arizona. The objective is to detect solar EUV photons with a wavelength of 30.4 nm that are resonantly scattered by singly ionized helium in the plasmasphere, the torus of cold dense plasma surrounding the Earth in the inner magnetosphere. A sophisticated computer deconvolution technique is used to translate the EUV photon counts registered by the instrument into images of the plasmasphere. detect solar photons. The imager consists of three identical sensor heads mounted one above the other in a common bracket; a common electronics module. Each sensor head has a FOV of 30°, the three sensors are tilted so that their FOVs overlap, giving the imager a fan-shaped IFOV of 30° by 84°. With each rotation of the S/C, the imager completes a 360° sweep of the sky, resulting in a TFOV of 84° by 360°. Spatial resolution is about 0.6° at apogee (EUV can distinguish plasma-spheric features with scale sizes down to about 640 km). This resolving power enables the study of fine-scale density structures.

¹⁴⁹⁹⁾http://pluto.space.swri.edu/IMAGE/HENA_description.html

FUV (Far Ultraviolet Imager), designed and built by UCB. The FUV instrument employs three detectors: ¹⁵⁰⁰⁾

- The Wideband Imaging Camera (WIC) to image the aurora in broad band for maximum spatial resolution day and night
- The Spectrographic Imager (SI) to measure different types of aurora and separating them by wavelength and to measure proton induced aurora by removing the bright geocorona emissions
- Geocorona photometers (GEO) to observe the distribution of the geocorona emissions to derive the magnetospheric hydrogen content responsible for neutral atom generation in the magnetosphere.

The **WIC** instrument is designed to image the whole Earth and the auroral oval from satellite distances greater than 4 Earth radii to the center of the Earth. A curved image intensifier is optically coupled to a CCD and the optics provides a FOV of $17^\circ \times 17^\circ$. Spectral range: 140-160 nm; resolution elements of $< 0.1^\circ$; temporal resolution of 120 s; the size of the final images is 256 x 256 pixel elements, corresponding to spatial resolutions of < 100 km at apogee distances.

SI is designed to image the whole Earth proton aurora from satellite distances greater than 4 Earth radii to the center of the Earth. It uses a reverse Wadsworth design to select the Doppler shifted Lyman H-alpha line at 121.82 nm in the ultraviolet part of the optical spectrum and to reject the non-Doppler shifted Lyman H-alpha from the geocorona at 121.567 nm. The FOV is $15^\circ \times 15^\circ$. The temporal resolution between two images is 120 s and the size of the final images is 128 x 128 pixel elements, corresponding to spatial resolutions of < 100 km at apogee distances.

GEO is designed to measure the Hydrogen Lyman-alpha emission of the neutral atmosphere. The three photometers have a field of view of $1^\circ \times 1^\circ$ and look into three different directions perpendicular to the spin axis of the satellite and tilted by $\pm 28^\circ$. They are ultraviolet photon counters with filters giving the desired bandpass. An additional O₂ gas cell provides an excellent throughput of the Hydrogen radiation and simultaneously rejects the photons at 130.4 nm from excited neutral Oxygen. The temporal resolution between two complete measurements around 360° is 120 s.

RPI (Radio Plasma Imaging, PI: B. W. Reinisch, University of Massachusetts at Lowell). The objective is to characterize plasma in the Earth's magnetosphere utilizing imaging in the radio frequency range. The RPI instrument is a low-power radar which operates in the radio frequency bands which contain the plasma resonance frequencies characteristic of the Earth's magnetosphere (3 kHz to 3 MHz). RPI can locate regions of various plasma densities by observing radar echoes from the plasma that are reflected where the radio frequency is equal to the plasma frequency. By stepping through various frequencies for the transmitted signal, features of various plasma densities can be observed and, by fitting contours and/or magnetospheric models to the features, a 3-D specification of the shape of the magnetosphere can be created.

The RPI instrument consists of an electronics enclosure, four 250 m wire antennae with deployers (including switches and couplers), and a z-axis boom canister containing two 10 m lattice boom antennae and two preamplifiers. Instrument mass = 49.8 kg, power = 133.98 W (peak) and 30.8 W (average). ¹⁵⁰¹⁾

K.16 IMP-8 (International Monitoring Platform)

This NASA/GSFC S/C is also known by the names of Explorer 50 and IMP-J. IMP-8 is the last in a series of ten IMP missions with the primary objective to perform detailed and near-

¹⁵⁰⁰⁾ <http://sprg.ssl.berkeley.edu/image/sidescript.html>

¹⁵⁰¹⁾ <http://image.gsfc.nasa.gov/rpi/>

continuous observations of the sun/Earth environment (solar wind monitoring, measuring the plasma/field environment of the magnetosheath and the magnetotail). Launch on Oct. 26, 1973 from the Eastern Test Range by a Delta vehicle. - The objectives of the extended mission are similar to the original goals with emphasis on providing solar wind parameters as input for magnetospheric studies, as 1-AU baseline for deep-space studies, and to continue solar cycle variations studies with a single set of well-calibrated and understood instruments.

IMP-8 is a drum-shaped spacecraft of 135.6 cm diameter and 157.4 cm length. It is spin-stabilized (23 rpm). The telemetry data rate is 1.6 kbit/s (VHF-band). The S/C is being tracked by the following ground stations: Wallops Island, VA; Redu, Belgium; Tasmania, Australia, Santiago de Chile; and Hawaii.

Orbit: Geocentric elliptical, apogee = 247,267 km, perigee = 189,024 km, inclination varies between 0-55° with a periodicity of several years, period = 12.6 days, spin vector direction = normal to ecliptic. IMP-8 spends 60% or more of each 12-day orbit in the solar wind, and the rest of its time in the magnetosheath and magnetosphere.

The IMP-8 satellite is operational as of the end of 2000 (the longest NASA mission so far). The CPME and EPE instruments have been operating for 27 years. They generated a wealth of high-quality data that have led to new discoveries and have resulted in hundreds of publications. Both the CPME and EPE instruments continue to perform without problems.

Sensors:¹⁵⁰²⁾

1) Field Investigations

- **GNF** = Magnetic Fields Experiment (PI: N. F. Ness, GSFC). Boom-mounted triaxial fluxgate magnetometer (mass=3.2 kg) in the range of ± 36 nT per sensor. The resolution per sensor is ± 0.3 nT. Vector measurements are performed every 40 ms.
- **GAF** = DC Electric Fields Investigation (PI: T. L. Aggson, GSFC). Instrument (mass=11.5 kg) utilizes two 60 m wire antennas to measure DC electric fields in the solar wind and magnetosheath.
- **IOF** = AC Electric and Magnetic Fields Experiment (PI: D. A. Gurnett, University of Iowa). The plasma wave instrumentation (mass=12 kg) consists of a 121.8 m tip-to-tip dipole antenna for electric field measurements (in the S/C spin plane) and a triaxial search coil for magnetic field measurements. Magnetic measurements are made in seven channels in the frequency range 40 Hz to 1.78 kHz (cycle time of 10.24 s for one set of measurements). The electric field is measured by a 15 channel spectrum analyzer operating between 40 Hz and 178 kHz, and a wide band receiver tunable to 2000, 500, 125, and 31.1 kHz.

2) Plasma Investigations

- **LAP** = Los Alamos Plasma Experiment (PI: S. J. Bane, Los Alamos National Laboratory). Solar Plasma Electrostatic Analyzer Experiment. The instrument (mass=6.3 kg) consists of a hemispherical plate electrostatic analyzer for the measurement of ion and electron distributions. Resolution time < 2 minutes.
- **IOE** = Low Energy Particles Investigation (PI: L. A. Frank, University of Iowa). The instrument (mass=2.6 kg) consists of a Low-Energy Proton and Electron Differential Energy Analyzer (LEPEDA) and a Geiger tube. LEPEDA measures fluxes of ions and electrons, separately and simultaneously, in each of 16 energy per charge channels (between 50 eV and 45 keV) in each of 16 azimuthal directions around the S/C spin vector. The Geiger tube measures electrons in the range > 45 keV. A full measurement cycle = 82 seconds.

¹⁵⁰²⁾J. H. King, "Availability of IMP-7 and IMP-8 Data for the IMS Period," The IMS Source Book, GSFC, pp. 10-20,

- **MAP** = Solar Plasma Faraday Cup Experiment (PI: H. S. Bridge, MIT). The instrument (mass=6.5 kg) consists of a split collector Faraday cup measuring ions in the energy range of 50 eV/q to 7 keV/q in 24 steps, and electrons in the range from 22 eV/q to 2 keV/q in 21 steps. An angular distribution is taken at each energy step. The measurement sequence is controlled by the measured flux. Typical measurements are 30 seconds in the solar wind and magnetosheath.

3) Energetic Particles Investigations

- **EPE** = Energetic Particle Experiment (PI: D. J. Williams, NOAA). The instrument (mass=3.3 kg) is a solid-state telescope which measures fluxes of ions in four energy channels ranging from 0.05 - 0.20 MeV to 2.1 - 4.5 MeV, and electrons in the ranges 30-90 and 100-200 keV.

The EPE particle detector assembly consists of a main magnet-detector assembly and two auxiliary detector heads. All detectors are fully depleted, surface barrier, solid state detectors, and are operated with bias voltages 1.25-1.5 times the values required for full depletion. To minimize radiation damage effects, all detectors directly exposed to ion fluxes are mounted with the aluminum contact exposed to the incoming beam.¹⁵⁰³⁾

The main detector assembly consists of (i) a three-element telescope (detectors A, B, and C), (ii) a sweeping magnet that keeps low energy electrons ($E_e \leq 200$ -300 keV) away from the telescope, and (iii) two detectors (D and E) to detect the swept electrons. The telescope covers the proton energy range $50 \text{ keV} \leq E_p \leq 25 \text{ MeV}$ and the alpha particle range $2.2 \text{ MeV} \leq E_\alpha \leq 35 \text{ MeV}$. Detectors D and E cover the electron energy range $30 \text{ keV} \leq E_e \leq 200 \text{ keV}$.

- **MAE** = Ion and Electron Investigation (PI: G. Gloeckler, University of Maryland). The experiment consists of two detector systems (mass=7 kg). An electrostatic deflection spectrometer (EDS) measures the energy per charge of incident ions in several ranges between 37 and 1200 keV/q.
- **CPME** = Charged Particle Measurement Experiment (PI: S. M. Krimigis and R. B. Decker, JHU/APL). The instrument is a solid-state telescope (mass=3.9 kg) measuring fluxes of protons in 11 energy channels between 0.29 and 140 MeV, and alpha particles in 6 channels between 0.64 and 52 MeV/n. Time resolution for the measurement cycle is 10.24 s.
- **GME** = Solar and Cosmic Ray Particles Investigation (PI: F. B. McDonald, GSFC). The experiment (mass=11 kg) consists of three telescopes intended to measure the energy spectra and composition of solar and galactic electrons, protons, and heavier nuclei. The lowest energy, solid-state telescope measures electrons ($>0.15, 0.35, 0.75 \text{ MeV}$), protons (between 0.05 and 25 MeV) and particles $2 \leq Z \leq 28$ (1.6 -12 MeV/n). The second telescope measures protons (0.8-4 MeV) and 4-20 MeV/n nuclei with $1 \leq Z \leq 26$. The third telescope uses CsI scintillator elements to measure electrons (2-12 MeV) and $Z=1$ to 30 nuclei (20-500 MeV/n).
- **CAI** = Electron Isotopes Investigation (PI: E. C. Stone, JPL). The instrument (mass=8 kg) consists of an 11 element solid-state telescope for composition and spectra measurements of galactic and solar cosmic rays in the energy range of 1-40 MeV/n.
- **CHE** = Cosmic Ray & Solar flare Isotopes Investigation (PI: J. A. Simpson, U. of Chicago). The instrument (mass=7.4 kg) consists of a pair of solid-state telescopes. The main telescope measures nuclei in the energy range of 10 to 100's of MeV/n, and electrons in the range of about 2 to about 25 MeV. The second telescope measures protons and alpha particles in the 0.5-1.8 MeV/n range.

Data: Telemetry primary transmitter (PCM) at frequency of 137.980 MHz, secondary transmitter at frequency 136.800 MHz. Science Data is archived at World Data Center A at GSFC.

The combined CPME-EPE data sets have been used to address a wide variety of scientific problems. These include studies of energetic particle activity in and around Earth's magnetosphere, solar energetic particle events, solar X-rays, shock accelerated ions and electrons in the interplanetary medium and near Earth's bow shock, iron group ions in high speed solar wind streams, the intensity gradients of galactic cosmic rays, and dynamical chaos in the magnetosphere. - The CPME measurements have been used to generate hourly averages of particle intensities published for over more than a decade in Solar Geophysical Data. These data have been used by the at-large science community for many correlative studies in a variety of scientific problems.

K.17 INTERBALL

Russian multi-spacecraft mission (IKI-RAN, Project Scientist: L. Zelenyi) with international cooperation (Austria, Bulgaria, Canada, Czech Republic, ESA, Finland, France, Germany, Hungary, Italy, Kirgizia, Poland, Romania, Slovakia, Sweden, UK, and Ukraine) on payload instruments within ISTP. Objectives: Study of solar-terrestrial transport phenomena (solar wind energy and interaction with the Earth's magnetosphere, its storage there and subsequent dissipation into the tail and auroral regions of the magnetosphere, ionosphere, and atmosphere during magnetospheric substorms). INTERBALL is coordinated with the following projects: GEOTAIL, WIND, POLAR, SOHO, FAST, and RELICT-2. 1504) 1505) 1506) 1507)

The program consists of four satellites (Prognoz series), in either a "Tail Probe" or an "Auroral Probe" configuration, each configuration is provided with a subsatellite; namely: "Tail C2-X" and "Auroral C2-A" (provided by Czech Republic). Nominal mission duration: 1 year. "Tail Probe" was launched August 3, 1995 with a Molniya-M vehicle from Plesetsk; the "Auroral Probe" launch occurred on August 29, 1996.

INTERBALL S/C data: Spin stabilized spacecraft with nominal spin rate of 0.5 rpm. Mass of Auroral Probe payload = 212 kg; mass of Tail Probe payload = 150 kg. Each satellite has three telemetry systems ; RTK (16 kbit/s max.), SSNI (32 kbit/s max.), and STO (60 kbit/s max.).

RTK = Radio Telemetrii Komplex

SSNI = System Sborna Natschnoi Informasii

STO = System Telemetrii

Earth Orbits:

- Auroral Probe (coplanar with subsatellite C2-A, also referred to as Magion-5): Apogee = 19,196 km; perigee = 791 km; inclination = 62.8° ; distance between Auroral Probe and C2-A = 10 - 1000 km.
Status: The Auroral Probe operations stopped in Feb. 1999. The Magion-5 spacecraft is operational as of June 2001.
- Tail Probe (coplanar with subsatellite C2-X, also referred to as Magion-4): Apogee = 191,907 km; perigee = 793 km; inclination = 62.8° ; distance between Tail Probe and C2-X = 10 - 10000 km.

1507) "Interball - Mission and Payload," document of 410 pages, by RKA, IKI, and CNES, May 1995

Status: The Tail Probe reentered the atmosphere on Oct. 16, 2000 in an operational state. The Magion-4 operations lasted until Oct. 1997.

The study objective of the subsatellites is aimed to distinguish the space and time dependence of the measured plasma parameters for moving satellite systems in moving plasmas (transport phenomena). Measurement of the correlation vector of the magnetic field, plasma 3-D flux and ion 3-D flux is from two points separated between 1 and 1000 km.

The simultaneous measurements of the same plasma parameters on the mother satellite and the subsatellites permits the determination of the space and time variations. The plasma measurements are done at very high time resolution (0.2-1 s), providing study of the fine structure of the magnetospheric boundaries. The overlapping plasma sensors further allow a study of 3-D distribution functions of ions (separately for several species) and electrons in a wide range of energy with good resolution and experiment reliability.

K.17.1 “Auroral Probe” Sensors

Project manager: R. A. Kovrazhkin, IKI, Moscow

1) Auroral Plasma Experiments:

- **SKA-3** = Electron/Proton Distribution Experiment (PIs: A. K. Kuzmin, F. K. Shuiskaya, IKI); objective: measurement of electron and proton distribution. Energy range = 0.03 - 15 keV; electron and ion anisotropy ($M=1, 4, 16$), $E=30-500$ keV/Q; time resolution = 1.5 and 0.2 s/sample; data rate = 3 kbit/s; mass = 32 kg
- **ION** = Ion Spectra Experiment (PIs: J. A. Sauvaud, CESR, France, R. A. Kovrazhkin, IKI, Moscow); objective: measurement of ion spectra and anisotropy ($M=1, 4, 16$), $E=0.005-20$ keV/Q; time resolution = 3.2 s/sample; data rate = 3 kbit/s; mass = 17 kg
- **PROMICS-3** = 3-D Spectrometer - Ion Composition Experiment (I. Sandahl, IRF, Kiruna, Sweden; N. Pissarenko, IKI, Moscow); ion energy range: 4 eV to 70 keV with mass separation; electron energy range: 12 eV to 35 keV; time resolution = 1.2 and 2.6 s/sample; data rate = 2 kbit/s; mass = 12.9 kg

2) Magnetic, Electric Fields and Wave Experiments

- **FM-3I** = Investigation of Magnetic Fields (PIs: A. Bochev, Bulgaria, V. Stiazhkin, Russia); Objective: measurements of three components in frequency range from DC to 10 Hz with two dynamic ranges: 200 nT with 0.1 nT resolution, and 1000 nT with 1 nT resolution; time resolution = 0.12 s/sample; data rate = 0.5 kbit/s; mass = 4.9 kg
- **IESP-2** = Electric Field and Intensity Experiment (PIs: M. Mogilevsky, Russia; G. Stanev, CLKI Bulgaria; S. Pezzant, France); measurement range = 0 - 50 Hz; time resolution = 0.03 s/sample; data rate = 7.2 kbit/s; mass = 6.7 kg
- **NVK-ONCH** = VLF Electromagnetic Waves Experiment (PIs: M. Mogilevsky (Russia); A. Goljavin, IZMIRAN); measurement range = 20 Hz - 20 kHz; data rate = 2×12 kHz; mass = 17 kg
- **MEMO** = Analyzer of Magnetic Waves (PIs: F. Lefeuvre, LPCE, France; M. Mogilevsky, IKI); measurement range < 2 MHz; time resolution = 0.25 and 120 s/sample; data rate = 20 kbit/s; mass = 14.5 kg
- **POLRAD** = Polish Radiometer - Auroral Kilometric Radio-radiation Experiment (PIs: I. Hanasz, Poland, M. Mogilevsky, IKI, Moscow); measurement range = 20 kHz - 2 MHz; data rate = 2.3 kbit/s; mass = 22.5 kg

3) Thermal Plasma Experiments

- **HYPERBOLOID** = Ion Mass-Analyzer (PIs: J. J. Berthelier, CRPE, France; T. Muliazhik, IKI); $E = 0.0 - 100 \text{ eV}$; $v = 0.1 - 20 \text{ km/s}$; species: H^+ , He^+ , O^+ , O^{++} , N^+ , N_2^+ , NO^+ , O_2^+ ; time resolution = 1 s/sample; data rate = 8 kbit/s; mass = 15 kg
- **KM-7** = Cold Plasma Experiment (PIs: J. Smilauer, Prague, Czech Republic; V. V. Afonin, IKI); measurement of plasma electrons; temperature range $< 10 \text{ eV}$; time resolution = 0.1 s/sample; data rate = 0.3 kbit/s; mass = 2.7 kg
- **ALPHA-3** = Trapped Ion Experiment (PI: V. Bezrukikh, IKI); $N > 1 \text{ cm}^{-3}$; energy $< 25 \text{ eV}$; time resolution = 1 s/sample; data rate = 0.16 kbit/s; mass = 3.5 kg
- **RON** = Ion Emitter Experiment (PIs: W. Riedler, Space Research Institute, Graz, Austria; R. Schmidt, ESA/ESTEC; Yu. Galperin, IKI); N_2^+ , In^+ ; current = $1 - 10 \mu\text{A}$; data rate = 0.2 kbit/s; mass = 7.5 kg

4) Energetic Particles Experiment

- **DOK-2A** = Electron and Proton Experiment (PIs: K. Kudela, Institute of Experimental Physics, Kosice, Czech Republic; V. M. Lutsenko, IKI); $E_e = 10\text{-}400 \text{ keV}$; $E_p = 15\text{-}1000 \text{ keV}$; time resolution = 1 s/sample; data rate = 0.8 kbit/s; mass = 5.5 kg

5) Auroral Oval Image Experiments

- **UFSIPS** = Radiation Emission Experiment (PIs: A. K. Kuzmin, IKI; K. Palazov, IKI-BAN Bulgaria;); measurement in the lines: 1304\AA , 1356\AA , and 1493\AA ; time resolution = 1 line per rotation; data rate = 0.2 kbit/s; mass = 25 kg;
- **UVAI** = UV Auroral Imager (PIs: L. L. Cogger, U. of Calgary, Canada; Yu. I. Galperin, IKI); range = $1400 - 1600\text{\AA}$; time resolution = 1 picture per rotation; data rate = 3 kbit/s; mass = 20 kg

6) Subsatellite C2-A

- **C2-A (Magion-5)** = Measurement of electric and magnetic fields, VLF waves, plasma and energetic particles (PIs: P. Triska, Ya. Voita, Geophysics Institute, Prague); data rate = 40 kbit/s; mass = 68.5 kg.

K.17.2 “Tail Probe” Sensors

Project manager: M. Nozdrachev, IKI, Moscow

1) Plasma Experiments

- **SKA-1** = 3-D Ion Distribution Measurement (O. Vaisberg, L. Avanov, IKI); energy range = $0.05 - 5 \text{ keV/Q}$; time resolution = 3.7 s/sample; data rate = 2 kbit/s; mass = 26.1 kg
- **ELECTRON** = 3-D Electron Distribution Function (PIs: J. A. Sauvaud, CESR, France; O. Vaisberg, N. Borodkova, IKI); range = $0.01 - 30 \text{ keV}$; time resolution = 120 or 3.7 s/sample; data rate = 1 kbit/s; mass = 6.5 kg
- **PROMICS-3** = 3-D Ion Composition Spectrometer (PIs: I. Sandahl, IRF, Sweden; N. Pissarenko, IKI; H. Koskinen, FMI, Finland); $M = 1, 32$; $E = < 100 \text{ keV/Q}$; time resolution = 1.2 or 2.6 s/sample; data rate = 2 kbit/s; mass = 12.9 kg
- **VDP** = 3-D Ion Faraday Cups (PIs: G. Zastenker (IKI); Z. Nemecek, Charles University Prague, Czech Republic); $E_i > 0 \text{ eV}$; time resolution = 0.1 s/sample; data rate = 1 kbit/s; mass = 4.9 kg. Omnidirectional fast measurements of the integral ion or electron flux and its direction.

- **AMEI-2** = Energy-Mass Analyzer (PIs: R. Koleva, STIL, Bulgaria; V. Smirnov, IKI); (M = 1-16); E = 0.1 - 10 keV/Q; time resolution = 120 s/sample; data rate = 0.2 kbit/s; mass = 9 kg. Measurement of energy spectra of H⁺, He⁺, He⁺⁺, O⁺ and heavier ions in all directions.
- **MONITOR-3** = Solar Wind Analyzer (PIs: A. Feodrov, IKI; Ya. Shafrankoya, Charles University, Prague, CR); E = 0.4 - 15 keV/Q; time resolution = 1 s/sample; data rate = 8 kbit/s; mass = 7.8 kg. High-resolution measurements of the solar wind ion fluxes and energy-angular directions of H⁺ and He⁺⁺ in sun direction.
- **CORALL** = Wide-Range 3-D Ion Spectrometer (PIs: R. Himenez, Cuba; Yu. Yermolaev, IKI); range = 0.1 - 30 keV/Q; time resolution = 120 s/sample; data rate = 1 kbit/s; mass = 5 kg. Angular-energy ion distribution in all directions.

2) Thermal Plasma Experiment

- **ALPHA-3** = Ion Trap Experiment (PI: V. Bezrukikh, IKI); N > 1 cm⁻³; E < 25 eV/Q; time resolution = 16 s/sample; data rate = 1 kbit/s; mass = 3.5 kg

3) Energetic Particles and X-Ray Experiments

- **SKA-2** = Spectrometric Device Complex (PIs: E. Morozova, IKI, S. Fisher, CR); low and energetic charged particle composition and anisotropy; E_e = 40 - 200 keV; E_i = 50 keV - 150 MeV; time resolution = 120 s/sample; data rate = 0.25 kbit/s; mass = 22.4 kg
- **DOK-2X** = Electron and Proton Experiment (PIs: K. Kudela, Institute of Experimental Physics, Kosice, Slovakia; V. Lutsenko, IKI); measurement of fluxes and anisotropy; E_e = 10 - 400 keV; E_i = 15 - 1000 keV; time resolution = 120 or 1 s/sample; data rate = 2 kbit/s; mass = 5.5 kg
- **RF-15** = Solar X-Ray Experiment (PIs: O. Likin, IKI; F. Farnik, Astr. Institute, CR; J. Silvester, Poland); range = 2 - 200 keV; time resolution = 0.1 s/sample; data rate = 0.01 kbit/s; mass = 10 kg
- **SOSNA-2** = Dosimeter (PIs: V. Bengin, V. Petrov, IMBP, Moscow; S. Kuznetsov, Moscow University).

4) Fields and Wave Experiments

Complex ASPI = Analysis of Plasma Spectra Instabilities (Project manager: S. Romanov, Science manager: S. Klimov, IKI). ASPI consists of the following instruments: OPERA, MIF-M, IFPE, ADS, PRAM; the subsatellite C2-X wave experiment is also included.

- **OPERA** = Onde di Plasma Et Radiazioni Aurorali (PIs: E. Amata, CNR/IFSI, Italy; S. Savin, IKI); measurement in frequency range of 0 - 150 kHz; time resolution = 2 or 64 sample/s; data rate = 3 kbit/s; mass = 3.7 kg. FGM-1 magnetic field data acquisition and processing.
- **MIF-M** = Multicomponent Investigations of Fluctuations of the Magnetic Field DC/AC (PIs: S. Romanov, M. Nozdrachev, IKI); frequency range = 0 - 40 kHz; time resolution = 1 or 64 samples/s; data rate = 2.5 kbit/s; mass = 8.5 kg
- **IFPE** = Investigations of Fluctuations of Protons and Electrons (PIs: J. Büchner, MPE, Berlin; H. Lehmann, DLR Berlin; S. Romanov, IKI); frequency range = 0.1 - 1000 Hz; time resolution = 1 or 64 sample/s; data rate = 2.5 kbit/s; mass = 4.9 kg.
- **ADS** = Analyzer of Dynamic Spectra (PIs: J. Juchnievicz, Space Research Institute, Poland; S. Klimov, IKI); frequency range = 0.1 Hz - 40 kHz; time resolution = 8 or 1 s; data rate = 1 kbit/s; mass = 5 kg. Nine-channel spectra-analyzer and cross-correlator, two-component measurements of current fluctuations.

- **FGM-1** = 3-D Magnetic Field (J. Rustenbach, MPE Berlin; S. Savin, IKI). Measurement range 0-25 Hz in the range of 0.25-256 nT.
- **PRAM** = Adaptive Processing of Wave Information (PIs: S. Romanov IKI); data rate = 4 kbit/s; mass = 2.4 kg, digital processing of MIF-M, IFPE and RF-15 information.
- **FM-3I** = 3-D Magnetometer (PIs: M. Nozdrachev, IKI; V. Styazhkin, IZMIRAN); measurement range = 0.2-200 nT; resolution = ± 0.05 nT; time resolution = 0.12 s/sample; data rate = 0.5 kbit/s; mass = 4.9 kg.
- **AKR-2** = Analyzer of Kilometric Radiation (PIs: L. Fisher, Komensky, University of Bratislava, Slovakia; V. Grigorjeva, Astronomical Institute of Moscow University); frequency range = 100 kHz - 1.5 MHz; time resolution = 0.06 s/sample; data rate = 1.8 kbit/s; mass = 2.1 kg

Figure 268: The INTERBALL S/C models and trajectories

5) Subsatellite C2-X

The subsatellite is referred to as Magion-4 (PI: P. Triska, see K.5.1). Its objective is to monitor the propagation of electron beams and plasma injected by the parent spacecraft as well as to monitor plasma of natural origin. Measurement of electric and magnetic fields, waves, plasma and energetic particles (PIs: P. Triska, Ya. Voita, Geophysics Institute Prague, Czech Republic); data rate = 20 kbit/s; mass = 58.7 kg; wave experiment (magnetic field: 0.1 Hz - 20 kHz; electric field: 0.1 Hz-250 kHz; plasma current: 0.1 Hz - 256 kHz). Note, C2-X is incorporated in the ASPI Complex.

K.18 ISEE (International Sun-Earth Explorer)

A NASA/ESA cooperative program involving three satellites. The ISEE-1 and ISEE-3 S/C were the principal contributions of NASA, while ISEE-2 was built and managed by ESA.

K.18.1 ISEE-1 and -2 Mission

Objectives: Observation of the near-Earth magnetosphere and its boundaries, better understanding of many phenomena, such as the Earth's bow shock, the magnetosheath and magnetopause, interactions between the tail and aurorae, and particle populations and flows in the tail.

Joint launch of ISEE-1 and -2 S/C on Oct. 22, 1977 (by NASA). Highly eccentric orbit around the Earth with an apogee of 23 R_E . Both S/C in the same orbit plane with a controllable separation distance, inclination = 28.9°. Both S/C reentered during Sept. 1987.

Sensors:¹⁵⁰⁹⁾ Only a very brief overview is given; the reader is referred to the references for more information. Note: the ISEE sensor acronyms are 3-letter words: The first two letters refer to the PI followed by one letter designating the S/C: ISEE-1 = M (Mother), ISEE-2 = D (Daughter), ISEE-3 = H (Heliocentric).

ANM/AND = Electrons & Protons Instrument (ISEE-1 and -2, PI: K. A. Andersen, UCB). Objectives: Study of the various energetic particle phenomena found in the Earth's magnetosphere, magnetopause, magnetosheath, bow shock, and upstream medium. Measurement over a wide range of energies, from ~ 1.5 to 300 keV for both electrons and protons.

BAM/PAD = Fast Plasma Experiment (on ISEE-1 and -2, PIs: S. J. Bame, Los Alamos Scientific Lab, G. Paschmann, MPI Garching). Three electrostatic analyzers (with 90° spherical section) provide electron and proton measurements. Each instrument uses a divided secondary emitter system to intercept the analyzed particles. ISEE-1 carries also a solar wind experiment (SWE) to measure solar wind ions with high resolution.

Protons	5 eV - 40 keV	ISEE-1
Electrons	5 eV - 20 keV	ISEE-1
Ions	50 eV - 40 keV	ISEE-2
Electrons	5 eV - 20 keV	ISEE-2

Table 449: Measurement ranges of BAM/PAD

FRM/FRD = Low Energy Protons & Electrons (ISEE-1 and -2, PI: L. A. Frank, U. of Iowa) Objective: study of directional intensities of positive ions and electrons over a large solid angle. Energy range: $1 \text{ eV} \leq E/Q \leq 50 \text{ keV}$ in 63 bands with 17% resolution.

GUM/GUD = Plasma Wave Investigation (ISEE-1 and -2, PI: D. A. Gurnett, U. of Iowa). Objective: Study of wave/particle interaction in the Earth's magnetosphere and in the solar wind. The instrument on ISEE-1 uses three electric dipole antennas with lengths of 215 m, 73.5 m, and 0.6 m for the electric field measurements, and a triaxial search coil antenna for magnetic field measurements. The ISEE-2 instrument uses two electric dipoles with lengths of 30 m and 0.6 m, and a single-axis search coil antenna for magnetic field measurements.

Magnetic field levels	10 - 100 kHz (3 axis, 16 channels)
Electric field levels	10 Hz - 10 kHz (3 axis, 12 channels)
Sweep frequency spectrum	10 kHz - 200 kHz (128 steps), analysis of the electric field signals

Table 450: GUM/GUD parameters

HAM = Plasma Density Experiment (ISEE-1, PI: C. C. Harvey, ESTEC)

Objective: Study of total electron density by means of radio techniques.

The propagation experiment measures the phase velocity of a radio wave of frequency 683 kHz and 272.5 MHz (transmitted from the Mother S/C ISEE-1 and received on the daughter S/C, ISEE-2).

RUM/RUD = Fluxgate Magnetometer Experiment (ISEE-1 and -2, PI: C. T. Russell, UCLA). Objective: Study of the dynamic plasma (magnetospheric phenomena) and field environment of the Earth.

Magnetometer is mounted on a 3 m boom. The instrument has two commandable ranges of $\pm 256 \gamma$ and $\pm 8192 \gamma$ with an accuracy of 0.025%.

EGD = Solar Wind Ion Experiment (ISEE-2, PIs: E. Egidi, G. Moreno, CNR Frascati). Objective: Study of the transient phenomena in the solar wind to obtain a spatial gradients of the interplanetary plasma.

The instrument is based on two identical hemispherical electrostatic energy selectors for the measurement of positive ions in two different energy windows.

- Ions: 50eV/q - 25 keV/q
- Electrons: 35 eV - 7 keV

HEM = VLF Wave Propagation Experiment (ISEE-1, PI: R. A. Helliwell, Stanford) Objective: Study of VLF-wave-particle interactions in the magnetosphere (note: VLF = Very Low Frequency in the 10 - 30 kHz range). A second goal is the determination of the effects upon energetic particles in the magnetosphere of electrical power transmission line radiation. The instrument setup consists of three separate elements:

- a broadband VLF receiver on ISEE-1
- a broadband VLF transmitter located at Siple station in the Antarctic
- ground stations in the Antarctic and Canada

HPM = DC Electric Field Experiment (ISEE-1, PI: J. P. Heppner, GSFC)

Objective: Study of the transfer mechanisms (mass, momentum, and energy at the magnetopause), in particular the spatial extent and variability of the zone of strong electric fields, or fast convection in adjacent magnetospheric regions.

Instrument: 8 channel spectrum analyzer. Measurement ranges: 0.1 Hz - 3200 Hz in 9 steps.

HOM = Low Energy Cosmic Ray Experiment (ISEE-1, PI: D. Hovestadt, MPI Garching). Objective: Measurement of elemental abundances, charge state composition, energy spectra, and angular distributions of energetic ions in the energy range of 2 keV/charge to 80 MeV/nucleon, and of electrons between 75 - 1300 keV. The instrument consists of three sensor systems:

- ULECA is an electrostatic deflection analyzer, its energy range from about 3 to 560 keV/charge
- ULEWAT is a double dE/dX versus E thin-window flow-through proportional counter/solid-state detector telescope covering the energy range from 0.2 to 80 MeV/nucleon (Fe).
- the ULEZEQ sensor consists of a combination of an electrostatic deflection analyzer and a thin-window proportional counter. The energy range is 0.4 MeV/nucleon to 6 MeV/nucleon. Objective: collection of composition data in the trapped radiation zone.

MOM = Quasi-Static Electric Field Experiment (ISEE-1, PI: F. S. Mozer, UCB). Objectives:

- study of the quasi-static electric field over a dynamic range of 0.1 - 200mV/m
- study of wave electric fields at frequencies <1000 Hz with a sensitivity <1 μ V/m (Hz)^{1/2} at all frequencies
- study of plasma density and temperature

Measurements are made of the potential difference between a pair of 8 cm diameter vitreous carbon spheres which are mounted on the ends of wire booms and are separated by 73.5 m in the spin plane of the satellite.

OGM = Fast Electron Spectrometer Experiment (ISEE-1, PI: K. W. Ogilvie, GSFC) Objective: Study of three-dimensional plasma distribution in the solar wind, magnetosheath, outer magnetosphere, and near tail regions.

Instrument with three energy ranges: 7.5-512 eV, 11-2062 eV, and 109-7285 eV.

SHM = Ion Composition Experiment (ISEE-1, PI: R. D. Sharp, Lockheed, Palo Alto) Objective: Study of the composition of the hot magnetospheric plasma. Ion composition of the ring current, the plasma sheet, the plasmasphere, the magnetosheath, and the solar wind in order to establish the origin of the plasmas in the various regimes of the magnetosphere and to identify mass and charge dependent acceleration, transport, and loss processes.

The instrument consists of two ion mass spectrometers which can be operated independently. The spectrometers point 5° above and 5° below the ISEE-1 spin plane. Measurement ranges: 1 AMU to > 150 AMU in 64 channels at each of 32 energy channels covering the energy per charge range from 0 to ~17 keV/e.

WIM/KED = Medium Energy Particles Experiment (ISEE-1, -2, PI: D. J. Williams, NOAA, Boulder CO). Objective: Study and identify the physical mechanisms of medium energy particles associated with acceleration, source and loss processes, and boundary and interface phenomena throughout the orbits of ISEE-1 and -2.

The experiment consists of the WIM instrument (Wide Angle Particle Spectrometer and a Heavy Ion Telescope) on ISEE-1 and the KED instrument (five sensor systems mounted at various angular positions with respect to the S/C spin axis) on ISEE-2.

- | | |
|---|--------|
| - Protons: 20 keV - 2 MeV in 8 channels, in 16 channels | ISEE-1 |
| - Electrons: 20 keV - 1.2 MeV in 8 channels, in 16 channels | ISEE-1 |
| - Protons: 20 keV - 2 MeV in 12 channels | ISEE-2 |
| - Electrons: 20 keV - 300 keV (to 1.2 MeV for 90° unit) | ISEE-2 |

K.18.2 ISEE-3 Mission

Objective: Measurement of the ingredients of the interplanetary medium: the properties of the solar-wind plasma, magnetic and electric fields, solar and heliospheric charged particles and galactic cosmic rays. Exploration of the distant geomagnetic tail.¹⁵¹⁰⁾

ISEE-3 S/C: Launch Aug. 12, 1978 (NASA) by Delta vehicle from Cape Canaveral.

Orbit: ISEE-3 was first placed 1.5 million km (~240 Earth radii, R_e) sunward from the Earth in a halo orbit around the so-called Lagrangian Point L₁ (also referred to as liberation point). At L₁ the S/C co-rotated with the Earth around the sun during the course of each year.

ISEE-3 was redirected in mid-1982 from its L₁ position (which it had occupied for more than 4 years) to study the distant Earth's magnetic tail throughout most of 1983. After that ISEE-3 was redirected into a heliocentric orbit to fly past the Giacobini Zinner comet on Sept. 11, 1985, and upstream of Halley's comet on March 28, 1986. The S/C was renamed ICE (International Cometary Explorer) in 1984.

Sensor complement:

The ISEE-3 payload consisted of 13 instruments provided by both US and European groups.

¹⁵¹⁰⁾K. P. Wenzel, "Earth's Distant Geomagnetic Tail Explored by ISEE-3 Spacecraft," ESA Bulletin 37, 1984 pp. 46-50

- **ANH = X-Rays and Electrons Instrument** (PI: K. A. Anderson, UCB)
 - Measurement of solar flare X-ray bursts and transient cosmic gamma-ray bursts. A proportional counter and scintillation detector cover the energy range from 5 - 228 keV.
 - Measurement of electrons from ~ 2 keV to ~ 1 MeV with high energy and angular resolution. (Study of interplanetary and solar electrons in the energy range between the solar wind and galactic cosmic rays).
- **BAH = Solar Wind Plasma Experiment** (PI: S. J. Bame, Los Alamos Scientific Lab)
Two electrostatic analyzers (with 135° spherical section) provide electron and ion measurements. Each instrument uses a divided secondary emitter system to intercept the analyzed particles.

Figure 269: ISEE-3 spacecraft trajectory overview

- **HKH = High Energy Cosmic Ray Experiment** (PI: H. H. Heckman, UCB)
Multidetector cosmic ray experiment to identify the charge and mass of incident cosmic ray nuclei from H through F_e species (over energy ranges from 20 to 500 MeV/nucleon).

- **HOH = Low Energy Cosmic Ray Experiment** (PI: D. Hovestadt, MPI Garching)
Objective: Study of nuclear and ionic composition of solar, interplanetary, and magnetospheric accelerated and trapped particles.
Measurement of elemental abundances, charge state composition, energy spectra, and angular distributions of energetic ions in the energy range of 2 keV/charge to 80 MeV/nucleon, and of electrons between 75 - 1300 keV.
- **DFH = Low Energy Proton Experiment** (PI: R. J. Hynds, Imperial College, London).¹⁵¹¹⁾ Objective: Study of low energy protons from a solar flare to relate particle fluxes measured near the Earth to fluxes in the upper corona (investigation of the gross scale of coronal control).
DFH experiment to measure low energy protons in the energy range from 35-1600 keV.
- **MEH = Cosmic Ray Electrons and Nuclei** (PI: P. Meyer, U. of Chicago). Objective: Study of the long and short-term variability of cosmic ray electrons and nuclei.
Measurement of the energy spectrum of cosmic electrons in the range of 5-400 MeV. In addition, determination of the energy spectra and relative abundances of nuclei from protons in the iron group (energies from 30 MeV/n to 15 GeV/n).
- **OGH = Plasma Composition Experiment** (PI: K. W. Ogilvie, GSFC)
Objective: Study of the dynamics and energetics of the solar wind acceleration region. Ion mass spectrometer for the measurement of ionic composition of the solar wind.
- **SCH = Plasma Wave Instrument** (PI: F. L. Scarf, TRW, Los Angeles)
Objective: Study of interplanetary wave-particle interactions in the spectral range from 1 Hz to 100 kHz.

Measurements of magnetic field and electric field components on long booms (90 m tip to tip). Magnetic field levels: 8 channels, 60 dB range, 20 Hz - 1 kHz. Electric field levels: 16 channels, 80 dB range, 20 Hz - 100 kHz.
- **SBH = Radio Mapping Experiment** (PI: J. L. Steinberg, Meudon Observatory, Paris)
Objectives: a) monitoring the solar wind flow and perturbations of the magnetic field in conjunction with simultaneous measurements on ISEE-1 and -2 (bow shock, magnetopause, neutral sheet), and b) propagation studies of particle fluxes and shock waves in the solar wind (large scale structure of the magnetic field).
Measurement of the interplanetary scintillation of natural radio sources using two dipole antennas, one in the spin plane (90 m tip to tip) and one along the spin axis (15 m tip-to-tip). Each of these antennas drives two radiometers (10 kHz bandwidth and 3 kHz bandwidth).
- **SMH = Helium Vector Magnetometer** (PI: E. J. Smith, JPL)
Objective: Continuous observation of the interplanetary magnetic field near 1 AU (structure, direction, polarity north-south component, magnitude, dynamic phenomena).
Boom-mounted magnetometer sensor (3 m) with the following characteristics:
 - 8 dynamic ranges of: ± 4 , ± 14 , ± 42 , ± 144 , ± 640 , ± 4000 , ± 22000 , ± 140000 γ
 - frequency response: 0 - 3 Hz within three bands (0.1 - 1, 1 - 3, and 3 - 10 Hz) to measure fluctuations parallel to the S/C spin axis.
- **STH = Heavy Isotope Spectrometer Telescope, HIST** (PI: E. C. Stone, CIT)
Objective: measurement of the isotopic composition and energy of solar, galactic, and interplanetary cosmic ray nuclei for the elements Li through Ni in the energy range from ~ 5 to 250 MeV/nucleon.
Charge, isotope, and energy range: Z 3 - 28 (Li to Ni); A 6 - 64 (${}^6\text{Li}$ to ${}^{64}\text{Ni}$)
Mass resolution: Li 0.065 - 0.83 proton masses; Fe 0.18 - -0.22 proton masses.

¹⁵¹¹⁾A. Balogh, R. J. Hynds, J. J. van Rooijen, G. A. Stevens, T. R. Sanderson, K. P. Wenzel, "Energetic Particles in the Heliosphere - Results from the ISEE-3 Spacecraft," ESA Bulletin 27, 1981, pp. 4-12

- **TYH = Medium Energy Cosmic Ray Experiment** (PI: T. Y. von Rosenvinge, GSFC)
Objective: measurement of the charge composition of nuclear energetic particles over the energy ranges from ~ 1 - 500 MeV/ nucleon, and charges from $Z=1$ to $Z=28$. The experiment consists of two telescopes. The combined charge, mass, and energy intervals covered by these two telescopes are as follows:
 - Nuclei charge of energy spectra: $Z = 1-30$, energy range 1-500 MeV/nucleon
 - Isotopes: $Z=1, \Delta M=1$, from 4-70 MeV/n
 $Z=2, \Delta M=1$ from 1-70 MeV/n
 $Z=3-7, \Delta M=1$ from 30-140 MeV/n
 - Electrons: $\sim 2-10$ MeV
 - Anisotropies: $Z=1-26$ (1-150 MeV/n for $Z=1,2$); Electrons: 2-10 MeV

K.19 POLAR

NASA/GSFC¹⁵¹²⁾¹⁵¹³⁾ solar-terrestrial mission within GGS and ISTP with the objective to study the ionospheric role in substorm phenomena and in the overall magnetospheric energy balance (measurements of plasma entry and transport into the northern dayside cusp regions at high altitudes and over the southern polar cap at low altitudes, global imaging of the northern auroral zone).

The Polar launch occurred on February 24, 1996 with a Delta II vehicle from Vandenberg Air Force Base. Spacecraft mass = 1297 kg (269 kg propellant, 264 kg science payload). Nominal lifetime = 3 years. S/C is spin-stabilized at 10 rpm (a smaller platform of the S/C is despun and can be pointed to maintain the viewing field of certain instruments), 2.4 m diameter, 1.8 m height, cylinder with conductive surfaces. Solar arrays provide 440 W, including 186 W for payload. The S/C was built by Lockheed Martin Astro Space.

Orbit: Polar elliptical orbit with an apogee of $9 R_E$ (56,500 km) and a perigee of $2 R_E$ (11,500 km); inclination = 86° ; period = 18 hours.

Sensor complement:¹⁵¹⁴⁾

1) Observation of local electromagnetic fields in the low frequency range

MFE = Magnetic Field Experiment (PI: C. Russell, UCLA). Objectives: Study of the coupling of the solar wind and the magnetosphere through currents driven in the polar cusp (energy and momentum exchange with the magnetosphere at the cusp-magnetosheath interface).

Instrument: two fluxgate magnetometers; sampling of the magnetic field within the frequency range from 0 - 50 Hz. Magnetic field strengths between 10^{-6} and 0.6 Gauss are detectable.

EFI = Electric Fields Instrument (PI: F. Mozer, U. of California, Berkeley). Objectives: Study of the electric field structure of the high-latitude magnetosphere, the cusp, and the plasma mantle.

EFI is a dual-probe instrument. Sampling of the electric field between 0 and 20 kHz. Electric field strengths between 0.1 and > 1000 mV per meter at a rate of 40 samples per second in the normal mode, more than 1000 samples per second in the burst mode. The burst will be coordinated with HYDRA and TIDE instruments.

PWI = Plasma Wave Instrument (PI: D. Gurnett, U. of Iowa). Objectives: Study of wave/particle processes mediated by electromagnetic turbulence (momentum transfer in the

¹⁵¹²⁾“The Solar-Terrestrial Science Project of the Inter-Agency Consultative Group for Space Science,” ESA SP-1107, November 1990, pp. 11-15

¹⁵¹³⁾“ISTP Global GEOSPACE Science - Energy Transport in Geospace,” ESA/NASA/ISAS brochure, 1992 of GSFC

¹⁵¹⁴⁾http://www-spf.gsfc.nasa.gov/istp/polar/polar_inst.html

geospace system, particularly in the boundaries). The PWI instrument samples electric field noise above the highest EFI frequencies well into the radio band. Magnetic-loop and search coils are used to sample the magnetic fluctuations above the highest frequencies detectable by MFE (identification of the characteristic modes of plasma behavior).

The PWI employs seven distinct sensors for detecting the electric and magnetic fields of plasma waves. These sensors consist of: a pair of orthogonal two-sphere electric antennas in the spin plane of the S/C with sphere-to-sphere separations of 100 m and 130 m respectively, shared with the EFI; a short two-sphere electric antenna aligned along the spacecraft spin axis with a sphere-to-sphere separation of 14 m, also shared with EFI; a triaxial magnetic search coil mounted on the end of a rigid stacer boom, shared with EFI; and a magnetic loop antenna mounted on the same boom and oriented parallel to the 100 m electric antenna in the spin plane. The spheres on the electric antennas are 9 cm in diameter and each contains a high-impedance preamplifier that provides signals to the boom deployment mechanisms. Amplifiers in the deployment mechanisms buffer signals to EFI and PWI independently. Each of the three magnetic search coils consists of two bobbins mounted on high permeability micro-metal cores 40 cm long. The loop sensitivity constant is 385 micro V/nT Hz and the resonance frequency is 45 kHz.

HYDRA = Hot Plasma Analyzer Experiment (PI: J. Scudder, GSFC). Objectives: Study of low-energy electrons in the global magnetic topology. Study of electron and ion signatures that accompany geomagnetic substorms, auroral arcs, field-aligned currents, and particle precipitation.

The HYDRA ensemble of electrostatic analyzers is one part of the HYDRA instrument. It measures electrons and ions in energy per unit charge between 1 eV and 30 keV and observes them in 12 directions simultaneously. In addition, a device with a position-sensitive array, called ‘parallel plate analyzer,’ images electrons within and near the magnetic field with a 1.5° angular resolution, energy ranges between 10 eV and 10 keV. Sampling rates: 2/second.

TIDE/PSI = Thermal Ion Dynamics Experiment / Plasma Source Investigation (PI: T. Moore, MSFC). Objectives: Study of low-energy ions (transport mechanisms) to evaluate the ionosphere as a source of plasma for the magnetosphere. TIDE samples ions extracted from the ionosphere (whose mass is determined by a time-of-flight scheme). Energy range: 0.1 eV per charge to 100 eV per charge.

2) Observation of particle populations associated with electromagnetic fields

TIMAS = Toroidal Imaging Mass-Angle Spectrograph (PI: E. Shelley, Lockheed Palo Alto Research Lab.). Objectives: Study of the properties, location, and morphology of the polar cusp, which is the principal source region for entry of solar wind plasma and hot ionospheric plasma into the magnetosphere. The TIMAS instrument samples ions of resolved mass that are either energized ions of ionospheric origin or stored particles of solar wind origin. Energy range: 50 eV - 30 keV. Sampling rate is 10 times per minute (one per satellite spin). TIMAS data is used in combination with data from TIDE and from SWICS on the WIND satellite.

Parameter	Value	Parameter	Value
Energy range	0.015-32 keV/e	Time resolution	0.375 (s, 2-D); 3 (s, 3-D)
Energy resolution	0.08 ($\Delta E/E$)	Instrument mass, power	15.7 kg, 14 W
Mass range	1-32 (AMU/e) 64 chan.	Data rate	4.1 kbit/s
IFOV	2° x 157° azimuth 10° elevation	Solid angle coverage	4 pi x 0.98 sr
		Angular resolution	11.25° x 11.25°

Table 451: Key TIMAS instrument parameters

CAMMICE = Charge and Mass Magnetospheric Ion Composition Experiment (PI: T. Fritz, Los Alamos National Lab.). Objectives: Study the mechanisms that control the energization, storage, and precipitation of particles in the high-latitude magnetosphere.

CAMMICE permits determination of the composition of major ion constituents in the near-Earth plasma sheet and in the ring current. Energy ranges between 6 keV per charge and 60 MeV per ion. For full angular distribution, CAMMICE measures at a rate of 10 samples per minute, or once per spin of the S/C. The angular resolution approaches 0.2° .

CEPPAD (Comprehensive Energetic-Particle Pitch Angle Distribution), PI: B. Blake, The Aerospace Corporation, El Segundo, CA). Objectives: Investigation of quantitative information on the sources, energization, transport, and losses of energetic particles in the magnetosphere. Measurement of the rate of particle precipitation into the Earth's upper atmosphere. The CEPPAD investigation uses a variety of techniques to provide detailed energy spectra and angular distributions of energetic particles. The instrument consists of three packages. Two are spacecraft body mounted and the third is located on the despun platform. The first body-mounted package consists of the Imaging Proton Sensor (IPS) and the Digital Processing Unit (DPU). The second consists of the Imaging Electron Sensor (IES) and the High Sensitivity Telescope (HIST). The single despun platform package is the SEPS (Source/Lose-Cone Energetic Particle Spectrometer). The IPS, IES and HIST all use the body-mounted DPU. The SEPS sensor is independent of the body mounted sensor and contains a separate digital processing unit. This approach was taken because of the limitations inherent in communicating between the spacecraft body and despun platform.

- **IPS** (Imaging Proton Sensor). The IPS measures protons over the energy range from about 14 - 1500 keV in 16 energy bands over nine separate look directions. It uses a spectrometer which incorporates MSSD (Microstrip Solid State Detector) having a planar configuration with six individual elements. The nine detectors are arranged to be at the polar angles: 10° , 30° , 50° , 70° , 90° , 110° , 130° , 150° , and 170° with respect to the S/C spin axis. Each detector has an IFOV of 20° (polar direction) \times 11.25° (azimuthal direction). The total IFOV is $180^\circ \times 11.25^\circ$. A full coverage of the unit sphere is obtained once every 6 second spin.¹⁵¹⁵⁾ Although designed to measure ions in-situ, the IPS detects also ENAs with high efficiency.
- **IES** (Imaging Electron Sensor). The IES measures electrons over the energy range from about 25 - 400 keV using a spectrometer which incorporates a MSSD with a 0.5 cm \times 2.1 cm planar configuration and five individual elements. The MSSD forms the image plane for a sensor segment with a "pin-hole" aperture. The MSSD has a thick "dead layer" and thus does not respond to protons with energies below about 250 keV. The "pin-hole" aperture accepts electrons over a 60° angular segment in a plane containing the satellite spin axis. Each of the five detector elements in the MSSD detects electrons in a 12° angular subinterval of the 60° FOV. The complete IES system has a nominal geometric factor of $6 \times 10^{-3} \text{ cm}^2$. The nominal angular resolution of a detector element is $12^\circ \times 12^\circ$ and its elemental geometric factor is approximately 3.8×10^{-4} .
- **SEPS** (Source/Lose-Cone Energetic Particle Spectrometer).¹⁵¹⁶⁾ SEPS consists of two independent telescopes which measure both the energetic electron and ion fluxes in the vicinity of the magnetic field-aligned loss, and source cone regions with high sensitivity and with fine angular and time resolution. The electron telescope has twice the sensor area of the ion telescope and uses aperture wheels to vary its dynamic range. Particle angular imaging is obtained using pinhole camera apertures in front of the electron XY position-sensitive detectors. The ion telescope is similar to the electron telescope except for the reduced sensor area and the fact that the aperture wheels are replaced by magnets which sweep out electrons.

3) Imaging instruments for spatial observations

UVI = Ultraviolet Imager (PI: M. Torr, MSFC). Objectives: Study of the spatial and temporal descriptions of the aurora and images of total particle flux, characteristic energy, thermospheric neutral composition, and ionospheric conductances. UVI images the dayside

and nightside auroras in the vacuum UV range using five specially designed filters. The detector is an intensified CCD used in conjunction with a fast reflective optical system to image an 8° FOV at a nominal rate of two frames per minute. The UVI is able to detect and provide images of very dim emissions with a wavelength resolution never achievable before. The resulting images permit to quantify the overall effects of solar energy input to the Earth's polar regions. The key wavelengths imaged are: 130.4 nm (OI 1304 filter), 135.6 nm (OI 1256), 140-160 nm (LBH short), 160-175 nm (LBH long), and 175-190 nm (solar). LBH stands for Lyman-Birge-Hopfield (spectral bands in the 140-180 nm range).

VIS = Visible Imaging System (PI: L. Frank, U. of Iowa). Objectives: Quantitative assessment of the dissipation of magnetospheric energy into the auroral ionosphere. Development of an energy flow model within the magnetosphere using VIS data in three ways: to illustrate the topology of the magnetosphere, to delineate the response of the magnetosphere and the magnetotail to substorms and solar-wind conditions, and to identify the locations of and mechanisms for suprathermal charged-particle acceleration.

The VIS instrument consists of a set of three low-light-level cameras. Two of these cameras share primary and secondary optics and are designed to provide images of the night-time auroral oval at visible wavelengths (FOV = 20° x 20°). A third camera is used to monitor the FOV directions of the sensitive auroral cameras with respect to the sunlit Earth. The two auroral cameras have spatial resolution of 10 km (0.011° x 0.013°) and 20 km (0.22° x 0.25°) respectively from an orbital altitude of 8 R_E. A CCD image has a size of 256 x 256 pixels and takes 12 s to acquire. VIS uses an image intensifier readout through 12 visible narrow-band filters producing five separate auroral images per minute.¹⁵¹⁷⁾

PIXIE = Polar Ionospheric X-ray Imaging Experiment (PI: W. Imhof, Lockheed Palo Alto Research Lab.). Objectives: Study of the morphology and spectra of energetic electron precipitation and its effect on the atmosphere. Derivation of the total electron energy deposition rate, the energy distribution of the precipitating electrons, and the altitude profile of ionization and electrical conductivity.

PIXIE uses a pinhole camera concept to measure the spatial distribution and temporal variation of X-ray emissions from the Earth's atmosphere. The time resolution of images is 60 seconds or better (the optimal radial distance to obtain the best images is 6 R_E).

Investigation	Experiment Acronym	Mass (kg)	Data Rate (Bit/s)
Magnetic Field Experiment	MFE	5.0	500
Electric Field Instrument	EFI	31.9	2500
Plasma Wave Instrument	PWI	18.4	2520

Table 453: Instrument summary of the Polar S/C payload

Data: On-board recording capability of science data (1.3 Gbit digital tape recorder). Science data transmission of 56 kbit/s (RT) and 512 kbit/s (PB) to DSN (four 60 minute nominal contact periods per day). The Polar S/C provides on-board interconnection of instrumentation for data communication. Data sharing among the instruments can be triggered by pattern recognition schemes in on-board computers.

K.19.1 SAC-B (Satélite de Aplicaciones Científicas-B)

SAC-B is a cooperative solar mission between CONAE (Comisión Nacional de Actividades Espaciales) of Buenos Aires (CONAE is the civilian space agency of Argentina) and NASA for the study of solar physics and astrophysics (measurement of solar flares, gamma-ray burst sources and the diffuse soft X-ray cosmic background).¹⁵¹⁸⁾ CONAE is responsible for the design and construction of the SAC-B satellite (the S/C is built by INVAP S.E. of San Carlos de Bariloche, Argentina), NASA provides two instruments and launch services on a Pegasus XL vehicle.

The launch of SAC-B (along with HETE) took place on Nov. 4, 1996 from NASA/WFF, VA. The third stage of the Pegasus XL failed to separate properly - both S/C are still attached to the third stage in low Earth orbit. About 12 hours of checkout could be obtained after launch on battery power. The solar panels of SAC-B remained in solar shadow by the attached 3rd stage of the launcher and its avionic system. Hence, no operational status could be achieved.

Figure 271: The SAC-B S/C model

The design life is three years or more. CONAE provides a single ground station (Buenos Aires) for mission operations and science data collection. NASA plans to provide DSN and Wallops Island station support for initial orbit monitoring and emergency backup throughout the mission life. Mission program managers: D. Caruso of CONAE and David Gilman of NASA/HQ.

The S/C mass is 191 kg; three-axis stabilized (two momentum wheels in a "V" configuration for roll and yaw control). Pitch axis control and momentum unloading is accomplished using magnetic torquers; attitude control by a coarse sun sensor, a two-axis Fine Sun Sensor (FSS) and a three-axis magnetometer (TAM); power storage with two 10 Ah NiCd batteries; all sensors are thermally controlled. The S/C body is basically a rectangular parallelepiped 62 cm x 62 cm wide by 80 cm high with four extended solar panels (62 cm wide by 76 cm long), the solar power is 256 W. The HXRS and SOXS instruments are mounted on the sun-
¹⁵¹⁸⁾Information provided by D. Gilman and J. L. LaBrecque of NASA/HQ

facing end of the S/C along with the FSS with FOV toward the sun. The GRaBS sensors mount to the solar platform (bottom of S/C) with a FOV on the opposite sides of the S/C normal to the sun line. The CUBIC and Italian ISENA instruments are mounted on the top (anti-sun facing side) of the S/C. CUBIC's FOV is normal to the sun line. SAC-B will be sun-facing with various roll angles to accommodate the CUBIC experiment requirements. - Data: on-board storage of HK data in central memory and science data storage in instrument memories; data transmission in S-band at 100 kbit/s.

Orbit: Circular orbit, altitude = 550 km, inclination = 38°

Sensor complement:

HXRS (Hard X-Ray Spectrometer) provided by IAFE (Argentina Institute of Astronomy and Space Physics). Objective: observation of the solar flare hard X-ray spectrum between 20 and 320 keV of rapidly varying events on time scales as short as tens of milliseconds. In addition to the study of the temporal evolution of X-ray emissions during solar flares the instrument will provide the temporal evolution of nonsolar γ -ray bursts.

GXRE (Goddard X-Ray Experiment) provided by NASA/GSFC. The instrument has two sets of detectors (in separate modules).

The **SOXS** (Soft X-Ray Spectrometer) performs coordinated observations with HXRS by observing soft X-ray emissions from solar flares.

The other module is referred to as **GRaBS** (Gamma Ray Burst Spectrometer). It provides time profiles of the X-ray emission of nonsolar γ -ray bursts in the energy range 20 keV to > 300 keV. There are two modules of GRaBS, one on each side of the SOXS instrument.

CUBIC (Cosmic Unresolved X-Ray Background Instrument using CCDs, PI: G. P. Garimore) designed and built by Penn State University, University Park, PA. The objective is to observe the spectrum of the diffuse X-ray background with high sensitivity and spectral resolution between the energy ranges of 0.2 to 10.0 keV over large portions of the sky in order to study the multiple components of this background radiation. The instrument consists of a pair of X-ray CCDs operated in photon-counting mode and exposed directly to the sky through an aperture with a $5^\circ \times 5^\circ$ FOV for energy levels < 1 keV, and $10^\circ \times 10^\circ$ FOV for all other energy levels. - Once in orbit, CUBIC will be operated by students from Penn State via the Buenos Aires ground station.

ISENA (Imaging Spectrometer for Energetic Neutral Atoms) provided by CNR/IFSI (Institute of Physics of Interplanetary Science, Frascati, Italy, PI: S. Orsini).¹⁵¹⁹ Partner institutions: Max-Planck Institut für Aeronomie, Katlenburg-Lindau; Physics Department, University of Arizona, Tucson, AZ. The objective of ISENA is detection of energetic neutral atoms emitted from the inner magnetosphere through charge-exchange between the magnetospheric energetic ions and the geo-coronal neutral gas. The instrument covers a 60° by 60° FOV (Field of View) using two sensors with an angular resolution of 15° by 3° . Mass and energy resolution (in the range between 5/8 keV to 150 keV) are made possible by the simultaneous detection of the flow velocity (using the time-of-flight technique) and of the energy (using a solid-state detector) of the incident energetic neutral atoms. Instrument mass = 6 kg; power = 6 W.

K.20 SME (Solar Mesosphere Explorer)

Atmospheric mission in NASA's Explorer Program (Explorer 64) operated by the University of Colorado at Boulder (JPL management of SME project, S/C was built by Ball Aerospace, Boulder, CO). NASA launch: Oct. 6, 1981 with a Thor Delta vehicle from VAFB, CA (UoSAT-1 was a passenger payload on this flight). The satellite was operational until April

¹⁵¹⁹) Information provided by R. Ibba of ASI, Rome, Italy

13, 1989. Objective: Study of atmospheric (mesosphere) ozone and the processes that form and destroy it. 1520) 1521) 1522) 1523) 1524) 1525)

SME was a spin-stabilized S/C at 5 rpm; the spin axis was maintained nearly perpendicular to the orbit velocity vector by means of a magnetic torquing attitude control system. The spacecraft body was a cylinder approximately 1.7 m x 1.25 m (S/C mass = 417 kg) and consisted of two major modules: the observatory module that housed the scientific instruments, and the spacecraft bus. The command system was capable of executing commands in real time or from stored program control. Power was supplied by a solar cell array. The telemetry system was used either in a real-time or in a tape-recorder mode. The payload (instrument package) was developed at the Laboratory for Atmospheric and Space Physics (LASP) of the University of Colorado.

Orbit: Sun-synchronous near-circular orbit; altitude = 534 km, inclination = 97.5° , period = 95.5 minutes.

Figure 272: The SME S/C model

Sensor complement: (total of five instruments with four limb-scanning optical instruments)

UV Ozone Experiment. Objective: observation of ozone concentrations (ozone absorption of Rayleigh scattered sunlight at the limb) in the altitude region of 50 - 70 km. The instrument is a dual-channel Ebert-Fastie spectrometer operating in the spectral range of 1800 - 3100 Å (channel A) and 2230 - 3404 Å (channel B). There were 208 or 11 grating steps per scan, respectively. The Cassegrain telescope focal length = 250 mm. FOV = $0.1^\circ \times 1.5^\circ$.

1525) Ch. Barth, et al., "Solar Mesosphere Explorer: scientific objectives and results," Geophysical Research. Letters, Vol. 10, No. 4, p. 237, 1983

Infrared Radiometer (passive 4-channel device). Objective: radiance measurements in the infrared region. The radiometer/telescope had the following spectral ranges: 17.2 - 13.2 μm (carbon dioxide emission), 15.7 - 14.7 μm , 10.6 - 8.6 μm (ozone emissions), and 7.2 - 6.1 μm (water emissions). The full widths at half-maximum were 4.0, 1.0, 2.0, and 1.1 μm , respectively. All four channels utilized HgCdTe detectors. Wavelength separation was accomplished with multilayer bandpass filters. The instrument line of sight was normal to the spin axis. IFOV sweeps through a 4° angle that is equivalent to a limb scan from 20 - 150 km in altitude. Each channel is sampled 20 times per S/C revolution.

Airglow Instrument. Objective: measurement of the ozone altitude profile by limb scanning at 1.27 μm . The instrument consisted of a grating spectrometer (Ebert Fastie) and an uncooled detector system with a narrow FOV.

Visible Nitrogen Dioxide Experiment. Objective: measurement of nitrogen dioxide concentrations in the altitude region from 20 - 40 km (NO_2 absorption of Rayleigh scattered sunlight at the limb). The instrument is an Ebert-Fastie spectrometer (of same design as before). Solar radiation was measured between 4390 to 4420 \AA and between 3200 to 6400 \AA . There were 512 and 438 grating steps per scan, respectively. The instrument line of sight was normal to the spin axis.

Solar UV Monitor. Objective: monitoring of solar flux scattered from a diffusing screen. The instrument was an Ebert-Fastie spectrometer (same design as for UV Ozone Experiment). Operation of instrument in two modes: 1. scanning of the spectral range of 1600 \AA to 3100 \AA by rotation of the grating; 2. setting of the grating to a required wavelength with the instrument monitoring the solar flux. The instrument was mounted to the side of the S/C scanning once per S/C revolution across the sun. The look direction was 45° to the spacecraft axis of rotation. There were 512 grating steps per scan.

Data: The SME data are archived in the NSSDC (National Space Science Data Center) at GSFC and in the SME database at the University of Colorado.

K.21 SMEX (Small Explorer Program)

A NASA/GSFC satellite program (since 1989) with the objective to introduce innovative technologies into low-cost spacecraft design.

The design philosophy employs an end-to-end approach. Emphasis is placed on design simplicity (also a reduction of redundancies), functional independence at subsystem level, and flexibility to accommodate growth. The modular architecture applies to hardware, software, and to services of the system. Communication between subsystems flows via the MIL-STD-1553 data bus. The instruments and subsystems communicate with the computer using this bus. For instruments that produce high data rates, there are four EIA RS422 Direct Memory Access (DMA) interfaces to the computer memory.

A SMEX spacecraft consists of a one-piece cast aluminum structure (a thermally conductive composite S/C structure). The following on-board technologies are employed: the computer is a single-board 80386/80387 RISC processor (Loral RAD-6000 32-bit) featuring dynamic memory management; fiber-optic data bus; GaAs solar arrays (modular); high-density solid-state recorder; high torque reaction wheels, and NiCd batteries. Attitude sensors: coarse sun and fine sun sensors, star tracker, magnetometer (3-axis fluxgate), gyroscopes. Actuators: magnetic torquers and reaction wheels. S/C communications: RF transmitters with 4 Mbit/s X-band downlink, QPSK modulation and 3.5 W RF power; RF receivers with 4 kbit/s S-band uplink, BPSK modulated directly on the S-band carrier with Bi-phase L capability. All communications (format, procedure, etc) are in CCSDS standard. S/C baseline configuration: minimum operational lifetime of one year, S/C mass of 75 kg plus up to 225

kg of payload mass, power = 150-400 W for payload use.¹⁵²⁶⁾

The overall SMEX missions include the following S/C: SAMPEX, FAST and SWAS (Sub-millimeter Wave Astronomy Satellite), TRACE and WIRE (Wide-Field Infrared Explorer).

K.21.1 SAMPEX (Solar Anomalous and Magnetospheric Particle Explorer)

SAMPEX (Explorer 68) is a NASA/GSFC SMEX mission with the objectives to measure energetic electrons as well as ion composition of particle populations from about 0.4 MeV/nucleon to hundreds of MeV/nucleon from a zenith-oriented satellite in near polar orbit; to study the energy, composition, and charge states of particles from supernova explosions, from the heart of solar flares, and from the depths of nearby interstellar space; also to monitor the magnetospheric particle populations which occasionally plunge into the middle atmosphere of the Earth. Mission design life = 1 year, with a goal of 3 or more years of operation.¹⁵²⁷⁾

Figure 273: The SAMPEX S/C model

SAMPEX is a momentum-biased, sun-pointed S/C that maintains the experiment view-axis in a zenith direction. It points its solar arrays at the sun by aiming the momentum vector

¹⁵²⁶⁾J. G. Watzin, "SMEX-LITE: NASA's Next Generation Small Explorer," Proceedings of the 10th Annual AIAA/USU Conference on Small Satellites, Logan, UT, Sept. 16-19, 1996

¹⁵²⁷⁾D. N. Baker, G. M. Mason, O. Figueroa, G. Colon, J. G. Watzin, R. M. Aleman, "The Solar, Anomalous, and Magnetospheric Particle Explorer (SAMPEX) Mission," Preprint 93-128, U. of Maryland - see also (by the same authors): IEEE Transactions on Geoscience and Remote Sensing, Vol. 31, No. 3, May 1993, pp. 531-541

toward the sun and rotating the S/C one revolution per orbit about the sun/spacecraft axis. The ACS (Attitude Control System) uses a combination of three orthogonal torque rods to act against the Earth's magnet field, and one momentum-biased reaction wheel to provide the bias momentum. A two-axis digital sun sensor, a three-axis magnetometer and a set of five coarse sun sensors are used for attitude determination (ACS estimation of sun location during orbit eclipse to continue three-axis attitude solution). Two solar arrays of 1.7 m² area provide an average orbit power of 100 W. One 9 Ah NiCd battery is used. The payload mass is 40 kg, the total S/C mass is 157 kg (aluminum structure, passive thermal control). The solid-state recorder has a capacity of 30 MByte. On-board fiber optic data bus (Mil-Std 1773). The S/C features two omni antennas and a near-Earth 5 W S-band transponder.

SAMPEX was launched on July 3, 1992 from NASA's Western Test Range/VAFB, Ca. from a Scout launch vehicle. As of the end of 1997 SAMPEX is fully operational.

Orbit: Polar orbit, perigee = 512 km, apogee = 687 km, inclination = 82°, period = 96.7 minutes.

Sensor complement:

LICA (Low-Energy Ion Composition Analyzer). Sensor mass = 7.4 kg, power = 4.9 W, bit rate = 1.3 kbit/s. PI: Mason. Objective: to measure 0.5 - 5 MeV/nucleon solar and magnetospheric ions (He through Ni) arriving from the zenith in twelve energy bands. LICA is a time-of-flight spectrometer that monitors incident ion mass and energy by simultaneously measuring the time-of-flight and the kinetic residual energy of particles that enter the telescope and stop in an array of four solid-state detectors. The time-of-flight is determined by start and stop pulses from chevron microchannel plate (MCP) assemblies that detect secondary electrons emitted from the entrance foil and a foil in front of the solid state detector, respectively, when the ion passes through them. These secondary electrons are accelerated to approximately 1 kV and deflected onto the MCPs by electrostatic mirrors. The measured energy and velocity are combined to yield the mass of the ion and the energy per nucleon.

HILT = Heavy Ion Large Telescope (MPE Garching/NASA). Sensor mass = 22.8 kg, power = 5.7 W, bit rate = 0.9 kbit/s. Objectives: to measure the charge, energy, and mass of cosmic rays in the energy range of about 8.0 - 310 MeV/nucleon. Specifically, the energy ranges were: He: 3.9 - 90 MeV/nucleon; C: 7.2 - 160 MeV/nucleon; O: 8.3 - 310 MeV/nucleon; Ne: 9.1 - 250 MeV/nucleon; and Fe: 11 - 90 MeV/nucleon. The instrument consists of a three-element ion drift chamber with two thin multilayer entrance windows followed by an array of 16 solid-state detectors and a scintillation counter with photodiodes. HILT uses a flow-through isobutane system for the drift chamber.

MAST = Mass Spectrometer Telescope (Caltech/GSFC). Instrument mass = 7.5 kg, power = 3.3 W, bit rate = 1.4 kbit/s. MAST monitors the isotopic composition of elements from Li (Z=3) to Ni (Z=28) in the range of about 10 MeV/nucleon - several hundred MeV/nucleon. MAST consists of a combination of surface barrier and lithium-drifted solid-state detectors (11 total). Combined matrix detector positions determine the particle trajectories, allowing accurate corrections to be made for the path length variation with angle and detector response for nonuniformities. MAST also performs measurements of stopping He isotopes from about 7 - 20 MeV/nucleon.

PET = Proton/Electron Telescope (Caltech/GSFC). Instrument mass = 7.5 kg, power = 1.2 W, bit rate = 0.5 kbit/s. PET complements MAST by monitoring the energy spectra and relative composition of protons (18 - 250 MeV) and helium nuclei (18 - 350 MeV/nuclei) of solar, interplanetary, and galactic origins, and the energy spectra of solar flare and precipitating electrons from about 0.4 to about 30 MeV. The instrument measures both trapped and precipitating energetic particles in different parts of the SAMPEX orbit.

Energy Range for:	LICA	HILT	MAST	PET
Electrons	-	-	-	0.4-30 MeV
H	0.76 - 6.1	-	-	18 - 250 MeV
He	0.45 - 6.1	4.3 - 38	7 - 20	18 - 350 MeV/n
C	0.44 - 11.4	7.2 - 160	14 - 210	34 - 120 MeV/n
Si	0.33 - 5.5	9.6 - 177	21 - 330	54 - 195 MeV/n
Fe	0.21 - 3.1	11 - 90	27 - 450	70 - 270 MeV/n
Charge range for elements	1 - 26	2 - 28	2 - 28	1 - 2 (1 -28*)
Charge range for isotopes	2 - 16	2	2 - 28	1 - 2 (1 - 10*)
Geometry factor (cm ² sr)	0.8	60	7 - 14	0.3 - 1.6
FOV (°, full angle)	24 x 20	68 x 68	101	58
Mass (kg)	7.4	22.8	8.8	(incl. with MAST)
Power (W)	4.9	5.6	5.3	(incl. with MAST)
Telemetry (kbit/s)	1.3	0.9	1.4	0.5
* commandable low-gain mode				

Table 454: Performance overview of SAMPEX instruments

Data: On-board data storage is provided by solid-state memory (26.5 Mbyte of data storage). Data transmitted to the ground is formatted as a “Packet Telemetry” stream in accordance with CCSDS standards. S/C operation by GSFC on a continuous basis. Data are transmitted to the ground twice per day via the Wallops Flight Facility.

K.21.2 FAST (Fast Auroral Snapshot Explorer)

NASA/GSFC ¹⁵²⁸⁾ ¹⁵²⁹⁾ mission within SMEX. The objectives are to measure and to study the rapidly varying electric and magnetic fields and the flow of electrons and ions in the aurora regions of the Earth, to study the physical causes of complex auroral displays, and to investigate how electrical and magnetic fields accelerate electrons, protons, and other ions in the auroral regions. The S/C instrument data will be correlated with observations by other S/C as well as by geomagnetic ground stations from Earth. The S/C is spin-stabilized with its spin-axis oriented parallel to the orbit axis. It spins in a cartwheel mode with a period of about 5 seconds (12 rpm). Spin rate and spin-axis orientation are maintained by two magnetic torquer coils, one spinning sun sensor, one horizon crossing indicator, and a magnetometer. The ACS provides a closed-loop spin-rate control. The body-mounted solar array contains 5.6 m² of solar cells (52 W of average orbit power). Total S/C mass of 190 kg, S/C length = 0.86 m, diameter = 1.17 m, design life = 1 year, payload of four instruments (payload mass of 51 kg). The communication system uses an S-band transponder, 2.25 Mbit/s downlink and 2 kbit/s uplink data rate. ¹⁵³⁰⁾

The launch date was August 21, 1996 (placing FAST into the ISTP program) with an enhanced Pegasus vehicle (XL) from Vandenberg, CA. PI for mission: C. W. Carlson of UCB (University of California at Berkeley).

Orbit: Non-sun-synchronous elliptical orbit, perigee = 351 km, apogee = 4175 km (apogee maximum at northern latitude), inclination = 83°, period = 133 minutes. The satellite crosses the auroral zones (which form ovals at about 65°-70° magnetic latitude North and South) four times an orbit. The orbit was designed to have a Northern apogee during January and February of 1997 for coordinated ground-based and optical observations.

Sensor complement:

ESA = Quadrispherical Electrostatic Electron Analyzer (UCB). The objective is to measure electrons and ions with high time resolution. ESA consists of an ion spectrometer and an electron spectrometer to make detailed distribution function measurements; in addition

¹⁵²⁸⁾ D. Baker, G. Chin, R. Pfaff, “NASA’s Small Explorer Program,” *Physics Today*, Dec. 1991, pp. 44-51

¹⁵²⁹⁾ C. W. Carlson, “The Fast Auroral Snapshot Explorer,” *EOS*, Vol. 73, No. 23, 1992, pp. 249, 253, 254

¹⁵³⁰⁾ <http://sunland.gsfc.nasa.gov/smex/fast/>

there are electron-stepped ESAs to make very high time resolution electron measurements with lower energy and angle resolution. The electron-stepped ESAs provide a 64-step energy sweep, covering a range of 3 eV to 30 keV. Sixteen ESAs are configured in four stacks placed around the S/C (360 FOV).¹⁵³¹⁾

TEAMS = Time-of-Flight Energy Angle Mass Spectrograph (U. of New Hampshire and Lockheed, Palo Alto Research Lab). TEAMS is a high sensitivity mass-resolving spectrometer that measures the full 3-D distribution functions of the major ion species with one spin of the S/C. TEAMS typically looks for H^+ , He^{++} , He^+ , O^+ , and a combination of O^{++} and NO^+ over an energy range of a few eV to 5 keV. TEAMS combines the selection of ion by energy/charge by electrostatic deflection and subsequent time-of-flight analysis.

Figure 274: The FAST S/C model

EFLPI = Electric Field / Langmuir Probe Instrument (UCB).¹⁵³²⁾ The objective is to measure the vector electric field from DC to 2 MHz, thermal plasma density and temperature, density fluctuations, propagation velocity of structures, and wavelength measurements using three orthogonal boom pairs, two of which have spherical probes at two locations. The electric field measurement has eight spherical sensors located on four wire booms (two each) in the spin plane and two that are on rigid axial booms. All of the spherical sensors can operate in “voltage mode” in which they measure the local plasma potential with respect to the payload. The electric field signals are measured by sensor pairs which form 56 m, 7.7 m,

¹⁵³¹⁾ <http://sprg.ssl.berkeley.edu/fast/>

¹⁵³²⁾ R. E. Ergun, C. W. Carlson, F. S. Mozer, et al., “The FAST Satellite Fields Instrument,” Space Science Review, 2000

or 5 m dipoles. Six of the sensors can operate in “current mode” as Langmuir probes which measure plasma current. In current mode, the probe is biased at a fixed potential. EFLPI includes a wave/particle correlator. The total mass of EFLPI is 28.45 kg, power = 15.9 W.

MFI = Magnetic Fields Instrument (UCLA). The objective is to measure vector DC and AC magnetic fields using a three-axis fluxgate magnetometer and a three-axis search-coil magnetometer (up to 20 kHz in 2 axis and 1.2 kHz in the 3rd axis). The two magnetometers are boom-mounted 180° apart.

Data: On-board storage capability of 1 Gbit solid-state memory. The instruments acquire data at a maximum rate of 8 Mbit/s (snapshot data collection, with a maximum period of about 100 s of data can be acquired per auroral pass). On-board data preprocessing capability. Continuous synoptic data are collected at a slower rate to put the “snapshots” into proper context. Real-time data are acquired at stations in the auroral zone, memory dumps can be acquired at other NASA stations.

Note: in the ‘sample array’ column of Table 456, the designation ‘4Mx48Ex64Ω’ refers to: 4M (mass) x 48E (energy) x 64 Ω (solid state array).

Measurement	Compo- nents	Frequency Range	Sampling Resolution	Range	Resolution	Data Rate (max.) kbit/s
DC E-Field	3-axis	0-300 Hz	30 μs	±1.6 V/m	0.05 mV/m 16 bit	5000

K.21.3 TRACE (Transition Region and Coronal Explorer)

A NASA/GSFC mission in the SMEX (Small Explorer) program with the objective to study the three-dimensional magnetic structures which emerge through the visible surface of the

¹⁵³³⁾Information provided by C. Cattell of UCB

sun - the photosphere - and to define both the geometry and dynamics of the upper solar atmosphere - the transition region and corona. TRACE is the name of the prime instrument (as well as of the mission), which is mounted onto a SMEX spacecraft designed and built by GSFC. 1534), 1535)

The spacecraft is three-axis-stabilized using the TRACE telescope as a fine sun sensor. A S/C pointing accuracy of 20 arcseconds is required. Mission design life = 1 year. S/C mass = 250 kg. The S/C was air-launched April 2, 1998 on a Pegasus XL vehicle, released off the central California coastline.

- The ACS (Attitude Control System) uses three magnetic-torquer coils, one digital sun sensor, six coarse sun sensors, four reaction wheels, one three-axis magnetometer, and three two-axis inertial gyros. The ACS use the S/C computer to perform closed-loop attitude determination and control.
- The command and data handling system uses a 32-bit on-board processor (80386/80387) with 300 MByte solid-state memory for science data.. A MIL-STD-1553 data bus is used to connect all subsystems and instruments. Science data is passed over the RS-422 interface at rates up to 900 kbit/s. A 5 W S-band transponder is used to down-link 2.25 Mbit/s of data up to six times a day. Commands are uplinked at 2 kbit/s.
- Power of 222 W is provided by GaAs solar cells, deployed in four panels with a total area of 2 m². A 28 V unregulated bus distributes the power, a 9 Ah super NiCd battery provides energy storage.
- S/C operations from GSFC; ground stations at Wallops, VA, and Fairbanks, Alaska.

Orbit: Sun-synchronous polar orbit (permitting continuous observation of uninterrupted image sequences of the sun), altitude=700 km, inclination=98.2°, period=96 minutes.

Sensor:

TRACE (Transition Region and Coronal Explorer, built at Lockheed of Palo Alto, CA; PI: A. M. Title, the science team is from diverse institutions). The objective is to collect comprehensive multispectral images of solar plasmas at temperatures from 10⁴-10⁷ K with 1 arcsecond spatial resolutions and excellent temporal resolution and continuity. An overall science TRACE goal is to explore the relation between diffusion of the surface magnetic fields and changes in heating and structure throughout the transition region and corona. The TRACE instrument is a high-resolution multispectral spectrometer (in the EUV and UV region) featuring a 30 cm diameter Cassegrain telescope (160 cm in length, 8.66 m focal length) and a filter system which feeds a CCD detector array (1024 x 1024 Lumigen coated, front illuminated, three-phase CCD). The detectors are passively cooled to -65°C.

Each quadrant of the primary mirror is coated for sensitivity to a different wavelength range. Light entering the instrument passes first through the entrance filter assembly which transmits only far and extreme UV. Visible and near UV radiation (hence, most of the solar energy) are reflected back into space. Radiation transmitted through the entrance filters passes to a shutter that blocks three quadrants of the aperture, so that only one quadrant of the telescope is illuminated at a time. Photons passing the shutter's open quadrant proceed to the primary mirror, encountering a multilayer coating for a narrow-band EUV quadrant, or a broadband coating for the UV quadrant. The segmented coatings on solid mirrors form identically sized and perfectly coaligned images.

The reflected beam from the primary mirror proceeds to the secondary mirror which reflects it towards the focal plane. The secondary mirror is active to correct for pointing jitter and has coatings matching those on the four quadrants of the primary mirror. - Further stations in the radiation path are the filter wheels and the focal plane shutter. The final element

1535) TRACE www page of GSFC and of Lockheed

in the optical train is the CCD camera. The on-board computer permits very flexible use of the CCD array, including adaptive target selection, data compression, and fast operation for a limited FOV. TRACE is of SXT heritage of Solar-A (Yohkoh).

Parameter	Value	Parameter	Value
Primary mirror diameter	30 cm	Image stabilization	± 0.1 arcsec
Effective focal length	8.66 m	Offset pointing	Disk center $\pm 1^\circ$
FOV	8.5 x 8.5 arc min	CCD read-out time	2.1 s
CCD size	1024 x 1024 pixels	Average data rate	3.6 Gbit/day
Pixel size	21 x 21 μm (.5x.5 arcsec)	Telescope dimensions	37 x 37 x 188 cm
Quantization	12 bit	Instrument mass	51 kg

Table 457: TRACE instrument parameters

The time frame of the TRACE mission has the advantage of operating simultaneously with the SOHO (ESA/NASA, November launch 1995) mission. This implies coordination of observations from both S/C and the merging of datasets collected from TRACE and SOHO.

TRACE applications: study of magnetic field structure and evolution; coronal heating and magnetic fields; on-set of coronal mass ejections; flaring X-ray bright points; etc.

Figure 275: TRACE telescope layout

Band (\AA)	Bandwidth (\AA)	Ion	Region of Atmosphere	Solar Temp. Range Log (T)
2500	Broad	continuum (C)	Photosphere	3.6 - 3.8
1700	Broad	continuum	Tmin & Chromosphere	3.6 - 4.0
1570	30	C I, Fe II, continuum	Tmin & Chromosphere	3.6 - 4.0
1550	30	C IV	Transition Region	4.8 - 5.4
1216	84	H I, Lyman α	Chromosphere	4.0 - 4.5
171	11	Fe IX	Corona	5.2 - 6.3
195	14	Fe XII	Corona	5.7 - 6.4
284	14	Fe XV	Corona	6.1 - 6.6

Table 458: TRACE spectral bands

K.22 SMM (Solar Maximum Mission)

NASA/GSFC mission. Objectives: Observation of solar flares (trigger mechanisms) over a wide band of wavelengths in the UV, X-ray and gamma-ray regions of the spectrum; coverage of the maximum period of a sunspot cycle; better understanding of the violent nature of the sun and its effects on the Earth; measurement of radiation fluxes. Launch Feb. 14, 1980 by Delta vehicle from Cape Canaveral. Satellite mass = 2315 kg. End of mission: 1989. Launched during a period of maximum solar activity, SMM observed more than 12,000 flares and over 1,200 coronal mass ejections during its lifetime. ^{1536), 1537)}

SMM performed flawlessly until an attitude-control system failure (actually a failure of a fuse) occurred on Nov. 23, 1980, which kept the S/C from pointing precisely at the sun. In April 1984 SMM became the first satellite to be retrieved, repaired, and redeployed in orbit by a Shuttle crew (STS-41C). The opportunity was also used to replace in orbit a dish antenna, enabling SMM to transmit its data via TDRS-1. SMM collected data until November 24, 1989, and re-entered on December 2, 1989.

Figure 276: The SMM S/C model

¹⁵³⁶⁾S. P. Maran, B. E. Woodgate, "A Second Chance for Solar Max," *Sky & Telescope*, June 1984, pp. 498-500
¹⁵³⁷⁾A. Chaikin, "Solar Max: Back from the Edge," *Sky & Telescope*, June 1984, pp. 494-497

SMM is of modular design (built by Fairchild) measuring approximately 4 m in length, fitting into a circular envelope 2.3 m in diameter. The instrument module occupies the top 2.3 m and contains the solar payload instruments together with the fine-pointing sun-sensor system. Below the instrument module is the Multimission Modular Spacecraft (MMS) containing the systems for attitude control, power, communication, and data handling. Between the instrument module and the MMS is the transition adaptor, supporting two fixed solar paddles that supply between 1500 and 3000 W of power. ^{1538), 1539)}

Orbit: circular Earth orbit, apogee = 569 km, perigee = 566 km, inclination = 28.5°, period = 96 min (the S/C spends about 60 min of each orbit in full view of the sun).

Sensor complement:

ACRIM = Active Cavity Radiometer Irradiance Monitor (PI: R. C. Willson, JPL).¹⁵⁴⁰⁾

Objective: regular observations of total solar irradiance. The goals of the experiment are:

- i) to begin a long-term climatological database on solar irradiance variability
- ii) to provide a shorter-term database for solar physics investigations.

ACRIM has three active cavity radiometer (ACR) type IV sensors. The sensors view the sun through a 5° (full angle) field of view. ACRIM uses black-body cavity to measure the total irradiance of the visible hemisphere of the sun.

ACRIM is a cavity pyrheliometer, with solar input during half of each 131.072 s measurement interval and servo-adjusted heat input during the rest of each cycle, when the shutter blocks the solar input. The solar irradiance at the Earth is therefore proportional to the difference between the heating rates with shutter open and closed. The accuracy of each irradiance measurement obtained in this way is about 0.1%.

C-P = Coronagraph - Polarimeter (PI: R. M. MacQueen, NCAR Boulder, CO). Objective: corona change monitoring over time, observation of the corona's large-scale magnetic structures and their evolution. The C-P instrument is an externally occulted Lyot coronagraph with a vidicon detector. Images of the corona with 10" spatial resolution are built up in four quadrants by means of sector mirrors (spectral range: 4465 - 6385 Å in 7 bands). In addition, with seven filters and three polaroids with principal axes 60° apart, the C-P is able to obtain measurements of coronal electron densities and distinguish ejected material from coronal features at chromospheric temperatures.

GRS = Gamma-Ray Spectrometer (PI: E. L. Chupp, U. of New Hampshire). The instrument includes seven integral-line calibrated NaI(Tl) detectors for nuclear lines between 0.3 and 0.9 MeV. The energy resolution (full width at half maximum) of these detectors is > 7% at 0.662 MeV. In addition, a thick CsI(Na) crystal, along with the NaI(Tl) spectrometers, is sensitive to γ-rays in the range 10-140 MeV and to neutrons with energies above 20 MeV. An auxiliary system of two NaI detectors yields hard X-ray fluxes from 10 to 140 keV. Time resolutions are typically about 2 s and 16 s, but can be as fine as 64 ms for the 300-350 keV energy band.

Among other things, GRS made important contributions to the international study of Supernova 87A, which in Feb. 1987 provided astronomers with their first local opportunity since 1604 to study such an explosion.

HXRBS = Hard X-Ray Burst Spectrometer (PI: B. R. Dennis, GSFC). Objectives:

- to determine the nature of the mechanisms which accelerate electrons to 20-200 keV in the first stage of the solar flare, and to >1 MeV in the second stage of many flares
- to characterize the spatial and temporal relation between electron acceleration, storage and energy loss throughout the solar flare.

¹⁵³⁸⁾ "NASA's Solar Maximum Mission: A Look at the New Sun," June 1987, NASA brochure, edited by J. B. Gurman

¹⁵³⁹⁾ "The Solar Maximum Mission Experiments," Solar Physics, Volume 65, pp. 5-109

¹⁵⁴⁰⁾ R. C. Willson, S. Gulkis, M. Janssen, S. H. Hudson, G. A. Chapman, "Observations of Solar Irradiance Variability," Science, Volume 211, Feb. 1981, pp. 700-702

The instrument is a collimated X-ray spectrometer. The detector consists of two primary scintillation crystal components. Scintillation events in its actively collimated CsI(Na) detector are read out every 128 ms in fifteen energy channels between ~ 25 to ~ 500 keV. A circulating memory is able to accumulate relatively brief periods of data during the more intense flares with time resolution down to 1 ms. The full width at half maximum field of view is $\sim 40^\circ$.

HXIS = Hard X-Ray Imaging Spectrometer (PI: C. de Jager, Astronomical Institute, Utrecht, NL, and U. of Birmingham, UK). Objective: study of the energy problem associated with hard X-ray generating electrons. Study of flare models and mechanisms. The instrument consists of an imaging collimator of ten grid plates, each divided into 576 sections, and a position-sensitive detector system consisting of 900 mini-proportional counters. The grids form a coarse FOV 6.35 arcmin in extent and a fine field of view 2.67 arcmin across (with 8 arcsec square pixels). Each pixel is sampled in six energy bands ranging from 3.5 to 30 keV, with time resolution down to 1.25 s.

HXIS served as “flare alarm” to alert the other instruments electronically. Note: HXIS malfunctioned in June 1981 and could not be repaired in the SMM rescue mission in April 1984. The 1980 HXIS data set, however, forms a most impressive record of the spatial and energetic distribution of X-rays in solar flares, with a spatial resolution never before achieved at such high energies.

UVSP = Ultraviolet Spectrometer and Polarimeter (PI: E. Tandberg-Hanssen, MSFC). Objective: Study of UV radiation from the solar atmosphere, in particular from the active regions, flares, prominences, and the active corona. UVSP consists of an aplanatic Gregorian telescope of about 2” resolution, an Ebert-Fastie spectrometer, and five photomultiplier detectors. The telescope secondary is mounted on gimbals and may be rastered to build up an image of an area on the sun of up to 256×256 arcsec, in steps of as little as 1 arcsec. The entrance apertures range in size from 1×1 arcsec to $15 \text{ arcsec} \times 286 \text{ arcsec}$, and the exit slits range from 0.1 to 3.0 Å in second order.

A polarimeter may be inserted behind the exit aperture; it consists of two systems: a three-quarter wave retarder for those wavelengths where the spectrograph grating is an effective linear polarizer, and a quarter-wave retarder and linear polarizer for use at wavelengths at which the grating polarization is very low. The instrument is sensitive to wavelengths of 1170 - 1800 Å in second order and up to 3600 Å in first order.

In April 1985, the UVSP grating drive mechanism became stuck; the grating appeared to be fixed at a wavelength of about 1380 Å (second order; about 2760 Å in first order). During periods of solar activity, UVSP is used in second order to provide pointing and timing information for other SMM instruments; at other times, first order measurements of ozone concentration in the Earth’s atmosphere are carried out at S/C sunrise and sunset (occultation measurements). These unique observations make possible a mapping of ozone concentrations at latitudes of $\pm 50^\circ$ at altitudes of 50 - 75 km. Approximately 20,000 separate ozone altitude profiles were obtained from late 1985 through March 1989.¹⁵⁴¹⁾

XRP = (Soft) X-Ray Polychromator (PIs: J. L. Culhane, U. College, London; K. J. H. Phillips, RAL, UK; K. T. Strong, Lockheed, Palo Alto, CA). Objective: investigation of those aspects of solar activity that lead to the production of plasma temperatures in the 1.5 to 50 million degree range.

The XRP consists of two distinct instruments, the **BCS** = Bent-Crystal Spectrometer (PI: J. L. Culhane) and **FCS** = Flat-Crystal Spectrometer. The FCS is able to rotate its crystals to provide its seven detectors with access to the spectral range 1.40-22.43 Å. The BCS, with a collimator field of view of $6'$, is able to obtain spectra in the range 2-3 Å, at a resolving power $\lambda/\Delta\lambda$ of $\approx 10^4$ with eight position-sensitive proportional counters.

¹⁵⁴¹⁾A. C. Aikin, W. Henze, D. J. Kendig, R. Nakatsuka, H. J. P. Smith, “Variations of Mesospheric Equatorial Ozone as observed by the Solar Maximum Mission,” *Geophysical Research Letters*, Vol. 17, No. 3, March 1990, pp. 299-300

Data: The downlink for science data was considerably improved with the availability of TDRS in April 1983. Data from ground-based sun observations (collation of telescopic data and magnetograms with Solar Max's maps) served as forecasts event-predictions on the sun for instrument precision pointing setup of the flare watch on the actual flare site.

K.23 SOHO (Solar and Heliospheric Observatory)

ESA/NASA collaborative mission within ESA's 'Solar Terrestrial Science Programme' (STSP), part of ISTP (International Solar Terrestrial Physics Programme). So far, SOHO represents the most comprehensive space mission devoted to the study of the sun and of the heliosphere. The following overall mission objectives are pursued:

- Solar spectroscopy at soft X-ray and EUV wavelengths (study of the composition of the solar corona, of the structure and dynamics of the magnetic structures making up the corona, and of coronal holes, etc.)
- Study of the structure and dynamics of the solar interior through the observation of minute oscillations on the sun's surface (helio-seismology).
- Study of the solar wind and solar energetic particles, interaction with the Earth, plasma processes in both the solar and magnetospheric context.

Figure 277: The SOHO S/C model

The spacecraft, built by Matra Marconi Space (MMS), has dimensions of 2.5 m x 2.9 m x 3.9 m (height, and 9.5 m span of the solar array). It is three-axis stabilized within 10 arcsec, with a sun-pointing stability of 1 arcsec over a period of 1.5 minutes. Actuators are 4 reaction wheels and two sets of eight thrusters. Attitude is measured by two fine-pointing sun sensors, two star trackers, and three gyros. Power = 1500 W (solar cells) and 950 W from two 20

Ah NiCd batteries. S/C launch mass = 1875 kg, scientific payload mass = 650 kg, nominal lifetime = 3 years. Within the collaborative mission, the functions are divided in the following way: ESA is responsible for S/C procurement, integration and testing; NASA provides the launch and mission operations from GSFC. A launch from Cape Canaveral occurred on December 2, 1995 aboard an ATLAS-II AS vehicle. ^{1542) 1543) 1544)}

Note: Operational control of the SOHO S/C was lost on June 25, 1998 (when SOHO spun out of control and communication was lost). The first successful attempts to regain control were conducted on Sept. 16, 1998. The S/C was directed to turn its face and solar power panels fully towards the sun. Instrument re-commissioning started on Oct. 5, 1998 with SUMER and ended with CELIAS on Oct. 24, 1998. Final recovery from ESR (Emergency Sun Re-acquisition mode) and full S/C operation of SOHO was regained Feb. 1, 1999. A gyroless mode of operation was devised and installed with a new software patch for a modification of the AOCS (Attitude and Orbit Control Subsystem), making SOHO the first three-axis-stabilized S/C of ESA to be operated without a gyro.

Orbit: Halo orbit around the sun/Earth Lagrangian Point (L1), about 1.5 million km from Earth (see Figure 394 and Table 547). The pointing accuracy of the S/C in the direction of the sun is ≤ 1 arcsec. SOHO was inserted into its halo orbit around L1 on Feb. 14, 1996 (six weeks ahead of schedule - it retained practically all of its hydrazine supply).

Sensor complement: (eight from Europe, three from USA) ^{1545) 1546)}

1) Solar Atmosphere Remote Sensing Instruments

SUMER = Solar Ultraviolet Emitted Radiation (PI: K. Wilhelm, MP Ae, Katlenburg-Lindau, Germany)

Study of plasma flow characteristics (turbulent motions, waves, temperatures, and densities of the plasma in the upper atmosphere of the sun).

The instrument takes images of the sun in EUV light with high resolution in space, wavelength and time. The spatial resolution is 1.2 arcsec; the spectral resolving power is characterized by a $\lambda/\delta\lambda$ of up to 4.0×10^4 ($\delta\lambda$ corresponds to the pixel size). Spectral shifts can be determined with sub-pixel accuracy. Wavelength range = 500 - 1600 Å. Integration can be as short as 1 second. Data: on-line profiles, shifts and broadenings, ratios of temperature- and density-sensitive EUV emission lines in the range between 10^4 and 2×10^6 K.

CDS = Coronal Diagnostic Spectrometer (B. E. R. Harrison, RAL, UK)

Study of the transition region and corona temperature and density (intensity ratios of selected EVU line pairs, with spatial and temporal scales appropriate to the fine-scale features of the solar atmosphere). There will be close collaboration and correlation with SUMER. ¹⁵⁴⁷⁾

The instrument features a Wolter-Schwarzschild type II telescope [designed by MPE Garching, outer f-number = 9.48, focal length = 257.83 cm, FOV = 4 arcmin, on-axis resolution = 2 arcsec (FWHM)], a normal incidence spectrometer (NIS) with a wavelength = 2 bands in 240 - 800 Å range, and a grazing incidence spectrometer (GIS) with a wavelength = four bands in the 150 - 800 Å range.

EIT = Extreme-Ultraviolet Imaging Telescope (J. P. Delaboudinière, IAS/CNRS, France). Study of the evolution of chromospheric and coronal structures (identification and interpretation of the spatial and temperature fine structures of the solar atmosphere). EIT provides full disk images in emission lines formed at temperatures that map the solar structures. Images in four narrow band passes are obtained using normal incidence multilayered optics deposited on the quadrants of a Ritchey-Chrétien telescope. Temperature range of solar structures to be measured: 6×10^4 - 3×10^6 K. Resolution = 1 arcsec (uniform over FOV = 50×50 arcmin). EIT is able to measure the solar transition region and inner corona in four, selected bandpasses in the extreme ultraviolet (EUV):

- Fe IX/X, 171 Å
- Fe XII, 195 Å
- Fe XV, 284 Å
- He II, 304 Å

Using either full-disk or subfield images, the EIT can image active regions, filaments and prominences, coronal holes, coronal “bright points,” polar plumes, and a variety of other solar features. EIT was designed to be used in conjunction with other instruments, in particular LASCO, SUMER and CDS.

UVCS = Ultra-Violet Coronagraph Spectrometer (J. L. Kohl, SAO, USA)

Study of electron and ion temperatures, densities and velocities in the corona (for interpretation of coronal heating, solar wind acceleration, and solar wind composition). Spectroscopic measurements of the solar corona out to 10 solar radii from the sun’s center.

The UVCS instrument consists of an occulted telescope and a high resolution spectrometer assembly. Three off-axis paraboloidal mirrors focus co-registered images of the extended corona onto the three entrance slits of the spectrometer assembly. The spectrometer has three sections. One section is optimized for line profile measurements of H I Lyman- α ; its wavelength range is 1148 - 1248 Å. Another section is optimized for line intensity measurements of O VI λ 1032; it is also used to observe Si XII λ 499 and 521 in second order. The first order range is 932 - 1068 Å. The Mg X doublet at λ 610 and λ 625 may be observed in first order. The third section is used to measure polarized radiance of the visible corona.

Telescope: off-axis parabolic mirror, focal length = 750 mm, image scale = 0.218 mm/arcmin, FOV = 42° (tangential) \times 141° .

Spectrometer: gratings = 105 (disp) \times 70 mm; nominal radius = 750 mm; radius ratio = 1.0259 (1216 Å), = 1.0215 (1032 Å, 625 Å), = 1.0040 (visible); ruling frequency = 2400 mm⁻¹; reciprocal dispersion = 5.63 Å/mm (1st order), = 2.82 Å/mm (2nd order).

Spectral Line	Observed Quantity	Spectral Resolution FWHM (Å)	Spatial Resolution FWHM
H I 1216	Profile	0.2	10" \times 10"
H I 1216	e ⁻ Profile	2.0	1.6' \times 1'
Fe XII 1242	Intensity	1.23	1' \times 1'
Fe XII 1242	Profile	0.14	10" \times 5'
O VI 1032/37	Intensity	1.23	1' \times 1'
O VI 1032	Profile	0.14	10" \times 5'
Si XII 499/521, 2nd order	Intensity	0.61	1' \times 1'
Si XII 499, 2nd order	Profile	0.07	7" \times 5'
Mg X 610/625, 2nd order	Intensity	0.61	1' \times 2.5'
MG X 610, 2nd order	Profile	0.07	7" \times 5'

Table 459: Observational parameter specifications for the UVCS instrument

LASCO = Large-Angle and Spectrometric Coronagraph (PI: G. E. Brueckner, NRL, USA)

Study of structure evolution, mass, momentum and energy transport in the corona. Measurement of electron column densities from just above the limb, at 1.1 R_{sun}, out into deep

heliospheric space, at $30 R_{\text{sun}}$. Spectral analysis of the inner corona with a high resolution scanning, imaging interferometer. Measurement of spectral profiles of three emission lines and one Fraunhofer line for each pixel (providing temperatures, velocities, turbulent motions and volume densities). Direction of coronal magnetic fields via polarization analysis. The LASCO instrument consists of the coronagraph optical system (with three optical systems and CCD cameras) and the instrument control system.

SWAN = Solar Wind Anisotropies (J. L. Bertaux, CNRS, France)

Study of solar wind mass flux anisotropies and temporal variations. The SWAN instrument is a Lyman photometer which maps the sky's interplanetary hydrogen emission almost entirely every other day. From these sky maps, the latitude distribution of the solar wind mass flux from the equator to the pole can be measured, as well as the variation of this distribution (time scale \approx one month).

The instrument consists of two identical sensor units placed on opposite sides of the S/C and driven by a common electronic box. Each sensor consists of a two-mirror scanning system, a light baffle (to keep out stray light), a hydrogen cell in which a tungsten filament is alternately heated to produce Lyman- α absorbing hydrogen atoms and cooled to produce the reference signal. Resolution of Lyman- α light distribution is 1° .

2) Solar Wind “In Situ” Instruments

CELIAS = Charge, Element and Isotope Analysis (D. Hovestadt, MPI, Garching, Germany). Study of ionic energy distribution and composition. Measurement of the mass, ionic charge and energy of the low and high speed solar wind, of suprathermal ions, and of low energy flare particles.

Sensor	Area, Geometric Factor	$\Delta E/E$	Efficiency of the TOF unit
CTOF	0.08 cm^2	0.04	0.25 - 0.65
MTOF	0.013 cm^2	0.03-5	0.03 - 0.1
PM	$7 \times 10^{-5} \text{ cm}^2$	0.05	-
STOF	$0.1 - 0.2 \text{ cm}^2 \text{ sr}$	0.1	0.2 - 0.8

Table 460: Measurement capabilities of the CELIAS instrument

CELIAS includes three mass- and charge-discriminating sensors based on the time-of-flight technique: CTOF (Charge Time-of-Flight) for the elemental, charge and velocity distribution of the solar wind; MTOF (Mass Time-of-Flight) for the elemental and isotopic composition of the solar wind, MTOF also includes a proton monitor (PM); and STOF (Suprathermal Time-of-Flight) for the mass, charge and energy distribution of suprathermal ions. Mass resolution: $M/\Delta M > 100$ MTOF; charge resolution: $\Delta Q \approx 0.3 - 1$, $4 < M < 60$ (typical for CTOF and STOF).

CEPAC = COSTEP/ERNE Particle Analyzer. Collaboration (PI: J. Torsti, ERNE Finland, H. Kunow, U. of Kiel, Germany). Note: COSTEP = Comprehensive Suprathermal and Energetic Particle Analyzer. Three sensors are furnished by the COSTEP consortium: LION (Low Energy Ions and Electrons), MEICA (Medium Energy Ion Composition Analyzer), and EPHIN (Electron Proton Helium Instrument).

Study of energy distribution of particles, energy spectrum and composition. Measurement of particle emissions from the sun over a wide range of species (electrons through iron) and energies (60 keV/particle to 500 MeV/nucleon).

LION instrument consists of two sensor heads each containing a double telescope to measure energy spectra of ions and electrons in the range of 60 keV - 5 MeV for protons, and 60 keV - 300 keV for electrons.

EPHIN is a multielement array of solid state detectors with a plastic scintillator guard counter to measure energy spectra of electrons in the range of 150 keV to $> 5 \text{ MeV}$, and hydrogen and helium isotopes in the range of 4 MeV/n to $> 53 \text{ MeV/n}$.

3) Helio-seismology Instruments

GOLF = Global Oscillations at Low Frequencies (PI: A. Gabriel, IAS/CNRS, France)

Study of the internal structure of the sun by measuring the spectrum of free global oscillations [global velocity and magnetic field oscillations (low degree modes)]. GOLF measures both p and g mode oscillations, with the emphasis on the low order long period waves which penetrate the solar core (frequencies between 10^{-7} and 6×10^{-3} Hz, with a sensitivity of 1 mm/s). The method involves an extension to space of the ground-based technique for measuring the mean line-of-sight velocity of the viewed solar surface. A sodium vapor resonance scattering filter is used in a longitudinal magnetic field to sample the two wings of the solar absorption line.

VIRGO = Variability of Solar Irradiance and Gravity Oscillations [PI: C. Froehlich, WRC (World Radiation Center), Davos, Switzerland] ¹⁵⁴⁸⁾

Study of irradiance oscillations (low degree modes) and the solar constant. The total irradiance is measured with active cavity radiometers PMO6-V and DIARAD (Differential Absolute Radiometer), the spectral irradiance by three-channel Sunphotometers (SPM), and the radiance with 12 resolution elements on the solar disk using LOI (Luminosity Oscillations Imager). A scientific objective is probing the solar interior by helioseismology with p- and g-mode solar oscillations determined from spectral irradiance (SPM) and radiance (LOI) variations to the mission time on time scales of minutes.

VIRGO consists of a number of subunits. The optical system of the VIRGO assembly consists of a Ritchey-Chrétien type telescope with a 1300 mm focal length, diameter of 55 mm, and central obstruction 25 mm. Detector: Deep diffused silicon photodiode with 12 scientific and 4 guiding pixels.

- **PMO6-V** (Physikalisch-Meteorologisches Observatorium, 6th radiometer - VIRGO), built by WRC of Davos, is an active cavity radiometer (absolute instrument) measuring continuously the degradation of the active instrument. Some parameter specifications are: life variation: 30 ppm/year, absolute accuracy: 0.17%, sampling rate: 1 solar total irradiance/2 minutes, duty cycle: 17%, resolution: 50 ppm.
- **DIARAD** (Differential Absolute Radiometer), built by IRMB, Brussels. An active cavity radiometer. It is composed of two cylindrical cavities coated inside with diffuse black and mounted next to each other on the same heat sink. Some parameter specifications are: lifetime variation: 30 ppm/year, absolute calibration: 0.15%, sampling rate: 1 solar total irradiance/3 minutes, duty cycle: 11%.
- **SPM** (Sunphotometer), built by WRC. There are two instruments to measure to measure the spectral irradiance at 335, 500, and 865 nm with a bandwidth of 5 nm.
- **LOI** (Luminosity Oscillations Imager), built by ESA. Measurement of the sun diameter variations with a precision of about 0.3 arcseconds for a 1.5 hour integration time. The LOI wavelength and bandpass is chosen to be the same as the 500 nm channel of SPM. This allows the instruments to be calibrated to each other.

MDI = Michelson Doppler Imager (P. H. Scherer, Stanford University, CA, USA)

Study of velocity oscillations (high degree modes). Measurement of line-of-sight velocity by Doppler shift, transverse velocity by local correlation tracking, line and continuum intensity, and line-of-sight magnetic fields with both 4 and 1.4 arcsec resolution (2 and 0.7 arcsec pixels, respectively).

MDI provides velocity maps by sampling the solar Ni I 6768 Å line profile at four points and finding the Doppler shift by determining the phase of the first Fourier coefficient of the line shape with respect to a reference wavelength.

SOHO Data: On-board recording capability of 1 Gbit of data (requirement of 48 h autonomous operation without ground contact) on a tape recorder and 2 Gbit in solid-state memory. Science data transmission via S-band (2.245 GHz). Downlink data rate at 40 kbit/s (160 kbit/s when MDI is in high rate mode).

¹⁵⁴⁸⁾ <http://virgo.so.estec.esa.nl/>

Some SOHO Highlights

Since SOHO began its mission in 1995, the observatory has provided an unparalleled wealth of information about the sun, from its interior, through the hot and dynamic atmosphere, out to the solar wind. Only a few items are listed here.¹⁵⁴⁹⁾

- Global structure and dynamics of the solar interior: The unprecedented accuracy of helioseismic data from SOHO's MDI, GOLF and VIRGO instruments has enabled substantial improvement in models of the solar interior, and has even shown the importance of considering mixing effects, who in turn solve existing riddles in the isotopic composition of the sun.
- Transition-region dynamics: Several types of transient events have been detected in the quiet sun. Explosive events have been studied using SUMER instrument data.
- Corona: LASCO and EIT are principal instruments. These instruments observed coronal mass ejections (CMEs) that generated subsequent disturbances. These disturbances were observed by other S/C to establish the cause-and-effect relationship for a solar system event that extended from the sun to the solar wind to Earth's magnetosphere and ionosphere. EIT has discovered large-scale transient waves (Coronal Moreton Waves) in the corona that propagate outward from the active regions below CMEs.
- Solar wind: The first tracing of the slow-speed solar wind near the equatorial current sheet
- Solar wind composition: The first detection of elements and isotopes in the solar wind (composition of calcium and nitrogen) observed from data of the CELIAS/MTOF instruments
- Comet hunter SOHO: On Feb. 4, 2000, SOHO discovered its 100th comet. On Aug. 25, 2000, astronomers announced that SOHO had recorded its 200th sun-grazing comet.
- The first image of the convection zone of a star

The scientific achievements of the continuing SOHO mission are the result of a concerted, multi-disciplinary effort by a large international community of solar scientists.

K.24 SOLAR-A (Yohkoh)

Japanese (ISAS) solar-terrestrial mission. The primary objective is the study of high energy phenomena on the sun through X-ray and gamma-ray observations.¹⁵⁵⁰⁾

The S/C has dimensions of 1 m x 1 m x 2 m (height), mass = 420 kg (100 kg science payload), power supply = 450 W (solar cells). Launch on Aug. 30, 1991 by an ISAS M-3SII-6 vehicle; nominal life = 2 years; S/C is three-axis stabilized pointing toward the sun. Status of Yohkoh: As of 4/2001 nominal S/C operations are conducted.

Orbit: apogee = 792 km, perigee = 525 km, inclination = 31.3°, period = 97 minutes

Sensor complement:

- **HXT** = Hard X-ray Telescope. Multipitch bi-grid modulation collimators with NaI scintillators. HXT is a Fourier telescope with 64 collimators covering an energy range from 10 - 100 keV at 7 arcsec resolution for the whole solar disk. HXT mass = 48 kg.
- **SXT** = Soft X-ray Telescope¹⁵⁵¹⁾ (US-Japan collaboration between Lockheed Palo Alto Lab and Tokyo Astronomical Observatory). A grazing incidence soft X-ray mirror with an X-ray CCD detector. SXT uses a 23 cm diameter Wolter-Nariai optics of 155 cm focal length; it covers the energy range from 0.25 - 3 keV at 2 arcsec resolution. Imaging

¹⁵⁵⁰⁾ "The SOLAR-A Mission," The Solar-Terrestrial Science Project of the Inter-Agency Consultative Group for Space Science, ESA SP-1107, November 1990, pp. 74-76

is provided by a 1024 x 1024 pixel CCD behind two six-position filter wheels. Mass = 27 kg. - SXT has produced more than 1 million images of the sun since the S/C was launched.

Figure 278: The Solar-A S/C model

- **BCS** = Bragg Crystal Spectrometer (UK-Japan collaboration, Mullard Space Science Lab and RAL, and Tokyo Astronomical Observatory). Bent crystals with position sensitive proportional counters. Mass = 13 kg
- **WBS** = Wide-band Spectrometer. A set of proportional counters, an NaI scintillator and two BGO scintillators. Measurement ranges: 2 - 30 keV, 20 - 400 keV, and 0.2 - 100 MeV. Mass = 16 kg

Data: On-board recorder (80 Mbit capacity, magnetic bubble). Real-time data transmission of 32 kbit/s, or 262 kbit/s playback data, both to Kagoshima. Downlink communication in S-band and X-band.

K.25 Solar-B

Solar-B is an approved ISAS solar physics mission, a successor to the successful Yohkoh/Solar-A mission of Japan/US/UK. The SOLAR-B mission will be conducted as a multi-institutional and international collaboration including Japan with ISAS (Institute of Space and Astronautical Science), the United States with NASA (GSFC and MSFC), and the United Kingdom with PPARC (Particle Physics and Astronomy Research Council). As the lead agency, ISAS is responsible for the spacecraft, spacecraft integration and the optical telescope. The Solar-B payload consists of a set of high-resolution solar telescopes and spectrometers. The overall goal is to study and understand the dynamic sun and its effect on terrestrial climate (global change) and space weather. Further major science objectives are:

- Comprehensive study of the sun's magnetic fields and a new view into the magnetic dynamics of the plasma universe (first space-based observations of the sun's vector magnetic fields). Understanding basic plasma astrophysics such as the dynamo and magnetic reconnection processes.
- Study of the physics of the sun's luminosity and its variation
- Study of the processes which produce the UV and X-ray emission in the chromosphere and corona
- Study of solar wind energetics. Eruption and expansion of the sun's atmosphere.

The Solar-B spacecraft is three-axis stabilized pointed toward the sun. It is being developed/integrated by Mitsubishi Electric Corporation (MELCO) of Tokyo under ISAS management. Attitude is sensed by IRU (Inertial Reference Unit) gyros with a combination of two sun sensors and a star tracker providing absolute calibration; attitude actuation is provided by four reaction wheels. The pointing stability is in the order of 0.1 arcsec over 10 seconds while finer image stabilization of 0.02 arcsec is achieved for the optical telescope using its own correlation tracker/tip-tilt mirror system. Power of 500 W is provided by two solar arrays (total power of 1 kW). The S/C mass is 900 kg, the mission life is three years.^{1552) 1553)}

The SOLAR-B spacecraft is scheduled for launch in the summer of 2005 on an ISAS M-V-7 launch vehicle from the Kagoshima Space Center (KSC). This will keep the instruments in continuous sunlight, with no day/night cycling for nine months each year.

Figure 279: Illustration of the Solar-B spacecraft ¹⁵⁵⁴⁾

Orbit: Sun-synchronous circular orbit, altitude = 600 km, inclination = 97.9°

An on-board solid-state recorder has a capacity of 5 Gbit. An on-board data compression technique (a special purpose, 12-bit JPEG/DPCM chip) provides either lossy or lossless image compression, dependent on the type of imagery processed. RF communications are provided in X-band and S-band. Downlink data rates are 4 Mbit/s (X-band).

Sensor complement:

SOT (Solar Optical Telescope). SOT represents a joint development between Japan and the US, in which Japan (ISAS and NAO) provides the telescope optics and the US (NASA/GSFC) the FPP (Focal Plane Package). The objective is to obtain continuous high-resolution imagery of the sun. SOT is designed to achieve a consistent 0.2 arcsec spatial resolution.

SOT is a diffraction-limited, aplanatic Gregorian telescope with an aperture of 0.5 m. It provides an angular resolution of about 0.2 arcsec over the field of view of about 328 x 164 arcsec. The focal plane package of the optical telescope consists of a broad- and narrow-band filtergraphs (filter vector magnetographs) and a spectro-polarimeter. This combination allows to obtain, for the first time, a continuous series of high-precision vector magnetograms, Dopplergrams, and filtergrams with sub-arcsec resolution.

XRT (X-Ray Telescope). A cooperative instrument between NASA and ISAS. NASA provides the grazing-incidence mirror optics while ISAS provides the CCD camera. XRT images the high temperature (0.5 to 10 MK) corona with improved angular resolution, say approximately 1 arcsec, a few times better than Yohkoh's soft X-ray telescope.

EIS (EUV Imaging Spectrometer). PPARC provides the EIS instrument with NASA and ISAS participating with some hardware and software. EIS is primarily aimed at observing the dynamics of the solar corona. The objective of EIS is to determine velocity fields and other plasma parameters in the corona and the transition region, thus helping to relate coronal dynamic behavior, observed with the XRT, to the underlying photospheric magnetic field, observed with the optical telescope. The EIS instrument is also expected to unveil inflow and outflow of magnetic reconnection, and hence together with the two other telescopes, to finally solve long-standing controversies on coronal heating and dynamics.

K.26 STEREO (Solar-Terrestrial Relations Observatory)

The STEREO mission is a strategic element of NASA's Sun-Earth Connection program, a multi-institutional and international collaboration involving participants from France, Germany, the Netherlands, Belgium, Switzerland, the United States, and the United Kingdom. The overall objective is to increase the understanding of the origin and consequences of CMEs (Coronal Mass Ejections). The mission consists of two nearly identical spacecraft in heliocentric elliptical orbit in the ecliptic plane at approximately 1 AU from the sun: one drifting ahead of the Earth and one behind. Simultaneous image pairs are obtained by the satellites instruments at gradually increasing separations over the course of the two-year mission. A launch is scheduled for 2004. ¹⁵⁵⁵⁾ ¹⁵⁵⁶⁾ ¹⁵⁵⁷⁾ ¹⁵⁵⁸⁾ ¹⁵⁵⁹⁾

The STEREO S/C bus consists of a box-like structure of size 2.61 m x 1.85 m x 1.73 m. The S/C is built and integrated by JHU/APL with NASA/GSFC procuring the instruments and launch vehicle. The satellite is three-axis stabilized. Attitude sensing is provided by a star camera, two DSAD (Digital Solar Attitude Detector) ¹⁵⁶⁰⁾ systems, an IMU (Inertial Management Unit), and a pointing error signal generated by the instrument guide telescope. Actuation is provided by four reaction wheels and 12 thrusters. A S/C pointing accuracy of 20 arcsec is provided. Two deployed solar arrays generate a power of 544 W (EOL). A Super

NiCd battery of 21 Ah is used for eclipse phase operations. The bus is designed around the IEM (Integrated Electronics Module) and the PSE (Power System Electronics) unit. The IEM contains the RF uplink and downlink cards, power converter cards, and an AIE (Attitude Interface Electronics) card. The cards within the IEM communicate over a PCI (Parallel Communication Interface). The Power System Electronics unit contains relays and control circuitry for the S/C power system. A MIL-STD-1553 bus architecture is used for on-board command and telemetry transmission between the IEM, the instruments, attitude sensors, and the PSE. The spacecraft has a mass of 335 kg and a design life of two years.

An on-board solid-state recorder has a capacity of 7.5 Gbit. RF communications are provided in X-band. The downlink data rate is variable up to about 357 kbit/s. The downlink data modulation is bi-phase shift keyed (BPSK). The uplink modulation is phase modulated (PM). Mission operations are conducted by JHU/APL in conjunction with each POC (Payload Operations Center) for instrument operations.

Figure 280: Illustration of a STEREO satellite ¹⁵⁶¹⁾

S/C operations scenario. The design enables nearly autonomous operations with occasional uplink support and to recover science data on a daily basis. The instrument/satellite operations are decoupled, operating independently from each other. In this setup, the instrument science teams are responsible for the following tasks: a) planning, scheduling and generating of commands; b) instrument health; c) instrument calibration; and d) synchronization of instrument operations with the S/C.

¹⁵⁶¹⁾ Image courtesy of Leslie M. Cusick, NASA/GSFC

The current standard for sun observations is the SOHO (Solar and Heliospheric Observatory) mission with its instrument package. The science objectives of the STEREO project are obviously set to improve on the SOHO observations and to find answers to such questions as:

- Are CMEs driven primarily by magnetic or non-magnetic forces?
- What configuration of the corona leads to CMEs?
- What mechanism initiates a CME?
- What accelerates CMEs?
- How does a CME interact with the heliosphere?
- How do CMEs cause space weather disturbances?

The STEREO mission makes use of simultaneous interplanetary spacecraft operation and stereographic image reconstruction to develop a comprehensive 3-D description of the sun and the heliosphere.

Orbit: Heliocentric elliptical orbit in the ecliptic plane drifting at about 22° from the Sun-Earth line (at nearly 1 AU). The mission profile calls for solar imaging and heliospheric environment sampling by two identical spacecraft (with identical sensor complements) at gradually increasing angular separations from Earth (one drifting ahead of Earth and one behind).

- STEREO Nr. 1 leads Earth by 22° after 1 year
- STEREO Nr. 2 lags Earth by 22° after 1 year

Sensor complement: ¹⁵⁶²⁾

All STEREO instruments involve participation and collaboration of teams from a number of institutions. This applies to instrument design and development as well as to instrument operations, data sharing and analysis.

Phenomenon	Feature size resolved (and/or time step)	Physical properties
CMEs near the sun	40, 000 km = 2×10^{-4} AU (6 min)	Density, velocity, internal structure, extent
Flares	2,000 km	Position, density, structure
Moreton waves	5,000 km	Wave front shape, velocity, underlying magnetic field
Coronal loops	2,000 km	Temperature, density, structure, deflection by waves
Coronal streamers	40,000 km	Distortion by CMEs, extent
Coronal holes	2,000 km	Footprint, spreading
SEPs (Solar Energetic Particles)	2 minutes	3-D distribution function
CMEs near Earth	0.01 AU (images), 1 minute (plasma)	Magnetic field, density, velocity, shape, extent, temperature
Interplanetary shocks	0.02 AU (5 seconds)	Extent, velocity, strength

Table 461: STEREO measurement objectives

The overall measurement strategy calls for:

- Imaging of the solar atmosphere and heliosphere from two perspectives simultaneously
- Tracking of disturbances in 3-D from their onset at the sun to beyond Earth's orbit
- Measurement of energetic particles generated by the disturbances
- Sampling of fields and particles in the disturbances as they pass Earth's orbit.

SECCHI (Sun-Earth Connection Coronal and Heliospheric Investigation), PI: Russell A. Howard of NRL. The instrument is named after one of the first solar physicists, namely A.

¹⁵⁶²⁾ <http://sd-www.jhuapl.edu/STEREO/Inst/payload.html>

Pietro Secchi (1818-1878), who used the new medium of photography to record solar eclipses. The overall objective is to study the 3-D evolution of CMEs from birth at the sun's surface through the corona and interplanetary medium to its eventual impact at Earth. SECCHI consists of a suite of remote sensing instruments: an EUVI (Extreme Ultraviolet Imager), two white-light coronagraphs (COR1 and COR2), and an HI (Heliospheric Imager) package. The EUVI+COR1+COR2 devices are collectively referred to as SCIP (Sun Centered Imaging Package). The SEB (SECCHI Electronics Box) supports all of the SECCHI instruments. The total mass of the SECCHI instrument is 48.1 kg (SCIP=30.2 kg, HI=6.0 kg, SEB=11.9 kg), total power = 44 W.¹⁵⁶³⁾

Parameter	COR1	COR2	HI	EUVI
Instrument type	Internally occulted Lyot coronagraph	Externally occulted Lyot coronagraph	Externally occulted coronagraph	EUV narrow-band-pass Ritchey Chretien telescope
Observable	K-corona and CMEs	K-corona, F-corona and CMEs	K-corona, F-corona and CMEs	Emission line corona and upper chromosphere
FOV (Field of View)	1.25 - 4 R _{sun}	2-15 R _{sun}	12 to > 215 R _{sun} HI-1: 12-84 R _{sun} HI-2: 66-318 R _{sun}	0 to 1.5 R _{sun}
Spatial scale	7.5 arcsec pixels	14 arcsec pixel	HI-1: 35.2 arcsec HI-2: 120 arcsec	1.6 arcsec pixels
FPA (Focal Plane Array)	1024 x 1024 (2kx2k array summed 2x2)	2048 x 2048	1024 x 1024 (2kx2k array summed 2x2)	2048 x 2048
Bandpass	650-750 nm	650-750 nm	450-750 nm	He II: 30.4 nm Fe IX: 17.1 nm Fe XII: 19.5 nm Fe XIV: 21.1 nm
Exposure times	1 s, 3 required for pB	3 s, 3 required for pB	HI-1: 12 s, HI-2: 60 s Exposures >8 required	Fe IX: 3 s Fe XII: 5 s Fe XIV: 7 s He II: 10 s
Maximum cadence	15 s	22 s	HI-1: 1 min HI-2: 8 min	11 s at full resolu. in Fe IX (4.75 s at half resolution)
Synoptic cadence	8 min	20 min	HI-1: 1 hour HI-2: 2 hours	20 min full resolu. 2.5 min half resolu.
Absolute pointing required	7 arcsec occulter positioning	30 arcsec occulter positioning	30 arcmin	3 arcmin FOV overlap
Pointing stability required	1.5 arcsec over pB sequence (7 s)	1.5 arcsec over pB sequence (17 s)	0.5 arcsec for HI-2 sequence (1 hr)	1.7 arcsec over 1 exposure
Long-term pointing required	7 arcsec over a month to obtain background subtraction (F-corona+ stray light) for total B determination		5.0 arcmin to obtain background model	N/A
Aperture diameter	36 mm	30.5 mm	HI-1: 16 mm HI-2: 21 mm	98 mm
EFL (Effective Focal Length)	f/20	f/6	HI-1: f/5 HI-2: f/2 - f/4	f/18
Stray light/disk light rejection	10 ⁻⁶ B _{sun}	10 ⁻¹¹ B _{sun}	HI-1: 10 ⁻¹³ B _{sun} HI-2: 10 ⁻¹⁴ B _{sun}	10 ⁻¹² ratio of visible/EUV
CCD detectors	EEV 42-40, 2kx2K, 13.5 μm pixels, backside illuminated, AR coated (except EUVI), >100 k e ⁻ full well			
Camera	Common electronics, 1 MHz readout rate, 14 bit/pixel quantization			

Table 462: SECCHI instrument specification

The **SCIP** (Solar Centered Imaging Package) contains three compact telescopes to view the solar disk and solar corona. The SCIP structure provides the required alignments, stiffness, and modularity to the three instruments. SCIP also contains the GT (Guide Telescope) that provides fine-pointing information to the S/C attitude control system and to ISS (Instru-

¹⁵⁶³⁾ R. A. Howard, J. D. Moses, D. G. Socker, "Sun Earth Connection Coronal and Heliospheric Investigation (SECCHI)," Proceedings of SPIE, Vol. 4139-26

ment Stabilization System) of the EUVI. The pointing strategy is based on pointing the S/C to minimize the scattered light in COR1 and relying upon the SCIP structure to assure that COR2 and EUVI are within acceptable pointing tolerances. The SCIP and the HI assemblies have their own camera electronics inside their enclosures. These units are known as CEB (Camera Electronics Box). The SCIP camera electronics are composed of three circuit cards with a common backplane interface. The CCD (Charge Coupled Device) camera electronics are designed for independent control of all instrument (COR1, COR2, HI, and EUVI) CCDs, a camera readout rate of 1 Mpixel/s through either of two CCD output ports, and 14-bit data quantization.

- **EUVI** (Extreme Ultraviolet Imager). EUVI observes the chromosphere and innermost corona underlying the same portions of the corona and the heliosphere observed by COR1, COR2, and HI. Four EUV emission lines between 17.1 and 30.4 nm are observed. The EUVI design uses a small Ritchey-Chretien telescope of EIT (EUV Imaging Telescope) heritage on SOHO and of TRACE (Transition Region and Coronal Explorer) mission heritage. The improved mirror coatings, detector array, and telemetry allocation provide a higher sensitivity and image cadence of the EUVI instrument than previously possible. The optical system of EUVI, consisting of entrance filter, shutter, filter wheel, primary mirror and active secondary mirror, and a CCD array, provides pixel-limited imaging throughout the FOV in a compact envelope. The EUVI optics are fully baffled. The CCD detector assembly uses a backside-illuminated, backside-thinned and pacified array of size 2k x 2k with an EUV quantum efficiency >70%. The detector is passively cooled by a radiator. EUVI has its own ISS to satisfy its jitter requirements. The ISS includes the EUVI secondary mirror as the actuator and GT as the high-accuracy angular motion sensor. The EUVI secondary mirror is actuated to compensate for the S/C jitter. The GT is used to provide fine-pointing angular measurements to orient the boresights of the SECCHI telescopes to point toward the geometric center of the sun.
- **COR1** (Coronagraph1 Imager). The objective is to explore the inner corona in white light and pB down to 1.25 R_{sun} . COR1 observes the inner (1.25 - 4 R_{sun}) corona with a high frequency and polarization precision. The COR1 optical design is an all-refractive 7-element system. The instrument FOV is 1.25-4 R_{sun} for a full field width of 2.13° and an aperture diameter of 36 mm. The spectral range is 650-750 nm. Images are collected at three different linear polarization angles. The occulter is attached to the second optical element in COR1, a doublet field lens. The final stage consists of two doublets, along with the filter and polarization optics. The stage takes the chromatically aberrated image of the corona, near the occulter, and relays it onto the CCD detector. The 2k x 2k detector data is summed on-board to 1k x 1k images to produce 7.5 arcsec pixels.
- **COR2** (Coronagraph2 Imager). The objective is to explore the outer corona (2-15 R_{sun}) in white light and pB with high spatial and temporal resolutions. The COR2 design is of LASCO heritage on SOHO. The optical design of the instrument uses a classical externally occulted Lyot design with an entrance aperture diameter of 30.5 mm and an overall length of 1348 mm. The spectral range and polarization technique is the same as COR1 to provide a seamless transition between the two regions.
- **HI** (Heliospheric Imager). The objective is to extend the concept of traditional externally occulted coronagraphs to a new regime, by observing the heliosphere from the sun to the Earth (12-300 R_{sun}). The HI assembly consists of two instruments, HI-1 and HI-2, the exterior baffle systems, the hinged baffle cover, the focal plane packages, the HI camera electronics, and the radiators for the CCDs. - HI-1 looks at the inner heliosphere to within 3.28° of the sun with an opening angle of 20°. The HI-1 camera uses a five-vane forward linear baffle system and a matching linear internal occulter, a 20° full field angle lens, and a 2048 x 2048 pixel format CCD.

Figure 281: SECCHI instrument illustration

The HI-2 camera looks further out, from an elongation of 18.36° , with an opening angle of 70° . The HI-2 objective is set deep within the forward baffle system shadow at a diffraction angle of 16.5° . The HI-2 camera consists of a wide-angle fisheye lens and a CCD detector array.¹⁵⁶⁴⁾

The SEB (SECCHI Electronics Box) provides all command and data handling functions and is the only electronic interface with the S/C. SEB consists of a control computer, interfaces for the camera and CCD, fine-pointing and jitter control electronics, a housekeeping and data acquisition system, and power conversion. A RISC-based single board computer RAD6000 (32 MHz) of Lockheed Martin is used. The image processing and compression software employs such compression routines as Rice (lossless) and a lossy wavelet compression (H-compress) technique.

IMPACT (In-situ Measurements of Particles and CME Transients), PI: Janet G. Luhmann of the Space Sciences Laboratory of UCB (University of California at Berkeley).¹⁵⁶⁵⁾ The IMPACT investigation science focuses on the magnetic connections to the sun and topology of interplanetary CME-related interplanetary disturbances, and the energetic particles that precede and accompany these disturbances as they move toward Earth. IMPACT addresses these with a combination of solar wind electron and solar energetic particle instrumentation that, with the PLASTIC solar wind ion measurements provide the comprehensive, identical in-situ measurements at the two STEREO spacecraft locations necessary to relate what is seen in the SECCHI images to the space weather environment at 1 AU. IMPACT's solar wind electron instruments and magnetometer are mounted on the STEREO boom, while the SEP (Solar Energetic Particles) instruments are on the spacecraft body. All of these instruments use the IDPU (IMPACT Instrument Data

Processing Unit), which serves as a single interface to the spacecraft. The PLASTIC solar wind ion instrument also uses the IMPACT IDPU. IMPACT's boom instruments consist of the electron instruments SWEA (Solar Wind Electron Analyzer) and STE (Suprathermal Electron Telescope) and the magnetometer. The SEP package is also a multi-instrument (4) system, but it is more physically integrated, and so included under one heading here.

SWEA (Solar Wind Electron Analyzer). The objective is designed to measure the distribution function of the solar wind core and halo electrons from about 1 eV to several keV, with high spectral and angular resolution over practically the full spherical range. This capability allows the distinction between these components in detail during both undisturbed periods

¹⁵⁶⁴⁾ <http://www.pxi.com/SECCHI>

¹⁵⁶⁵⁾ <http://sprg.ssl.berkeley.edu/impact/>

and the passage of CME generated disturbances, when the interplanetary field rotates far out of the ecliptic plane.

SWEA consists of a hemispherical top hat ESA (ElectroStatic Analyzer) that provides a 360° FOV in a plane, combined with electrostatic deflectors to provide nearly 4π coverage when SWEA is mounted at the end of the STEREO boom. The inner plate radius is 3.75 cm and the plate separation is 0.28 cm. The resulting energy resolution dE/E is 18%, and the geometric factor is $0.01 \text{ cm}^2 \text{ sr E (eV)}$. SWEA compensates for the effects of spacecraft potential on the lowest energy particles by having an outer hemisphere that can be biased according to the plasma density measured by the PLASTIC solar wind ion instrument.

STE (Suprathermal Electron Telescope). STE is a new instrument that covers electrons in the energy range of about 2-20 keV with approximately 50 times the sensitivity of previous instruments. These higher energy electrons are frequently accelerated in flares or impulsive flare-like bursts, and they produce solar type III radio bursts as they escape the sun. They provide a unique tracer of the footpoints of CME and normal interplanetary magnetic fields, and allow the measurement of the length of those field lines. In addition, an electron superhalo is continuously present in the interplanetary medium at those energies. STE utilizes passively cooled SSDs (Silicon Semiconductor Devices) that measure all energies simultaneously. The STE consists of two detector arrays of four SSDs in a row, each about 0.1 cm^2 in area and about $500 \mu\text{m}$ thick. Each array looks through a rectangular opening that provides a FOV of about $20^\circ \times 80^\circ$ for each SSD with the 80° direction perpendicular to the ecliptic. Adjacent FOVs are offset for a total FOV of about $80^\circ \times 80^\circ$. The two arrays are mounted back-to-back, looking in opposite directions, centered about 25° from the average Parker Spiral field direction. STE is located just inboard of SWEA on the STEREO boom to clear its FOV and remain in shadow.

MAG (Magnetometer). The MAG system is a simplified version of the magnetometers flown on Mars Global Surveyor and Lunar Prospector. It is a triaxial fluxgate design, mounted on the STEREO boom (about 4m) just inboard of the SWEA and STE instruments. The fluxgate sensors use a ring core geometry, with magnetic cores consisting of permalloy. The units are compact, low power, and ultra-stable. To optimize sensitivity at the low field values to be found in interplanetary space, the magnetometer dynamic range is divided into 8 ranges that are automatically switched whenever the field being measured exceeds or falls below predetermined levels. The maximum range is sufficiently large to allow IMPACT MAG magnetic field measurements in the Earth's magnetic field during the commissioning phase orbits.

SEP (Solar Energetic Particles) package. SEP consists of 4 separate instruments that cover the full solar energetic particle energy, flux and composition ranges needed to meet the STEREO science goals. The SEP instruments include the SEPT (Solar Electron Proton Telescope), SIT (Suprathermal Ion Telescope), LET (Low Energy Telescope), and the HET (High Energy Telescope). Together, the SEP instruments measure electrons, protons and heavier ions from several tens of keV to approximately 100 MeV (or MeV/nucleon).

- **SEPT** (Solar Electron Proton Telescope). SEPT consists of two dual, double-ended magnet/foil solid state detector particle telescopes that cleanly separate and measure electrons in the energy range 20-400 keV and protons from 20-7000 keV, while providing anisotropy information through the use of several FOVs. Each SSD detector in SEPT is $300 \mu\text{m}$ thick and 0.53 cm^2 in area. A rare-earth permanent magnet is used to sweep away electrons for ion detection, while a parylene foil transmits electrons but stops protons. SEPT is divided into two pieces for FOV reasons. The SEPT-E telescope is housed with the rest of the SEP package, located on the body of the S/C. It looks in the ecliptic plane along the Parker Spiral magnetic field direction, both forward and backward. SEPT-N/S is housed separately at a different spacecraft location and looks out of the ecliptic plane perpendicular to the nominal magnetic field, both north and south. The viewing cones for the SEPT telescopes are each about 60° .

- **SIT** (Suprathermal Ion Telescope). SIT is a time-of-flight ion mass spectrometer that measures elemental composition of He-Fe ions over the energy range of about 30 keV/nucleon to 2 MeV/nucleon. The FOV angles are $17^\circ \times 44^\circ$, with the 44° angle in the ecliptic plane, centered approximately 60° from the spacecraft-sun line to avoid sunlight while still intercepting significant numbers of Parker Spiral field controlled energetic ion fluxes. The telescope analyzes ions that enter through thin entrance foils and stop in a solid state detector. A time-of-flight approach for determining the composition utilizes start and stop times obtained from secondary electrons entering a MCP (MicroChannel Plate) detector system. The MCP and SSD areas are each 6.0 cm^2 . The SIT geometric factor allows study of even small SEP events.
- **LET** (Low Energy Telescope). LET is a special double-fan arrangement of 14 solid-state detectors designed to measure protons and helium ions from about 1.5 to 13 MeV/nucleon, and heavier ions from about 2 to 30 MeV/nucleon. LET uses a standard dE/dx vs. E-technique, identifying particles that stop at depths of about 20-70 μm and about 70-2000 μm corresponding to two general energy ranges. The large FOV spans from 20° above to 20° below the ecliptic plane and extends 65° to either side of the forward and backward Parker Spiral field directions in the ecliptic plane. Like SIT, LET's large geometric factor also ensures the detection of even small SEP events.
- **HET** (High Energy Telescope). HET also uses the solid-state detector, dE/dx vs. E-approach, but in a six-detector, more traditional linear arrangement designed to measure protons and helium ions to 100 MeV/nucleon and energetic electrons to 5 MeV. HET identifies particles that stop at depths of 1 to 8 μm in the detectors. Some information will also be obtained on heavier nuclei up through Fe using the dE/dx vs. E signatures and ranges together, and penetrating particles will be analyzed. The FOV covers a 47.5° cone around the Parker Spiral field direction. SIT, LET and HET are all packaged together with the SEPT-E subsystem and a SEP CPU (Central Processing Unit) in the main SEP package on the spacecraft body, but they use the IMPACT IDPU to interface with the spacecraft together with the rest of IMPACT.

PLASTIC (PLAsma and SupraThermal Ion and Composition), PI: Antoinette Galvin of UNH (University of New Hampshire), cooperation of UNH, University of Bern, Switzerland, MPE Garching, Germany and NASA/GSFC. The objective of PLASTIC is to study coronal SW (Solar Wind) and solar wind-heliospheric processes. The science objective is to measure ions in the energy-per-charge range of 0.2 to 100 keV/e. The instrument performs three functions in one package: ¹⁵⁶⁶⁾

- Measurement of the distribution functions of solar wind protons and alpha particles (providing density, velocity, kinetic temperature and its anisotropy), with a time resolution of about one minute.
- The SW sector also provides, on at least five minute resolution, the elemental composition, charge state distribution, kinetic temperature, and velocity of the more abundant solar wind heavy ions (e.g., C, O, Ne, Mg, Si, and Fe).
- The PLASTIC Wide Angle Partition measures the distribution functions of suprathermal ions H through Fe, with a comparatively large geometrical factor that allows the study of suprathermal particles, including shock-accelerated particles and pick up ions. Together with IMPACT measurements, PLASTIC completes the required STEREO mission in-situ observations.

SWAVES (STEREO/WAVES), an interplanetary radio burst tracker. PI: Jean-Louis H. Bougeret of CNRS (Centre National de la Recherche Scientifique) Observatory of Paris. The goal of the SWAVES radio and plasma waves investigation is to obtain unique and critical observations for all primary science objectives of the STEREO mission, the generation of CMEs, their evolution and their interaction with Earth's magnetosphere. SWAVES can

¹⁵⁶⁶⁾ <http://stereo.sr.unh.edu/>

probe a CME from lift-off to Earth by detecting the coronal and interplanetary (IP) shock of the most powerful CMEs, providing a radial profile through spectral imaging, determining the radial velocity from about $2 R_{\text{sun}}$ (from center of sun) to Earth, measuring the density of the volume of the heliosphere between the sun and Earth, and measuring important in situ properties of the IP shock, magnetic cloud, and density compression in the fast solar wind stream that follows. SWAVES achieves these goals by measuring IP (Interplanetary) type II and type III radio bursts, both remotely and in-situ.¹⁵⁶⁷⁾

- SWAVES antenna system. SWAVES uses three mutually orthogonal monopole stacer antenna elements as its prime sensors, each 6 meters in length. The three monopoles are deployed away from the sun so that they remain out of the fields of view of sunward looking instruments. The antenna design optimizes the radio burst tracking in the 16MHz - 30kHz range and maintains a high SNR for expected solar type II, type III and other solar and IP radio emissions.
- Preamplifiers. A high input impedance preamplifier is connected to each of the three electric monopoles.
- Radio receivers. There are five radio receivers in the SWAVES instrument to cover the following frequency ranges: 1) LFR Lo: 10-40 kHz; 2) LFR Hi: 40-160 kHz; 3) HFR: 0.125-16 MHz; 4) FFR1: 50 MHz fixed frequency; 5) TDS: 250,000 samples/s time series snapshots.
- Housekeeping and low-rate science. This system provides digitized and selectable housekeeping data to monitor the status and health of the various parts of the instrument.
- Calibration. The instrument contains its own internal calibration circuitry. An internal calibration sequence will be invoked about once per day.

The focal point of SWAVES instrument commanding and operations will be performed at the UMN (University of Minnesota).

Space weather data. “Real-time” in situ space weather data products from IMPACT and PLASTIC, consisting of approximately 1 minute cadence information on solar wind electrons and ions, solar energetic particles and magnetic fields are packaged in the data stream from the IMPACT IDPU with the regular coded science and housekeeping telemetry from the instruments.

K.27 TWINS (Two Wide-angle Imaging Neutral-atom Spectrometers)

TWINS is a collaborative Sun-Earth connection two-satellite mission of NASA, LANL (Los Alamos National Laboratory), JHU/APL, SwRI (Southwest Research Institute), USC (University of Southern California), WVU (West Virginia University), and The Aerospace Corporation. The overall mission objective is to demonstrate a new capability of stereoscopic imaging of the magnetosphere. By imaging the charge exchange neutral atoms over a broad energy range (about 1-100 keV) using two identical instruments on two widely spaced high-altitude and high-inclination spacecraft, TWINS will enable the 3-three-dimensional visualization and the resolution of large scale structures and dynamics within the magnetosphere for the first time. Areas to be studied by TWINS include:¹⁵⁶⁸⁾ ¹⁵⁶⁹⁾

- Neutral atoms and charged particles
- The Earth’s magnetic field
- Geomagnetic storms and substorms
- Auroras
- The 11-year solar cycle
- Space weather - the effects of the sun on human life on earth and in space.

¹⁵⁶⁷⁾ <http://www-lep.gsfc.nasa.gov/swaves/swaves.html>

¹⁵⁶⁸⁾ D. J. McComas, “Two Wide-Angle Imaging Neutral-Atom Spectrometers,”

¹⁵⁶⁹⁾ <http://nis-www.lanl.gov/nis-projects/twins/>

The feasibility of magnetospheric imaging using ENAs (Energetic Neutral Atoms), which arise from the charge exchange process between cold geocoronal neutral hydrogen and local energetic ion populations, was first demonstrated in the early 1990s (ENAP on ATLAS-1 (STS-45 flight, launch March 24, 1992). The POLAR mission (launch Feb 24, 1996) flies the CEPPAD/SEPS (Comprehensive Energetic-Particle Pitch Angle Distribution / Source Loss Cone Energetic Particle Spectrometer) instrument package capable of detecting ENAs. The SAC-B mission (launch Nov. 4, 1996) had ISENA (Imaging Spectrometer for Energetic Neutral Atoms) of CNR/IFSI on-board. Unfortunately, the third stage of the SAC-B launch vehicle failed to separate from the S/C, thus preventing any operations. The IMAGE mission of NASA (launch March 25, 2000) employs three ENA imagers (LENA, MENA, HENA). It is expected that the imagery obtained by the TWINS constellation (two widely-spaced high-altitude spacecraft) may revolutionize the study of the magnetosphere.

Each S/C is three-axis stabilized and approximately nadir pointing.

The first TWINS S/C is planned to be launched by early 2002, and the second one by early 2004, providing a full two year stereo mission beginning in 2004.

Orbit: An EEO (Elliptical Earth Orbit) or a Molniya-type orbit, perigee = 300 km, apogee = $7.2 R_E$ or 46,000 km, inclination = 63.4° , period about 12 hours. The majority of the orbital period is spent near apogee.

Sensor complement: The instrument package consists of TEI and a Lyman imager to monitor the geocorona. Both instruments are mounted on a rotating actuator platform to allow 360° azimuthal viewing.

TEI (TWINS ENA Imager). TEI is of MENA instrument heritage flown on NASA's IMAGE mission. TEI measurements of neutral H, He, and O cover an energy range of about 1-100 keV with $4^\circ \times 4^\circ$ angular resolution and a 1 minute time resolution. The sensor heads and the signal processing electronics of TEI, including signal amplification, trajectory calculation, time-of-flight (TOF) determination, and pulse height analysis, are identical to those of MENA on the IMAGE mission.

The primary differences between MENA and the TEI are the DPU and the way the viewing plane is moved across the sky, both of which are spacecraft-driven. For IMAGE, the S/C spin sweeps the MENA field of view (FOV) across the sky. Because the TWINS S/C are three-axis stabilized, the sensor heads are mounted on a rotatable actuator which sweeps the FOV over all pertinent look directions. The fundamental measurements made by TEI are:

- Trajectory measurement of an ENA using the detected positions of the ENA and secondary electrons emitted as the ENA transits an ultrathin foil
- TOF measurement between an ENA and its correlated secondary electrons
- Pulse height analysis of the detected signals.

Imaging is derived from the trajectory measurement. Speed is derived from the trajectory and TOF measurements, and the ENA mass is inferred from the speed and pulse height analysis.

The collimator plates have a 2.7 cm inner radius and a 9.8 cm outer radius. The gap between adjacent plates is 0.5 cm. This geometry yields a 4° FWHM azimuthal FOV and, with the plates alternately grounded and biased to +10 keV, rejects ions and electrons up to an energy of 130 keV/q, where q is the ion charge.

ENAs and associated secondary electrons strike a standard 10 cm x 10 cm MCP (Micro-channel Plate) detector in a chevron (2-plate) configuration. An electric field, which is applied at the entrance surface of the MCP detector, using a grounded suppression grid and a +100 V bias on the front of the MCP detector, increases both the detection efficiency and the spatial resolution. TWINS employs MCPs with a 60:1 length-to-diameter channel ratio.

Parameter	Value	Comment
Geometric factor	0.038 cm ² sr	Two heads
Polar FOV	±60° FWHM	Imaged
Polar resolution (mass and energy dependent)	4° FWHM	Imaged, best case
Azimuthal FOV	±2° FWHM	Collimated
Azimuthal resolution	4° FWHM	Collimated
Energy range	1-100 keV	TOF window for H
Mass identification	H, O	TOF+PHD
Energy resolution ($\Delta E/E$)	0.4	TOF+mass
Time resolution	60 s	Actuator rotation period
UV rejection	4.7 x 10 ⁻⁹	Worst case

Table 463: Performance parameters of TEI

Lyman- α detector. The objective is the measurement of the geocoronal H density. The instrument consists of the following elements: Baffle, BP filter, and Channeltron detector. Data is collected with 2° azimuthal angle spacing.

Aperture area	3.2 cm ²
FOV (Field of View)	4° FWHM, 2 detectors with lines-of-sight offset by ±40° with respect to rotation axis
Wavelength, wavelength resolution	121.584 nm, ±5 nm
Sensitivity	0.1-0.5 counts/s/R
Sampling	Every 2° azimuthal motion (0.667 s)

K.28 Ulysses

A joint ESA/NASA project which started in 1977 under the name of 'Out-of-ecliptic' mission; it was later renamed ISPM (International Solar-Polar Mission), and was given its final

name 'Ulysses' in 1984. The overall objective of Ulysses is to explore the sun's polar regions (first-ever study of the particles and fields in the inner heliosphere at all solar latitudes, including the polar regions). Particular emphasis is on the study of the solar wind, the interplanetary magnetic field, and the complex wave and particle interaction phenomena that exist in the interplanetary medium. Naturally there is international collaboration and coordination of the Ulysses mission with other ISTP projects like: INTERBALL (K.17), SOHO (K.23), WIND (K.30), and SOLAR-A (Yohkoh, K.24). 1570) 1571) 1572) 1573) 1574)

The structure of the Ulysses S/C is a box-shaped aluminum bus. The S/C is spin-stabilized (5 rpm); a high-gain communication antenna (HGA) with a 1.65 m diameter dish is mounted onto the spin axis; the dish is pointing toward the Earth continuously. The AOCS (Attitude Control System) is comprised of the redundant sun-sensor system, the AOCE (Attitude and Orbit Control Electronics), the AME (Attitude Measurement Electronics) and the RCE (Reaction Control Equipment). Power is provided by RTG (Radio-isotope Thermoelectric Generator), with 285 W at start and 244 W at the end of the first solar cycle. Two sets of 4 x 2 N hydrazine thrusters (33 kg of propellant) provide spin control and trajectory corrections. The S/C is thermally controlled by passive means (radiators, thermal paints, and thermal blankets) and by heaters. S/C total mass of 370 kg, mass of science payload = 55 kg. Booms: radial dipole antenna of 72.5 m length, axial monopole antenna of 7.5 m length, and a radial magnetometer boom of 5.6 m length. Major contributions: ESA [funding of S/C, S/C operations, 50% of experiments by ESA member states]; NASA [funding of S/C launch, provision of RTG, use of DSN (Deep Space Network) and JPL control center, 50% of experiments]. The S/C was built by an industrial consortium with Dornier System as the prime contractor.

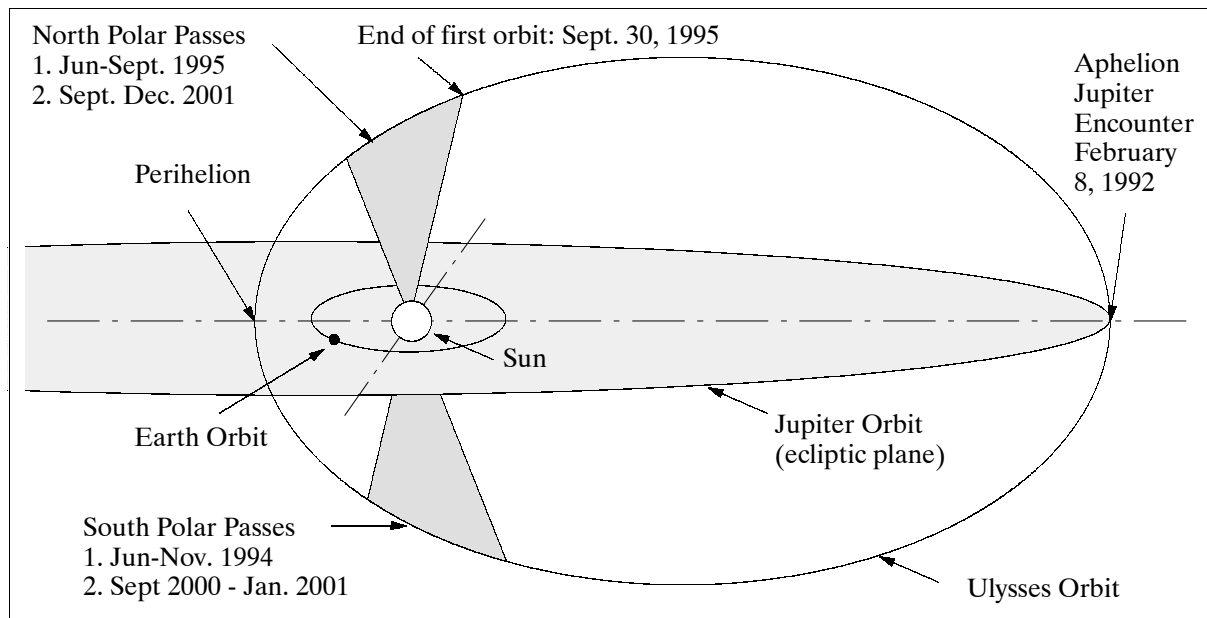

Figure 283: The Ulysses flight path as viewed from 15° above the ecliptic plane

Data communications: X-band downlink (20 W, 8.4 GHz frequency) and S-band uplink/downlink (5 W, 2112 MHz uplink and 2293 MHz downlink). Telemetry data at 1.024 kbit/s (real-time) and at 512 bit/s of storage data. Two redundant tape recorders have a capacity of

45.8 Mbit each. Ulysses is tracked 8 hours/day by the 34 m antennas of NASA's Deep Space Network. Mission operations are supported by a joint ESA/NASA team at NASA/JPL.

The Ulysses S/C along with the Inertial Upper Stage (IUS) was launched on the Shuttle mission STS 41 (Discovery), October 6, 1990, from Cape Canaveral, Florida.

Orbit: The Ulysses probe is the first S/C having left the ecliptic plane to observe the poles of the sun. ¹⁵⁷⁵⁾ ¹⁵⁷⁶⁾ ¹⁵⁷⁷⁾ The orbital change into a normal plane to the ecliptic was achieved with a sling-shot flyby, a gravity-assist maneuver, of Jupiter (Feb. 8, 1992). The S/C operates at heliocentric ranges which vary between 1.34 and 5.4 AU (where the solar flux varies between 1400 Wm^{-2} and 45 Wm^{-2}) inclined 79.1° to the ecliptic. The portions of the orbit when Ulysses is above 70° solar latitude have been designated as "polar passes." The first such polar pass occurred in 1994 (south) and 1995 (north). The S/C takes 6.2 years to complete one orbit of the sun. The second set of polar passes takes place from Sept. 2000 to Jan. 2001 (south) and Sept. to Dec. 2001 (north).

Figure 284: The Ulysses S/C model

Sensor complement:

COSPIN = Cosmic-ray and Solar Particle Investigation (PI: J. A. Simpson, U. of Chicago). Objective: Measurements of solar and interplanetary particles to characterize their intensities, energy spectra, anisotropy and composition as a function of solar latitude. The instrument comprises five solid-state detector telescopes and a double Cerenkov/semiconductor

telescope; energy range = 0.3-600 MeV/n for nuclei and 1-300 MeV for electrons. In addition, one of the telescopes provides measurements of the isotropic composition of galactic cosmic-ray nuclei up to iron (transport of particles). Mass=14.6 kg, power=14.7 W, data rate=160 bit/s.

DUST = Dust Experiment (PI: E. Grün, MPIK, Heidelberg). Objective: Measurement of the properties (mass, speed, direction, and electric charge) and distribution of cosmic dust particles in the solar system. The instrument consists of a large hemispherical sensor and a data processing unit. The sensor is made up of a grid system for the measurement of particle charge, an electrically grounded and gold-plated target (hemisphere), and a negatively biased ion collector. Instrument mass=3.8 kg, power=2.2 W, data rate=8 bit/s.

EPAC/GAS = Energetic Particle Composition Experiment/Interstellar Neutral Gas Experiment (PI: E. Keppler, MPAe, Lindau). Objective: Measurement of the intensities, anisotropies, composition and energy spectra of energetic interplanetary ions in the energy range 0.4-15 MeV/n. Study of the acceleration and transport of low-energy ions of both solar flare and interplanetary origin, with emphasis on their characteristics at high solar latitudes. EPAC consists of a four-telescope detector system. Each telescope contains one epitaxial detector and two surface-barrier detectors. The telescopes are arranged in such a way that between them they cover 80% of a full sphere per S/C spin.

GAS Objective: Direct observations of interstellar neutral helium atoms that have penetrated the heliosphere. Measurement of the parameters (density, bulk velocity relative to the solar system, and temperature) of interstellar gas. The instrument consists of a sensor employing CEM (Channel Electron Multiplier) detector elements. The instrument is mounted on a rotating platform with a scan angle of 180° and is mechanically attached to an electronics box. Total mass=4.3 kg, power=4.1 W, data rate=16 bit/s.

Event		Date
Launch		October 6, 1990
Jupiter flyby		February 8, 1992
1st polar pass of sun (a polar pass is considered the period above 70° solar latitude)	Start Maximum latitude (80.2°S) End	June 26, 1994 September 13, 1994 November 5, 1994
Perihelion		March 12, 1995
2nd polar pass of sun	Start Maximum latitude (80.2° N) End	June 19, 1995 July 31, 1995 September 29, 1995
Start of 2nd solar orbit		October 1, 1995
3rd polar pass of sun	Start Maximum latitude (80.2° S) End	September 8, 2000 November 27, 2000 January 16, 2001
Perihelion		May 26, 2001
4th polar pass of sun	start maximum latitude (80.2° N) end	September 3, 2001 October 13, 2001 December 12, 2001
End of mission		December 31, 2001 (or later)

Table 465: Key dates during the Ulysses mission

FGM/VHM = Fluxgate Magnetometer/Vector Helium Magnetometer (PI: A. Balogh, Imperial College, London). Objective: In-situ observations of the helio-latitude dependence of the interplanetary magnetic field (structure, characteristics, topology, dynamic properties, etc.). Both magnetometers are boom-mounted to eliminate the magnetic effects of the S/C (resolution of 4 pT in the most sensitive range). The FGM instrument is based on three ring-core fluxgate sensors arranged in an orthogonal triad. The VHM sensor measures magnetic fields by their effect on the efficiency with which metastable helium can be optically pumped. Changes in optical pumping efficiency are dependent on the magnetic-field intensity and its angle with respect to the optical axis of the sensor. Mass=4.7 kg, power=5.4 W, data rate=80 bit/s.

GRB = Gamma-Ray Burst Experiment (PI: K. C. Hurley, UCB). Objective: Measurement of the intensity and the spectral characteristics of X-ray and gamma-ray bursts of solar and cosmic origin. Localization of the sources of bursts of high-energy photons. The instrument consists of a gamma-ray sensor and a soft X-ray sensor mounted on the S/C radial boom, and a data processing unit inside the S/C. The gamma-ray sensor consists of two hemispherical CsI scintillation crystals coupled to PMT detectors; FOV = 4π (nearly unobstructed view); energy range = 15-150 keV. The soft X-ray sensor measures X-rays in the energy range 5-15 keV; it consists of two Si surface-barrier detectors and front-end electronics passively cooled to -50°C. Mass=2.0 kg, power=2.6 W, data rate=40 bit/s.

HI-SCALE = Heliosphere Instrument for Spectra Composition and Anisotropy at Low Energies (PI: L. J. Lanzerotti, AT&T Bell Labs). Objective: Measurement of interplanetary ions and electrons at the lowest energies covered by the suite of energetic-particle experiments. Ions at energies > 50 keV and electrons above 30 keV are detected by five separate solid-state detector telescopes, oriented to give essentially complete pitch-angle coverage of the spinning S/C. Two of the telescopes contain magnets that prevent low-energy electrons from reaching the detectors, permitting clean ion measurements. Thin aperture foils that stop low-energy ions but allow electrons to pass freely are included in the 3rd and 4th telescopes. The 5th telescope performs ion-composition measurements (three detector elements). Mass=5.8 kg, power=4.0 W, data rate=160 bit/s.

SWICS = Solar Wind Ion Composition Spectrometer (PI: G. Gloeckler, U. of Maryland; J. Geiss, U. of Bern). Objective: Measurement of the chemical and ionic-charge composition of solar-wind ions, as well as their temperatures and mean speeds. Detection of all major solar-wind ions from H through Fe, at solar-wind speeds ranging from 145 km/s (protons) to 1352 km/s (Fe^{+8}). The instrument consists of an electrostatic analyzer (fan-shaped collimator enclosing the electrostatic deflection system), a time-of-flight telescope (contained in a drum-shaped high-voltage bubble), and solid-state proton/alpha detectors. Measurement of ion energy per charge, mass, and total energy, determination of the atomic mass (by combining the speed and total energy signals), and the ionization state of the particle (by combining the energy per charge and total energy values). Mass=5.6 kg, power=4.0 W, data rate=88 bit/s.

SWOOPS = Solar Wind Observations Over the Poles of the Sun (PI: J. L. Phillips, LANL). Objective: Observation of the solar-wind flow at middle-to-high solar latitudes for the construction of a representative model of the heliosphere. Measurement of the bulk flow parameters (density, speed and direction) of the solar wind in three dimensions at all heliocentric distances and heliographic latitudes reached by the S/C. SWOOPS consists of two independent instruments, each making use of a curved-plate electrostatic analyzer and CEM (Channel Electron Multiplier) detectors. The CEMs are arranged so that particle velocity distributions can be resolved for all orientations of the S/C spin axis. Electrons with energies between 1-900 eV are detected; the measurement range for ions is 35 to 257 eV/Q. The ion instrument incorporates a stepper-motor-driven aperture wheel with seven apertures. Mass=6.7 kg, power=5.5 W, data rate=160 bit/s.

URAP = Unified Radio and Plasma-Wave Experiment (PI: R. J. MacDowall, NASA/GSFC). Objective: Detection of distant radio wave emissions (via remote sensing) and detection of locally-generated plasma waves; tracking of solar radio noise bursts as they travel away from the sun for the study of the heliospheric magnetic field and solar wind flows. The antennas used by this experiment consist of a pair of wire booms (72 m tip-to-tip) lying in the S/C spin plane forming a dipole, and an axial boom (7.5 m long) which forms a monopole antenna along the S/C spin axis. Mass=7.4 kg (excluding antennas), power=10 W, data rate=232 bit/s.

GWE = Gravitational Wave Experiment (PI: B. Bertotti, U. of Padua). Objective: Search for low-frequency wide-band gravitational waves thought to be emitted from various sources. If Ulysses is exposed to a burst of gravitational waves, then the S/C will experience a

minute perturbation in its orbital velocity, which in turn produces a characteristic noise component in the Doppler-shifted radio signal received on the ground.

SCE = Solar Corona Experiment (PI: M. K. Bird, U. of Bonn). Two radio-science experiments are being carried out with the Ulysses S/C by making use of the S/C and ground communication equipment (SCE and GWE). SCE conducts coronal sounding using dual-frequency ranging and Doppler measurements during times of superior conjunction in order to determine the electron flux density and solar-wind velocity in the solar corona (also mapping of the electron content in the high-latitude heliosphere).

Two radio science investigations, using the spacecraft and the ground communication equipment, were conducted during specific missions periods.

K.29 Viking

The Viking project is a Swedish satellite mission, funded by the Swedish Board of Space Activities, and managed by SSC (Swedish Space Corporation) with international cooperation on sensors. Objectives: Study of the physical processes associated with the interaction of the solar wind with the Earth's magnetosphere (establish the region for acceleration of auroral particles and the mechanisms involved, behavior of the resulting Aurora Borealis) in the high latitude medium height (1-2 R_e) regions. ¹⁵⁷⁸⁾ ¹⁵⁷⁹⁾ ¹⁵⁸⁰⁾

Launch Feb. 22, 1986 by Ariane V16 from Kourou (piggyback payload with SPOT-1). The satellite was attitude controlled (spin stabilized at 3 rpm, cartwheel mode, magnetic control), size approximately 1.9 x 0.5 m, satellite mass in orbit = 286 kg, payload mass = 44.7 kg (68 kg including booms and antennas). S/C size: 1.9 m diameter, 50 cm height. S-band downlink at 49.6 kbit/s data rate. Power from solar cells on spacecraft body totalling 2.2 m², providing 80 W average power. No onboard data storage.

The design life of Viking was 8 months, the satellite provided data for 15 months (end of mission May 12, 1987).

Orbit: Polar orbit, apogee = 13530 km, perigee = 817 km, inclination = 98.8°, orbital period = 262 min, drift of rising node = 0.17°/day, rotation of line of apsides = -0.50°/day. It took 8 months for the apogee to move from a starting point with a latitude of about 40° N up over the polar region and down to the equator. After these 8 months the apogee was in the southern hemisphere. Note: there was no on-board storage capability and there was no receiving station in the Antarctic region; hence, measurements could only be made at low altitudes from the Esrange/Kiruna ground station.

Sensor complement:

V1: Electric Field Experiment (PI: Lars Block of RIT, also involved: ESTEC and UC Berkeley). Measurement of the DC electric field by three orthogonal pairs of spherical probes.

- Four wire booms, each 40 m long
- Two rigid booms, 4 m each
- 53 or 106 samples per second
- data rate = 4.3 kbit/s
- mass = 4.7 kg (without booms)
- power = 7.3 W

¹⁵⁸⁰⁾ "The Viking Program," EOS Transactions, American Geophysical Union, Volume 67, No. 42, Oct. 21, 1986, pp. 793-795

Figure 285: The Viking S/C model

V2: Magnetic Field Experiment (PI Tom Potemra of APL, also involved: IRF-U. of Sweden, GSFC/NASA, and U. of Kyoto). The V1 and V2 experiments have the same sampling rates to determine whether the variations in the electric and magnetic fields are due to fine-scale currents or waves.

- three-axial fluxgate magnetometer system on a 2 m long radial boom
- 53 samples per second
- four ranges of measurement: from $\pm 65536 (\pm 8)$ nT to $\pm 1024 (\pm 0.125)$ nT
- data rate = 2.2 kbit/s
- mass = 2.1 kg
- power = 1.1 W

V3: Hot Plasma/Energetic Particle Experiment (PI R. Lundin of IRF, also involved: U. of Bergen, MPI Lindau, Los Alamos National Laboratory, Aerospace, APL, RAL). Measurement objectives:

- electrons with spectral resolution $\Delta E/E \sim 0.05$, from 10 eV to 40 keV
- electrons with angular resolution $\Delta \alpha \leq 2^\circ$ from 0.1 keV to 300 keV
- energy and pitch angle distributions of ions $\Delta E/E \sim 0.08$, $\Delta \alpha \leq 6^\circ$ from 40 eV to 40 keV
- three-dimensional distribution functions of ions from the satellite potential to 10 keV
- composition, energy, and pitch angle distribution of ions up to 10 MeV/nucleon.

All these measurements can be made simultaneously. The instrument consists of seven units covering different kinds of particles and different energy ranges.

- data rate = 12.4 kbit/s
- mass = 18.2 kg
- power = 13.7 W

V4L: Low-Frequency Wave Experiment (PI: G. Gustavsson of IRF-U, also involved IRF of Sweden, DSRI of Denmark, Cornell University, NY). The wave experiment is divided into two parts, depending on the frequency. V4L measures waves up to about 10 kHz. Two wave signals can be processed simultaneously that may come from any of the electric field antennas, from a magnetic loop antenna measuring fluctuations in the direction of the spin axis, or from the V1 experiment.

The experiment uses two wire booms from the Electric Field Experiment and in addition a magnetic coil antenna (mounted on a 2 m long rigid boom) to measure one component of the magnetic wave field.

- frequency range: 0 - 15 kHz
- measurement also of $\Delta N_e/N_e$ and the wave phase velocity

V4H: High-Frequency Wave Experiment (PI: A. Bahnsen of DSRI, also involved: CRPE of France, IRF-U of Sweden). V4H has two sets of eight filters each, with center frequencies from 4 kHz to 512 kHz, and a pair of stepped frequency analyzers from 10 kHz to 500 kHz. Analog signals are provided by one of the electric field antennas or from the magnetic loop antenna.

- the experiment uses the same sensors as the low-frequency experiment
- frequency range: 10 kHz - 500 kHz
- the experiment also contains an active resonance experiment which among other things gives the electron density from the plasma frequency.
- data rate = 25.6 kbit/s (for low and high frequency experiments together)
- mass = 11.4 kg (for low and high frequency experiments together)
- power = 21.2 W (for low and high frequency experiments together)

V5: Auroral Imaging Experiment (PI: C. Anger/S. Murphree of U. of Calgary, also involved: NRC of Canada, U. of York, Canada, U. of Saskatchewan, Canada, U. of Alberta, Canada, IRF of Sweden, MISU of Sweden). Study of the dynamic behavior of auroral forms. The instrument determines the auroral luminosity distribution over the polar cap and the auroral regions.

- field of view: $29^\circ \times 24^\circ$
- wavelength ranges: 1240-1500 Å and 1330-1900 Å (two different cameras)
- at apogee one pixel covers $20 \times 20 \text{ km}^2$.
- an image can be produced every spin (in 20 seconds)
- the aurora can be seen with good contrast also on the sunlit side of the Earth
- data rate = 5.1 kbit/s (a higher bit rate of 30.7 kbit/s can be used at the expense of the wave experiments)
- mass = 8.5 kg
- power = 5.3 W

K.30 WIND

NASA/GSFC solar-terrestrial mission within the US GGS (Global Geospace Science) ISTP initiatives/programs with the objective to study sources, acceleration mechanisms and propagation processes of energetic particles and solar wind. Investigation of solar wind mass momentum and energy) with input first from the day-side double lunar swingby orbit, and later from a small halo orbit at L_1 .

Launch: Nov. 1, 1994 with a Delta II vehicle from Cape Canaveral. S/C mass = 1250 kg (300 kg propellant, 195 kg science payload). Nominal lifetime = 3 years. Spin-stabilized S/C at 20 rpm around an axis within 1° of normal to the ecliptic. S/C size: 2.4 m diameter and 1.8 m height. Solar arrays provide 370 W, including 144 W for payload instruments. The Wind S/C was built by Martin Marietta Astro Space of Princeton, NJ.

Orbit: lunar swingby to a $250 R_E$ apogee and a perigee of at least $5 R_E$ during first two years; thereafter L_1 halo orbit (figure-eight orbit around the Earth and the moon on the sun side of the Earth).

Figure 286: The WIND S/C model

Sensor complement:

MFI = Magnetic Field Investigation (PI: R. Lepping, GSFC). Objectives: investigation of the structure and fluctuations of the interplanetary magnetic field (transport of energy and acceleration of particles in the solar wind).

Instrument: Magnetometer measures the intensity and direction of magnetic field vector. Measurement rate of 44 vectors per second.

WAVES = Radio and Plasma Wave Experiment (PI: J. Bouqueret, Observatoire de Meudon, France). Objectives: measurement of the plasma over a very wide frequency range.

SWE = Solar Wind Experiment (PI: K. Ogilvie, GSFC). Objectives: measurement ions and electrons in the solar wind and the foreshock regions. Rates of once per minute for ions and 20 times per minute for electrons. Deduction of solar wind velocity, density, temperature, and heat flux.

EPACT = Energetic Particles Acceleration, Composition, Transport (PI: T. von Rosen-vinge, GSFC). Objectives: investigation of the elemental and isotopic abundances of the minor ions making up the solar wind with energies in excess of 20 keV. Measurements at a rate of once per minute for ions and 20 times per minute for electrons. Deduction of solar-wind velocity, density, temperature, and heat flux.

TGRS = Transient Gamma Ray Spectrometer (PI: B. Teegarden, GSFC). Objectives: observation of transient gamma-ray events, spectroscopic survey of cosmic gamma-ray transients, measurements of gamma-ray lines in solar flares. Measurement ranges: 15 keV - 8.2 MeV.

SMS experiment, consisting of: **SWICS** (Solar Wind Ion Composition Study) and **STICS** (Mass Sensor, and Suprathermal Ion Composition Study); (PI: G. Gloeckler, U. of Maryland). Objectives: determine the abundance, velocity, spectra, temperature, and thermal speeds of solar-wind ions (plasma investigations in conjunction with EPACT).

PLASMA = 3-D Plasma and Energetic Particles Experiment (PI: R. Lin, U. of California, Berkeley). Objectives: measurement of ions and electrons with energies above that of the solar wind and into the energy particle range. Energy range: 0.03 - 30 keV, sampling rate: 20 times per minute; wide angular coverage, good directional sensitivity. Study of particles in the bow shock and in the foreshock regions.

KONUS = Gamma Ray Burst Investigation (PIs: E. Mazets/T. Cline, Ioffe Physical Technical Institute, St. Petersburg, GSFC, instrument is sponsored by Russia). Objectives: gamma-ray burst studies similar to the TGRS studies. KONUS has a lower resolution than TGRS but a broader coverage to complement TGRS. KONUS also performs event detection and measures time history.

Data: On-board recording capability (1.3 Gbit digital tape recorder). Transmission via DSN (Deep Space Network) for 2 hr nominal daily contact. Science data rates: 5.6 kbit/s realtime and 128 kbit/s playback data. The WIND S/C provides on-board interconnection of instrumentation for data communication. Data sharing among the instruments can be triggered by pattern recognition schemes in on-board computers.

Part L Space Stations

L.1 ISS (International Space Station)

The International Space Station is the largest space program that has ever been undertaken on the basis of international cooperation. It is being built and operated by five International Partners: the USA, Russia, Japan, Canada, and Europe. In Europe, ten member states of ESA are participating in the program: Belgium, Denmark, France, Germany, Italy, the Netherlands, Norway, Spain, Sweden, and Switzerland. In addition, Brazil is participating.

The built-up phase of ISS began with the launch of FGB (Functional Cargo Block) on Nov. 20, 1998, also referred to as Zarya (meaning ‘sunrise’), on a Proton vehicle from the Baikonur Cosmodrome in Kazakhstan. “Permanent” habitation of ISS started with the launch of the first crew on Oct. 31, 2000 (see chapter 1.4 for the various phases of ISS assembly).

The ISS will consist of various modules linked to a truss segment holding the solar panels. The US is the overall integrator of the ISS, it has the responsibility for developing and operating major elements and systems. US-provided systems are: FGB (Functional Cargo Block) or Zarya, built for NASA by KhSC of Moscow, the US Laboratory, known as node 1 (Unity), the ESA/Italian built nodes 2 and 3, the truss, and solar arrays. A robotic arm, provided by Canada, will run along the truss. Russia provides, among other contributions, the Service Module Zvezda (meaning ‘star’), including accommodation facilities, research modules and additional solar arrays. Three Japanese research elements [JEM-PM (Japanese Experiment Module-Pressurized Module), JEM-EF (JEM-External Facility), and ELM-PS (Experiment Logistics Module-Pressurized Section)], the European Columbus Laboratory, and three MPLMs (Multi-Purpose Logistics Module), provided to the ISS program by ASI of Italy, will be linked to the front of the US modules. There is also ELM-ES (ELM-Exposed Section), an unpressurized section of Japan which serves as a storage and carrier module for spare external hardware and user payloads. When completed the total mass of ISS will exceed 400,000 kg. The ISS power resources call for a minimum of 26 kW continuous support and 30 kW average power to payloads during standard and microgravity modes of operation.

Figure 287: ISS configuration at start of permanent habitation in 2000

RF communications for payload data via TDRS: ISS provides an on-board command and data distribution network associated with a forward (uplink) and return (downlink) anten-

na communication. A 72 kbit/s forward S-band link is used to send commands to payloads. A 150 Mbit/s Ku-band system is used for the payload downlink. On-board data are distributed from the payloads APS (Automated Payload Switch). APS distributes the data to a high-rate modem for distribution to the Ku-band system. Three types of connections are available:

- MIL-STD 1553B payload bus (through a payload multiplexer/demultiplexer)
- Ethernet 802.3
- Fiber-optic HRDL (High-Rate Data Link)

A 216 Gbit communications outage recorder is provided to record research data during loss of signal with the communication system.

The MCC (Mission Control Center) at NASA/JSC and the POIC (Payload Operations Integration Center) at NASA/MSFC provide integrated station mission and payload control. The ISS partners will operate POCCs (Payload Operation Control Center) in their own countries.; they are networked into the integrated research operations of ISS. ¹⁵⁸¹⁾

Orbit of ISS: circular orbit (non-sun-synchronous), target altitude of 410-460 km (about 350 km during the assembly phase), inclination = 51.6°, period of about 90 minutes.

Operational mode	Description
Standard	<ul style="list-style-type: none"> • Represents core operations when tended or preparing to support human presence • Provides a “shirt sleeve” environment • Internal and external operations supported, monitored and controlled
Reboost	<ul style="list-style-type: none"> • Used to obtain additional altitude while maintaining a habitable environment and supporting internal and external user payload operations • Attitude controlled propulsively
Microgravity	<ul style="list-style-type: none"> • Consists of capabilities required for microgravity research by user payloads in a habitable environment • Does not include effects of crew activity, but does include effects of crew equipment (e.g. exercise devices)
Survival	<ul style="list-style-type: none"> • Initiated upon command or when a warning of imminent threat (e.g., loss of attitude control, loss of thermal conditioning, available power out-of-range) is not acknowledged by the on-orbit crew, the Orbiter crew, or the ground • Autonomously attempts to correct the threatening condition and provides keep-alive utilities to ISS crew/core systems • Precludes support or commanding of external or internal operations
Proximity operations	<ul style="list-style-type: none"> • Provides capabilities related to supporting safe operations with other vehicles while maintaining a habitable environment and supporting internal and external user payload operations • Vehicle is actively determining and controlling attitude non-propulsively
Assured safe crew return	<ul style="list-style-type: none"> • Provides mitigation capability for life threatening illness, unrecoverable loss of ISS habitability, or extended problem requiring resupply/servicing, which is prevented from occurring due to launch problems • Consists of actions, operations and functions necessary to safely populate the CRV (Crew Return Vehicle), separate the CRV, return the CRV to Earth, and egress the CRV upon recovery on the ground
External operations	<ul style="list-style-type: none"> • Utilizes functionality related to supporting station-based external external operations while maintaining a habitable environment and supporting internal and external payload operations • Vehicle actively determining and controlling its attitude non-propulsively

Table 466: ISS modes of operations

L.2 ISS Utilization - Selected Payloads and Instruments

The ISS offers a great utilization potential for research including a wide range of applications in such fields as astronomy, microgravity, material science, biology, medicine, and

¹⁵⁸¹⁾J. D. F. Bartoe, L. Fortenberry, “One Year Old and Growing: A Status Report of the International Space Station and its Partners,” Acta Astronautica, Vol. 47, No. 2-9, 2000, pp. 589-597

technology demonstrations in virtually all disciplines. ISS will also serve as a platform for the wide field of Earth observation. The following sub-chapters represent short descriptions of the first candidate ISS external payloads and instruments that are being considered by ESA, NASA, NASDA, etc., **the emphases of selected topics is on Earth observation.**

For station-internal research payloads, ISS adopted standard accommodations with ISPR (International Standard Payload Rack). The 37 ISPR slots for science payloads on ISS provide a common set of interfaces regardless of location. Non-standard services are also provided at selected locations to support specific payload requirements. Each ISPR provides 1.6 m³ of volume. The rack mass is 104 kg and can accommodate a payload mass of up to 700 kg. In addition, the ISS offers a choice of several external sites for mounting payloads to be exposed to the surrounding space environment. These are:

- Four locations on the S3 segment of the US-provided Station Truss of 107 m in length
- Ten locations on the Japan-provided JEM (Japanese Experiment Module)
- Four locations for ExPAs (Express Pallet Adapter) on the Columbus module of ESA
- Mounting locations on the Russian segment.

Three options exist for US Attached Payload Resource Accommodations (Station Truss):

- 1) A standardized US-provided ExPA (Express Pallet Adapter), launched and retrieved by the Shuttle, allows payloads to be mounted at external sites on the ISS Truss structure. The pallets can be zenith- or nadir-pointing, allowing them to carry instruments requiring solar or celestial viewing (zenith) or Earth viewing (nadir). An ExPA facilitates the housing of six adapters, each capable of carrying a payload of up to 225 kg on a mounting surface of 1 m². An ExPA occupies an entire truss site using the truss attach system.
- 2) A US Express Pallet (allocation per pallet). The mounting platform dimensions are: 394 cm x 229 cm. The total payload mass may be up to 1360 kg.
- 3) A US Truss Site (payload allocation per site). Payload masses of up to 4990 kg can be accommodated with a maximum payload height of 3.1 m.

L.2.1 ACCESS (Advanced Cosmic-Ray Composition Experiment for Space Station)

ACCESS is a NASA space science instrument on ISS (program scientist: W. V. Jones) in collaboration with many universities and foreign institutions.¹⁵⁸² The overall objective is to determine the highest-energy cosmic rays by measuring the characteristics of individual elements over a wide range of mass and energy (the cosmic ray energies of supernovae are estimated to be in the order of 10¹⁵ eV (the charge range Z for high energy is: 1 ≤ Z ≤ 28). Cosmic rays are an important part of the dynamics of our Galaxy; their impact is largely hidden from us due to the Earth's magnetic field. Individual elemental spectra can be used to directly determine the source spectra of the cosmic-ray nuclei. ACCESS can study these spectra with unprecedented accuracy over more than 4 decades in energy in a single instrument. To collect enough of the very high-energy cosmic rays ACCESS must have a large effective collecting area of several m². In addition, ACCESS must also contain a calorimeter to provide an energy estimate for lighter cosmic rays. ACCESS is designed for a zenith-pointed site on ISS, consisting of the combination of a large-area transition radiation detector, referred to as TRD (Transition Radiation Detector) with a hadronic calorimeter (to analyze hydrogen, helium, and a number of heavier cosmic rays). The instrument mass is estimated to be 5900 kg (instrument size: about 2 m x 2 m x 3 m; power of 850 W; mission lifetime of 4 years). A Shuttle launch of ACCESS to ISS is planned for 2007.

¹⁵⁸² <http://lhea-www.gsfc.nasa.gov/ACCESS/>

L.2.2 ACES (Atomic Clock Ensemble in Space)

ACES is an ESA-selected nadir-oriented instrument. The core of the ACES project, developed by CNES, is a laser-cooled cesium atomic clock, called PHARAO (Project d'Horloge Atomique à Refroidissement d'Atomes en Orbite), that is exploiting the microgravity conditions onboard ISS to reach unprecedented precision not achievable on Earth. In fact, a cold atomic clock works more accurately under weightlessness than under Earth's gravity. This is related to the principle of "atomic fountain" which is used in the clock. Under microgravity, the cold atoms cloud can traverse the microwave cavity with a slower speed than on Earth. This permits to increase the interaction time between the cesium atoms and the microwave field to 5-10 s which in turn reduces the atomic resonance linewidth. - The result would be an improvement of the frequency stability and accuracy of the atomic clock by a factor of 100 over conventional devices on Earth. ¹⁵⁸³⁾

The operation of the laser-cooled cesium atomic clock PHARAO opens opportunities in various fields of fundamental research and application fields. The ultra precise measurement of time will also allow relativistic measurements and tests, applications in atmospheric physics and geodesy, navigation and advanced telecommunications.

L.2.3 AMS (Alpha Magnetic Spectrometer)

AMS is a NASA-selected payload, the first sensitive spaceborne magnetic spectrometer, with international cooperation of China, Finland, Germany, Italy, Russia, Switzerland, and Taiwan (the team is led by Samuel C. Ting of MIT). The key science objective is to search for antimatter and of the missing matter in the universe (broadly stated, the AMS goal is to provide first detailed observations of charged particles outside the Earth's atmosphere - in the cosmic void). The search is basically for anti-helium and anti-carbon with a detector sensitivity 10^4 to 10^5 times better than current limits. A predecessor AMS experiment was initially flown on Shuttle flight STS-91 (June 2-12, 1998). The early experiment was particularly helpful in calibrating the instrument. In 2003 (Shuttle flight UF-4), AMS will be positioned on an external payload attach site of ISS and remain there for 3-5 years. ¹⁵⁸⁴⁾ ¹⁵⁸⁵⁾

L.2.4 ARISS (Amateur Radio on the International Space Station)

ARISS is a US program that offers an opportunity for students to experience the excitement of Amateur Radio by talking directly with crew members of the ISS. ARISS is sponsored by ARRL (American Radio Relay League), AMSAT (Amateur Satellite Corporation), NASA, and FCC (Federal Communications Commission).

The ARISS communication package (initial radio station) was flown to ISS onboard STS-106 flight of Atlantis (Sept 8-20, 2000) to be available for the "Expedition One Crew." A Russian Soyuz rocket (launch Oct. 31, 2000) lifted the first expedition crew to ISS from Baikonur, referred to as ISS-2R (start of permanent habitation of ISS). The ARISS downlink VHF frequency is 145.80 MHz (worldwide for voice and packet); the voice uplink frequency is 144.49 MHz for regions 2 and 3, and 145.20 MHz for region 1. The packet uplink frequency is at 145.99 MHz (worldwide). ¹⁵⁸⁶⁾ ¹⁵⁸⁷⁾

L.2.5 CRESPO (Coral Reef Ecosystem Spectro-Photometric Observatory)

CRESPO is a UnESS (University Earth System Science Project) instrument (PI: M. Atkinson, University of Hawaii). CRESPO is a four-channel narrow spectral bandwidth and high spectral resolution imager. The overall objectives are:

¹⁵⁸³⁾ R. D. Andresen, G. Peters, "European Payloads Selected for Early Utilization on the International Space Station," ESA Bulletin No 98, June 1999, pp. 76-86

¹⁵⁸⁴⁾ <http://hpl3tri1.cern.ch/AMS/>

¹⁵⁸⁵⁾ http://ams.cern.ch/AMS/ams_homepage.html

¹⁵⁸⁶⁾ <http://spaceflight.nasa.gov/station/reference/radio/>

¹⁵⁸⁷⁾ <http://www.rac.ca/ariss.htm>

- To develop the first comprehensive and systematic global survey of coral reef “health” and status
- To produce a systematic synoptic spectral observations of reef benthic communities
- To provide direct and significant participation by students in all aspects of the CRESPO mission.

The instrument will obtain key multispectral data for over 9000 mapped reefs and other reefs identified on the basis of an autonomous data acquisition algorithm. These data will be the only global uniform data set for coral reefs, and will also improve the georeferencing of reefs by a factor of 10 in remote areas in the Pacific. - CRESPO will be installed on ISS using the Window Observational Research Facility (WORF, see L.2.18).

L.2.6 EUTEF (European Technology Exposure Facility)

EUTEF is a multi-user support facility of ESA. The objective is to provide a modular accommodation for a variety of technology payloads requiring space exposure. It consists of a material-property laboratory allowing periodic on-board measurements of surface degradation, and a comprehensive environment-monitoring package to characterize the ISS space environment, including high-energy cosmic radiation, the natural and ISS-induced plasma environment, atomic-oxygen concentration, etc. The servicing of the payloads is provided by a robotic arm (ASI-provided). EUTEF is planned for launch in 2005 (UF5).

L.2.7 FOCUS (Fire Detection and Analysis Sensor System)

FOCUS is a DLR-proposed ESA prototype instrument for HTE (High Temperature Event) detection/monitoring (PI: H. Röser of DLR, Berlin, in cooperation of various institutes from Spain, Italy, Germany, France, Greece, and Russia). FOCUS is a demonstration package (to be used in future operational missions) with a set of infrared instruments and related electronics and software for autonomous on-board detection and monitoring/classification of high-temperature events on Earth such as vegetation fires (biomass burning) and volcanic activity/eruptions. The FOCUS design concept features a new combination of spatial and spectral co-registered infrared data specifically tailored for high-temperature events. The following geophysical variables and data products are the main interest for: 1588)

- 1) Wildfire recognition
 - Physical characterization of hot spots: fire area and temperature, precise geolocation
 - Maps of active fires and burnt areas
 - Plume temperature, column content (density) and profile of the plume trace gases: CO₂, CO, NO, CH₄, H₂O, SO₂, CO/CO₂ ratio, CH₄/CO₂ ratio
 - Optical depth of smoke, aerosol particle size distribution
- 2) Volcanic activity observation
 - Surface temperature images of volcanic regions
 - Maps of near-vent surface temperature
 - Maps of geothermal anomalies
 - Volcanic plume radiance maps and spectral signatures
 - Volcanic gas species column content (in particular SO₂ flux estimates), estimation of non-SO₂ gas species flux/content, using the ratio with SO₂ flux/content.
- 3) Coal seam fire recognition
 - Physical characterization of hot spots: fire area and temperature, precise geo-location
 - Column content (density) and profile of CO₂, CO, including the CO/CO₂ ratio to characterize the combustion efficiency.

- 4) Pre-operational requirements for HTE (High-Temperature Events)
 - Near real-time on-board detection and messaging of the main parameters of HTEs
 - Comparison of the wildfire detection capability of a detected spaceborne sensor system with ground-based fire alert systems under various illumination, seasonal and local conditions
 - Feasibility and test of the plash plume tracking techniques in context with aviation security.
- 5) Scientific requirements to MTP (Moderate Temperature Phenomena)
 - Observation of urban heat islands is a study example in the category.

The FOCUS instrument, as considered in the extended feasibility study, consists of a wide-angle FFS (Fore-Field Sensor) for autonomous hot-spot detection, MS (Main Sensor) for detailed observation and analysis of high-temperature phenomena, and an on-board data handling and control system. The FFS is a forward-looking wide-field imager with three channels in VIS, MWIR, and TIR. MS is a combination of spatially highly-resolving imagers in the VIS to TIR spectral region and a profiling high-spectral resolution IR spectrometer.

The MVIR and TIR channels of the instrument feature a very large dynamic range of 20 bit and 14 bit, respectively (in comparison to comparable existing sensors), permitting to retrieve the high-temperature event and area unrestricted by sensor saturation.

Spectral bands: FFS	VIS (0.63-0.70 μm), MVIR (3.2-4.3 μm), TIR (8-10 μm)
Spectral bands: MS-Imager	VIS (0.63-0.70 μm), NIR (0.77-0.80), MVIR, TIR
Spectral range: MS-Spectrometer	3-15 μm
FFS	Swath: 355 km
MS-Imager	Swath: 70 km
MS-Spectrometer	Footprint diameter: about 7 km / 60 km in cross-track
Ground resolution	FFS = 340 m, MS-Imager = 70 m
Attitude knowledge (ISS); with star camera	0.53° or about 4 km; 0.06° or about 500 m
Thermal system	5 radiators on 3 sides
Source data rate	56 Mbit/s
Instrument mass; power;	221 kg; 111 W standby, 385 W operation;
Instrument size	115 cm x 85 cm x 101 cm

Table 467: FOCUS instrument parameters

The line detectors for the MVIR and TIR channels of FFS and MS-Imager consists of staggered arrays of 512 x 2 elements, both with an identical layout. Coolers provide detector temperatures of 100 K for MVIR and 80 K for TIR. - The forward-looking FFS functions as a scene survey instrument in front of the nadir-looking MS-Imager. This forward-looking observation, about 30 seconds ahead of the MS-Imager nadir observation, is required for the near real-time ADM (Autonomous Detection Mode) processing sequence, consisting of the following functions:

- Recording of the co-registered VIS, MVIR, and TIR channel data of FFS
- Autonomous hot spot detection
- Transmission of low-rate data with information of the hot spot clusters
- Selection of hot spot clusters for detailed observations by the MS-Imager
- Pointing of the MS-Spectrometer FOV toward the selected hot spot cluster (use of cross-track tilt mechanism).

A cross-track tilt mirror is the optical element providing a parallel cross-track positioning capability of $\pm 30^\circ$ (FOR) for the MS-Imager and the MS-Spectrometer. When funded FOCUS is expected to be installed in the timeframe of 2004.

L.2.8 GTS (Global Transmission Services)

GTS is a relatively small payload of ESA. The objective is to transmit highly accurate time and coded data signals for dedicated receivers on the ground. The GTS experiment,

mounted on the Russian Service Module, uses a transmitter accommodated on-board the ISS for signal distribution via an externally mounted antenna with a transmission cone half-angle of about 70°. The signals transmitted, at two dedicated frequencies in the 400 MHz (UHF) and 1.4 GHz (S-band) ranges, can be received for ISS overflight periods of 5-12 minutes several times per day by ground receivers with sufficient sensitivity. Some expected applications are:

- Accurate time receipt and automated local time conversion for mobile uses on the ground (wrist watches)
- Car theft protection (electronic car keys)
- Coding and re-coding of electronic cards (chip cards, smart cards, credit cards)

L.2.9 LCDE (Laser Communications Demonstration Equipment)

LCDE is a CRL (Communication Research Laboratory) experiment. The objective is to demonstrate large capacity (multi-gigabit/s) two-way communications (inter-satellite and ISS to ground). Experiments in uplink and downlink will be performed at data rates of 2.5 Gbit/s (uplink and downlink rates) using 1.5 µm wavelength technology (1.552 µm for transmit and 1.562 µm for receive) in EDFA (Er-doped Fiber Amplifiers) and lasers. LCDE employs a coaxial Cassegrain telescope with an antenna diameter of 15 cm. The tracking system has two modes: 1) coarse mode: with two-axis gimbals and a sensitive CCD detector array, 2) fine mode: with a quadrant photo detector and a fine-steering mirror. The tracking error requirement calls for <1 µrad (micro radian). The experiment has two windows, one on the Earth-facing panel and the other on the tilted top panel. LCDE is planned to be launch in 2005.

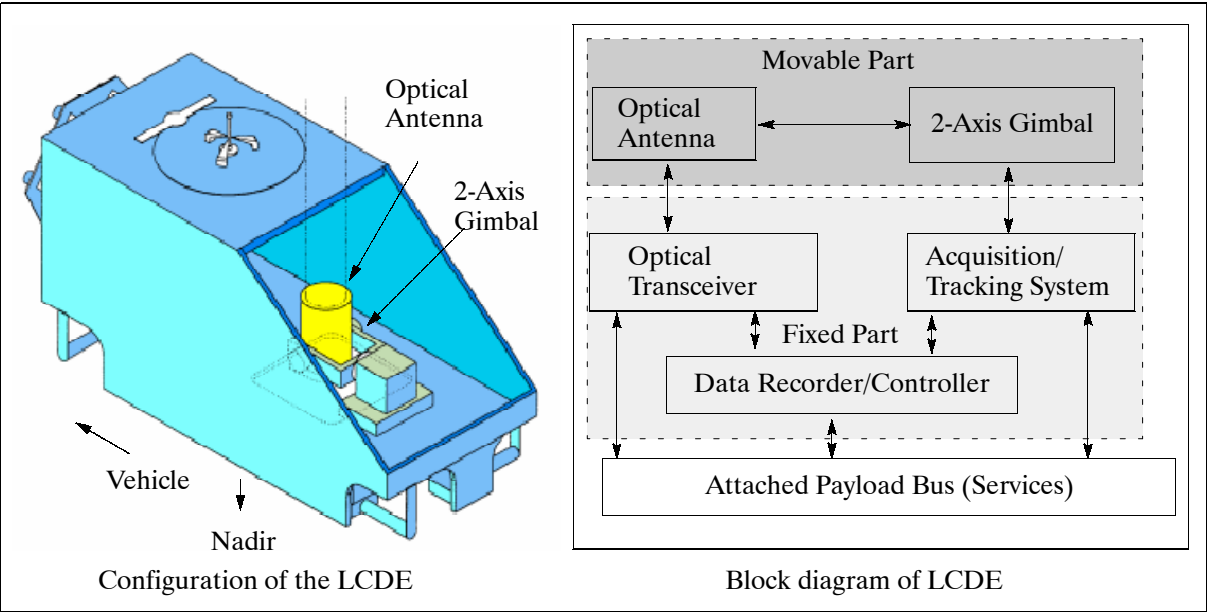

Figure 288: Illustration of LCDE

Antenna type	Coaxial Cassegrain type telescope with Coude optics
Antenna diameter	15 cm, f/D ratio 1.0 (TBD)
Tracking system - coarse	Two-axis gimbals and sensitive CCD detector, FOV more than 0.6°, Gimbal steering angle: azimuth: -30° to 210°, elevation: -60° to 90°
Tracking system - fine	Quadrant photodetector and fine-steering mirror, FOV > 0.02°
Tracking error	<1 µrad (rms, communication); <5 µrad (rms, debris detection, tracking of geodesic satellites)

1589) Information provided by Araki, Kenichi of the NASDA Tsukuba Space center
1590) http://jem.tksc.nasda.go.jp/kibo/kibomefc/lcde_e.html

Required optical power	-95 to -65 dBm (TBD, on the telescope aperture)
Optical communication rate	2.48832 Gbit/s (on transmit and on receive)
Modulation scheme	Intensity modulation using Return to Zero pulse
Demodulation scheme	Direct detection with polarization maintaining EDFA
Communication wavelength	1.552 μm (transmit) and 1.562 μm (receive)
Output power	400 mW (high power EDFA output)
Debris detection wavelength	1.552 μm (same as communication transmitter)
Debris detection sensitivity	SNR > 10 for a 1 cm sized debris at 2 km distance
Optical filter bandwidth	0.68 $\mu\text{m} \pm 0.002 \mu\text{m}$ (receiving beacon wavelength in communication mode)
Power dissipation	< 115 W for the LCDE mission equipment
LCDE mass	< 90 kg

Table 468: Performance characteristics of LCDE

L.2.10 PARCS (Primary Atomic Reference Clock in Space)

PARCS (PI: Donald Sullivan, NIST) is a US ISS experiment, an advanced cesium atomic clock, planned for the time frame 2004/5 with a mission duration of a year. The objective of PARCS is to test a variety of predictions of the Theory of Relativity. One of these predictions, is that clocks tick slower in strong gravity than they do in weak gravity. Such tiny shifts have already been made in previous experiment. The aim of PARCS is to measure them about two orders of magnitude more accurate than ever before. This requires extremely accurate clocks, on ISS as well as on ground. The timing function of the GPS constellation is used to compare the frequencies of both clocks. The knowledge of the frequency differences between each clock and the GPS system permits the calculation of the frequency difference between the ground clock and the space clock.¹⁵⁹¹⁾

Figure 289: Overall view of the PET facility (Express Pallet Mounting)

L.2.11 PET (Photovoltaic Engineering Testbed)

PET [PI: Geoffrey Landis of OAI (Ohio Aerospace Institute)] is a facility planned to fly on the ISS (in 2004) to test advanced solar cell types in a space environment. This will reduce

¹⁵⁹¹⁾<http://funphysics.jpl.nasa.gov/technical/lcap/parcs.html>

the cost of validating new technologies and bring them to spaceflight readiness by measuring them in the in-space environment. PET is expected to provide routine access to a space-based calibration and measurement facility. The PET calibration facility is configured to fit the space-station as a self-contained payload with a standardized interface to the station. The PET facility is not limited to testing of solar cells, but will also be valuable for testing the space degradation of solar-cell encapsulants and coverglass materials, solar-cell interconnect materials, and solar cell substrates. ¹⁵⁹²⁾

L.2.12 RACE (Rubidium Atomic Clock Experiment)

RACE (PI: Kurt Gibble, Yale University) is a follow-up experiment of PARCS with a planned launch in 2006/7 with a mission duration of a year. RACE will be used to perform a series of experiments to test Einstein's Theory of Relativity (with much greater accuracy than PARCS). RACE builds on the technology of the PARCS experiment using advanced shutters and laser cooling techniques to produce ultra-cold atoms with a temperature of 1×10^{-6} K above absolute zero. The RACE design employs a "two clocks in one" configuration, featuring two-back-to-back sets of clock cavities, with a source of ultra-cold atoms between them. - RACE will be compared with SUMO. ¹⁵⁹³⁾

L.2.13 SAGE-III (Stratospheric Aerosol and Gas Experiment III)

A launch of the SAGE-III instrument (NASA/LaRC) to ISS is planned for 2004. See SAGE-III description under G.8.

L.2.14 SEDA-AP (Space Environment Data Acquisition equipment-Attached Payload)

SEDA-AP is a NASDA instrument package of the Exposed Facility (EF) of Japan's Experiment Module, called Kibo [Kibo consists of four major elements as shown in Figure 290: PM (Pressurized Module), EF (Exposed Facility), the logistics modules attached to each of them, and RMS (Remote Manipulator System)]. The objective is to measure quantitatively the space environment (neutrons, light high-energy particles, heavy ions, cosmic dust, atomic oxygen, plasma, etc.), to study the environmental effects on materials and electronic devices, and to investigate the interaction with and from the space environment at Kibo's Exposed Facility. The data acquired by this mission will be useful for space equipment design, space-related scientific research, ISS operation, and space weather forecasting. ¹⁵⁹⁴⁾

The SEDA-AP package is composed of SEDA and APBUS (Attached Payload BUS). The APBUS structure size is: 80 cm x 100 cm x 185 cm, mass = 216 kg, power = 132 W. SEDA is a generic term for a number of space environment sensors, such as the NEM (Neutron Monitor), HIT/PLAM (Heavy Ion Telescope/Plasma Monitor), SDOM (Standard Dose Monitor), AOM (Atomic Oxygen Monitor), EDEE (Electronic Device Evaluation Equipment), and MPAC & SEED (Micro-Particles Capture & Space Environment Exposure Device). The NEM sensor extends about 1m from the structural body and measures neutrons. ¹⁵⁹⁵⁾

NEM measures thermal neutrons with energies of about 100 MeV neutron (using a Bonner Ball detector and scintillation fiber detector). PLAM measures the density and electron temperature of space plasma. SDOM measures the energy distribution of high energy light particles (such as electrons, protons, alpha particles etc.). AOM measures the amount of atomic oxygen on the ISS orbit. The objective of EDEE is to determine the single event phenomena and radiation damage of electronic parts. MPAC captures on-orbit micro-particles. SEED exposes materials for space use to real space environment.

¹⁵⁹²⁾<http://oai.org/PET/index.html>

¹⁵⁹³⁾<http://funphysics.jpl.nasa.gov/technical/lcap/race.html>

¹⁵⁹⁴⁾http://jem.tksc.nasda.go.jp/kibo/kibomefc/seda_ap_e.html

¹⁵⁹⁵⁾http://jem.tksc.nasda.go.jp/kibo/kibomefc/index_e.html

A portion of the instrument package, MPAC&SEED, and a HDTV (High Definition Television) camera will be flown to ISS in July 2001 (on a Russian Progress resupply vehicle) and will be attached to the outside of SM (Service Module) of ISS. The planned launch date of SEDA-AP is 2005.

Figure 290: Illustration of the Japanese Experiment Module Kibo

L.2.15 SMILES (Superconducting Submillimeter-wave Limb-Emission Sounder)

SMILES is a cooperatively developed Japanese instrument of NASDA, CRL (Communications Research Laboratory), and NAO (Nobeyama Radio Observatory), projected to fly on ISS/JEM (Japanese Experiment Module). The overall objective of SMILES is to observe submillimeter-wave (thermal) radiation or limb-emission spectra of the atmosphere and to demonstrate an ultra-sensitive submillimeter-wave sounder technology. The monitoring of trace gas distributions is performed in an altitude range of 10 to 60 km at height resolutions of about 3.5 km. The species to be measured are: O₃, ClO, HCl, HO³⁷Cl, BrO, NO, HNO₃, N₂O, HO₂, H₂O₂, O¹⁸O, and SO₂.

Species	LSB1-channel 624.32 - 625.52 GHz	LSB2-channel 625.12 - 626.32 GHz	USB-channel 649.12 - 650.32 GHz
O ₃	625.37	625.37	-
ClO	-	-	649.45
HCl	624.98 (³⁷ Cl)	625.92 (³⁵ Cl)	-
HOCl	625.07	-	-
⁸¹ BrO	624.77	-	650.18
HO ₂	-	-	649.70
H ₂ O ₂	625.04	-	-
HNO ₃	624.48, 624.78	-	650.28
SO ₂	624.89	625.84, 626.17	648.69, 649.05, 649.24

Table 469: Overview of trace gases and their observation frequencies measured by SMILES

Observations: SMILES on ISS/JEM, orbiting at an inclination of 51.6° at altitudes between 350 and 460 km, provides mappings of these molecules on a daily basis in a latitudinal range

between 65° N and 38° S. Analysis of the spectra provides an altitude profile of molecular abundance for each species. The antenna beam width is 0.083° in vertical and 0.055° in horizontal direction. This leads to a best altitude resolution of about 3.5 km. Observations are conducted between tangent altitudes of 10-60 km. 1596) 1597) 1598) 1599)

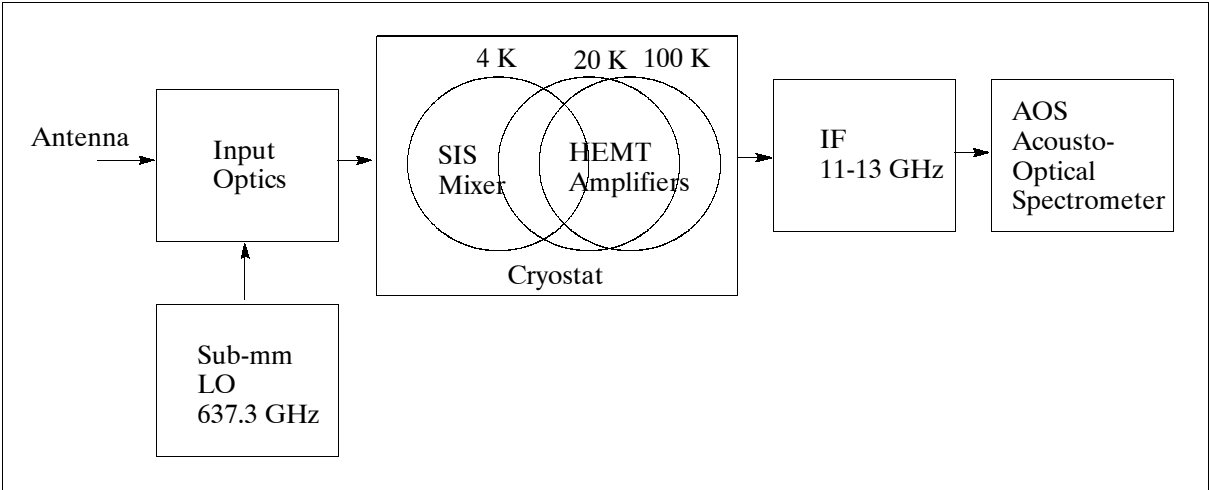

Figure 291: Schematic SMILES configuration

To achieve wideband heterodyne spectrometry, both of the LSB (Lower Side-Band) and USB (Upper Side-Band) are detected separately under SSB (Single Side-Band) conditions. The local frequency (LO) selected is 637.32 GHz. Three measurement channels are selected due to limited spectroscopic bandwidths and electromagnetic interference on ISS/JEM. Either the LSB1- or the LSB-2channel can be combined with the USB-channel in the measurement.

Observation method	Limb sounding
Observation altitude, height resolution	10 - 60 km, Δh=3.5 km
LO (Local Oscillator) frequency	637.3 GHz with 11-13 GHz IF (Intermediate Frequency)
Frequency bands (3) in GHz	624.32 - 625.52, 625.12 - 626.32, 649.12 - 650.32
Dynamic range, spectral resolution	3 - 300 K, 1.8 MHz
Total bandwidth	2,400 MHz
Antenna size, main beam size	400 mm (El) x 200 mm (Az); 0.083° (El), 0.17° (Az)
Antenna scan range	+5° to -40° in elevation
Sub-mm Mixer	4 K cooled SIS, mixer (Nb:AlOx:Nb)
IF Amplifier	20 K and 100 K cooled HEMT amplifiers
Cryostat	2 Stirling cycle + Joule Thomson cooler
Spectrometer; bandwidth resolution	2; 2.6 GHz, 1.8 MHz (3dB)
System noise	<500 K (SSB)
System sensitivity	<1 K rms
Integration time	0.47 s
Data quantization, data rate	16 bit, about 200 kbit/s
Instrument mass; power, size	<500 kg; <820 W, 0.8 m (W) x 1 m (H) x 1.85 m (L)
Mission life	1 year

Table 470: Some instrument performance characteristics of SMILES

1596) H. Masuko, T. Manabe, et al., “Superconducting Submillimeter-wave Limb Emission Sounder (SMILES) On-board Japanese Experimental Module (JEM) of International Space Station (ISS),” Proceedings of the IEEE/IGARSS 2000 Conference, Honolulu, HI, July 24-28, 2000

1597) <http://smiles.tksc.nasda.go.jp/index1e.html>

1598) J. Inatani, H. Ozeki, et al., Submillimeter Limb-emission Sounder JEM/SMILES aboard the Space Station,” SPIE’s 2nd International Asia-Pacific Symposium on Remote Sensing of the Atmosphere, Environment and Space, Sendai, Japan, Oct. 9-12, 2000

1599) H. Ozeki, Y. Kasai, S. Ochiai, S. Tsujimaru, et al., “Submillimeter-wave spectroscopic performance of JEM/SMILES,” SPIE’s 2nd International Asia-Pacific Symposium on Remote Sensing of the Atmosphere, Environment and Space, Sendai, Japan, Oct. 9-12, 2000

The SMILES instrument consists of the following basic elements: an antenna, receiver optics, a SIS (Superconductor-Insulator-Superconductor) receiver with a 637.32 GHz phase-locked oscillator and a low-noise InGaAs HEMT amplifiers, a cryogenic system, an IF subsystem with a bandwidth of 11-13 GHz, two acousto-optical spectrometers with a frequency resolution of 1.8 MHz, and a signal processing and control unit. In particular: ¹⁶⁰⁰⁾

- An offset Cassegrain-type antenna for decreasing sidelobes in the scanning direction. The main dish of the antenna has an elliptical feature with a long axis of 0.4 m to obtain a height resolution of 3.5 km. The antenna beam is tilted by 45° to the left-hand side, providing an observation coverage of up to 65° N latitude. The antenna is continuously scanned in the altitude range of -35 km to >80 km for tangent-height observations from 10-60 km.
- The local signal is produced by multiplying six times the signal of a phase-locked Gunn oscillator operated at 106.22 GHz. A new type device, referred to as MPI (Martin Puppert Interferometer) and a wire-grid polarizer combination, are used for the separate detection of the SSB, USB and LSB signals.
- A heterodyne-type SIS (Superconductor-Insulator-Superconductor) receiver with a wide-operation bandwidth of 30 GHz is used to achieve ultra-low noise temperature and conversion loss in the 637.3 GHz band..
- The SIS receiver (radiometer) is composed of SIS mixers operating at 4 K and HEMT (High Electron Mobility Transistor) amplifiers operating at 20 K and at 100 K. A Joule-Thomson mechanical cooler (developed by Sumitomo Heavy Industries, Ltd.), combined with a two-stage Stirling cycle, is utilized for cooling. The total mass and power of the cooler is about 60 kg and 250 W, respectively. The main body of the cooler (cryostat) has a size of 350 mm in diameter and 500 mm in length.
- Two AOS (Acousto-Optical Spectrometer) devices with a bandwidth of about 1.2 GHz and a spectral resolution of 1.8 MHz are used for channel combination.

JEM/SMILES is considered a “proof-of-concept” or demonstration mission before a similar instrument will be installed on ATMOS-C1 (Atmospheric Chemistry and Dynamics Mission). The SMILES instrument will be placed on the Exposed Facility of JEM (JEM-EF). A launch of JEM/SMILES is planned for 2005 by an H-IIA vehicle from the Tanegashima launch site in Japan.

L.2.16 Solar-A (Solar Monitoring Observatory)

SOLAR-A is an ESA experiment package consisting of three instruments, namely SOVIM (Solar Variability and Irradiance Monitor), SOLSPEC (Solar Spectral Irradiance Measurements), and SOL-ACES (Solar Auto-Calibrating EUV/UV Spectrophotometers). The overall objective is to measure the solar spectral irradiance with unprecedented accuracy. Knowledge of the “solar constant” and its variations is of great importance for atmospheric modelling, atmospheric chemistry, and climatology applications. The three instruments cover the combined wavelength range from 17-3000 nm in which 99% of the solar energy is radiated. The Solar-A package will be mounted on the ESA-developed CPD (Course Pointing Device), located on EPA of ISS. Integration of Solar-A on ISS is planned for 2005.

L.2.16.1 SOVIM (Solar Variability and Irradiance Monitor)

SOVIM is an ESA instrument, designed and developed at PMOD/WRC Physikalisch-Meteorologisches Observatorium Davos, World Radiation Center, Switzerland (PI: C. Fröhlich), in cooperation with investigators from Belgium, France, ESTEC, Switzerland, and USA. The overall objective is to measure TSI (Total Solar Irradiation) and SSI (Spectral Solar Irradiance). SOVIM is of SOVA heritage flown on EURECA-1 (launched July 31, 1992 and retrieved July 1, 1993).

¹⁶⁰⁰⁾ Y. Fujii, K. Kikuchi, et al., “Spaceborne 640 GHz SIS Receiver Based on 4-K Mechanical Cooler,” UV, Optical and IR Space Telescope Instruments, Proceedings of SPIE, Vol. 4013, pp. 90-99, 2000

The objective of SOVIM is to monitor the sun's irradiance with high precision, stability and accuracy; the pointing accuracy is of the order of 1° to compensate for ISS motions. SOVIM observations are conducted during the sun-pointed periods of 10-15 minutes per orbit throughout the mission. TSI measurements are performed with active cavity radiometers (PMO6 and DIARAD) which are traceable to the SI scale of irradiance through direct comparison with cryogenic radiometers on the ground and in vacuum for the PMO6, and thorough characterization in the laboratory for the DIARAD. SSI measurements are carried out by SPM (Sunphotometers) of the type now operating successfully in VIRGO/SOHO. A detector based calibration method, directly traceable to the scale established by cryogenic radiometers, is used to calibrate the SPM with high accuracy. Specific TSI and SSI objectives are: ¹⁶⁰¹⁾

- To obtain quasi-continuous high quality measurements of the solar irradiance variation
- To determine with high accuracy the amount of spectral redistribution of the solar output
- To search for the long periodicities or quasi-periodicities found in other solar parameters
- To study the influence of active regions and other large scale solar structures on the solar irradiance
- To investigate the energy storage in the convection zone in connection with the energy blocking of active regions
- To investigate the mechanisms of solar radiative forcing of climate change on seasonal to decadal time scales
- To continue the historical TSI monitoring record by linking the present SOLSTICE (UARS), VIRGO (SOHO), CERES (Terra), ACRIM-III (ACRIMSAT), and future CERES (Aqua), TIM, SOLSTICE (SORCE), TIM (NPP, NPOESS), and SOVAP (Picard) measurements.

The SOVIM instrument consists of three packages: SOVIM1, SOVIM2 and SOVIM3.

- SOVIM1, developed at IRMB, contains one absolute radiometer DIARAD (Dual Irradiance Absolute Radiometer). DIARAD is composed of two cylindrical cavities coated inside with diffuse black and mounted next to each other on the same heat sink. The flat bottom of the cavities are in fact heat flux transducers on which heating elements have been mounted. Both cavities see the same thermal environment through accurately known circular apertures. The operation is based on electrical substitution. The difference of the electrical power fed to the active channel when its shutter is open (exposed to the sun) and when it is closed is proportional to the incident solar irradiance. The SOVIM1 mass is 7.3 kg, power = 11.5 W.
- SOVIM2, developed at PMOD/WRC (Switzerland), contains two absolute radiometers, an IR Radiometer, four SPM with three independent channels each (type1: 402, 500 and 865 nm, type2: 310, 610 and 719 nm, all redundant) and a two axis pointing monitor (TASS). The SOVIM2 mass is 13.3 kg, power = 18.5W.
- SOVIM3, developed at PMOD, contains the microcomputer (80C86) based experiment controller, part of the data acquisition system and the power and data interfaces to ISS. The SOVIM3 mass is 3.4 kg, power = 3.5 W.

Data acquisition is performed by parallel VFCs (Voltage Frequency Converters) with a frequency of about 500 kHz. The basic sampling period is 10 s. Electrical calibrations are performed at zero, half scale and full scale. The pointing provided by CDP is $\pm 1^\circ$ (2 sigma) with a stability of 0.3° over 10 s. ISS position and attitude data are available for post-factum data analysis. SOVIM data are processed at SROC (Space Remote Operation Center) located at ESA.

L.2.16.2 SOLSPEC (Solar Spectral Irradiance Measurements)

SOLSPEC is an ESA instrument (PI: G. Thuillier of CNRS/SA, Verrieres le Buisson, France, with cooperation of Belgium, France, Germany, Switzerland, UK, and USA). SOLSPEC is of EURECA (1992-1993) and Spacelab-1 (Nov. 28- Dec. 8, 1983) heritage. The objective is the measurement of the solar irradiance in the spectral range from 180-3200 nm using three double spectrometers and an on-board calibration device.

L.2.16.3 SOL-ACES (Solar Auto-Calibrating EUV/UV Spectrophotometers)

SOL-ACES is an ESA instrument ¹⁶⁰²) (PI: G. Schmidtke of the Fraunhofer Institut für Physikalische Messtechnik, Freiburg, Germany, with co-investigators from Germany and USA). SOL-ACES is a new instrument covering the solar irradiance in the EUV/UV spectral range of 17-220 nm. Major elements of the instrument are: filter wheel, stepper motor, spectrometers, ionization chamber, gas supply, electronics unit (control, data acquisition, communication). Solar irradiance measurements (full disk) are obtained with four grating spectrometers. To obtain high radiometric accuracy of better than 10%, a double ionization chamber is assigned to each of the spectrometers as primary detection standard. Optical bandpass filters are mounted on a filter wheel and placed at the entrance apertures of the spectrometers and ionization chambers, they establish the radiometric link between the devices (instrument calibration uses the optical bandpass filters in conjunction with the double ionization chambers as radiometric standards). The grating spectrometers are designed as scanning monochromators operating at fixed incidence angles. The deflected radiation is monitored by rotating an assembly containing a parabolic mirror, an exit slit and a CEM (Channel Electron Multiplier). The dispersed radiation is focused through the spectrometer exit slit by a parabolic mirror and collected by CEM operated in a pulse counting mode. The optical length of the ionization chamber of 0.5 m is divided into two identical electrode sections. In addition, the transmitted radiation is measured by a silicon diode detector located at the end of the absorption path. The data permits the absolute quantification of the solar flux in the prescribed spectral range. - SOL-ACES has a mass of 23 kg and a size of 24 cm x 28 cm x 60 cm. The instrument will be installed on CPD (Coarse Pointing Device) of ISS for a mission length of about 1.5 years. The planned launch date is 2005.

L.2.17 SUMO (Superconducting Microwave Oscillator)

SUMO (PI: J. Lipa, Stanford University) is an ISS clock experiment consisting of a superconducting cavity-stabilized oscillator (SCSO) system. This is a distinctive type of clock that can be used for experiments in relativity. - A SCSO clock is built out of a microwave cavity constructed of a superconducting metal that operates at cryogenic temperatures. Since the timekeeping mechanism of SCSO is different from that of an atomic clock, a comparison between the two can give a fundamental understanding about changes in the universe. In addition, a comparison of SUMO against a more standard atomic clock may help to answer question of whether they vary for different places and velocities. This experiment will also help to determine how gravity and other factors have an effect on the speed of time.

SUMO will be installed in LTMPF (Low Temperature Microgravity Physics Facility), part of JEM-EF (Japanese Experiment Module-Exposed Facility). The planned launch date for SUMO is 2006.

L.2.18 WOLF (Window Observational Research Facility)

WOLF is an experiment rack located in the US Laboratory module Destiny on ISS (flown on Shuttle flight STS-98, Feb.7-20, 2001). The objective of WOLF is to support cameras

¹⁶⁰²) F. G. Wienhold, J. Anders, B. Galuska, U. Klocke, M. Knothe, W. J. Riedel, G. Schmidtke, et al., "The Solar Package on ISS: SOL-ACES," *Physical Chemistry of the Earth (C)*, Vol. 25, No 5-6, 2000, pp. 473-476

and other instruments that utilize the Earth-pointing window in the Lab (rack-mounted devices with a view through a porthole facing Earth). WOLF is effect an active payload isolation system. The control architecture and hardware design for this system are based on proven technologies such as the Mast Mounted Sight (MMS) equipment, employed in Bell helicopters, and the STABLE platform, flown on STS-73. The control system concept consists of an inner fine-pointing loop for high-frequency isolation about the x and z rotational axes and an outer position loop for all six degrees of freedom (no contact between the WOLF rack and the isolated platform). The performance analysis verified the close-loop requirements of pointing accuracies. The line-of-sight rotation requirements call for a pointing stability of 7.5 and 25 μ rad for large (<150 kg) and small payloads (<15 kg), respectively. ¹⁶⁰³⁾

EarthKAM (Earth Knowledge Acquired by Middle school students). NASA's KidSat program of a camera on three Shuttle flights (STS-76, STS-81, STS-86) was renamed to EarthKAM. In Feb. 2001, EarthKAM was flown to ISS on Shuttle flight STS-98 and installed on WOLF as a permanent resident. EarthKAM is one of several users on WOLF permitting for more continuous photography of Earth on student request. The EarthKAM program is based at the University of California, San Diego (UCSD). NASA,UCSD and TERC are EarthKAM partners, in addition there are many sponsors of the program. ¹⁶⁰⁴⁾

L.3 MIR-1 Orbital Station

MIR (=Peace) is Russia's (operator: RKK Energia) modular orbital station (launch of the MIR core module: Feb. 20, 1986) of considerable dimensions and payload capacities. The station has been occupied continuously by cosmonaut crews from Sept. 1989 to Aug. 1999. ¹⁶⁰⁵⁾

On April 4, 2000, the 14-year-old MIR was reoccupied by a cosmonaut crew. The mission of the two cosmonauts is to bring the aging craft back to life after it circled the Earth unoccupied for eight months. MirCorp of Amsterdam, Holland, leased the commercial rights of the station from Rosaviakosmos, the Russian Aviation and Space Agency.

MIR is comprised of the following separate modules and a Soyuz (Sojus) TM spacecraft functioning as a service vehicle:

- 1) the **MIR Core module**, which contains the cosmonaut crew quarters (mass = 20,000 kg, 4.2 m diameter), existing
- 2) the **Kvant 1 module** for astrophysics (mass = 11,000 kg), existing
- 3) the **Kristall module**, which is used to manufacture new materials in microgravity (mass = 20,000 kg), existing
- 4) the **Kvant 2 module**, which houses the airlock used by cosmonauts to exit MIR for space walks (mass = 20,000 kg), existing
- 5) the **Spektr (Spectrum) module**, was launched May 20, 1995 (Proton launch vehicle)
- 6) the **Priroda module**, which is used for Earth observation (this module was launched on April 23, 1996 (see chapter D.28 for Priroda).

One of MIR's objectives is Earth observation (resources, environment). The presence of an on-board crew is a great advantage for the maintenance and repair of all on-board equip-

¹⁶⁰³⁾S. A. Green, R. L. Boucher, J. T. Harduvel, "Active Precision Pointing for the Window Observational Research Facility on the International Space Station," Proceedings of the AIAA Space Conference and Exposition, Long Beach CA, Sept. 19,21 2000

¹⁶⁰⁴⁾<http://www.earthkam.ucsd.edu/public/iss/>

¹⁶⁰⁵⁾"Soviets to Set Record Pace for MIR Repairs," Space News June 10-16, 1991, p. 12

ment and for the collection of meaningful correlative information. The crew makes observations possible that require very intricate and complicated operational sequences or methods not easily susceptible to algorithmic definition. Between 1990 and 1993 a considerable amount of Earth observation (resources) activity was introduced and also new and more advanced sensor equipment.

Orbit: Altitude = 350 - 410 km; inclination = 51.6°.

The MIR station was deorbited in March 2001 with a final reentry into the Pacific Ocean on March 23, 2001. Like its Salyut predecessors, MIR had an edge over Skylab: It could be re-supplied by unmanned Progress freighters carrying fuel, oxygen, and other essentials. And with the help of mission controllers, cosmonauts kept MIR going three times as long as the five years its designers had envisioned. Some 104 cosmonauts and astronauts from 12 countries were living for a total of 4,591 days - more than 12 years - aboard the station. They performed 23,000 separate scientific experiments and made 78 spacewalks totaling 352 hours. Again and again, MIR was the setting for new space endurance records, culminating in Valeriy Polyakov's marathon stay of 438 days.

Sensors: (Earth Observation equipment (sensors, etc.) is located in the MIR core module)

- Module Kvant 2 - Camera KAP-350 (350 mm focal length). Provision of high-quality images (format 180 x 180 mm, scale 1 : 1000 000, resolution = 30 m)
- Module Kristall (was introduced in 1990)
Contains two cameras of the KFA-1000 type, which are mounted fan-like for extra-wide swath width (see D.31 for a KFA-1000 description). The two KFA-1000 cameras are also known under the designation: 'Priroda-5'.
- Module "I" is the "PRIRODA" complex, scheduled to be introduced at MIR in March 1996 (see D.28 for PRIRODA definition).
- Hasselblad camera 500-EL. Hand-held (portable) cameras for the crew to document their visual observations.
- Spectrometer - System "Gemma" (hand-held). Prototype testing on MIR as of 1989. Measurement of 456 narrow channels in the spectral range from 0.4 - 1.1 μm .
- MKS-M = Multichannel Spectrometer of DLR, consisting of the following systems:
 - MKS-M-AS = Atmospheric spectrometer (atm. corrections in the VIS range)
 - MKS-M-BS = Biospectrometer (determination of ocean phytoplankton).

Figure 292: Optical geometries of the KFA-1000 Camera (Priroda-5) on MIR

Data:¹⁶⁰⁶⁾ MIR data are being offered commercially to the user community by ‘Energia USA’ of Henderson, VA, a US subsidiary of RKK Energia, Moscow.

L.4 Salyut Space Station

USSR space station program. Salyut development began in the 1960s. The first launch occurred April 19, 1971. The different Salyut space stations were equipped with orbital maneuvering engines that permitted a controllable reentry capability (S/C debris could fall harmlessly into the oceans). The different space stations were raised periodically into higher orbits by visiting Soyuz spacecraft. ¹⁶¹⁰⁾

Earth observation sensors (civil program) on Salyut-6 and -7 consisting of a floor-mounted photographic complex.

Note: there was also an astronomical and a material science instrument package on-board.

Name	Launch Date	Apogee (km)	Perigee (km)	Inclination (°)	Remarks
Salyut-1	April 19, 1971	222	200	51.6	reentry Oct. 11, 1971
Salyut-2	April 3, 1973	260 296	215 261	51.6	reentry May 28, 1973
Salyut-3	June 25, 1974	270 275	219 253	51.6	reentry Jan. 24, 1975
Salyut-4	Dec. 26, 1974	270 355 369	219 343 349	51.6	reentry Feb. 3, 1977
Salyut-5	June 22, 1976	260 275	219 256	51.6	reentry Aug. 8, 1977
Salyut-6	Sept. 29, 1977	275 377 521	219 335 470	51.6 83	crew occupation for a total of 676 days reentry July 28, 1982
Salyut-7	April 19, 1982	260	212	51.6	crew occupation for a total of 812 days, reentry 1989

spectral bands and could cover 10 million km² of the Earth's surface with each film cassette. Spectral bands: 0.46-0.50 μm, 0.52-0.56 μm, 0.58-0.62 μm, 0.64-0.68 μm, 0.7-0.74 μm, 0.79-0.89 μm. Number of lenses = 6; focal length = 125 mm; mass of camera = 73 kg; power = 100 W; FOV=40.5°.

KATE-140 = Camera System. Spatial resolution of 50 - 70 m.

L.5 SKYLAB Space Station

Skylab was a manned, orbiting NASA space station composed of five parts, the Apollo telescope mount (ATM), the multiple docking adapter (MDA), the airlock module (AM), the instrument unit (IU), and the orbital workshop (OWS). The Skylab was in the form of a cylinder, with the ATM being positioned 90 deg from the longitudinal axis after insertion into orbit. The ATM was a solar observatory, and it provided attitude control and experiment pointing for the rest of the cluster. It was attached to the MDA and AM at one end of the OWS. The retrieval and installation of film used in the ATM was accomplished by astronauts during extravehicular activity (EVA). The MDA served as a dock for the command and service modules, which served as personnel taxis to the Skylab. The AM provided an airlock between the MDA and the OWS, and contained controls and instrumentation. The IU, which was used only during launch and the initial phases of operation, provided guidance and sequencing functions for the initial deployment of the ATM, solar arrays, etc. The OWS was a modified Saturn 4B stage suitable for long duration manned habitation in orbit. It contained provisions and crew quarters necessary to support three-person crews for periods of up to 84 days each. All parts were also capable of unmanned, in-orbit storage, reactivation, and reuse. ¹⁶¹¹⁾

Skylab size: 26 m length and about 6.8 m in diameter, the total mass was about 74,700 kg. Skylab was launched on May 14, 1973 (Saturn 5) and subsequently visited by three Apollo astronaut crews, who lived and worked in it for periods of 28, 59, and 84 days respectively (1st crew launch: May 25, 1973 to Feb. 8, 1974 (last splashdown of a crew). After hosting three teams of astronauts, the unmanned Skylab reentered the Earth's atmosphere on July 11, 1979.

Skylab-1	Launch: May, 14, 73 (unmanned)	34,981 orbits	Re-entry: July 11, 1973
Skylab-2	Launch: May 25, 73 (manned)	404 orbits	Re-entry: June 22, 1973
Skylab-3	Launch: July 28, 73 (manned)	858 orbits	Re-entry: Sept. 25, 1973
Skylab-4	Launch Nov. 16, 73 (manned)	1,214 orbits	Re-entry: Feb. 3, 1974

Table 473: Overview of Skylab missions

Orbit: Circular orbit, altitude = 435 km, inclination = 50°, period = 93.4 minutes.

Sensor complement: (only the Earth Resources Experimental Package is considered. There were in addition many other sensors).

S-190A = Multispectral Photographic Camera System (used six identical cameras with different film/filter combinations in order to view the same ground area simultaneously in the visible region). The S190A experiment consisted of six high-precision 70 mm cameras. The matched distortion and focal length camera array contained forward motion compensation to correct for S/C motion. The f/2.8 lenses, with a focal length of 15 cm, had a FOV of 21.1° providing surface coverage of about 163 km x 163 km. The system was designed for the following wavelength/film combinations: 1) 0.5-0.6 μm, Panatomic-X B+W; 2) 0.6-0.7 μm, Panatomic-X B+W; 3) 0.7-0.8 μm, IR B+W; 4) 0.8-0.9 μm, IR B+W; 5) 0.5-0.88 μm, IR color; and 6) 0.4-0.7 μm, high-resolution color. The spectral regions designated were se-

¹⁶¹¹⁾ "Skylab," Jane's Spaceflight Directory 1988-89, 4th Edition, pp. 117-122

lected to separate the visible and photographic infrared spectrum into bands that were expected to be most useful for multispectral analysis of earth surface features. Further spectral refinements were made by using different filter combinations. The camera system provided photos with a ground resolution of 30 to 46 m in the visible wavelengths and 73 to 79 m in the infrared wavelengths.

S-190B = Earth Terrain Camera. The S190B camera utilized a single 45 cm focal length lens with 12 cm film. Its field of view of 14.2° provided a surface coverage of about 109 km x 109 km. This camera was designed to use high-resolution color film and was operated from the OWS window, producing photos with a ground resolution of 17 to 30 m. The camera compensated for S/C forward motion through programmed camera rotation. Shutter speeds were selectable at 5, 7, and 10 msec with a curtain velocity of 2.8 m/s.

Table 474: Specification of S190A and S190B camera systems

S-191 = Infrared Spectrometer (camera system).¹⁶¹² Objective: to make an evaluation of the applicability and usefulness of sensing earth resources from orbital altitudes in the visible through near-infrared and in the far infrared spectral regions. The S191 experiment was basically a visible and infrared spectroradiometer (hand-held device). Measurement of radiation flux in the bands from 0.4 - 2.4 μm , and from 6.2 - 15.5 μm . FOV = 1 mrad (0.435 km diameter circular foot print), with a spectral resolution of 1 to 5%.. Note: The S191 and S192 experiments were operated from May 1973 to Feb. 1974. Both systems provided useful data. The data return was limited by the amount of magnetic tape that could be transported in resupply flights.

S-192 = Multispectral Optomechanical Scanner. Objectives: to assess the feasibility of multispectral techniques, developed in the aircraft program, for remote sensing of Earth resources from space. Specifically, attempts were made at spectral signature identification and mapping of ground truth targets in agriculture, forestry, geology, hydrology, and oceanography. The S192 optical mechanical scanner utilized a 30 cm reflecting telescope with a rotating mirror. The telescope and mirror were mounted outside the multiple docking adapter. Spectral range: 0.4-12.5 μm ; number of spectral bands = 13; use of silicon detectors for bands 1-12 (0.41 - 2.43 μm), while band 13 (10.2 - 12.5 μm) used photoconductive HgCdTe detectors; radius of circular scan = 42 km; swath width = 72.4 km; IFOV = 79 m (0.182 mrad.); instrument mass = 57 kg; power = 266 W (peak). The conical scan pattern was formed by giving the scanner a 9° forward tilt from nadir. Scanning was accomplished by a small flat fold mirror rotating on an arm to scan a circular zone of the image in the first focal plane of the telescope (primary spherical mirror of 51 cm diameter). The scan mirror scanned a zone of this known constant spherical aberration and subsequently corrected by the refocusing optics.

S-193 = Passive Microwave Radiometer/Active Scatterometer and Radar Altimeter (sometimes also referred to as RADSCAT). Objectives: simultaneous measurements of radar backscatter and radiometric brightness temperature in a number of scanning modes, primarily for the purpose of studying surface winds and precipitation over the oceans, and to provide engineering data for use in designing space radar altimeters.

¹⁶¹²P. Slater, "Remote Sensing," Optics and Electronics Systems, Addison-Wesley Publishing Co., 1980, pp. 456-462

This design represents a first implementation of a combined passive/active microwave sensor. All three instrument components operated at the same frequency of 13.9 GHz and shared a common gimballed antenna (mounted on the outside of the multiple docking adapter) and scan system. Spatial resolution = 16 km (circular footprint at nadir); mechanically scanning parabolic antenna (1.15 m diameter reflector) with dual polarization and a 2° IFOV (swath width = 180 km). The antenna was gimballed, permitting along-track and cross-track scanning. - Using a pulse width of 0.1 μ s this system was able to get a resolution of 15 m. It operated over short orbital segments only but it was able to demonstrate the measurement of coarse features of the marine geoid such as major ocean trenches. ¹⁶¹³⁾

The scatterometer measured the backscattering coefficient of ocean and terrain as a function of incidence angle ranging from 0 to 48°. The radiometer was a passive sensor which measured the brightness temperature, from a cell on the Earth's surface, as a function of incidence angle from the surface. The altimeter was a compressed-pulse radar system to measure average ocean-surface elevation variations with a resolution of about 0.9 m. The S-193 ground coverage was 48° forward and 48° to either side of the spacecraft ground track. All data were recorded on magnetic tape on one digitized channel. The radiometer/scatterometer data were recorded at 5.33 kbit/s, the altimeter data at 10 kbit/s.

S-194 = Passive Microwave Radiometer. Objectives: to measure the brightness temperature of the Earth's surface along the S/C track, which would provide ocean surface features, varying winds over ocean areas, and Earth surface features information (soil moisture). S-194 was a modified Dicke-type radiometer with tuned RF receiver and gain modulation. Frequency = 1.4 GHz (21 cm wavelength, L-band); fixed nadir viewing phased-array antenna. The system utilized a built-in calibration scheme that sampled known sources. The spatial characteristics were: an antenna half-power beam width of 15°, first null beam width of 37° (97% of power) and a circular footprint of about 124 km diameter (half-power). All data were recorded on magnetic tapes. The data output was at 200 bit/s.

Part M Technology Missions

M.1 ARGOS (Advanced Research and Global Observation Satellite)

ARGOS (also referred to as P91-1) is a large DoD research and development satellite mission, managed by the Tri-Service Space Division at Kirtland AFB (SMC/TE), Albuquerque, NM. It is part of the DoD Space Test Program (STP) with the objective to demonstrate several new space technologies and to fly payloads for global Earth sensing and celestial observations. ¹⁶¹⁴⁾ ¹⁶¹⁵⁾ ¹⁶¹⁶⁾

Figure 294: Illustration of the ARGOS satellite

The S/C was designed/built at Boeing North American, Anaheim and Seal Beach, CA. The ARGOS structure of modular panel design, it is three-axis stabilized. Navigation and attitude determination are supported by horizon sensors (to calibrate gyro drifts), three-axis gyros (ring laser gyro package), and an embedded GPS receiver. The attitude pointing accuracy requirement for the S/C is 0.05° (1 sigma). At the core of space vehicle flight computer processing is the Integrated Electronics Unit (IEU), which acts as the “brains” for space vehicle operations. An on-board automated mission planning system, developed by the University of Colorado, is used to optimize on-board data handling and power. The on-board solid-state recorder provides 2.6 Gbit of data storage. S/C mass = 2718 kg, power = 2.2 kW (average = 1 kW), design life = 3 years.

A launch of ARGOS on a Delta-II vehicle from VAFB (along with SUNSAT (University of Stellenbosch, South Africa) and Ørsted (Denmark) as secondary payloads) took place on Feb. 23, 1999.

¹⁶¹⁵⁾ <http://www.te.plk.af.mil/stp/argos/argos.html>

¹⁶¹⁶⁾ <http://www.pxi.com/brochures/argos/index.html>

Communication: The downlink data rate is 4 kbit/s or 128 kbit/s on carrier I, and 1, 4 or 5 Mbit/s on carrier II. The uplink data rate is 2 kbit/s.

Orbit: Sun-synchronous circular orbit, altitude = 835 km, inclination = 98.7°, equatorial crossings at 14:00 (daytime orbit) and 2:00 hours (night side orbit).

Sensor complement:

HTSSE-II (High Temperature Superconducting Space Experiment II), sponsored by NRO (National Reconnaissance Office), Navy, DARPA, BMDO, NASA, Canadian Government, and German Government. HTSSE-II is an NRL instrument with the objective to demonstrate and validate the performance of eight HTS (High Temperature Superconductor) materials/components in a microwave system setting (semiconductors and RF devices) with an accuracy sufficient to detect long-term changes. Measurement of power consumption, speed, space radiation effects, etc. at temperatures of 77 K (Note: HTS is an important emerging technology for the 21st century with the potential of major breakthroughs in commercial and military applications). Power reduction factors of two to three orders of magnitude are expected. The HTSSE-II instrument was designed and built in a partnership program between NRL industry and academia. The goal is the demonstration of an advanced mechanical cryocooler that may be used for focal plane arrays and cooled semiconductors as well as for HTS devices. ¹⁶¹⁷⁾ ¹⁶¹⁸⁾ ¹⁶¹⁹⁾

Table 475: Summary of electronic devices selected for HTSSE-II demonstration

The BAe (British Aerospace - now part of Astrium Ltd) Stirling-cycle cryocooler (Oxford design with demonstrated reliability; nominal cooling capacity of 780 mW at 75 K) was selected for the HTSSE-II cryogenic bus cooling source. The HTSSE-II payload is divided into five temperature-controlled zones: 1) the electronics deck, 2) the BAe cryocooler, 3) the cryogenic cold bus, 4) CBSS (Cold Bus Support Structure), and 5) the TRW experiment package. Operating temperatures for the electronic deck and the BAe and TRW cryocoolers are separately controlled. The HTSSE-II cryogenic subsystem design is unique to space-deployable cryogenically cooled electronics in general, and microwave applications in particular. The central cold bus is the heart of the cryogenic subsystem where seven of the eight HTS experiments are mounted and cooled by the BAe cryocooler. The 8th device is a stand-alone subsystem where the HTS device is integrated with its own cryogenic refrigerator.

HTSSE-II is instrumented to monitor and diagnose the in-flight cryocooler and cryogenic payload status. On-orbit measurements are performed in combination with a ground-

¹⁶¹⁸⁾ R. A. McKnight, M. F. Bahrain, et al., "On-Orbit Status of the High Temperature Superconductivity Space Experiment (HTSSE-II), AIAA-99-4486, 1999

¹⁶¹⁹⁾ <http://ssdd.nrl.navy.mil/www/htsse/htsse.htmlx>

based, calibrated signal source. This is referred to as “bent-pipe” mode of operation. In this approach, test signals are transmitted from an NRL ground facility; they are received by the payload, passed through the device under test, detected, digitized, and stored for a later downlink to the receiving site. Experiments are characterized using on-board parameter measurement equipment. In characterizing an experiment (e.g., multiplexer, channelizer, etc.) a received pulse-modulated signal is amplified, filtered and applied to the HTS experiment. Simultaneously, the same signal is applied to the reference channel (C-band or X-band). Both the experiment output and the reference signal are detected and digitized providing comparative amplitude outputs. Since the two signals are from the same antenna and RF front-end hardware, the pulse amplitude difference in the two paths is a measure of the response of the experiment.

Device or component	Major design features	Supplier
RF input/output cables	Low thermal loss stainless steel, coaxial cables of 0.53 mm diameter	Gore
MLI (Multi-Layer Insulation blanket for cryogenic cold bus	Aluminized mylar layers separated by silk net	Lockheed
Mechanical cryocooler using Stirling cycle	Maintain cryogenic cold bus at 77 K with 500 mW load Stand-alone cryogenic system at 65 K with 250 mW load CDE (Cryocooler Drive Electronics) with closed loop	BAe TRW Lockheed
Digital instrumentation	Digitization of data from RF processing system	Aeronics
RF and video instrumentation	Detection/processing of RF test signals	ITT Government Systems
HRT (HTSSE Remote Terminal)	Satisfy all command and data telemetry needs	Gulton
Receive antenna	Receive C- and X-band signals transmitted from ground	ACA (Antenna Corp. of America)

Table 476: Device summary of HTS experiments of the common cryogenic cold bus

The HTSSE-II RF payload consists of a dual-band antenna, associated payload receiver modules, a VPM (Video Processor Module), and IFMM (Instantaneous Frequency Measurement Module). The receiver module and the VPM have RF and video interfaces with the cold bus containing the HTSSE-II experiments. The VPM performs parameter measurements on the detected RF signals from the receiver. Additional interfaces are VPM to digitizer and to the HRT (HTSSE Remote Terminal). All receiver control functions, such as redundancy switching, attenuator controls, and channel selection, are received through the VPM from the HRT. The HRT receives this information from the ARGOS S/C command and control and data bus, which uses MIL-STD-1553 bus architecture.

The receiver consists of a superconducting X-band four-channel demultiplexer with 100 MHz-wide channels, four commercial monolithically integrated GaAs mixers, and four custom-designed hybrid-circuit detectors containing heterostructure ramp diodes. The superconducting frequency demultiplexer is fabricated from thin films of YBCO (Yttrium-Barium-Copper-Oxide) which were pulse laser deposited onto an MgO substrate. The composite receiver unit has been integrated into the payload of HTSSE-II. - The HTSSE-II instrument has a mass of 132 kg, the power is 98 W.

EUVIP (Extreme Ultraviolet Imaging Photometer, sponsored by the US Army and built by UCB). The objective is to investigate the upper atmosphere and plasmasphere for safe military communication system’s design, prediction of magnetic storms, and characterization of the aurora. EUVIP also observes the Earth’s horizon and stellar environment by measuring background radiation for future sensor design. The EUVIP experiment is mounted to the S/C body and oriented to view tangent altitudes from 200 to 550 km. EUVIP is also oriented to view the much of the same region of the sky measured by the HIRAAS limb scan.

The EUVIP experiment is essentially a telescope with a digital focal plane. The telescope design is based on a grazing incidence Wolter-Schwarzschild Type I optics. The entrance

aperture is a concentric ring with 40.3 cm outer diameter and 37.5 cm inner diameter, and 156 cm² geometric area and 80 cm² effective area in the EUV. The experiment detector uses a stack of microchannel plates and a wedge-and-strip anode for two dimensional imaging with 256 x 256 pixels. The overall instrument FOV is roughly 5¼ in diameter and aligned with the optical axis of the telescope. The instrument resolution is about 1.5 arcmin corresponding to 0.2 mm resolution at the detector focal plane. EUVIP dimensions are 89 cm x 58 cm x 53 cm, the instrument mass is 70.5 kg.

The detector is covered with three filters to isolate separate spectral regions. The three filter passbands measure the following constituents: 1) Lexan/B (7 - 20 nm); 2) Al/C (16-30 nm) and 3) Al/Sn (80 - 90 nm). The first and second filters measure astronomical sources and the Earth's magnetospheric emission from the He⁺ line at 30.4 nm. The third filter passband contains the dayside ionospheric emission from O⁺ at 83.4 nm, also measured by the HIRAAS and GIMI experiments.

USA (Unconventional Stellar Aspect), also referred to as NRL-801 experiment.¹⁶²⁰⁾ USA is an NRL payload (226 kg) with the objective to provide a research platform (testbed) for X-ray timing, time-resolved spectroscopy, and also to explore applications of X-ray sensor technology. A further objective of USA is to use **X-ray detectors to provide autonomous timekeeping and navigation capabilities** (use of X-ray binaries and pulsars as clocks and observing horizon crossings of bright X-ray sources). Observations of atmospheric occultations of X-ray sources, as in GIMI (Global Imaging Monitor of the Ionosphere) with stellar occultation observations in the far ultraviolet, can provide unique information about the composition and structure of Earth's upper atmosphere. Unlike in the UV, the atmospheric attenuation of X-rays is relatively insensitive to the chemical composition of the gas (i.e. whether atomic or molecular, nitrogen or oxygen), and can be used in both day and night conditions. Therefore, atmospheric occultation measurements with the USA experiment complement the upper atmospheric measurements made with GIMI and HIRAAS (High Resolution Airglow / Aurora Spectrograph).

USA conducts feasibility tests of X-ray satellite navigation and new computational approaches to autonomous parameter estimation that includes GPS inputs and a variety of redundant truth measures. X-ray attitude determination consists of directing an X-ray sensor at a field in the sky and comparing the detected sources with expectations based on the known maps of that field. The offset between the map and the observed pattern gives an error signal. Attitude is determined in inertial space. USA employs the method of two gimbaled sensors to obtain the full attitude solution with X-ray sources. -Satellite position determination is made in X-rays by observing transitional events such as horizon crossings or occultations of stars with known positions.¹⁶²¹⁾

The USA instrument design is based on the use of large-area proportional-counter detectors in the energy range of 1-15 keV. The detector assembly is mounted on a two-axis pointing system, which allows the detector to be pointed at celestial targets of interest during the space flight mission. The USA instrument is a reflight of the X-ray detectors on Spartan-1 (Shuttle flight STS-51G, June 17-24, 1985). Key characteristics of the USA instrument are:

- Long observing times on bright X-ray objects
- Large-area detectors with high time-resolution capability (area: 2000 cm², telemetry: 40 kbit/s with 128 kbit/s available for short periods; 1 µs time resolution (time is provided by the GPS receiver); USA also receives the output of the ring laser gyro package.
- Low-energy response (down to 1 keV)
- High flexibility in data handling.

¹⁶²⁰⁾ K. S. Wood, et al., "The USA Experiment on the ARGOS Satellite: A Low Cost Instrument for timing X-ray Binaries," SPIE Proceedings, Vol. 2280, 1994 p. 19

¹⁶²¹⁾ J. H. Beall, T. Crandall P. S. Ray, "Innovative Satellite Navigation Exercises Utilizing the USA Experiment and the ARGOS Satellite," http://www.pxi.com/brochures/argos/ARGOS_exp.pdf

There are reasons why X-ray navigation might prove to be attractive in the future. The advantages are associated mainly with drawbacks of optical methods or with potential advantages of X-ray characteristics that have no exact analogs in the optical wavelengths. These include:

- The ability to operate in wavelengths in which the ground cannot be seen, thereby removing any hazard of blinding by ground-based lasers
- Freedom from difficulties of dealing with scattered sunlight or the bright Earth
- Capability of performing multiple tasks (position, attitude, and timekeeping) with a single sensor
- Horizon sensing in wavelengths where only the upper atmosphere is traversed by a ray grazing the effective horizon, removing weather problems and making possible simple (smart) horizon sensors
- Feasibility of high-accuracy attitude sensing without optics
- Exploitation of a simpler sky in which many bright sources are available without distraction from nearby sources that are only slightly fainter
- Exploitation of spectral features of bright non-optical sources, such as the periodic intrinsic variability of many bright X-ray sources
- Straightforward exploitation of lunar occultations of celestial sources.

In addition, three radiation-hardened 32-bit space computers [RH32 (of Rome Laboratory, Rome, NY) and RH3000 (Harris)] are part of the USA platform. They are being space-qualified by performing real-time fault-tolerant applications. Both boards have full access of the full downlink telemetry data stream. A software package provides fault-tolerant features for the detection of in-flight transient errors.

ESEX (Electric Propulsion Space Experiment). The objective is to address the DoD space-lift and maneuvering requirements for global surveillance and communications orbits and the application of advanced technology in order to reduce life cycle costs. ESEX (built by TRW and managed by Phillips Laboratory of USAF) demonstrates high-power arcjet propulsion technology (reliable arcjet thruster operation) for orbit transfer, maneuvering capability, and attitude adjustment. With a power input of 26 kW and a mass of 450 kg, ESEX is so far the largest electric propulsion system to orbit. ESEX operations are being tracked with ground radars and optical sites to allow characterization of the arcjet's electromagnetic and visual signature.

SPADUS (Space Dust Experiment). A small ONR (Office of Naval Research) instrument with the objective to measure and to characterize orbital debris and dust in the LEO environment of highly populated sun-synchronous orbits. Generation of 3-D survey maps of the present dust distribution. SPADUS also includes ancillary diagnostics to measure the local radiation environment. The experiment results are expected to help spacecraft shielding and electronics design, extending space vehicle lifetimes. Instrument mass of 23 kg.

CIV (Critical Ionization Velocity). A PL (Phillips Laboratory) experiment with the objective to release Xenon and Carbon Dioxide to study ionization caused by plasma and collision processes in the upper atmosphere. CIV makes also use of the gas releases by the reactive control system of ARGOS to measure/identify the plumes and atmospheric wakes.

HIRAAS (High-Resolution Airglow/Aurora Spectroscopy).¹⁶²²⁾ Objective: test of a new technique for ionospheric and thermospheric remote sensing. An NRL instrument package with the objective to measure the naturally occurring thermospheric and ionospheric airglow (environmental model improvement for predicting effects of the ionosphere on communications). HIRAAS is a multi-instrument experiment package containing three UV spectrographs (HITS, LORAAS, and ISAAC) to measure naturally occurring atmospheric emissions. The three instruments look into the same direction and operate in parallel. The

¹⁶²²⁾ <http://ftpwww.gsfc.nasa.gov/ISSSR-95/hyperspe.htm> entitled: "Hyperspectral Imaging of the Global Ionosphere from the ARGOS Satellite,"

science objectives of HIRAAS experiment are to measure, by remote sensing, the densities and temperatures of the various upper-atmospheric atoms, molecules, and ions, and how they vary with altitude, position over the Earth, and solar activity. The gases to be measured include O₂, O, O⁺, N₂, N, NO, and H.

A limb scan is performed in the aft orbit direction from -10° to -37° relative to the S/C horizon corresponding to tangent altitudes from 750 km to 50 km (90 s per downward scan, 15 s flyback). The imagery of the ionosphere obtained is “hyperspectral” at wavelengths from 50 to 310 nm. An essential element of these investigations involves comparisons with ground-based ionosondes and radars to provide ground truth for remote sensing observations.

- **HITS** (High Resolution Ionospheric/Thermospheric Spectrograph). The goal is to measure FUV (Far UV) radiation in the spectral range is from 50 - 170 nm at a resolution of 0.03 nm. HITS features a 1 m focal length Rowland Circle spectrograph fed by a telescope consisting of a parabolic mirror coated with silicon carbide for maximum reflectivity in the EUV. The spectrograph uses a 4800 l/mm grating. A grating drive mechanism rotates and translates the grating to select 10 nm segments within the 50-170 nm total passband and maintains focus and resolution at each position. The HITS spectrograph uses a MCP (Microchannel Plate) detector with a wedge-and-strip readout anode and a cesium iodide photocathode. The detector format provides a one-dimensional spectrum with 1024 pixels in the dispersion direction once per second. The HITS spectrograph resolution of 0.03 nm is sufficient to resolve the fine structure of atomic and ionic multiplets (a multiplet refers to a spectrum line of several components) and the rotational structure of molecular bands. For example the O⁺ 83.4 nm multiplet is a triplet emission (83.267, 83.333, 83.447 nm) and with the HITS resolution all three components are resolved. Separating the three lines provides additional information for ionospheric remote sensing since the multiple scattering opacity varies with each line. Each line provides a solution to the ion density in a different opacity regime.

Figure 295: Illustration of the HIRAAS instrument

- **LORAAS** (Low Resolution Airglow/Aurora Spectrograph). Measurement of the FUV (Far UV) in the 80-170 nm range. The LORAAS instrument is a 0.25 m focal length

Wadsworth spectrograph with a stepper motor controlled scan mirror, mechanical grid collimator, grating and wedge-and-strip detector. Both the scan mirror and grating are coated with silicon carbide for maximum efficiency in the EUV. The scan mirror sweeps the FOV across the limb and is synchronized with the HIRAAS scan mechanism. The detector is coated with CsI and produces a linear array spectrum with 256 pixels in the dispersion direction once per second. LORAAS provides the entire 80-170 nm spectrum at moderate resolution (1.5 nm) while HITS measures subsets at high resolution. The LORAAS instrument is an exact copy of the **SSULI** (Special Sensor Ultraviolet Limb Imager) spectrograph that flies operationally on the DMSP Block 5D3 weather satellite series (G.1). Since the ARGOS satellite has an orbit similar to the DMSP satellites, LORAAS and HITS provide a validation and engineering test of the SSULI concept.

- **ISAAC** (Ionospheric Spectroscopy & Atmospheric Chemistry spectrograph). ISAAC measures in the mid-UV band from 180-310 nm. The ISAAC instrument is a modified 1/8 m Ebert-Fastie spectrograph fed by an off-axis telescope. The ISAAC detector is an intensified diode array which uses a microchannel plate stack, Cs₂Te photocathode, phosphor and fiber optic reducer. The spectrograph uses a stepper motor to select a 25 nm portion of the 180-310 nm passband. The ISAAC spectral resolution of 0.25 nm is sufficient to resolve the rotational structure of a number of molecular bands from which the temperature of the lower thermosphere and ionosphere can be determined. Additionally, the major molecular ion in the F1- and E- region of the ionosphere is NO⁺, and ISAAC can measure several bands of NO from which models will be used to infer the lower ionospheric distribution.

The HIRAAS measurements test a new technique for ionospheric and thermospheric remote sensing. Extreme UV imaging of the ionosphere is required to improve a number of DoD systems that depend on radio and microwave propagation through the upper atmosphere and ionosphere. Neutral density measurements support standing NORAD operational requirements to improve satellite drag forecasting and the ability to predict orbital life and re-entry impact locations. The end product is an improved environmental model for predicting effects of the ionosphere on communications and eventually a “weather” prediction of the upper atmosphere for operational use.

GIMI (Global Imaging Monitor of the Ionosphere).^{1623) 1624)} An NRL sensor with the primary objective to map and monitor the ionospheric O⁺ and electron density on a global basis, day and night, by wide-field imaging of ionospheric far-ultraviolet emissions. A secondary objective is to map and monitor neutral upper atmospheric constituents, specifically N₂, O₂, and NO. The first two are measured by observing the occultation of UV-bright stars. NO is measured by observing the UV night airglow emissions. Astronomical objectives of GIMI include obtaining an all-sky survey of both point and diffuse sources in the spectral range of 131-200 nm, and of point sources in the range of 92-110 nm. GIMI is mounted on the Earth-facing (nadir) panel of the ARGOS satellite to view the Earth limb and other directions in the zenith angle range 70.25 to 135.25°. The instrument consists of two wide-field UV imaging cameras, using electron-bombarded CCDs (EBCCDs), mounted on a two-axis gimbal system for nadir observations. The two cameras are co-aligned to permit simultaneous UV observations.

- GIMI camera 1 observes in the 75-110 nm range (EUV) and has a 10° square FOV. It is used primarily for observing O⁺ emissions at 83.4 nm in the day airglow, and stellar occultations in the 92-110 nm range for measurements of upper atmospheric N₂. It is also used for observing stars and other astronomical objects in the 92-110 nm range.
- The GIMI camera 2 observes in the 131-160 nm and 131-200 nm spectral ranges (FUV). The camera photocathode is split into two regions (using different materials).

¹⁶²³⁾G. R. Carruthers, T. D. Seeley, “Global Imaging Monitor of the Ionosphere (GIMI): a Far Ultraviolet Imaging Experiment on ARGOS,” SPIE Proceedings, Vol. 2831, 1996, p. 65

¹⁶²⁴⁾<http://spacescience.nrl.navy.mil/Branches/gimiwebpage.htm>

The 131-200 nm range provides a FOV of $3.3^\circ \times 10^\circ$ when viewing Earth, whereas the 131-160 nm range portion uses a FOV of $6.7^\circ \times 10^\circ$. Both spectral ranges are used to measure O_2 by observing stellar occultations. The longer range near 190 nm is used to observe NO nightglow emissions, the shorter range at 135.5 nm observes ionospheric O^+ recombination emissions.

Figure 296: Illustration of the GIMI instrument

Astronomical sky surveys are made using both ranges of camera 1. Camera 2 is used only at night (in Earth shadow), while camera 1 can be used day and night. The GIMI gimbal system allows the cameras to point in a zenith angle range from 75° to 135° in the orbit plane (forward or aft). The cameras may also be gimballed in the yaw direction (cross track) to observe auroras and other phenomena of interest. Observations of the moon and known stars are also used for in-flight calibration of GIMI.

For observations of the upper atmosphere and ionosphere, the cameras are pointed at a zenith angle of 112° (22° below horizontal), in which case the line of sight has a 300 km tangent altitude (altitude of closest approach of the line of sight to Earth). Repeating sequences of exposures are used to cover a continuous strip of up to 120° .

The HIRAAS, GIMI and EUVIP instruments on the ARGOS S/C provide a powerful remote sensing exploration of the global ionosphere. This unusual combination of hyperspectral imagers and imagers provides a unique database of global structure and variability of ionospheric structure.

Students (high school and college) have been involved in nearly all aspects of the design, development, and testing of GIMI prior to launch, and will likely continue to be involved after launch (in mission operations and data analysis). During the actual mission, it is planned that students will be able to access GIMI data by way of the Internet, in a manner

similar to that of the Moonlink education and public outreach program associated with the Lunar Prospector mission, which is implemented by Space Explorers, Inc.

Figure 297: Diagram of the EBCCC cameras

CERTO (Coherent Radio Topography Experiment). An NRL sensor with the objective to test and develop tomographic algorithms for reconstruction of ionosphere densities and irregularities. The experiment consists of a three-frequency radio beacon and radiating antenna mounted on the S/C. Receivers on the ground use differential phase techniques to derive the integrated electron density. CERTO data analysis permits an impact assessment on navigational accuracy, communication systems, and remote sensing by radar.

M.2 ARTEMIS (Advanced Relay and Technology Mission Satellite)

ARTEMIS is ESA's first GEO data relay communication satellite with the objective to demonstrate new communication technologies, principally for data relay and mobile services. The technology demonstrations include an optical intersatellite link, first European operational use of an electric ion propulsion system, and a transponder for the support of EG-NOS (European Geostationary Navigation Overlay Service) for signal enhancement of the GPS/GLONASS navigation satellite constellations. ^{1625) 1626) 1627)}

The S/C structure consists of a box-shaped three-axis bus of Italsat heritage (Alenia Spazio bus family, Alenia is also the prime contractor to ESA). The primary structure consists of the central cylinder (aluminum honeycomb skinned with carbon fiber), the main platform, the propulsion platform, and four shear panels. The secondary structure is made up of the N/S radiators, the E/W panels, and the Earth-facing panel. The central propulsion module houses the propellant tanks, LAE (Liquid Apogee Engine), the East panel with the L-band

antenna feed, the West panel with the IOL (Inter Orbit Link) antenna. The two antenna reflectors (2.85 m diameter) for IOL support are dominant features of the S/C structure.

Figure 298: Illustration of the ARTEMIS S/C

S/C attitude is measured by Earth/sun sensors and gyros. Reaction wheels serve as actuators. Thrusters of an RCS (Reaction Control System) are used for wheel off-loading. The UPS (Unified Propulsion System) employs a conventional bi-propellant system of a single 400 N LAE for insertion into GEO. The propellants are stored in two Cassini-type 700 liter tanks. E/W positioning is maintained by RCS. N/S positioning is maintained by electric ion thrusters. The IPS (Ion Propulsion System) comprises two thruster assemblies, RIT (RF Ion Thruster) and EIT (Electro-bombardment Ion Thruster). Each is powered and monitored separately, but a common propellant supply is used (40 kg of xenon), 600 W of input power is needed for operation.. S/C electric power of 2.8 kW (at equinox after ten years to a 42.5 VDC bus) is provided by two solar wings. BSR (Back Surface Reflecting) solar cells are mounted on each of the two solar wings. Two NiH₂ batteries provide energy of 60 Ah for eclipse protection. A S/C design life of 10 years is provided. The S/C launch mass is 3100 kg (550 kg payload, 1538 kg propellant).

A launch of ARTEMIS, along with BSAT-2B of BSS (Broadcasting Satellite System Corp. of Tokyo, Japan as co-passenger, took place on July 12, 2001 on an Ariane-5 vehicle from Kourou. An upper stage malfunction of Ariane-5 resulted in a lower orbit than GEO (the two satellites were left in an orbit with a perigee of 592 km and an apogee of 17,528 km instead of the intended GTO of 858 km x 35,853 km). ESA is planning recovery actions to get ARTEMIS into GEO using the kick motor as well as two experimental electric propulsion systems.

Orbit: Geostationary orbit at 21.4° eastern longitude.

Payload/experiment complement:

The S/C data relay payload provides feeder links between Artemis and the ground as well as IOLs (Inter Orbit Links) between ARTEMIS and the S/C in LEO (SPOT-4). The feeder links operate at 20/30 GHz, while the IOLs can operate in S-band (2 GHz), Ka-band (23/26 GHz), and optical frequencies.

The feeder link, S-band and Ka-band elements jointly comprise the SKDR (S/Ka-band Data Relay) payload, while the optical IOL payload element is called SILEX (Semiconductor Intersatellite Link Experiment). ARTEMIS data relay service support (via RF links) is planned to be provided to ENVISAT of ESA.

SKDR (S/Ka-band Data Relay). The objective of the IOL antennas (2.85 m diameter) is to track a LEO user satellite via either loaded table values and/or error signals - and to receive up to 450 Mbit/s of data in the Ka-band, or up to 3 Mbit/s in S-band for relay via the feeder link to Earth (return link operation). Up to 10 Mbit/s in Ka-band and 300 kbit/s in S-band may be transmitted by ARTEMIS to the LEO satellite (forward link operation).¹⁶²⁸⁾ In addition, ARTEMIS broadcasts a 23.540 GHz beacon to help the LEO satellite to track it.

- A single Ka-band transponder (plus one backup) provides return/forward frequencies of 25.25 - 27.5/23.2 - 23.5 GHz links in Rx/Tx, adjustable EIRP (Effective Isotropic Radiated Power) of 45-61 dBW, G/T of 22.3 dB/K, up to 150 Mbit/s each of the three channels LEO to ARTEMIS (return link), and up to 10 Mbit/s from ARTEMIS to LEO (forward link). RH/LHCP on command.
- One S-band transponder (plus one backup) provides return/forward frequencies of 2.200-2.290/2.025-2.110 GHz links in Rx/Tx, adjustable EIRP 25-45 dBW, G/T of 6.8 dB/K. The bandwidth is 15 MHz. Up to 3 Mbit/s of data can be transmitted in a single channel from LEO to ARTEMIS (return link), and up to 300 kbit/s can be transmitted from ARTEMIS to LEO (forward link). RH/LHCP on command.

Feeder link of SILEX and SKDR: Three transponders (plus one backup) act as ground-ARTEMIS links for SILEX and SKDR. The feeder Ka-band frequencies are: 27.5-30/18.1-20.2 GHz for Rx/Tx. The EIRP is 43 dBW, G/T of 0 dB/K, use of 234 MHz bandwidth, linear vertical polarization.

Technology Demonstrations:

SILEX (Semiconductor Intersatellite Link Experiment), an ESA laser experiment built by MMS, France. SILEX consists of two optical terminals, namely OPALE (Optical Payload for Intersatellite Link Experiment) located on ARTEMIS, and PASTEL (Passager SPOT de Télécommunication Laser) on-board SPOT-4. The objective is to beam data at rates of 50 Mbit/s (bit error rate of $<10^{-6}$) from the transmitter terminal on SPOT-4 in LEO - to the receiver (OPALE) on ARTEMIS for subsequent relay via feeder link to the SPOT ground segment in Toulouse. The SILEX terminal on-board ARTEMIS is also being used to support a second LEO experiment, namely an IOL between ARTEMIS and OICETS (Optical Inter-orbit Communications Engineering Test Satellite) of NASDA.

- **PASTEL** (Passager SPOT de Télécommunication Laser). A joint ESA/CNES passenger demonstration experiment. PASTEL is a prototype high data-rate intersatellite transmission system based on laser technology. The objective is to transmit imaging data from SPOT-4 to ARTEMIS. The aim of the experiment is to validate the PASTEL concept design in an operational environment. PASTEL is a gimbal-mounted assembly consisting of a telescope, an optical bench with a fine pointing system, communication detectors with avalanche photodiodes, a thermal control system for precision temperature control, a two-axis gimbal mechanism, and the launch locking mechanisms needed during the launch phase. The telescope mirrors and main structural elements are made of Zerodur. The acquisition and tracking sensors use CCD detectors. The laser diodes are of the GaAlAs type. The SPOT-4 - ARTEMIS optical links operate at wavelengths of 830 nm. The peak output power is 160 mW (60 mW continuous operation), the beamwidth is 0.0004°. Data to be transmitted include: HRVIR image data, pseudo-noise (PN) code, PASTEL telemetry.

¹⁶²⁸⁾ Note: In very elaborate communication systems with intermediate geostationary transmission satellites, the term 'uplink' is usually replaced by 'forward link' to avoid confusion. Similarly, the term 'downlink' is usually replaced by 'return link.'

- **OPALE** (Optical Payload for Intersatellite Link Experiment) terminal, mounted on the geostationary satellite ARTEMIS (a GEO terminal). The receiver employs Si-APD (Silicon Avalanche Photodiode) detectors and a low-noise trans-impedance amplifier of 1.5 nW useful receiver power.

Each SILEX terminal features a telescope of 25 cm diameter (which is mounted on a coarse pointing mechanism), and provides an ‘antenna’ gain of well above 100 dB. The disadvantage of these extreme antenna gains is the very narrow width of the transmitted beam, requiring very accurate pointing. The divergence tolerance of the optical communication beam for the SILEX configuration is 8 μ rad (or about 0.00046°). PASTEL and OPALE use a dedicated acquisition sequence. Initially, both terminals (OPALE and PASTEL) coarsely point to each other. This is done when OPALE scans a wide-angle (750 μ rad) beacon beam in the direction of PASTEL. On illumination of PASTEL by the beacon beam, it rapidly corrects its line of sight and directs in turn a narrow communication beam towards OPALE. Similarly, OPALE detects the incoming PASTEL signal, aligns its line of sight, and transmits its narrow communication beam towards PASTEL. The two terminals then remain locked on each other in closed-loop tracking, permitting subsequent communication.

LLM (L-band Land Mobile) payload. The objective of the communications payload is to permit two-way communications, via satellite, between fixed Earth stations and land mobiles, such as trucks, trains or cars, anywhere in Europe and North Africa. The LLM package is fully compatible with the EMS (European Mobile System) payload developed by ESA and flown on Italsat-2. Hence, full redundant support is provided. - The LLM receives the signals transmitted by the fixed users in Ku-band (14.2 GHz) and transmits them at L-band (1550 MHz) to the mobile users (forward link). The return link establishes the connection from the mobile user at L-band (1650 MHz) to the S/C, and at Ku-band (12.75 GHz) from the S/C to the fixed user in the ground segment. About 400 bi-directional user links can be established simultaneously.

ARTEMIS carries two antennas of 2.85 m diameter and a multiple element feed for pan-European coverage and three European spot beams. Three 1 MHz plus three 4 MHz SSPA (Solid-State Power Amplifier) channels, provide 400 2-way circuits with an EIRP > 19 dBW. The on-board L-band transmits to terminals (users) in the ground segment at 1550 MHz and receives data at 1650 MHz. A Ku-band feeder link at 14.2/12.75 GHz Rx/Tx transmits the data to the home stations. All channels are fully tunable and most commandable for LH/RHCP support.

IPP (Ion Propulsion Package). The electric propulsion system of ESA on-board ARTEMIS is being used for inclination control throughout the lifetime of the S/C (i.e., N/S station keeping maneuvers). IPP consists of a redundant pair of thruster assemblies, one mounted on each of the north and south faces. Each assembly comprises ITAM (Ion Thruster Alignment Mechanism) upon which two redundant thrusters from different sources are mounted. The entire IPP (2 RITA + 2 EITA) assembly has a mass of 84 kg (without propellants).¹⁶²⁹⁾

- **RITA** (Radio-frequency Ion Thruster Assembly) of DASA, Germany. The RIT-10 thruster for ARTEMIS has a beam diameter of 9.8 cm and delivers 15 mN thrust with an Isp of 3500 s and a system power of 560 W. The system provides 15,000 hours of operation at 15 mN (see O.14.2). A single RITA unit has a mass of 13.9 kg.
- **EITA** (Electron-bombardment Ion Thruster Assembly).^{1630) 1631) 1632)} EITA is an ion engine system mainly developed by DERA, UK. The UK-10 has an exit diameter of 10 cm diameter, it provides a maximum thrust of 23 mN at an Isp of 3400 s. The input pow-

¹⁶²⁹⁾ Information provided by R. Killinger of DASA (now Astrium GmbH)

¹⁶³¹⁾ Information provided by C. Edwards of DERA

er is 700 W. The EITA version for ARTEMIS is provided by MMS, UK. It delivers 18 mN of thrust. A single EITA unit has a mass of 15.2 kg.

EGNOS (European Geostationary Navigation Overlay Service) payload.¹⁶³³⁾ The objective is to provide enhanced navigation performance in terms of accuracy and integrity (with the required levels of availability and continuity) over the ECAC (European Civil Aviation Conference)¹⁶³⁴⁾ region. The service may later be extended to neighboring regions.

The EGNOS payload on ARTEMIS uses the Ku-band in the uplink and downlink (for S/C - fixed user communication in the ground segment). The uplink frequency is allocated at 13.875 GHz, and separate from the LLM feeder link frequency, while the downlink of the navigation payload is shared with the LLM channels (12.748 GHz). The transmitted EGNOS wide-area service signal is the GPS L1 frequency at 1575.42 MHz (L-band).

The total mass of the navigation payload, including structure, thermal control hardware and the DC harness, is 25 kg. Its total power consumption is about 110 W.

Receive frequency	13.875 GHz (Ku-band)
Transmit frequencies	12.748 GHz (Ku-band), 1575.42 MHz (L-band)
Useful bandwidth	4 MHz
G/T [(receiver) Gain / (noise) Temperature]	> -2.3 dB/K
EIRP (Effective Isotropic Radiated Power)	> 17 dBW for Ku-band; > 27 dBW for L-band
Polarization	LP for Ku-band, RHCP for L-band
Frequency stability	2x 10 ⁻¹² (10s); 10 ⁻⁹ (24 h); 2 x 10 ⁻⁷ (life)

Table 477: Some performance characteristics of the ARTEMIS navigation payload

The EGNOS payload on ARTEMIS serves as a geostationary wide-area augmentation system for all GPS signals in its large area of coverage by transmitting:

- GPS-like signals (ranging function)
- GPS health and integrity conditions obtained by ground monitoring stations. This is the RAIM (Receiver Autonomous Integrity Monitoring) function.
- Ranging errors (differential correction function) - these are the conventional DGPS services.

M.3 Bitsy-SX (Bitsy-Spacecraft in Future-X)

Bitsy-SX is a Shuttle demonstration payload in NASA's Future-X program, referred to as SPASE (Small Payload Access to Space Experiment), designed and built around AeroAstro's Bitsy-SX spacecraft kernel.

Background: In 1998 NASA announced a new program, Future-X, managed by MSFC, with the aim to support a series of flight demonstrations to validate new technologies. The idea is to prove technologies that improve performance and lower development, production and operating costs of future earth-to-orbit and in-space transportation systems.

Bitsy™ is a trade name, representing a line of spacecraft "kernel" modules, designed and developed by AeroAstro of Herndon, VA.¹⁶³⁵⁾ The "Bitsy™ concept" as such is an enabling technology, meaning that one does not fly a Bitsy (though among its design requirements is that it can behave as a fully functional spacecraft); rather one uses Bitsy as the starting point in the development of a full spacecraft. The kernel approach applies COTS (Commercial-

of-the-Shelf) and standardization concepts to the fullest extent to obtain significant cost and turnaround advantages over conventional bus development.

The first Bitsy-SX implementation (the total mass of the Bitsy-SX with a NASA microgravity payload is about 35 kg) will fly on the SPASE vehicle in Nov. 2001 (Shuttle flight STS-108). SPASE uses Bitsy-SX, perched upon an octagonal experiment structure, that fits inside a GAS (Get Away Special) canister on Shuttle. The outside of the experiment housing is covered with solar panels. Bitsy-SX contains lithium-ion batteries, providing 7 Wh of energy (average orbital power is 5 W) during orbital eclipse phases. The ACS (Attitude Control System) of SPASE is passive, using hysteresis rods and permanent magnets to keep the S/C body rates below 10^{-5} g for the crystal growth experiment. The payload interaction consists primarily of keeping the crystal growth cavity within a specified temperature range, commanding a digital camera to take images periodically, and downloading those images when a ground station contact occurs.

Deployment of the SPASE free-flyer vehicle from the GAS canister is attended by the Shuttle crew (Hitchhiker launch). It occurs at an altitude high enough above the atmosphere to remain under the 10^{-5} g requirement for the science experiment. Communications (in UHF at 9.6 kbaud) with SPASE as well as S/C operations are conducted from a ground station at the University of Alabama in Huntsville. SPASE uses internally RS-232 interfaces to communicate with the payload. Simple timed commanding is supported as well as threshold monitoring of all S/C and payload functions. The science mission is designed to last 6 months prior to vehicle reentry into the atmosphere.

M.4 DODGE (Department of Defense Gravity Experiment)

A DoD engineering technology satellite, built and operated by JHU/APL, with the objective to study a number of advanced biaxial and triaxial gravity-gradient stabilization techniques at near-synchronous altitudes. Secondary objectives included obtaining measurements of the Earth's magnetic field at near-synchronous altitudes and black-and-white and color TV photography of the entire Earth's disk.¹⁶³⁶⁾

The S/C structure was in the form of an octagonal aluminum shell with a truncated pyramid at the top and a 25.4 cm diameter cylindrical mast extending 1.57 m from the satellite base. The satellite body was 2.41 m long and 1.22 m in diameter (S/C on-orbit mass of 102 kg). A total of 10 knobbed booms were carried on board. Upon radio command, these booms could be independently extended or retracted along three axes to various limits out to 45.75 m. The cylindrical mast housed a 4.6 m boom that extended through the end of the mast, two 15.25 m long damper booms that extended in the x-y plane, and triaxial vector magnetometer sensors. The remaining seven booms were contained in the satellite body along with a two-camera (one color and one black-and-white) vidicon camera system. The command system consisted of a dual command receiver, dual command logic, and power switching circuitry. The telemetry system included two directional antennas mounted on the mast, two 38-channel commutators for housekeeping data, and a dual transmitter system that transmitted analog data at a frequency of 240 MHz and TV data at 136.8 MHz. The satellite was successfully stabilized 12 days after launch by means of the gravity-gradient booms and libration dampening systems. It was oriented with its base and mast directed toward the center of the Earth's disk.

DODGE was launched on July 1, 1967 on a Titan III-C vehicle (multiple S/C launch along with DATS 1, LES 5, and IDCSP 16, 17, and 18.) from Cape Canaveral, FL. The satellite was operational for over 3 years.

Orbit: apogee = 33,659 km, perigee = 33,270 km, inclination = 6.2°, period = 1318.9 minutes.

¹⁶³⁶⁾<http://nssdc.gsfc.nasa.gov/nmc/sc-query.html>

Sensor complement:

Dual Vidicon Cameras. Objectives were to determine the S/C alignment with respect to the Earth and to measure the amount of solar and gravitationally induced bending of the downward-pointing stabilization boom. In addition, the cameras were capable of providing information on the structure and dynamics of global cloud systems, cloud heights, airglow, and auroras. The cameras were mounted in the base of the satellite and viewed down the 1.57 m long cylindrical mast toward the Earth. - The camera system consisted of two vidicon cameras, one with a 22° FOV, the other with a 60° FOV, and associated electronics and power converters. Both cameras were equipped with a 2.54 cm vidicon tube (512 lines/scan) and a special slow scan (200 sec/scan) video pickup. The 60° FOV camera took black-and-white pictures only and used a simple blade-type shutter. The 22° FOV camera, however, took both color and black-and-white pictures. It used a rotating eight-channel color wheel placed in front of the camera, which provided shuttering action. Three of the channels were equipped with blue, green, and red filters, one channel was left blank, and the remaining four had various shortwave cutoff (haze or Rayleigh) filters. High-purity quartz cover plates were placed over the optical filters for protection against radiation damage. On July 25, 1967, the 22° FOV camera took the first color picture of the Earth ever made from a near-synchronous altitude. In all, over 25, 000 pictures were obtained.

Three-Axis Fluxgate Magnetometer. Objectives: study of the Earth's magnetic field and geomagnetic micro-pulsations and other temporal variations. The detector consisted of a triaxial fluxgate magnetometer mounted at the end of a 158 cm cylindrical mast which protruded from the bottom of the S/C. The magnetometers each had a range of ± 250 gamma, and a sensitivity of .2 gamma. Inflight calibration was performed once each hour in a cycle occurring at the start of each hour for which the magnetometers were commanded to record continuously. A 20 Hz low pass filter with zero attenuation between 0 and 0.5 Hz and a 3 db attenuation between 0.5 and 10 Hz limited the frequency response of the satellite. After nine months in orbit, the operations schedule permitted the acquisition of vector magnetic data on a regular basis. The observations were limited to the region between 0 - 150° west and $\pm 6.3^\circ$ latitude.

M.5 DS1 (Deep Space 1)

DS1 is the first satellite mission in NASA's New Millennium Program (NMP). A major objective of NMP is to identify and to test new technologies in spacecraft and instrument design as well as in spacecraft operations, to validate new and high-risk concepts in the spaceborne environment, thereby advancing the horizons of future missions. DS1 is in particular a low-cost minisatellite technology demonstration mission of NASA/JPL with the following objectives: 1637) 1638) 1639)

- 1) Demonstrate the in-space flight operations and quantify the performance of the following five advanced technologies:
 - Solar electric propulsion (SEP)
 - Solar concentrator arrays
 - Autonomous navigation
 - Miniature camera and imaging spectrometer
 - Small deep-space transponder

In addition, the objectives called for the testing of any three of the following six advance technologies:

1637) M. D. Rayman, Ph. Varghese, D. H. Lehman, L. L. Livesay, "Results from the Deep Space 1 Technology Validation Mission," 50th International Astronautical Congress, Amsterdam, The Netherlands, Oct. 4-8, 1999, IAA-99-IAA.11.2.01, the paper is also published in Acta Astronautica, Vol. 47, No 2-9, pp. 475-487, Sept. 2000

- Ka-band solid-state power amplifier
- Beacon monitor operations
- Autonomous remote agent
- Low-power electronics
- Power actuation and switching module
- Multifunctional structure

Figure 299: The DS1 S/C in stowed configuration

- 2) Acquire the data necessary to quantify the performance of these advanced technologies by the end of the primary mission (Sept. 1999).
- 3) Utilize the on-board IPS to propel the DS1 spacecraft on a trajectory to encounter an asteroid in 1999.
- 4) Assess the interaction of the IPS operations with the S/C and its potential impact on charged particle, radio waves and plasma, and other science investigations on future SEP-propelled missions. - A twelfth technology, a miniature integrated ion and electron spectrometer, PEPE, was not included in the mission success criteria, but it was on board and received a thorough evaluation.

The S/C structure consists of an octagonal aluminum space frame (1.1 m x 1.1 m x 1.5 high), the overall stowed S/C dimensions are: 2.5 m high, 2.1 m deep, and 1.7 m wide, based on the MSTI (Miniature Seeker Technology Integration) spacecraft, built by Spectrum Astro, Inc. of Gilbert, AZ (SA-200HP bus). With most of the components mounted on the exterior of the bus, their accessibility simplifies replacement during integration and test. The S/C is powered by batteries and two solar panels attached to the sides of the frame which span of

11.75 m when deployed. The solar panels, designated SCARLET II (Solar Concentrator Arrays with Refractive Linear Element Technology) constitute one of the technology tests on the spacecraft (see SCARLET below). The pair of solar arrays produced 2.5 kW of power at 1AU. Each array is comprised of four panels and a single-axis gimbal controls to point the panels in the more sensitive longitudinal axis toward the sun. - The total mass of the S/C is about 486.3 kg, composed of 373.7 kg dry spacecraft, 31.1 kg of hydrazine, and 81.5 kg of xenon for IPS.

Communications are via a high gain antenna, three low gain antennas, and a Ka-band antenna, mounted on top of the spacecraft. One low-gain antenna is mounted on the service boom and points toward Earth. The CCSDS protocol suite is used for all data communications.

The launch of DS1 took place on October 24, 1998 on a Delta launcher (7326-9.5 with three strap-on solid propellant rockets) from Cape Canaveral Air Station, FL (secondary payload: SEDSAT-1). Its first destination was the near-Earth asteroid “1992 KD” with an estimated diameter of 2-5 km. The primary mission of DS1 ended on September 18, 1999, completing its mission of demonstrating the new technologies.

Orbit: The SEDSAT-1 microsatellite (University of Alabama, Huntsville) was ejected from the second stage. The Delta vehicle entered a 185 km parking orbit, then fired again to enter an orbit: 174 km x 2744 km, inclination of 28.5°. The third stage separated and accelerated to a solar orbit with the DS1 satellite, while the second stage burned again with SEDSAT-1 for an orbit of: 556 km x 1042 km, inclination of 31.5°.

DS1 was injected into a solar orbit with the third stage burn. Orbital period: 453.00 d, inclination = 0.4°, periapsis = 0.99 AU, apoapsis = 1.32 AU, eccentricity = 0.14300, epoch start date/time = 1998.297:12:08:00 (24 Oct.).

M.5.1 Advanced technology payload complement

The DS1 payload consists of 12 technologies, two of them happen to be science instruments.

IPS (Ion Propulsion System). Objective: validation of system performance. IPS, provided by NSTAR [(NASA SEP Technology Application Readiness), where SEP is the acronym for Solar Electric Propulsion], uses a hollow cathode to produce electrons to ionize xenon by collision. The Xe^+ is electrostatically accelerated through a potential of up to 1280 V and emitted from the 30 cm diameter thruster through a pair of molybdenum grids. A separate electron beam is emitted to produce a neutral plasma beam. The power processing unit (PPU) of the IPS can accept as much as 2.5 kW, corresponding to a peak thruster operating power of 2.3 kW and a thrust of 92 mN. Throttling is achieved by balancing thruster and Xe feed system parameters at lower power levels; and at the lowest PPU thruster power, 525 W, the thrust is 19 mN. The specific impulse decreases from 31,400 m/s at high power to 19,000 m/s at the minimum throttle level. - A comprehensive diagnostic system is also on the spacecraft to validate system performance. The diagnostic instrument suite includes a retarding potential analyzer, two Langmuir probes, search-coil and fluxgate magnetometers, a plasma wave sensor, and two pairs of quartz-crystal microbalances and calorimeters.

At the end of the primary mission in Sept. 1999, IPS had operated for about 3000 hours. The IPS operated over a broad range of its 112 throttle levels, from input power levels of 580 W to 2140 W, with corresponding specific impulses of 19,375 m/s and 31,200 m/s, respectively (determined by radio navigation). Up to June 30, 1999, there were 1799.4 hours of thrusting by IPS, the total Xe consumption was 11.4 kg, providing 699.6 m/s. By August 31, 2000 IPS had accumulated > 5200 hours of operations, a longer time period than any propulsion system on any S/C so far. There were a total of 34 IPS starts in the mission from Nov. 24 1998 to June 30 1999. All other S/C systems operated normally during IPS thrusting.

AutoNav (Autonomous navigation). ¹⁶⁴⁰⁾ Objective: evaluation of autonomous on-board orbit determination (determination of S/C location in the solar system and in its flight path)

and control capability with the intent to free ground-segment resources. The AutoNav system (a software package including a baseline trajectory, a star catalog, the ephemerides of the asteroids, operations procedures, sequences, etc.) photographs reference asteroids against the background of fixed stars. With the knowledge of time, AutoNav computes the position of the asteroids. By measuring where the asteroids appear relative to the stars, it computes where the S/C must be. It then can project its path to its destination and use its propulsion system to make any course changes that are required.

AutoNav began functioning immediately upon activation of the S/C. The ACS (Attitude Control Subsystem) used a commercial star tracker to determine its attitude. Then the real-time part of AutoNav correctly provided ACS with the position of the sun as reference so that ACS could turn the S/C to the attitude required to illuminate the solar arrays. About once per week throughout the mission, AutoNav was invoked by the operating sequence to acquire optical navigation images. The system then issues commands to ACS and the integrated camera and imaging spectrometer (MICAS) to acquire visible-channel images, each with one beacon asteroid and known background stars. A heliocentric orbit is computed with a sequence of these position determinations combined with estimated solar pressure, and on-board knowledge of the thrust history of IPS. The trajectory then is propagated to the next encounter target, course changes are generated by the maneuver design element. - Typical AutoNav heliocentric orbit determinations differed from radiometric solutions (references to test AutoNav) by <1000 km in position and <0.4 m/s in the velocity vector. Later refinements improved these values substantially.

MICAS (Miniature Integrated Camera Spectrometer). MICAS (heritage of Pluto Integrated Camera Spectrometer) was designed and built by a team from USGS, SSG Inc., the University of Arizona, Boston University, Rockwell Science Center, and JPL. The MICAS package, combines the functionality of a framing camera (staring mode) with that of an imaging spectrometer. It features two visible-range imaging channels (APS and CCD - labeled after the detector type used), an ultraviolet imaging spectrometer, and an infrared imaging spectrometer, plus thermal and electronic control. The CCD array of size 1024 x 1024 pixels is the prime detector, operated in staring mode, for obtaining frame images. The CMOS active pixel sensor (APS) includes the timing and control electronics on-chip with the detector. The UV spectrometer has a spectral range of 80 to 185 nm with 2.1 nm spectral resolution. The infrared spectrometer covers the range from 1200 to 2400 nm with spectral resolution of 12 nm. The imaging spectrometers operate in pushbroom mode. - All four detector systems share a common optical system, namely a telescope with an aperture of 10 cm diameter. With a structure of a highly stable SiC, no moving parts are required. Spacecraft pointing directs individual detectors at the desired targets.

Parameter	UV Spectrometer	VIS (APS) Spectrometer	VIS (CCD) Spectrometer	IR Spectrometer
Spectral range	80 - 185 nm	500 - 1000 nm	500 - 1000 nm	1200 - 2400 nm
Focal length	17.1 cm	67.7 cm	67.7 cm	75.2 cm
Detector elements	35 x 164	256 x 256	1024 x 1024	256 x 256
Pixel size	54 μ m	12 μ m	9 μ m	40 μ m
FOV	0.63° x 0.03°	0.26° x 0.26°	0.69° x 0.78°	0.7° x 0.003°

Table 478: Some parameters of the MICAS instrument ¹⁶⁴¹⁾

MICAS serves three functions on Deep Space 1. First, as with all the advanced technologies, tests of its performance to establish its applicability to future space science missions (demonstration of lightweight imaging technology). Second, the visible CCD channel is used to gather images for AutoNav's use. Third, it collects scientific data during this mission at the asteroid flyby and possibly the two comets. The MICAS instrument mass is 12 kg.

¹⁶⁴⁰⁾D. Normile, "NASA Craft to Take the Controls in Flight," Science, Vol. 282, Oct. 23, 1998, pp. 604-605

¹⁶⁴¹⁾J. Oberst, B. Brinkmann, B. Giese, "Geometric Calibration of the MICAS CCD Sensor on the DS1 Spacecraft: Laboratory versus In-flight Data Analysis," Proceedings of ISPRS, Amsterdam, The Netherlands, July 16-23, 2000, Vol. XXXIII B1, pp. 221-230

PEPE (Plasma Experiment for Planetary Exploration). The objective was to assess the performance of this highly integrated, low-mass and low-power instrument. The instrument provided measurements of the three-dimensional plasma distribution over its field of view (2.8π steradians). PEPE, built by Southwest Research Institute (SwRI) and Los Alamos National Laboratory (LANL), combines multiple instruments into one compact 5.6 kg package. The instrument includes a very low-power-consumption, low-mass microcalorimeter, provided by Stanford University, to help understand the plasma/surface interactions. - During the cruise phase, PEPE measures the solar wind energy spectrum of electrons and ions from 8 eV to 33 keV per unit charge with at least 5% resolution. Instead of using moving parts, it electrostatically sweeps its field of view, achieving a resolution of 45° in azimuth and 5° in elevation. PEPE also measures ion mass in the range of 1 to 500 amu per unit charge at a mass resolution of 5%.

PEPE validates the design for a suite of plasma physics instruments in one package; it assists in determining the effects of the ion propulsion system on spacecraft surfaces and instruments and on the space environment, including interactions with the solar wind; and it may make scientifically interesting measurements during the cruise phase and the encounter with the asteroid and possibly the two comets. During the asteroid flyby, the instrument was used to search for material outgassed from, or produced by photo-ionization of the asteroids surface.

PEPE made measurements of the solar wind with the IPS on and off. The main result is that SEP (Solar Electric Propulsion) can be used on future missions without interfering with the science payload.

SDST (Small Deep Space Transponder), built by Motorola and a **Ka-band solid-state power amplifier**, developed by Lockheed Martin. The SDST package combines the devices of: receiver, command detector, telemetry modulator, exciters, beacon tone generator, as well as the control functions into one unit with a mass of 3 kg (less than half the mass than would be required without this new technology). SDST allows X-band uplink and downlink as well as a Ka-band downlink. The Ka-band signal is amplified by a solid-state power amplifier to 2.3 W with an overall efficiency of 13%.

In addition to characterizing the operation of the Ka-band solid-state power amplifier, DS1 provided Ka-band signals for DSN use in verifying systems for acquiring, demodulating, decoding, and processing telemetry as well as in producing 2-way Doppler and ranging data. As the Earth-S/C range increased, certain tests were repeated to assure that the transition through threshold in a selected Ka-band region was observed.

SDST has also the ability to generate beacon signals in **Beacon Monitor Operations** (Beacon Monitor includes a software that diagnoses the spacecraft's condition). The system then transmits one of four tones to indicate to the operations team the urgency of the spacecraft's need for DSN (Deep Space Network) coverage. The four tones correspond to 1) the S/C is healthy and doesn't need any assistance, 2) reporting the occurrence of an unusual but not threatening event permitting network scheduling procedures, 3) alerting the ground that intervention is needed to prevent the loss of important data or to assist in resolving problem, and 4) requiring immediate assistance because the S/C has encountered a mission-threatening emergency. In each case, when tracking is initiated, the data summarization system provides a synopsis of the pertinent S/C data.

ARAEX (Autonomous Remote Agent Experiment). This is a software package consisting of the following three modules: PS (Planner/Scheduler), EXEC (Smart Executive), and MIR (Mode Identification and Recovery). The objective of this ambitious experiment involves turning over the responsibility (i.e. control) for the S/C to an autonomous agent. The concept involves a new architectural approach, taken by a team from JPL, AMES and the Carnegie Mellon University (Pittsburgh, PA), which uses an agent of the ground team onboard the spacecraft. This remote agent is tested in a restricted case on DS1, in preparation for more ambitious experiments on subsequent flights. The Remote Agent includes an on-board mission manager that carries the mission plan, expressed as high-level goals. A plan-

ning and scheduling engine uses the goals, comprehensive knowledge of the spacecraft's state, and constraints on spacecraft operations, to generate a set of time-based or event-based activities, known as tokens, that are delivered to the executive. The executive expands the tokens to a sequence of commands that are issued directly to the appropriate destination on the spacecraft. The executive monitors the response to these commands (through the mode identification and reconfiguration module) and reissues or modifies them if the response is not what was anticipated. Several faults are being simulated during the remote agent experiment on DS1.

On May 17, 1999 the primary S/C command was given over to **Remote Agent** for three days of S/C operations. In this period, Remote Agent successfully planned DS1 activities on-board and then carried out the plan without ground intervention.¹⁶⁴²⁾ The software detected, diagnosed and fixed simulated problems, showing that it can make decisions to keep the mission on track. This Remote Agent capability, a precursor to self-aware and self-controlled robots, will reduce the cost of future S/C operations as computers become “decision-making partners” along with humans.

Low Power Electronics Experiment (MIT/LL). The objective is to validate the performance of electronic devices throughout the life of the mission, with particular interest in the effects of radiation. A low-power electronics experiment contains a ring oscillator, multiplier, and discrete transistors to test 0.9-volt logic and 0.25 nm gate lengths (achieved with 248 nm lithography).

PASM (Power Actuation and Switching Module), a joint development of JPL, Lockheed and Boeing. The objective is to determine the working performance of PASM (internal test load of up to 40 V and 3 A). PASM contains two sets of four power switches, each set is controlled by its own mixed signal ASIC, providing voltage and current sensing and current limiting. High-density packaging technology quadruples the packing density over the current state of the art.

Multifunctional Structure Experiment, provided by USAF/PL and Lockheed Martin Astronautics. Objective: performance test of a multifunctional structure (attached to the S/C bus) consisting of electronic connection systems for embedded devices and the thermal control of a test panel. This new packaging technology combines load-bearing elements with electronic housings and thermal control, thus greatly reducing the mass of S/C cabling and traditional chassis.

SCARLET-II (Solar Concentrator Array with Refractive Linear Element Technology), built by AEC-Able Engineering Co., of Goleta, CA. SCARLET is the high-power solar array of DS1; it uses cylindrical silicone Fresnel lenses to concentrate sunlight onto a strip of photovoltaic cells and acts to protect the cells. Each array is composed of four panels of size 160 cm x 113 cm. The multijunction GaInP₂/GaAs/Ge photovoltaic cell modules are interconnected in series to produce about 2500 W (at 100 V) at the beginning of the mission. - The dual-junction cells achieved an average efficiency of 22.5% established during in-flight analysis.

M.5.2 Major events and status of extended mission in 2000

On July 29, 1999, DS1 successfully performed a close flyby of asteroid 9969 Braille using the AutoNav system.¹⁶⁴³⁾ At about 27 km separation, it was by far the closest flyby of an asteroid ever attempted.

Two months after the end of its extremely successful primary mission, the Star Tracker of DS1, responsible for the spacecraft's orientation, ceased operating. NASA decided it could

¹⁶⁴²⁾ It turned out that remote agent did have a problem (which, of course, is the reason for testing it!) that prevented it from continuing for the entire three days. The experiment was successful in that the bug was found. However, the bug did not present a risk to the spacecraft, so another experiment was designed and allowed the remote agent to complete all of its test objectives.

afford to go ahead with a risky extended mission for a comet encounter. Thereafter, JPL engineers devised a way (a long-distance rescue mission) to restore the spacecraft's sense of direction by writing new computer programs to use the camera (MICAS) as a substitute Star Tracker. The rescue also involved developing new operational procedures (new methods of flying the spacecraft) that went along with the new software. The challenging task was completed in June 2000 to resume thrusting in time to give DS1 a chance to encounter a comet Borrelly in September 2001.

There were formidable obstacles prior to achieving this feat. For one, the camera's field of view is 100 times smaller than the Star Tracker's. Also, while the Star Tracker could estimate the probe's orientation in space four times every second, MICAS produces a computer file that takes more than 20 seconds to transfer to the computer for analysis. Updates from the camera would be at least 80 times slower than the original guidance system.

After all preparations were completed and tested successfully, the ion engine was turned on June 21, 2000 (after a hiatus of 7 months) for tests of operating it with the new control system. On June 28 thrusting began in the direction required to reach comet Borrelly. - At launch, the plan for a possible extended mission was to go to Borrelly. After the spacecraft had been flying for about half a year, JPL decided that the mission was going so well and the advanced technologies were working so well that comet Wilson-Harrington could be added to the extended mission proposal. When the star tracker failed, project management reverted to the earlier plan.

M.6 EO-1 (Earth Observing-1)

EO-1 is a mission in NASA's NMP (New Millennium Program) Earth science program (a Landsat-7 follow-up and a Landsat-8 predecessor) with the overall objectives to perform Landsat-like measurements and to explore new remote sensing technologies (instruments, spacecraft, ground segment) that advance and enhance capabilities [evaluation/validation of technologies and performance, intersatellite calibration (comparison of data), evaluation of lunar calibration, autonomous navigation/instrument operation, use of proven new technologies for other missions]. A number of baseline validation scenarios are defined (generation of test scenes, ground proofs in conjunction with major field campaigns, airborne underflights, tandem flights with Landsat-7, etc.) in support of the overall objectives. S/C design life = 1 year. The paradigm of "faster, better and cheaper" applies to all aspects of the mission. A launch from VAFB on a Delta 7320-10 launch vehicle took place on Nov. 21, 2000 (along with SAC-C (CONAE, Argentina), and Munin (Sweden) as secondary payloads).^{1644) 1645)}

The EO-1 spacecraft, managed and operated by GSFC, was built and integrated by Swales Aerospace of Beltsville, MD as prime contractor. The S/C bus (of MIDEX heritage) features an Al structure, hexagonal in shape with 1.25 m diameter (across flats) and 0.73 m high (bus mass of 370 kg, payload mass of up to 110 kg). The S/C is three-axis stabilized for inertial and nadir pointing, an autonomous star tracker provides three-axis attitude knowledge. Four 1 N thrusters of a hydrazine propulsion system provide a pointing accuracy of 0.03°, the jitter is < 5 arcseconds. The PPT, a secondary propulsion system, represents a new technology which may eventually replace the reaction wheels. S/C orbit and attitude adjustment is based on GPS receivers and ACS (Attitude Control System) sensors (demonstration of autonomous maneuver capabilities initiated by GPS). A versatile ACS software permits S/C slewing to celestial bodies; this provides also a cross-track pointing capability to observe adjacent tracks. A hydrazine propulsion system with 22.3 kg propellant mass is used

¹⁶⁴³⁾ Note: The asteroid, discovered in 1992, was only recently (1999) named in honor of Louis Braille (1809-1852), the Frenchman, who invented the alphabet for the blind.

¹⁶⁴⁴⁾ S. G. Ungar, "Technologies for Future Landsat Missions," PE&RS, Vol. LXII, No. 7, July 1997, pp. 901-905

¹⁶⁴⁵⁾ <http://eo1.gsfc.nasa.gov/Technology/Documents/InstrumentOverview.html>

for orbit maintenance and formation flying. An on-board solid-state recorder provides science data storage of up to 40 Gbit. S/C total mass = 529 kg, power = 600 W EOL (300 W orbit average) and 50 Ah super NiCd battery (28 ± 7 V DC power). The OBC uses a Mon-goose V processor with 12 MHz and 1.8 Gbit of TT&C data storage. A lightweight fiber optic data bus with ATM (Asynchronous Transfer Mode) protocol is used to transfer on-board data.

Figure 300: The EO-1 S/C model

Communications: The EO-1 antenna complement is comprised of two transmit/receive S-band omni antennas and a transmit-only electronically steerable XPAA (X-band Phased Array Antenna). The 64-element XPAA is nadir pointing. The XPAA is LHCP polarized with a 3 dB beam width which varies from 18° - 30° depending on scan angle. It scans a 360° azimuth angle within a 65° half cone angle from boresight. Each of the 64 XPAA transmit elements contains its own solid-state power amplifier. One of the omni antennas is zenith facing, the other is nadir facing. Use of CCSDS protocols in S/C communications. The science data downlink is in X-band: frequency = 8225 MHz, data rate = 105 Mbit/s, minimum EIRP = 22.0 dBW, encoding scheme = modulo-4 gray code differential encoding, modulation = QPSK. The TT&C links are in S-band, either direct or via TDRSS. The downlink data rate is selectable from 2 kbit/s to 2 Mbit/s (2, 32, 1000, or 2000 kbit/s), the uplink data rate is 2 kbit/s. The ground network consists of the following stations: SGS (Spitzbergen Ground Station) at Svalbard, Norway; AGS (Alaska Ground Station) at Fairbanks, AK; WOTS (Wallops Orbital Tracking Station) at Wallops Island, VA; and MSG (McMurdo Ground Station) at Antarctica. SGS is the primary station. In addition, there is the TDRSS White Sands Station for links via TDRSS. EO-1 mission operations are provided at NASA/GSFC.

Orbit: Sun-synchronous circular polar orbit, altitude = 705 km, inclination = 98.7° , period = 99 minutes, descending nodal crossing time of 10:15 AM. A coordinated tandem orbit within a minute of Landsat-7 is prescribed for reasons of data calibration and synergetic use of data.

M.6.1 Sensor Complement

ALI (Advanced Land Imager), designed/built by MIT/LL [focal plane system: Raytheon/Santa Barbara Remote Sensing (SBRS), optical system: Sensor Systems Group, Inc. (SSG)]. ALI is a hybrid multisensor system, a technology verification instrument, for the measurement of Earth surface reflectance. A prime objective is to provide continuity with data from earlier Landsat missions at reduced sensor/operating costs (introduction of a new measurement approach).

The ALI design features a WFT (Wide Field Telescope) and a highly integrated multispectral and panchromatic instrument. The telescope employs a reflective Cooke triplet design

with a 12.5 cm unobscured aperture diameter and a field of view (FOV) of 15° (across-track) x 1.26° (along-track) and is providing a ground swath of 185 km nominally centered along the nadir ground-track. The design uses four mirrors; the primary is an off-axis asphere, the secondary is an ellipsoid, and the tertiary is a concave sphere; the fourth mirror is a flat folding mirror. This technology enables the use of large arrays of detectors at the focal plane for covering an entire swath of 185 km. The optical design features a flat focal plane and telecentric performance, which greatly simplifies the placement of the filter and detector array assemblies. The design uses silicon carbide mirrors and an Invar structure with appropriate mounting and attachment fittings. The detector array assembly has 10 spectral bands in VNIR and SWIR. ¹⁶⁴⁶⁾

Figure 301: ALI FPA and optics schematic illustration (left) and instrument (right)

ALI (EO-1)			ETM+ (Landsat-7)		
Band No.	Wavelength (μm)	GSD (m)	Band No.	Wavelength (μm)	GSD (m)
PAN	0.480 - 0.690 VNIR	10	PAN	0.50 - 0.90 VNIR	13 x 15
MS-1'	0.433 - 0.453 VNIR	30			
MS-1	0.450 - 0.515 VNIR	30	MS-1	0.450 - 0.515 VNIR	30

MS-7	2.080 - 2.350 SWIR	30	MS-7	2.080 - 2.350 SWIR	30
			MS-6	10.40 - 12.50 TIR	60

Table 479: Spectral parameter comparison of ALI and ETM+ instruments

The focal plane assembly (FPA) for ALI is populated with four sensor chip assemblies (SCA) providing a continuous FOV of 3° x 1.625° for a fully populated focal plane, each SCA providing a cross-track coverage of 37 km. [There are four SCAs per module. Each module covers a ground swath swath of about 37 km. A fully populated focal plane would have five populated modules, i.e., 20 SCAs in all. ALI has only one module as a low-cost

¹⁶⁴⁶⁾<http://eo1.gsfc.nasa.gov/Technology/ALImultispectral.htm>

technology demonstration.] The system operates in pushbroom fashion providing panchromatic and multispectral imagery. A single hybridized SCA is employed for PAN/MS (panchromatic multispectral) detection in the VNIR/SWIR spectral range (0.4 - 2.4 μm). This includes a PAN band, six VNIR bands (identical with Landsat ETM+), plus two additional VNIR bands (primed in Table 479), and three SWIR bands. The focal plane is only partially populated with SCAs resulting in only partial coverage by the various SCAs.

- Four MS SCAs are used side by side. Each SCA contains nine rows consisting of 320 MS detector cells in the cross-track direction. The dimension of each MS cell is $39.6\text{ }\mu\text{m} \times 39.6\text{ }\mu\text{m}$, providing a GSD (Ground Sample Distance) of 30 m
- The PAN detector cells are integrated directly into each MS SCA as a 960-element row, providing overlapping coverage to the MS bands, but at a 10 m GSD.

Figure 302: Illustration of the ALI instrument

The HgCdTe SWIR detectors provide high performance over the 0.9 to 2.5 μm wavelength region at temperatures which can be reached by passive or thermoelectric cooling. The nominal focal plane temperature is 220 K and is maintained by the use of a radiator. Application of detectors of different materials to a single readout integrated circuit (ROIC) enables a large number of arrays covering a broad spectral range to be placed close by together. This technology is extremely effective when combined with the WFOV optical design being used on ALI. - The VNIR bands feature a new SiC (Silicon Carbide) detector technology. SiC offers the advantage of a very high stiffness-to-density ratio and a very high conductivity to heat capacity ratio. These characteristics are superior to currently used materials for reflective optical systems. The high stiffness-to-density ratio of silicon carbide (SiC) allows mirrors of very low weight to be designed and still maintain the necessary surface figure to provide the performance required for high-resolution optical imaging. SiC optics and structures have the potential of lowering optical system weights an order of magnitude over current conventional systems.

ALI is the prime instrument of EO-1. It is mounted to and aligned to an interface plate, bolted to the S/C. The instrument-to-S/C alignment is within 20 arcseconds. A comparison of ALI/ETM+ instruments (see also Tables 479, 480, and 482) reveals the following: ALI can gather higher-quality imagery than ETM+ but is smaller and less expensive (one-

forth); its mass is one-fourth, with one-half its size it requires only one-fifth the power of ETM+.

Parameter	ALI (EO-1)	ETM+ (Landsat)
Instrument mass	106 kg	425 kg
Instrument power	100 W	545 W
Instrument size	0.2 m ³	1.4 m ³
Nr. of VNIR/SWIR bands	10	7
Detectors per band	6200	16
Thermal bands	None	1
Data rate	300 Mbit/s	150 Mbit/s
Pan resolution	10 m	15 m
Relative SNR	4 x	1 x

Table 480: EO-1/Landsat instrument parameter comparison

Hyperion. The Hyperion instrument is of HSI (Hyperspectral Imager) heritage on the Lewis S/C (launch Aug. 23, 1997, control of the S/C was lost Aug. 26, the S/C was lost and reentered the atmosphere Sept. 28, 1997) and was built by TRW of Redondo Beach, CA. The instrument is a grating imaging spectrometer, the design includes a telescope, two grating spectrometers with the supporting focal plane electronics, and the cooling system.

The fore-optics design is based on the EOC (Electro-Optical Camera) instrument of the KOMPSAT mission (KARI of Korea). The telescope provides for two separate grating image spectrometers to improve SNR. A focal plane array provides separate VNIR and SWIR detectors (HSI heritage). The SWIR detectors are cooled by a cryocooler. A dichroic filter in the system reflects the band from 400 to 1,000 nm to one spectrometer and transmits the band from 900 to 2,500 nm to the other spectrometer. The SWIR overlap with the VNIR from 900 to 1000 nm permits cross calibration between the two spectrometers. Both spectrometers use a JPL convex grating design in a 3 reflector Offner configuration. The VNIR spectrometer uses a 60 (spectral) x 250 (spatial) pixel detector array, which provides a 10 nm spectral bandwidth over a range of 400-1000 nm. The SWIR spectrometer has HgCdTe detectors in an array of 160 (spectral) x 250 (spatial) channels, cooled to 120 K. The SWIR spectral bandwidth is 10 nm. The telescope is a three-mirror astigmatic design, the high resolution hyperspectral imager is capable of resolving 220 spectral bands (from 0.4 to 2.5 μm) with a 30 meter resolution. All of the mirrors in the system are constructed from coated aluminum; the structure holding the optical elements is also constructed from aluminum so that the mirrors and housing all expand and contract at the same rates.

A common calibration system is provided for both the VNIR and SWIR spectrometers. Dual calibration lamps produce reference signals to monitor detector performance following image acquisition. Calibrations are also performed with the sun, ground target sites, and the moon. The solar calibration utilizes a diffuse reflector on the backside of the optical cover to provide uniform illumination across the focal plane arrays. Direct viewing lunar calibration is accomplished by scanning the instrument across the lunar surface. Solar and in-flight calibration data is used as the primary source for monitoring radiometric stability, with ground site and lunar calibration as secondary alternatives.

Spectral coverage	400 - 1000 nm (VNIR); 900 - 2500 nm (SWIR)
FOV	0.624° (i.e., 7.5 km swath width from a 705 km orbital altitude)
IFOV (spatial resolution)	42.55 mrad (30 m)
Detectors	60 x 250 silicon CCD array in VNIR; 160 x 250 HgCdTe array
Spectral resolution	10 nm in VNIR and SWIR (220 bands)

Table 481: Hyperion instrument parameters

The instrument typically images surface scenes of 7.5 km (swath) by about 100 km in length, providing detailed spectral mapping across all 220 channels with high radiometric accuracy.

The data is typically processed into cubes (19.8 km long by 7.5km wide) to facilitate data handling in current desktop computers. Each image cube consists of 75 MByte of data. A typical acquisition consists of multiple image cubes.

LAC (LEISA Atmospheric Corrector). The objective is to provide atmospheric correction data (water vapor) for ALI and ETM+ on Landsat-7. LAC is a high spectral, moderate spatial resolution hyperspectral imager based on wedge filter technology (heritage of WIS and LEISA). The spectral coverage is from 0.89 - 1.6 μm ; in addition there is a separate channel at 1.380 μm to detect cirrus clouds. Spatial resolution = 250 m. LAC is coaligned with the ALI WFT assembly to cover the full swath of 185 km.

The instrument uses three 256 x 256 pixel InGaAs infrared detector focal plane assemblies in a single module. Each array is placed behind a lens covering a FOV of 5° to obtain a swath width of 185 km (15°). A wedged dielectric film etalon filter (a linear variable etalon) is placed in very close proximity to a 2-D detector array. This produces a 2-D spatial image that varies in wavelength along one dimension. The filter size is 1.024 cm x 1.024 cm and covers the 890 to 1600 nm spectral region at a resolution of 30 to 40 cm^{-1} , with a linear dependence of wavenumber on position. Reflective $\frac{1}{4}$ -wave stacked layers placed on both sides of one, or more, $\frac{1}{2}$ -wave etalon cavity(s) provide the spectral resolution. Order-sorting of the etalon is accomplished with lower resolution filter layers. In operation, the 2-D spatial image is formed by a small, wide field of view lens. Unlike the grating spectrometer that captures the spectra at a point “instantaneously,” the spectrum for the LAC is obtained as the orbital motion of the spacecraft scans the image across the focal plane in wavelength, thereby creating a 3-D spectral map. The spatial resolution of a pixel is 360 mrad x 360 mrad, or about 250 m x 250 m at nadir.

Parameter	Multispectral Instruments		Hyperspectral Instruments	
	ETM+ (Landsat-7)	ALI (EO-1)	Hyperion (EO-1)	LAC (EO-1)
Spectral range	0.4 - 2.4 μm (excluding TIR)	0.4 - 2.4 μm	0.4 - 2.5 μm	0.89 - 1.6 μm
Spectral resolution	30 m	30 m	30 m	250 m
Swath width	185 km	37 km	7.5 km	185 km
Spectral resolution	Variable	Variable	10 nm	2-6 nm
Spectral coverage	Discrete	Discrete	Continuous	Continuous
PAN band resol.	13 m x 15 m	10 m	N/A	N/A
Nr of bands	7	10	220	256

Table 482: Comparison of some instrument parameters on EO-1 and Landsat-7

M.6.2 Demonstration of seven new technologies on EO-1

XPAA (X-band Phased Array Antenna), built by Boeing Co. XPAA is a communication experiment with the objective to demonstrate link-pointing capability with the use of a body-fixed low-mass and low-cost phased array antenna. The antenna is mounted on the Earth-facing side of EO-1 to allow communications with ground stations (downlink of high-rate data from the EO-1 solid-state recorder). XPAA is composed of a flat grid of 64 radiating elements whose transmitted signals are combined spatially to produce the desired antenna directivity. The phases of each of the radiating elements are varied by computer to point the beam in the desired direction. The antenna’s mass is 5.5 kg. It has an Effective Isotropic Radiated Power (EIRP) of approximately 160 W and transmits data at 105 Mbit/s. An inherent advantage of the body-fixed design is to permit simultaneous capture and transmission of data, avoiding perturbations to instrument measurements.

CCR (Carbon Carbon Radiator). A material science experiment with the objective to demonstrate various uses of carbon-carbon. The composite material is used in the primary structure of EO-1, serving as both an advanced thermal radiator and a load bearing struc-

ture. The advantages of carbon-carbon are: high thermal conductivity (including through thickness) and good strength and weight characteristics. The use of CCR technology may simplify thermal radiator design in some applications (e.g., no need for actively cooled radiators) and support increased science payload mass ratios for future missions.

LFSA (Lightweight Flexible Solar Array). The objective of this photovoltaic system is to demonstrate significant improvements in the power to weight ratios of solar arrays. LFSA features copper indium diselenide (CuInSe_2 or CIS) solar cells and shape memory alloys for the hinge and deployment systems. The shockless deployment technique could improve the S/C dynamics during deployment. It is also much safer than conventional solar array systems using conventional pyrotechnics for deployment. The goal of LFSA is to achieve >100 W/kg power efficiency ratios (conventional solar arrays of the late 1990s provide <40 W/kg).

WARP (Wideband Advanced Recorder Processor). WARP) is a high-rate solid-state recorder on EO-1. The objective is to demonstrate a number of high density electronic board advanced packaging techniques. WARP utilizes advanced integrated circuit packaging (3-D stacked memory devices) and “chip on board” bonding techniques to obtain very high density memory storage per board (24 Gbit/memory card). It also includes a Mongoose V processor which can perform on-orbit data collection, compression and processing of land image scenes. WARP consists of a high-rate (up to 840Mbit/s capability), high-density (48 Gbit storage), low mass (< 25 kg) solid-state recorder/processor with X-band modulation capability. It is in fact the highest rate solid-state recorder NASA has ever flown.

PPT (Pulsed Plasma Thruster), built by General Dynamics (formerly Primex Aerospace) for NASA/GRC). The system is also referred to as PRS-101 (Plasma Rocket System-101), its model number. The objective is to demonstrate on-orbit electromagnetic propulsion technology and to provide a S/C precision-pointing capability. [The EO-1 primary propulsion is provided by the hydrazine system for orbit maintenance and formation flying. The PPT is being used during limited periods of the mission to demonstrate the capability of a PPT system by performing the function of a momentum wheel. When in operation, the pitch axis momentum wheel is being idled and the PPT takes over control of the pitch axis.] The PPT consists of a coiled spring to feed the Teflon propellant, an igniter plug to initiate a small trigger discharge and an energy storage capacitor and electrodes (also: on-board electronics to convert the low voltage from the S/C to appropriate charging voltage for the capacitor, to provide energy to fire spark plugs, and to isolate PPT discharge from the S/C power bus). Plasma is created by the ablation of the Teflon propellant from discharge of the storage capacitor across the electrodes. The plasma is accelerated by the Lorentz force in the induced magnetic field to generate thrust. Impulse levels of 10-1000 μNs are achieved; the specific impulse is 880-1170 m/s; the average power consumption of PPT is between 1-100 W. PPT is used to maintain S/C attitude (fine pitch attitude control pointing requirements while meeting stringent electromagnetic and contamination constraints for the mission). A series of fine pitch pointing maneuvers are planned after the end of the primary imaging mission. The total mass of the PPT is 4.87 kg.¹⁶⁴⁷⁾

FODB (Fiber Optic Data Bus). The objective is to demonstrate high aggregate bandwidth data transfer capabilities on-board EO-1 - with low mass and low power requirements. FODB was developed as a standard high-speed (Gbit/s) data interface for future spacecraft. It complies with the IEEE P1393 (Spaceborne Fiber Optic Data Bus) standard. The bus concept is based on a ring topology of 2 to 128 nodes which provides flexibility to meet differing payload requirements. The master node is a Controller Fiber Bus Interface Unit (CFBIU) and up to 127 slaves are implemented with a Fiber Bus Interface Unit (FBIU). The interface between nodes is implemented in fiber optics, it reduces weight and provides for an EMI/EMC problem-free system. The FODB on EO-1 is implemented with four nodes. In this configuration, the WARP data system contains the master controller node

¹⁶⁴⁷⁾Information provided by Andrew Hoskins of General Dynamics

(CFBIU) and one slave node (FBIU). An external instrument terminal box, mounted on the spacecraft, contains two slave nodes, glue logic, power, and ALI instrument interface connectors. The FODB bus employs an ATM (Asynchronous Transfer Mode) with minimum overhead which simplifies the node interface design. Transfer rates between 200 Mbit/s and 1 Gbit/s are supported by FODB.

EFF (Enhanced Formation Flying), developed at a.i. solutions Inc. The objective is to demonstrate an on-board software package capable of autonomously planning, executing, and calibrating routine spacecraft maneuvers to maintain satellites in their respective constellations and formations. The long-term goal of this technology is to enable many small and inexpensive spacecraft to fly in formation and gather concurrent science data in a “virtual satellite”. This “virtual satellite or virtual platform” concept lowers total mission risk, increases science data collection and adds considerable flexibility to future Earth and space science missions.

The EFF features include an innovative use of fuzzy logic decision making capabilities and natural language to resolve multiple conflicting constraints; scripting environment enables algorithm updates without software changes; flight wrapper interfaces directly with the command and data handling subsystem for input and output; multiple operating modes allow execution control; generic closed-loop formation flying control algorithms applicable to many missions; modular architecture design is flexible enough to control execution of multiple and varying algorithms from several partners.

The EO-1 spacecraft is using a Tensor GPS receiver of Space Systems/Loral (SS/L) for active on-board navigation and attitude control.

M.7 EO-3 (Earth Observing-3, GIFTS-IOMI Mission)

EO-3 is the second Earth-observing technology mission in NASA’s New Millennium Program (NMP). The joint NASA, Navy, and NOAA mission consists of a single instrument, namely GIFTS (Geosynchronous Imaging Fourier Transform Spectrometer) to be flown on a geosynchronous satellite. The goal of GIFTS is to serve as a testbed for the following planned next-generation instruments: ¹⁶⁴⁸⁾ ¹⁶⁴⁹⁾

- Demonstration/validation of advanced Earth observation capabilities from GEO using the newly developed instrument GIFTS
- Support of the Navy’s IOMI (Indian Ocean METOC Imager) project
- Demonstration of the required ABS (Advanced Baseline Sounder) capabilities for NOAA’s GOES program (technology infusion, demonstration of forecast utility).

The S/C is three-axis stabilized and employs the T310 bus of TRW (prime S/C integrator). The bus is a cube of 170 cm side length; the GIFTS instrument is mounted to the nadir face of the spacecraft. The overall deployed configuration has a length of 8.5 m (2 solar panels). The boresight pointing is $<0.017^\circ$ (3 sigma), the attitude stability is $<10 \mu\text{rad}$ rms per axis. A star tracker assembly is the main attitude sensor. The bus has the capability to accommodate up to 379 kg of payload mass and to provide 585 W of payload power. The design life of the spacecraft is 9 years.

The mission is planned to be launched in late 2004 on a Delta-4 vehicle from Cape Canaveral, FL., as part of the US Air Force’s Space Test Program.

Orbit: Geosynchronous orbit at three successive locations: Eastern Pacific and Western Atlantic during 2005 and 2006. The Indian Ocean location is planned for the time frame 2007-2012 in support of the Navy’s IOMI project.

¹⁶⁴⁸⁾ W. L. Smith, et al., “Geostationary Fourier Transform Spectrometer (GIFTS)—The New Millennium Earth Observing-3 Mission,” IRS ’00: Current Problems in Atmospheric Radiation, edited by W. L. Smith and Y. U. Timofeev, A. Deepak Publishing, Hampton Virginia, 2001.

¹⁶⁴⁹⁾ <http://nmp.jpl.nasa.gov/eo3/index.html>

RF communications: TT&C data employ the S-band, the uplink data rate is 1 kbit/s (encrypted), the downlink has a variable rate of 8-512 kbit/s (encrypted). The payload data are downlinked in X-band at a rate of 80 Mbit/s.

Figure 303: Illustration of the EO-3 spacecraft

Sensor complement:

GIFTS (Geosynchronous Imaging Fourier Transform Spectrometer) of NAST and HIS heritage.^{1650) 1651) 1652)} The GIFTS instrument design includes advanced technologies in imaging, active cooling, fast data processing, pointing and control, radiation protection, and lightweight materials. The overall objective is to space-qualify the new technologies and to introduce the new concepts into next-generation instruments of operational weather observing systems for enhanced prediction analysis and service capabilities. The instrument is being designed/developed in partnership by NASA/LARC (prime), SSEC (Space Science and Engineering Center) of the University of Wisconsin, Madison, and the Space Dynamics Laboratory (SDL) of Utah State University. GIFTS is an advanced geosynchronous sounding instrument with the following measurement capabilities:

- Regional to full-disk visible and multispectral infrared imaging with 1 to 5 minute temporal frequency
- Full-disk temperature, moisture, and tracer wind sounding with 1 to 3 hour temporal frequency for global numerical weather prediction
- Regional half-hourly high-resolution sounding for mesoscale intense weather observation and forecasting
- Soundings of chemical composition for monitoring pollutant and greenhouse gas episode evolution and transport.

The science objectives are: a) to measure temperature, water vapor, tracer wind, and chemical composition distribution with high spatial and temporal resolution for considerable improvements in observational weather observation and air quality monitoring; b) to provide dynamic observations of cloud spectral radiance and associated atmospheric properties in support of NASA's ESE missions; c) to observe the transport of radiantly active pollutants and greenhouse gases in support of the Aura atmospheric chemistry mission.

¹⁶⁵⁰⁾ <http://oea.larc.nasa.gov/PAIS/GIFTS.html>

¹⁶⁵¹⁾ <http://its.ssec.wisc.edu/~bormin/GIFTS/>

¹⁶⁵²⁾ <http://danspc.larc.nasa.gov/GIFTS/>

The technology objectives are to validate advanced technologies in support of improved remote sensing capabilities of future missions from geosynchronous orbit.

- FTS (Fourier Transform Spectrometer). An LFPA of 128 x 128 elements is employed. The FTS feature enables the simultaneous measurement of infrared radiation spectra by each detector element with a spectral resolution (up to 0.6 cm^{-1}) sufficient for resolving the structure of the atmosphere with high vertical resolution.
- LFPA (Large area format Focal Plane detector Array). The LFPA component provides the nearly continuous observation of large geographical areas ($512 \text{ km} \times 512 \text{ km}$ - anywhere on the visible disk) with high horizontal resolution ($4 \text{ km} \times 4 \text{ km}$ in the infrared, and $1 \text{ km} \times 1 \text{ km}$ in the visible region) within time intervals of 10 s.
- Data readout and digital signal processing electronics. Demonstration of a signal and data processing architecture capable of handling the massively parallel data stream. This involves a new generation of data processing and compression hardware and algorithms to reduce the data rates transmitted.
- Radiation shielding
- Lightweight structures and optics
- Redundant miniature cryogenic coolers. Validation of low-power, high-efficiency mechanical cryocoolers and thermal switches.

The GIFTS optics subsystem uses a 24 cm diameter aperture yielding diffraction limited spatial resolutions. The footprint size is 4 km but the resolution ranges from 4 km at the shortest wavelength to about 8 km at the longest wavelength of the GIFTS spectrum. Nyquist spatial sampling is obtained by using four times as many detector elements (twice as many in each areal dimension) than required for a 4 km spacing of the measurements.

GIFTS uses two detector arrays to cover the spectral bands 685 to 1130 cm^{-1} (14.6 - $8.85 \text{ }\mu\text{m}$) and 1650 to 2250 cm^{-1} (6.06 - $4.45 \text{ }\mu\text{m}$). The FTS approach (of the Michelson interferometer) for GEO applications allows spectral resolution to be easily traded for greater area coverage or higher temporal resolution. Full disk sounding coverage can be achieved in about 7 minutes. High vertical resolution soundings and atmospheric chemistry measurements of GIFTS require a spectral resolution of 0.6 cm^{-1} and a longer stare time, thereby reducing the area coverage and/or frequency of observation relative to the imagery mode of operation. Nevertheless, GIFTS can cover a major portion of the visible disk with high vertical resolution soundings in less than 0.5 hour. This feature is important for obtaining wind profiles from GEO temperature and moisture sounding data. A relatively long dwell time and a more limited area coverage “self-validation mode” of operation enables spectral resolutions of 0.6 cm^{-1} with high radiometric precision. - Periodic views of on-board references and cold space are used to achieve high calibration accuracy.

A low visible light sensitive camera, using 512×512 active pixel detector arrays, provides quasi-continuous imaging of clouds at 1 km spatial resolution. Extended Earth coverage is achieved by step-scanning the instrument FOV in a contiguous fashion across any desired portion of the Earth. The radiance spectra observed at each time step are transformed to high vertical resolution (1-2 km) temperature and water vapor mixing ratio profiles.

Mode of operation	Spectral resolution	Spatial coverage	Observation time (scan speed of 0.17 m/s and 1 s telescope step time)
Regional imaging	36 cm^{-1}	$6,000 \text{ km} \times 6,000 \text{ km}$	3 minutes
Global sounding	18 cm^{-1}	$10,000 \text{ km} \times 10,000 \text{ km}$	7 minutes
Regional sounding and chemistry	0.6 cm^{-1}	$6,000 \text{ km} \times 6,000 \text{ km}$	25 minutes
Self validation (radiometric precision $>0.1 \text{ K}$)	0.6 cm^{-1}	$1,000 \text{ km} \times 1,000 \text{ km}$	60 minutes

Table 483: GIFTS operation modes in GEO orbit

Figure 304: Schematic illustration of the GIFTS instrument

Parameter	GOES (I-M) Sounder	GIFTS
No of channels	19	1724
Detector elements	4	16,384
Spatial footprint/spacing	8/10	4/4
Coverage rate per 3000 km x 3000 km area	about 42 minutes	about 7 minutes
Spectral coverage	0.70 - 14.71 μm	4.45 - 6.06 μm 8.85 - 14.6 μm

Table 484: Comparison of GIFTS performance parameters with current sounders in GEO

The profiles are obtained on a 4 km grid and converted to relative humidity profiles. Images of the horizontal distribution of the relative humidity for the various layers, vertically separated by about 2 km, are constructed for each spatial scan. The sampling period ranges from minutes to an hour, depending on spectral resolution and area coverage. Successive images of clouds and the relative humidity for each layer are then animated to reveal the motion of small-scale thermodynamic features of the atmosphere. Automated auto-correlation feature tracking programs are then used to compute the speed and direction of the features, thereby providing a measure of the wind velocity distribution. The net result is a dense grid of temperature, moisture and wind profiles which can also be used for atmospheric analysis and operational weather prediction. Feature tracking can also be used for mixing ratio profiles of O_3 and CO , derived from their spectral radiance features observed by the instrument, providing a direct measure of the transport of these pollutant and greenhouse gases. It is the imaging interferometer technique (i.e. the combination of the FTS and the LFPA) in GEO that enables the tracer wind profile and trace-gas transport measurements.

GIFTS has a mass of 130 kg and a power consumption of 320 W (max). The instrument data rate is 60 Mbit/s (max).

M.8 ETS (Engineering Test Satellite)

NASDA's ETS satellite series is aimed at developing and demonstrating common base technologies. The program started with the launch of ETS-I (Kiku-1), NASDA's first satellite, on Sept. 9, 1975, from Tanegashima Space Center using an N-I launch vehicle.

S/C	Launch/ Service life	Objective/Comment
ETS-I	Sept. 9, 1975/ April 28, 1982	Circular orbit of 1000 km, 47° inclination, S/C mass = 82.5 kg
ETS-II	Feb. 23, 1977/ Dec. 10, 1990	Japan's first GEO S/C at position 130° E, S/C mass = 130 kg, S/C diameter = 1.4 m
ETS-III	Sept. 3, 1982/ March 8, 1985	Data for designing earth observation satellites with high power requirements; testing of three-axis attitude control; S/C mass = 385 kg; Circular orbit of 1000 km altitude, 45° inclination.
ETS-IV	Feb. 11, 1981/ Dec. 24, 1984	GTO orbit with 225 km perigee and 36,000 km apogee, inclination=28.5°; S/C mass = 640 kg
ETS-V	Aug. 27, 1987/ March 31, 1989	Test of GEO three-axis bus system technology and experiments for mobile communications satellite. GEO orbit at 150° E. S/C mass of 550 kg
ETS-VI	Aug. 28, 1994/ July 9, 1996	Confirm the technology required for a GEO three-axis satellite bus system for high performance S/C and test of advanced communication equipment. S/C mass of 2000 kg (660 kg payload), 10 year design life for S/C bus. Also feature of a high precision attitude control system Injection into GEO failed due to an apogee engine malfunction
ETS-VII	Nov. 28, 1997	Rendezvous-docking and space robotic experiments
ETS-VIII	2003	Demonstrate support of mobile communications with S/C in GEO

Table 485: Overview of early ETS series satellites

M.8.1 ETS-VII (Engineering Test Satellite VII)

ETS-VII (Kiku-7) is a NASDA technology demonstration satellite with the objective to conduct rendezvous-docking and space robotic experiments. In the rendezvous-docking experiment, the chaser satellite conducts rendezvous-docking with the target satellite by both automatic and remotely piloted controls, and in the space robotic experiments, unmanned space work is carried out by teleoperation. In addition, the space robotic experiments by MITI/ETL, CRL and NAL (National Aerospace Laboratory) are carried out.

The ETS-VII system consists of two spacecraft: a chaser satellite (Hikoboshi) with a total mass of 2,540 kg, and a target satellite (Orihime) of mass 410 kg. Both satellites are three-axis stabilized. The mission design life is 1.5 years.

A launch of ETS-VII took place on Nov. 28, 1997 from Tanegashima Space Center on the H-2 launch vehicle. ETS-VII experienced an attitude stability problem on Nov. 30, 1997 that could be corrected.

Orbit: Circular orbit, altitude = 550 km, inclination = 35°, period = 96 minutes.

Rendezvous-docking experiment:

The overall objective was to acquire/retrieve materials to/from a satellite in orbit. The following experiments were carried out:

- Demonstration of rendezvous-docking equipment in orbit
- Evaluation of both automatic and remotely piloted rendezvous-docking in orbit
- Demonstration of simultaneous operation of two spacecrafts.

To enable the unmanned autonomous rendezvous docking experiment, the Rendezvous docking equipments: GCC (Guidance Control Computer), DM (Docking Mechanism), PXS (Proximity Sensor), RVR (Rendezvous Laser Radar), and GPSR (GPS Receiver) are developed and used in the Rendezvous-docking demonstrations.

For each experiment, the chaser satellite detaches the target satellite and drifts away to distances of up to 9 km); subsequently, a rendezvous-docking maneuver brings the chaser satellite back close to the target resulting in a final docking maneuver.

The rendezvous-docking operations were conducted from the NASDA ground stations using NASA's TDRS (Tracking and Data Relay Satellite) system. ¹⁶⁵³⁾ ¹⁶⁵⁴⁾ ¹⁶⁵⁵⁾

- On July 7, 1998, the first experiment was successfully performed. In this flight, autonomous docking from 2 m was demonstrated. The Chaser detached the Target based on "separation command" from the ground. The Chaser automatically conducted formation flight for 15 minutes at the range of 2 m from the Target and docked again. The Chaser conducted six degree-of-freedom (6DOF) control using the PXS navigation.
- The second rendezvous docking experiment was initiated on Aug. 7, 1998. In this flight attitude anomalies occurred, and the Chaser made a flight to 12 km in range. As a result, the Chaser successfully docked with the Target on Aug. 27 using not only the PXS navigation but also the relative GPS navigation and the RVR navigation.
- The third experiment flight was performed in Oct. 26-27, 1999 with the following test sequence: 1) Flight remotely controlled from the ground; 2) Collision Avoidance Maneuver (CAM) flight; 3) R-bar approach flight (approaching from the side of the Earth).

Through these experiment flights, the autonomous rendezvous docking technologies from the relative approach to the docking (from 10 km to docking) were verified on orbit.

Figure 305: Illustration of the ETS-VII spacecraft

Space robotic experiments:

The objective was to acquire the basic capability to teleoperate a space robot and to analyze the engineering data for the development of future advanced space robots.

- After the successful launch and initial check out of the satellite, various space robot experiments were conducted between Mar. 1988 to May 1999. All planned robotic experiments were successfully conducted. Further experiments were additionally conducted until Nov. 1999.

¹⁶⁵⁵⁾ M. Mokuno et. al., "Experimental Result of Autonomous Rendezvous Docking on Japanese ETS-VII satellite," *Proceedings of the Annual AAS Guidance and Control Conference*, AAS99-022

- On March 16, 1999 NASDA conducted successfully the telemanipulation experiment of the robot arm on ETS-VII. Objective: to evaluate (compare) the difference of operation of the Shuttle remote manipulator and the ETS-VII onboard robot arm.
- Joint NASDA ESA experiments: In the period April 6-9, 1999, ESA demonstrated autonomous robot manipulations and robot user interactions with VIABLE (Vision Interactive Autonomy Bi-Lateral Experiment).¹⁶⁵⁶⁾ The ESA experiments concerned advanced schemes for planning, commanding, controlling and monitoring the activities of a space robot arm system. One set of experiments tests an operational mode called “interactive autonomy”, whereby the robot motions are split into typical “tasks” of medium complexity. Ground operators can interact with the tasks (parameterizing, commanding, rescheduling, monitoring, interrupting them as needed), relying on the fact that each task is autonomously executed using appropriate sensor-based control loops. The second group of experiments dealt with vision-based robot control. Using the Japanese-provided on-board vision system (including a hand camera and a scene-overview camera). It has been demonstrated that reliable automatic object localization and grasping can be performed even without the artificial markers which are typically used to guide telemanipulation.
- Joint NASDA DLR and IRF experiments: Teleoperation experiments of the onboard robot arm on ETS-VII were conducted April 19-21, 1999 using NASDA’s robot operation facility at Tsukuba Space Center and GETEX (German Teleoperation Experiment) of DLR/IRM and of IRF (Institute for Robotics Research), University of Dortmund).

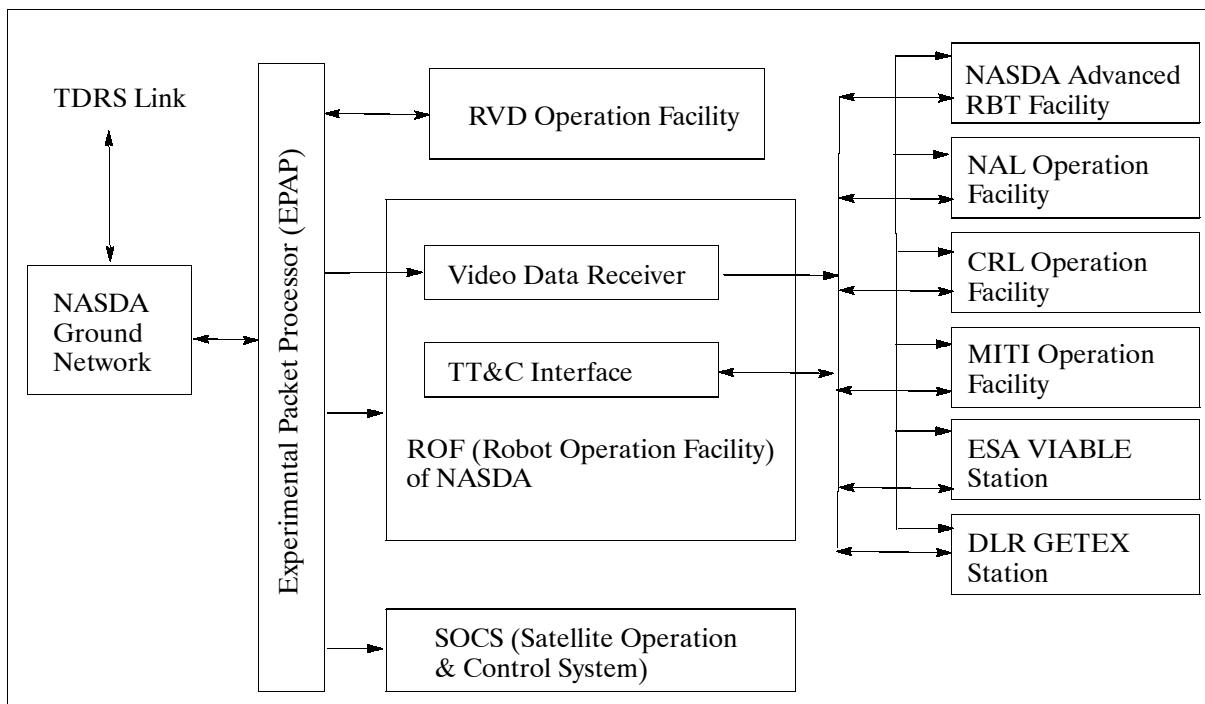

Figure 306: ETS-VII ground segment configuration with guest experiment stations

- On Sept. 1, 1999 the first successful Target Capture experiment of ETS-VII took place. In the experiment, the satellites’ docking mechanism was first loosened, allowing Orihime to float freely within certain limits; specifically, Orihime was made to float about 200 mm from the robot arm aboard Hikoboshi. Starting from this state, the robot arm then automatically approached Orihime without assistance from the ground, and successfully grasped the handle on Orihime using the finger attached to its tip. The suc-

¹⁶⁵⁶⁾ G. Visentin, F. Didot, “Testing Space Robotics on the Japanese ETS-VII Satellite,” ESA Bulletin No. 99, Sept. 1999, pp. 61-65

successful release, tracking, and capture of the satellite without help from the ground was a first in space history. Previous automatic docking activities, such as those conducted with Russian Soyuz and Progress spacecraft, have used either operator assistance or ground control computers. The United States has not conducted a robotic docking in space.

M.8.2 ETS-VIII (Engineering Test Satellite VIII)

ETS-VIII is an advanced NASDA satellite with the aim to develop and verify the world's largest geostationary satellite-bus technology, considered to be necessary for space missions at the beginning of the 21st century. The mission objectives are to conduct orbital experiments on the following structures/systems: (the first three are required to realize mobile satellite communications with hand-held terminals, similar to popular cellular phones).

- LDR (Large-scale Deployable Reflector) developed by NASDA, a system needed for large-scale space structures. The LDR structure features a 2.4 mm rms surface precision and antenna diameter expendability. It consists of 14 hexagon-shaped modules. ETS-VIII is equipped with two LDR modules, one of data transmission and the other for reception.
- HPT (High-Power Transponder), developed by ASC (Advanced Space Communications Research Laboratory)
- OBP (On-Board Processor), provided by ASC and CRL (Communications Research Laboratory)
- Moreover, the ETS-VIII S/C carries a high precise clock system for satellite positioning experiments, developed by NASDA and CRL.

The S/C shape is a rectangular box with deployable solar paddles. The satellite design employs a number of features such as:

- A light structure to improve the payload to bus system ratio to 40% from the conventional 30%
- The bus system consists of several modules to reduce development time through concurrent work to integration
- The bus power supply voltage was changed from the conventional 50V to 100V for greater electrical power
- The MIL-STD-1553B data bus standard is used for commonality
- In addition, the CCSDS packet protocol suite was chosen for all data communication with the ground segment
- The thermal subsystem uses heat pipes to connect the north and south panels of the satellite thereby expanding the effective radiation surface
- Use of an attitude control system with fault-tolerant functions and in-orbit reprogramming capability.

The satellite consists of three modules: bus, payload, and propulsion module.^{1657) 1658)} It is three-axis stabilized, the accuracy of the AOCS (Attitude Orbit Control System) is: roll/pitch axes = $\pm 0.05^\circ$ max., yaw axis = $\pm 0.15^\circ$ max. The AOCS employs an Earth sensor assembly, a sun sensor and an integrated rate gyro assembly for attitude sensing. Actuation is provided by four reaction wheels, each of 50 Nms, in a skewed arrangement. In addition, 13 accelerometers are installed to monitor the dynamic behavior of the deployed structure. The S/C mass is 2900 kg at the beginning of mission life with a payload mass is 1100 kg. S/C electrical power is 7.5 kW with a regulated 100 V of bus voltage. The NiH₂ batteries provide a capacity of 100 Ah for eclipse operations. The overall length of the spacecraft is 40 m measured along the axis of the solar panels, and 37 m measured along the axis of the two LDRs.

Two propulsion systems are used: a) an apogee (bi-propellant) engine in the 500 N class with 22 N thrusters (used for attitude control and E-W station-keeping), and b) a Xenon ion engine providing a thrust of 25 mN, two ion engines are used for N-S station-keeping. The S/C bus has a design life of 10 years, the mission design life is three years.

Figure 307: The ETS-VIII deployed S/C configuration

The launch of ETS-VIII with an H-IIA launch vehicle from Tanegashima Space Center is planned for 2003.

Orbit: Geostationary orbit of ETS-VIII at 146° E longitude.

TT&C communications are provided in S-band. All data transmission is done with CCSDS protocols. The MIL-STD-1553B data bus is used for all on-board data handling. The OBP design supports autonomous FDIR (Fault Detection, Isolation and Reconfiguration) functions.

Parameter	OBP (Onboard Processor)	OPS (Onboard Packet Switch)
Modulation	35 k symbol/s, $\pi/4$ QPSK	512 k symbol/s, $\pi/4$ QPSK
Access method	MC-TDMA (5 channels/carrier)	Slotted ALOHA
Information rate	5.6 kbit/s (voice)	4 - 32 kbit/packet
Number of channels	500	128 packets/carrier (max)
Satellite EIRP/Carrier and G/T	49 dBW, 13 dB/K	52 dBW, 13 dB/K
Ground terminal EIRP and G/T	9 dBW, -24 dB/K	18 dBW, -21 dB/K

Table 486: Specification of the onboard processors

Parameter	Feeder Link	Mobile Link
Frequency band	Ka-band	S-band
Antenna aperture	0.8 m diameter	13 m diameter
EIRP (Effective Isotropic Radiated Power)	44 dBW @ NPR=20 dB	65 dBW @ NPR=16 dB
G/T [(receiver) Gain/(noise) Temperature]	15 dB/K	15 dB/K
Beam scanning range	N/A	$\pm 2^\circ$

Table 487: RF subsystem performance

Mobile satellite communications and broadcasting experiments:

S-band communications and broadcasting experiments are being conducted to demonstrate a mobile satellite communications and broadcasting system technologies with small-scale ground terminals such as hand-held terminals. These experiments employ the following devices:

- **Large-scale Deployable Reflector:** The entire spacecraft structure is dominated by the two large deployable antenna reflector structures, each of size 19.2 m x 16.7 m with a 13 m aperture. Each mesh deployment antenna consists of 14 modules. Each module in turn consists of a gold-plated Molybdenum mesh surface, a spatially determined cable network, and a deployable truss as supporting structure. The entire antenna system fits in a stow-volume of 1 m diameter x 4 m in height.

Antenna layout	Offset parabola
Aperture size, F/D	13 m, 0.8
Offset angle, surface error	52.5°, less than 2.4 mm rms (S-band: $\lambda/50$)
Beam pointing error	Less than 0.83° (static)/0.0045° (dynamic)
Antenna mass	<400 kg (2 reflectors, include supporting booms, adjustment mechanisms and deployment drive electronics)
Antenna stiffness	>0.1 Hz (in orbit) >40 Hz (during launch in longitudinal direction) >20 Hz (during launch in lateral direction)

Table 488: Design specifications of the antenna reflectors

- **Active-Phased-Array Feeder:** The phased array feeder systems are combined with the LDRs to create multiple steerable MSS (Mobile Satellite communication Systems) and to support mobile BSS (Broadcasting Satellite System) experiments (3). The transmission side feeder consists of 31 solid state power amplifiers (300W in gross output), and the receiving side feeder of 31 low noise amplifiers. The on-board beam-forming network controls the amplitude and phase of the signals to/from the feeder elements to create multiple steerable beams and to form the desired beam patterns.
- **On-board signal switching:** Two sets of onboard baseband switching equipment are installed to realize onboard signal routing. One is an on-board processor (OBP), which is designed to perform voice channel switching among mobile users or between mobile users and ground network users and has 500 channel capacity. The other is an onboard packet switch (OPS) for high-speed packet data communications.

Satellite positioning experiments:

Positioning experiments (in S- and L-band) are conducted to study basic satellite positioning system characteristics and to demonstrate the feasibility of new satellite positioning system concepts (consisting of MEO and GEO constellation elements). A high-accuracy time signal, which is similar to the GPS data, created by an atomic cesium frequency standard on the satellite is transmitted. Furthermore, the TCE (Time Comparing Equipment) is used to conduct precise time comparison between the on-board atomic clock and the ground reference clocks. High-accuracy orbit determination is supported by SLR (Satellite Laser Ranging) stations.

Frequency	L-band (1598.88 ± 7.5 MHz), S-band (2491.005 ± 7.5 MHz)
EIRP	38 dBW
Transmit signal	Spread spectrum signal with navigation message (50 bit/s)
PN code	1.023 Mchirp/s, 1.705 Mchirp/s, 3.41 Mchirp/s, 5.115 Mchirp/s
Objective accuracy	<100 m, orbit determination < 10 ns, clock synchronization without TCE (Time Comparing Equipment) <10 ps, clock synchronization with TCE

Table 489: Specification of the positioning system

In the experiment, time signals from two sources, namely the GPS constellation and from the on-board atomic clock are used to determine the position of the satellite. The intend is to reduce the number of spacecraft in the constellation of a future navigation system (if sufficient accuracy can be achieved by this method of orbit determination).

M.9 FedSat-1 (Federation Satellite One)

FedSat-1 is an Australian microsatellite to commemorate the centenary celebration of Australian Federation in 2001.^{1659) 1660) 1661) 1662)} The program is managed by CSIRO (Commonwealth Science and Industrial Research Organization - Canberra, Australia) with participation from universities and industry (Auspace Ltd, Canberra; and Vipac Engineers and Scientists Ltd, Canberra are the prime contractors). The Australian Government created a new entity in 1997, CRCSS (Cooperative Research Center for Satellite Systems). The specific mission of CRCSS is to promote Australian space research and to create a favorable and sustainable environment for Australian industry, government agencies and universities, involved in services, applications, and research. As of 2000, there are more than sixty CRCs (Cooperative Research Centers) in Australia active in engineering, science, medicine, and technology. The main objectives of the FedSat mission are in the fields of: communications, space science, remote sensing, engineering research, and education/training.

Figure 308: Illustration of the FedSat spacecraft

The S/C structure resembles a cube of 50 cm side length and is based on a variant of the standard MicroSIL bus, built by SIL (Space Innovations Limited) of Newbury, Berks, UK, a commercial platform provider (SSTL of Surrey purchased SIL as of 2000). The design is based around six honeycomb outer panels, and an interior double shelf, dividing the platform subsystems on the lower shelf from the payload instruments on the top shelf. FedSat-1 is three-axis stabilized. The S/C attitude is measured by three digital sun sensors (linear array of 256 photodiodes) and a three-axis fluxgate magnetometer. Attitude is controlled by

three precision reaction wheels, three magnetorquers, and three solid-state rate gyros as actuators. The attitude knowledge accuracy is $\pm 1^\circ$. The ACS (Attitude Control System) is provided by CSA (Canadian Space Agency) and built by Dynacon Enterprises Ltd. of Mississauga, Ontario.¹⁶⁶³ Power (60 W max) is provided by surface-mounted solar cells (19 strings of GaAs cells on Ge substrates). In addition, there are 16 NiCd battery cells, each with a capacity of 6 Ah for eclipse phase operations. On-board data storage of 2.56 Gbit is provided. The S/C mass is 58 kg. The S/C design life is three years with a goal of five years of operations.

Communications: The S/C features two S-band patch antennas, plus a UHF quarter-wave whip, and Ka-band isoflux antenna. The S/C TT&C communications are in S-band. The S-band transmitter has an output power of 2 W. Uplink frequency = 2205 MHz, downlink frequency = 2030.4375 MHz. Downlink data rates of up to 1 Mbit/s are supported. Suppressed carrier BPSK modulation is employed. The on-board receiver accepts telecommand data, BPSK modulated, on to a subcarrier, with uplink rates between 8 bit/s to 4 kbit/s. Redundancy is provided through the experimental communications payload, with a UHF uplink at 4 kbit/s, and a Ka-band downlink with 125 kbit/s or 250 kbit/s capability. The communications protocol is known as the Packet Utilization Standard. It is basically an ESA augmentation of CCSDS.

Spacecraft operations are provided by CRCSS (Cooperative Research Center for Satellite Systems) through its participating organization ITR (Institute for Telecommunications Research) at the University of South Australia in Adelaide. All communications with the S/C are supported by one ground station, located at Adelaide, offering 2-3 passes per day. A piggyback launch of FedSat-1 is planned on the H2A vehicle of NASDA (second flight) along with ADEOS-II in early 2002.

Orbit: Sun-synchronous circular orbit, altitude = 802.9 km, inclination = 98.67° , equator crossing time on ascending node at 10:30 AM.

Sensor complement:

CPE (Communications Payload/Experiment), developed at ITR of UniSA (University of South Australia) and at UTS (University of Technology, Sydney) in cooperation with CRCSS. The objective is the study of new Ka- L-, and UHF-band techniques for communications and data delivery (modulation, coding and multiple access techniques, on-board data reduction, regeneration and processing). The following subsystems are part of the communications payload/experiment:¹⁶⁶⁴

- **ADAM** (Advanced Data Acquisition and Messaging System) of UniSA. A portion of ADAM's functionality include the "old-fashioned" DCS (Data Collection System) services. ADAM consists of a BBP (Baseband Processor) unit and a UHF transceiver unit. It provides the functionality of two-way packet communications for remote environmental monitoring and forward messaging.
- Ka-band payload module (CSIRO)
- Ka-band Earth terminals (UTS)
- Ground control station for FedSat TT&C services (UniSA).

The Ka-band unit is used for bent-pipe and regenerative communications, and as a testbed to space-qualify an GaAs MMIC (Microwave Monolithic Integrated Circuit) device of CRCSS. BBP provides on-board processing of the Ka- and UHF-band units; it also acts as a low-power single modem with flexible operations support (study of communication protocols). Key features of the BBP include turbo coding on the uplink (QPSK modem with a bit error rate of 10^{-10} , it operates on a signal SNR as low as 2 dB, and a data rate of 2 Mbit/s), highly flexible operation including reconfigurable field programmable gate arrays

¹⁶⁶³)S. C. O. Grocott, "Modular Attitude Control System for Microsatellites with Stringent Pointing Requirements," Proceedings of the 14th AIAA/USU Conference on Small Satellites, Logan, UT, Aug. 21-24, 2000, SSC00-VIII-6

¹⁶⁶⁴)<http://www.crcss.csiro.au/reports/rept2000/Part05.htm>

(FPGAs), low power consumption (<5 W), and burst demodulation. A copy of ADAM will be flown on KAISTSAT-4 (launch in 2002) of KAIST/SaTReC of Korea (see D.19.3) as its DCS (Data Collection System). ADAM is also planned to be flown on a satellite by ATSB of Malaysia.

Potential applications of the UHF and BBP units include ARGO (Array for Real-time Geostrophic Oceanography) and mobile communications.¹⁶⁶⁵⁾ The ARGO program involves data collection services, i.e. uploading of data from a large number of floating buoys in the Southern Ocean and forwarding this information to a ground station. A portion of the ARGO array consists of submergible buoys called PALACE floats (these are Lagrangian buoys which may float at any altitude in the Ocean, measuring temperature and salinity). Two-way link capabilities (with multiple access scheme and error control techniques) permit a reconfiguration of the floats; turbo-coding techniques permit much larger messages per packet. Mobile applications include communications with land-mobile, laptop and hand-held terminals in remote areas for data and messaging experiments.¹⁶⁶⁶⁾

NewMag (Magnetometer Experiment). A space science experiment in solar-terrestrial physics, developed at the University of Newcastle, New South Wales, Australia, with the objective to measure electrical currents and perturbations in the Earth's magnetic field in the frequency range of 0.1 Hz to 1 kHz. The aim is to observe naturally occurring electromagnetic wave signatures (oscillating wave fields, including ULF hydrodynamic waves and lower ELF-band ion cyclotron waves) and field-aligned currents in the ionospheric F-region and the exosphere (plasma-wave model improvement of the ionosphere and exosphere). The NewMag and BlackJack ionospheric measurements contribute to this objective. NewMag is a three-axis fluxgate magnetometer. It is designed and built at UCLA (C. T. Russell) and is of MFI (Magnetic Fields Instrument) heritage, flown on the FAST mission (launch of FAST on Aug. 21, 1996, K.21.2). Other missions of MFI heritage are ISEE-1/2 (launch Oct. 2, 1977), AMPTE-UKS (launch Aug. 16, 1984), POLAR (launch Feb. 24, 1996), and Galileo (launch 1989). NewMag has a dynamic range of ± 65536 nT with 16 bit resolution (± 0.2 nT), and a bandwidth of 10Hz (vector sample rates: internal = 1000/s, standard = 10/s, burst mode = 100/s). The instrument is mounted at the end of a 2.55 m boom (to avoid magnetic interference from the satellite itself), it has a mass of 3 kg and a power consumption of 3 W.¹⁶⁶⁷⁾

BlackJack (GPS Flight Receiver), built by SpectrumAstro of Gilbert, AZ, under the designation **AstroNav**. BlackJack is provided by NASA/JPL (cooperative research agreement with CRCSS) in exchange for BlackJack data availability to US researchers.¹⁶⁶⁸⁾ On the Australian side, the project is conducted in cooperation with QUT (Queensland University of Technology) and the Department of Physics of La Trobe University. There are two major measurement objectives: 1) determination of precise S/C timing, position and attitude, and 2) to obtain dual-frequency ionospheric soundings, permitting the derivation of total ionospheric electron density profiles, by the method of refractive occultation monitoring. The TEC (Total Electron Content) occultation observations of BlackJack provide slant range measurements which can be converted into vertical profiles. The instrument is a single-antenna navigation version of JPL's BlackJack receiver. A small patch antenna, facing backward in the anti-velocity direction, is mounted onto FedSat. The instrument is configured to track up to 16 GPS satellites simultaneously (3 channels per satellite). The tracking modes supported are: Code Phase L1 (1575.42 MHz) C/A code, L1 P Code/Codeless, L2 (1227.6 MHz) P Code/Codeless & Carrier Phase (Integrated Doppler) on both L1 & L2. The Black-Jack assembly has a mass of 2.4 kg and a power consumption of about 11 W.

¹⁶⁶⁵⁾ Note: ARGO is a component of the international Global Ocean Data Assimilation Experiment (GODAE).

¹⁶⁶⁶⁾ C. Graham, M. Petkovik, S. Russell, E. S. Seumahu, M. Vesely, "The FedSat Microsatellite," Proc. of ICICS'99 (International Conference on Information Communications and Signal Processing), Singapore, Dec. 7-10, 1999

¹⁶⁶⁷⁾ B. J. Fraser, C. T. Russell, J. D. Means, F. W. Menk, C. L. Waters, "FedSat - An Australian Research Microsatellite," Advances in Space Research, Vol 25, Issue 7-8, pp.1325-1336, 2000.

¹⁶⁶⁸⁾ Information provided by Thomas P. Yunck of JPL and Bill Falkenberg of SpectrumAstro Inc.

The receiver operation has a duty cycle imposed (10 minutes on, 40 minutes off, repeated indefinitely) due to FedSat power limitations. Hence, it is planned to take data only at regular navigation measurements (1 sample every 30 s), this rate may be exceeded for short periods only.

HPCE (High Performance Computer Experiment). HPCE is a cooperative experiment between QUT and JHU/APL. The objective is to study reconfigurable computing in space. The HPCE design employs a modular and reconfigurable FPGA (Field Programmable Gate Array) logic. The hardware configuration of wire connections are determined by downloading from memory a stream of configuration bits. These reconfigurations can also be uplinked during the mission. Each FPGA is capable to reconfigure itself in a very short time. The reconfigurable technology permits a change of physical FPGA circuits via software control.

M.10 MDS (Mission Demonstration Satellite)

MDS is a NASDA technology program, initiated in 1997, with the objective of short-term and economical satellite development, implementation of advanced missions and space demonstration of mission equipment. The strategy is to use a conventional bus and existing support equipment in this mission scenario.

M.10.1 MDS-1

The objectives of MDS-1 are to verify the use of commercial parts in orbit, to verify minimization technology for components, and to collect space environment data (e.g., radiation on equipment, etc.). The MDS-1 design is based on the concept of integrating proven technologies. The bus, an aluminum honeycomb structure, consists of box of size: 1.2 m x 1.2 m x 1.5 m. The spin axis of the S/C is perpendicular to the solar panels and to the boom. A magnetometer is mounted onto the deployable boom (3 m in length) to measure the Earth's magnetic field. The nominal spin rate is 5 rpm with a general boom orientation toward the sun (the angle between the sun direction and spin axis is 10°). A S/C power of >900 W (EOL) is provided by two deployable solar panels (3.3 m² total area and GaAs cells). The overall length of the satellite is 7.8 m from tip to tip. Two NiMH battery sets provide energy of 20 Ah for eclipse operations. Attitude sensing is provided by SAS (Sun Aspect Sensor), a horizon sensor, and a magnetometer. Occasional actuation is provided by thrusters to keep sun orientation (but MDS-1 is basically spin-stabilized). A reaction control subsystem utilizes hydrogen for initial spin-up. The S/C mass is 480 kg. The S/C design life is one year.

MDS-1 will be launched into the geostationary transfer orbit by an H-IIA vehicle from the Tanegashima Space Center in 2001/2. The co-passenger on this flight is VEP#3 (H-IIA Vehicle Evaluation Payload). ^{1669) 1670) 1671) 1672) 1673)}

Orbit: Geostationary transfer orbit (GTO), perigee = 500 km, apogee = 36,000 km, inclination = 28.5° .

RF communications: The on-board communication subsystem provides a USB (Unified S-band) command reception, telemetry transmission, and ranging (turn-around transmission of the ranging tone from/to the ground station) function. The downlink frequency is 2.212 GHz with data rates ranging from 128 bit/s (housekeeping data) to 16 kbit/s (mission data);

the uplink frequency is 2.036 GHz with a data rate of 500 bit/s. The on-board recorder has a capacity of 1 Gbit.

Figure 309: Illustration of the MDS-1 spacecraft (two views)

Sensor complement / demonstration of commercial devices or components

SEDA (Space Environment Data Acquisition). Objective: measurement of the space environment for performance evaluation of the demonstration equipment. The data obtained is also used to improve environmental models. SEDA is an instrument package consisting of the following instruments:

- **SDOM** (Standard Dose Monitor). SDOM measures the energies of electrons, protons and alpha particles.
- **DOS** (Dosimeter). The objective is to measure the radiation absorption.
- **HIT** (Heavy Ion Telescope). HIT measures heavy ions incident on the sensor with regard to type, energy and direction.
- **MAM** (Magnetic Monitor). MAM measures the magnetic flux in the MDS-1 orbit.

CSD (Commercial Semiconductor Device). This package represents a collection of commercial semiconductor devices, fabricated with different processes and materials, exposed to the radiation environment. The objective is to obtain data on the “total ionizing dose effect” and the “single event effect.” The results in space are also compared with ground test data. The aim is to establish evaluation methods for ground tests by comparing ground and space tests. CSD contains the following test devices: 4 Mbit SRAM, 64 Mbit DRAM, 1 Mbit EEPROM, 4 Mbit FLASH memory, FPGA, and 1 M Gate Array.

TSC (Terrestrial Solar Cells). The experiment consists of a collection of ground-used solar cells exposed to the radiation environment. The objective is to utilize the data obtained for the design of future solar cells with such features as: higher efficiencies, superior radiation tolerance, low mass and low cost. The following solar cell types are part of the experiment: Poly Si cell, n-type base Si cell, InGaP/GaAs tandem cell, CIS (Copper Indium di-Selenide) cell, NRS/BSF (Non-Reflective Surface/Back Surface Field) Si cell (space use), GaAs/Ge cell (space use).

Demonstration and space qualification of miniature lightweight components of high functionality and reliability intended for installation in future spacecraft or instruments.

CPV (Common Pressure Vessel type battery). The objective is to test a new battery type in space that might lead to substantial reductions in size and mass of the electrical power subsystem of a S/C. Demonstration of CPV type NiH₂ batteries with regard to battery charge/discharge control using high-frequency switching devices. The CPV battery consists of two cells (there are 16 mini cells to each cell); the capacity of each CPV cell is 5 Ah. The energy/unit mass of a CPV system is in the order of 35 Wh/kg. - Note: The Clementine spacecraft (launch Jan. 25, 1994, orbit to the moon, the S/C experienced a malfunction on May 5, 1994 after its lunar mission was completed) of DoD and NASA was probably the first mission to demonstrate the CPV battery technology in space.

SSR (Solid State data Recorder). The objective is to evaluate the SSR performance by using commercial semiconductors. The instrument consists of a control unit (64 Mbit DRAM) and stack memory modules in 3D high-density layout as memory unit, the storage capacity is 32 Gbit.

PCS (Parallel Computer System). Objective: demonstration and evaluation of parallel processing in combination with the “fault tolerant technique” with the use of MPU (Multi Processing Unit) to accomplish higher performances and reliabilities.

M.11 MightySat

MightySat is a long-term, multi-mission, small satellite program (started in 1994) of the Space Experiments Directorate of Phillips Laboratory (USAF/PL) at Kirtland Air Force Base, Albuquerque, NM (as of 1998 designated as AFRL (Air Force Research Laboratory)). The overall program objectives are to provide an environment for frequent, inexpensive, on-orbit demonstrations of emerging space system technologies and to accelerate their transition into operational use. The MightySat spacecraft are modular and functionally standardized platforms and buses capable of supporting a wide range of experimental payloads. Launches are considered from STS (Shuttle) or with multi-service launch systems. The emphasis is on low-cost projects, with fast building periods from contract to launch, with high-risk and high-payoff technologies. ^{1674) 1675) 1676)}

M.11.1 MightySat I

MightySAT I is a single mission project which uses an all-composite bus (similar in configuration to its aluminum XSAT predecessor of NASA) with significant mass reduction. ¹⁶⁷⁷⁾ The S/C was built by OSC of McLean, VA (formerly CTA Space Systems). The S/C structure is characterized by three decks supported by six structural frames which make up a hexagonal prism body. The S/C mass is 63 kg, the payload mass is 17 kg (average power of 12 W), orbit average power = 14-27 W. The S/C is spin-stabilized (3 rpm) with the spin axis oriented normal to the orbit plane. Attitude sensing and actuation is provided by a three-axis magnetometer, two coarse sun sensors, and three torque coils. A coarse attitude knowledge of $\pm 5^\circ$ is required. S/C design life of one year.

The S/C has four subsystems: C&DH (Command & Data Handling) made up of nine electronic boards, EPS (Electrical Power Subsystem) consisting of seven solar panels and a

¹⁶⁷⁵⁾ R. J. Davis, J. F. Monahan, T. J. Itchkawich, “MightySAT I: Technology in Space for about a Nickel,” Proceedings of the 10th Annual AIAA/Utah State University Conference on Small Satellites, Sept. 16-19, 1996

¹⁶⁷⁶⁾ B. Braun, R. Davis, T. Itchkawich, T. Goforth, “MightySat-I: In Space,” Proceedings of 13th Annual AIAA/USU Conference on Small Satellites, Logan Utah, Aug. 23-26, 1999, SSC-99-I-3

¹⁶⁷⁷⁾ <http://www.vs.afrl.af.mil/factsheets/msat.html>

single 21-cell NiCd battery (4 Ah), RF (Radio Frequency - communications) consisting of a receiver, transmitter, transmit/receive switch, and a four-blade antenna, and ADACS (Attitude Determination and Control Subsystem). Data transmission is in UHF-band (306.775 MHz) at 9600 bit/s (downlink, BPSK modulated) and at 2400 bit/s (uplink, FSK modulated). The link margin is about 20 dB for uplink and downlink above a 5° elevation angle.

MightySat I was launched by ejection from the Space Shuttle using HES (Hitchhiker Ejection System) on Dec. 14, 1998. The entire satellite, HES, and avionics were stowed away into a standard Hitchhiker canister of 0.14 m³ in volume prior to launch. Deployment was initiated by the Shuttle crew on Dec. 14, 1998. The entire MightySat I deployment sequence took about 10 minutes. The launch of Shuttle flight STS-88 took place on Dec. 4, 1998 (landing of STS-88 on Dec. 15 at KSC).¹⁶⁷⁸⁾

MightySat mission operations are conducted by SMC/TEO at Kirtland AFB. All communications are via AFSCN (Air Force Satellite Control Network). The operations concept is largely based upon experience from similar satellite programs, most notably RADCAL.

Orbit: altitude = 385 km (initial altitude), inclination = 51.6°. The MightySat I S/C reentered the Earth's atmosphere on Nov. 16, 1999 due to its relatively low orbital altitude. All of the mission objectives were accomplished.

Payload complement: MightySat I has five AFRL-developed advanced technology demonstration experiments. Two of the demonstrations are tests of experimental bus components.

ACS (Advanced Composite Structure). Objective: technology test. The S/C structure (a hexagon with a diameter of 50 cm and a height of 53 cm with a mass of about 8 kg) consists of a composite frame, three decks, and seven solar panel substrates. The composite material is graphite fiber. However, ACS has no data interfaces to the S/C (the structure was ground-tested). The S/C frames were fabricated by using the so-called "SnapSat" approach (developed by Composite Optics Inc.), in which the elements are cut from cured flatstock layups and fitted together using a mortise&tenon technique.

ASCE (Advanced Solar Cell Experiment). Objective: advance of in-space power generation technology. Use of dual-junction solar cells (average efficiency of 21%) which provide a 15% performance gain over conventional GaAs cells. The cells are covered with a GaInP (gallium indium phosphate) layer which captures and converts the short wavelength spectrum. ASCE consists of 13 strings of 40 GaAs cells (2cm x 4 cm) and six strings of 18 GaInP cells (2 cm x 2 cm) for comparison of cell performance. The cells are bonded directly to the solar panel substrates. An objective is also to determine aging effects in the space environment.

MAPLE-1 (Microsystem and Packaging for Low Power Electronics). The objective is to provide an on-orbit demonstration of advances in low-power electronics including performance (emerging electronics and packaging technologies in space). The MAPLE-1 experiment suite is a collection of five sub-experiments, brokered by a central controller that supplies power and communications through interfaces to the MightySat I host satellite. MAPLE sub-experiments explore flight-worthiness, issues associated with low-power, commercial and radiation tolerant microelectronics, advanced microelectronics packaging, MEMS (Micro-Electromechanical Systems) devices, circuits, associated subsystems, and components. Particular experiments are:

- In-situ operation of MEMS commercial cantilever beam accelerometers. Two accelerometers are used, a local 5 gram full-scale unit and a remote 2 gram full-scale unit.
- Monitoring of advanced packaging structures through reliability monitoring integrated circuit die (monitoring of moisture, dust, and material property changes in electronic components), developed by SNL. The SSRB (Solid State Recorder Board) was

¹⁶⁷⁸⁾B. Braun, R. Davis, T. Itchkawich, T. Goforth, "MightySat-I: Transitioning Space Technology to the Warfighter," AIAA-99-4484, 1999

designed to evaluate the performance of HCSM (High Capacity Spaceborne Memory) SRAM module in the space environment. The EMB (Environment Monitor Board) was designed to measure the temperature inside the Maple-1 enclosure.

- Total ionizing dose dosimetry
- Advanced thin film high density interconnect multi-chip modules
- Comparison of military grade commercial and radiation hardened bulk silicon anti-fuse-based field-programmable gate arrays.

SMARD (Shape-Memory Actuated Release Device). Objective: demonstration of a new class of low-shock release devices. SMARD devices are based upon a shape-memory alloy (Nitinol) which is used as the driving force to actuate the release of a fastener. - The SMARD payload consists of four release devices mounted on a common, instrumented deck (a conventional pyrotechnic device, a linkwire device, and two shape-memory actuated devices are used). The SMARD experiment involved measuring the response of a three-axis MEMS accelerometer to the shock wave generated when a test “separation bolt” was fired.

MPID (Micro-Particle Impact Detector) of NASA/LaRC.¹⁶⁷⁹⁾ The objective is to collect information on orbital debris. Measurement of direction and time of impact of spaceborne micro-particles with time of impact resolution of 0.1 s. The primary element in this experiment consists of two MOS (Metal Oxide Semiconductor) discharge capacitor detectors that discharge upon hypervelocity particle impact. MPID consists of two small plates (4 cm x 8 cm, each the size of a credit card), mounted on the bottom outside surface of the satellite, providing indications of micro-particle impacts (recording of time of impact). Each particle impact causes an impact event record that is stored in the S/C control unit for later down-link. Each impact event record stores time of impact and output from two coarse sun sensors. Data from the coarse sun sensors is used to help determine attitude of the spacecraft.

M.11.2 MightySat II.1 (Sindri)

The MightySat II program, initiated in March 1996, represents a series of up to five small satellite missions over a decade. The S/C structure is of modular design (built by Spectrum Astro Inc. of Gilbert, AZ). The size of the payload envelope is: 61 cm x 61 cm x 46 cm. The S/C is three-axis stabilized (inertial pointing); attitude knowledge/control = $0.15^\circ/0.18^\circ$. The S/C has deployable solar arrays (Si), and a total mass of 121 kg (57 kg of payload mass); power = 330 W (BOL, 100 W average) with 28 V unregulated bus. In addition, there are three NiCd batteries, each with 4 Ah, for eclipse operations. A RAD6000 CPU is used. The S/C design life is 1 year.^{1680) 1681) 1682)}

Figure 310: The MightySat-II.1 spacecraft illustration

Attitude determination is provided with a star tracker and an interferometric fiber optic gyro, attitude control (actuation) uses three orthogonal reaction wheels. Secondary control

¹⁶⁸¹⁾ <http://www.spectrumastro.com/>

¹⁶⁸²⁾ <http://www.vs.afrl.af.mil/factsheets/msat2.html>

may be achieved with three torque rods, the torque rods serve also to dissipate reaction wheel momentum. The ACS (Attitude Control Subsystem) also autonomously controls solar array articulation. The command and data handling subsystem provides 380 MByte of solid state storage at data rates of 20 MByte/s. Communications are in S-band, data rates of 2 kbit/s uplink, 1 Mbit/s downlink for payload data (encrypted uplink/downlink). S/C operations are conducted by SMC/TEO from Kirtland AFB. A launch of MightySat II.1, dubbed “Sindri,” on an OSC Minotaur vehicle (a converted Minuteman-2 missile motor combined with the upper stages of the Pegasus-XL booster), took place on July 19, 2000 from VAFB, CA.

Orbit: Sun-synchronous circular orbit, altitude = 550 km, inclination = 97.6°, local crossing at 11:15 on a descending node.

Sensor/experiment complement:

MightySat II.1 carries a total of ten new technologies, including both experimental bus components and stand-alone experiments.

FTHSI (Fourier Transform HyperSpectral Imager) designed and built by Kestrel Corporation of Albuquerque, NM, and the Florida Institute of Technology, Melbourne, FL, heritage of airborne version of FTVHSI. The objective is to demonstrate spaceborne hyperspectral imaging technologies (FTHSI is the first functioning spaceborne hyperspectral imager). The FT-approach is considered to be promising for spaceborne hyperspectral concepts (FTHSI demonstrates the advantage of Fourier systems over dispersive hyperspectral imagers, in that it can record the full spectra without any time delay and can decouple the spatial and spectral signatures). The FTHSI instrument contains three major optical subsystems: a monolithic Sagnac interferometer which produces the spatially modulated interferogram; a Fourier transform lens, which frees the spectral properties of dependence on aperture geometry and allows the wide FOV; and a cylindrical lens, which re-images one axis of the input aperture onto the detector array providing the one dimension of imaging. The 1-D image is passed through the interferometer where the rays are split, slightly separated, and recombined to create an interference pattern (interferogram) in one dimension. From the interferometer, a Fourier lens collimates the light and a cylindrical lens images the energy onto the detector array, preserving the one by n spatial dimension.¹⁶⁸³⁾

Spectral range	475 - 1050 nm
Spectral resolution	87 or 44 cm ⁻¹ (corresponding to: 15-95 nm or 10-48 nm)
Number of usable spectral bands	145 or 290
FOV (Field of View)	3.0 °
IFOV (Instantaneous Field of View)	0.0058° or 0.0029°
Spatial resolution (best cross/along track)	28 m x 30 m
Swath width	7-29 km
Scene length range of imagery	10 km to 473 km
Instrument pointing (control/knowledge)	0.15°/0.15°
Instrument mass, power	20.45 kg, 66/60 W (peak/average)
Source data rate	20 MByte/s

Table 490: Some performance characteristics of FTHSI

The optical system of FTHSI employs a Ritchey-Chretien telescope with a clear aperture of 165 mm. The camera is an adaptation of a commercial camera made by Silicon Mountain Devices. The system has an f/3.4 number in the spatial and an f/5.3 number in the spectral dimension. A solid-block design is used to maintain alignment of the Fourier optics and cylinder lens. The detector assembly consists of a large-format CCD array (1024 x 1024) with a

¹⁶⁸³⁾L. J. Otten III, A. D. Meigs, et al., “The engineering model for the MightySat II.1 hyperspectral imager,” Proceedings of the Sensors, Systems and Next Generation Satellites, SPIE Vol. 3221-54, Sept. 1, 1997, London, UK, pp. 412-420

12 bit full-frame readout capability at up to 120 frames/s. Four operating modes are available to vary on command the spectral and spatial imagery resolutions, respectively: 512 x 512, 512 x 1024, and 1024 x 1024.

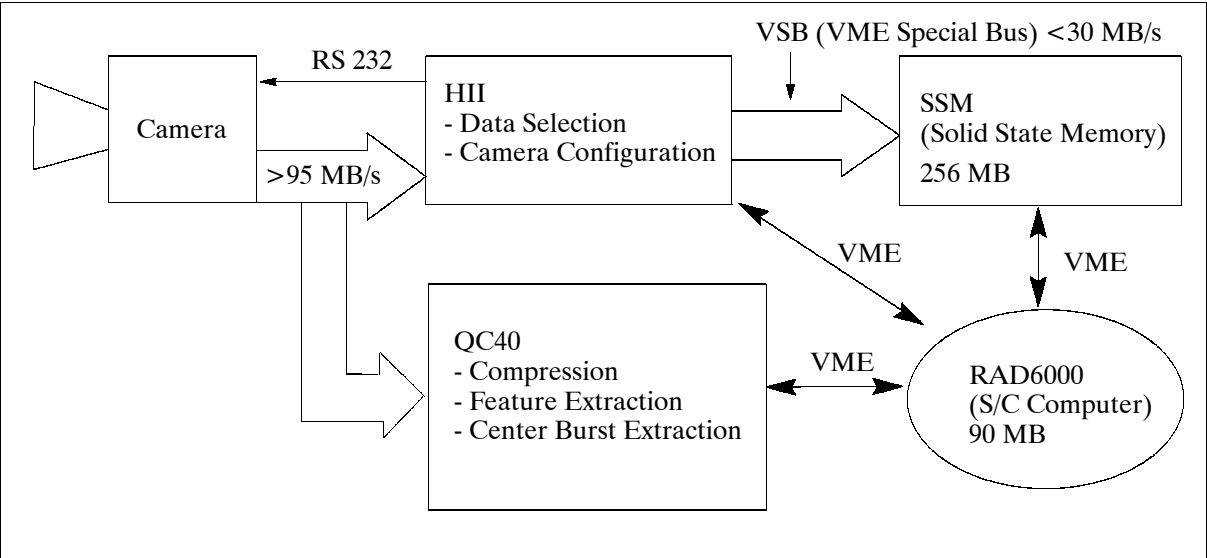

Figure 311: Block diagram of data-handling system of FTHSI

The instrument is operated with a maximum of 137 usable bands out of the 256 available, required by the limiting Nyquist sampling rate (to improve SNR). Note: an FT-type sensor creates data from zero wavenumbers to the Nyquist cutoff. Since the sensor cannot see wavenumbers lower than about 9523 cm^{-1} (1050 nm), there is information lost due to the sensor detectivity. The higher spectral resolution mode that operates the detector in the completely unbinned mode is not being used.

Data management: ¹⁶⁸⁴⁾ The FTHSI instrument takes advantage of the VME satellite bus services by storing source data directly in an allocated RAM of 134 MByte. The data transfers are provided by the custom-built HII (Hyperspectral Imager Interface) card, which handles packing and delivery to the S/C memory, it serves also as the RS 232 controller interface to the camera. A typical data collect (observation) lasts from 6-30 s. Total scene sizes are limited by the resolution selected and the storage capacity of 134 MByte RAM.

Function	Selections available	Default mode
Camera frame rate (frames/s)	15, 30, 60, 110	60
Camera gating time (s^{-1})	1, 1/125, 1/250, 1/500, 1/1000	1
Data bit depth	12 or 8 bit	12 bit
Nr. of imaging tiles per record	1, 2 or 4	4
Camera binning modes	1 x 1, 1 x 2, 2 x 1, 2 x 2	2 x 2
Data block length	0 to 134 MByte	134 MByte
Camera gain	1 or 4	1

Table 491: FTHSI camera operating modes and performances

SAC (Solar Array Concentrator). SAC focuses more light on each solar cell, increasing the solar energy available and reducing the number of cells needed to produce the same amount of power. The objective is to test the new solar panel array design. The steerable SAC is capable to focus more light on each solar cell, increasing the solar energy available. SAC covers one-third of one of the four solar panels. The cells are made of GaAs material (22-24% efficiency). The SAC provides a concentration ratio of 3:1 and has a 20° pointing tolerance toward the sun. SAC generates 37 W (BOL, 27.5 W EOL), its mass is 0.74 kg.

¹⁶⁸⁴⁾ Courtesy of Leonard John Otten III of Kestrel Corporation, Albuquerque, NM

MFCBS (Multi-Functional Composite Bus Structure). The spacecraft design incorporates new materials to be flight-tested as a lighter, more flexible alternative to the traditional aluminum bus structure. The MFCBS design includes an integrated thermal management system, robust structural integrity, high-attitude control accuracy, and precision three-axis stabilization.

NSX (NRL SGLS Transponder), with SGLS referring to “Space-to-Ground Link System.” NSX is a miniaturized satellite communications unit, about 70% smaller and lighter than the current industry product, the objective is to test its functionality. NSX has a mass of 1.5 kg and a size of 14.5 cm x 14.5 cm x 7 cm. It consists of a COMSEC (Communications Security) transmitter and receiver segment and is connected to the VME card. An encryptor/decryptor feature is provided in COMSEC. NSX requires 6 W in receive mode and 23.2 W in transmit/receive mode.

QC40 (Quad-TMS320C40 processor). Objective: test of the space radiation susceptibility of critical new forms of microelectronic components through an advanced, and high-speed processor. In particular, QC40 performs on-board processing and compression of the FTHSI raw data (also interferogram conversion), increasing the number of images that may be downlinked to a ground station. Feature extraction involves comparing and matching collected interferograms with on-board interferograms of known materials. Real-time center burst extraction allows ground operators to obtain a quicklook of the collected image to assess its further handling. - QC40 consists of two VME cards. One board is comprised of four COTS TMS320C40 microprocessors (120 Megaflop), while the other board provides the interface between the processor board and the S/C electronics. QC40 has a mass of 1.4 kg, the power is 17 W.

SMATTE (Shape Memory Alloy Thermal Tailoring Experiment). Objective: an experiment involving actuation of a bi-modal composite sheet with respect to performing vibration isolation, structural control, deployment, and separation functions. SMATTE can change its physical properties, such as stiffness, damping, and shape, as a function of tailored thermal input signals. However, when SMATTE is heated above its transition temperature, it returns to its memorized shape. SMATTE consists of a layer of polymer matrix composite with a thin strip of shape memory alloy on each side; it is interfaced with the VME card and uses 5.3 W of power. Stress induced from thermal warping of the composite is automatically relieved by opposing stress in the shape memory alloy film. Optical fiber strain gauges monitor the performance of SMATTE.

SAFI (Solar Array Flexible Interconnect). SAFI incorporates copper leads embedded in a flexible, composite film reducing the weight and complexity of traditional hard wiring (SAFI connects the solar cells and routes the current off the panel). The objective is to test a technology which might lead toward multi-functional bus technology. SAFI is bonded to the solar panel, it has a thickness of <0.25 mm.

PICOSAT1.1. MightySat II.1 flies the Aerospace Corporation’s designed and built launcher assembly and two tethered sub-satellites. They are referred to as PICO20 and PICO22, according to their nodal positions in a prescribed array of picosats. Both PICOSATs are of the same hardware design as the PICOSAT1.0 assembly, flown on OPAL (launch of OPAL on Jan. 26, 2000, see chapter N.11.3). The software of PICOSAT1.1 is updated to reflect the lessons learned by the ground operations from the OPAL flight. The overall objectives are:

- To extend the PICOSAT1.1 mission life (to about a week) by accurate ejection knowledge and improved coordination with the USAF SSN (Space Surveillance Network)
- Test of improved flight software, designed to reduce power usage - to extend mission life
- To demonstrate the system functionality after long-term storage on a host S/C. The PICOSAT1.1 system is planned to be ejected after one year of the MightySat II.1 launch, in July 2001.

- To demonstrate repeatability and robustness of a low-cost platform for advancing MEMS in space systems applications
- To demonstrate radically new operating concepts for future systems. The PICOSAT1.1 experience will serve as a low-cost risk mitigator for the release and flight of small bodies from a primary S/C, in support AFRL and DARPA small-satellite programs like TechSat 21, XSS (Experimental Spacecraft System), and MEPSI (MEMS-based Pico-Sat Inspector), the launch of the latter one is planned for 2003.

Each PICOSAT, a box of size: 25 mm x 75 mm x 100 mm and a mass of 0.275 kg, uses a small, battery operated, very low power radio with a ground-link and a cross-link (PICOSAT to PICOSAT) capability. The tether, of 32 m length, contains a gold wire, serving as radar 'target' to facilitate ground based radar tracking (with SSN). A sensor board in each PICOSAT has one chip containing 4 MEMS RF switches (a 100 V charge pump on the sensor board is needed by the switches) that are operated in space after deployment. ¹⁶⁸⁵⁾

SOR (Starfire Optical Reflectors). The Starfire Optical Reflectors are utilized by the Starfire Optical Range, an optical research facility at Kirtland Air Force Base, to develop optical sensing, imaging, and propagation technologies to support Air Force aerospace missions. Two COTS optical reflector mirrors are affixed to the coarse sensor boom on the S/C top deck (the reflectors are passive with a mass of 1.76 kg). The Starfire Optical Range at Kirtland performs active ranging of satellite position via ground-based laser.

M.12 MINISAT

MINISAT is a national space program of Spain, funded by the Inter-Ministerial Committee of Space Science and Technology (CICYT) and by INTA, supported by the Center for the Development of Industrial Technology (CDTI), and managed by INTA (National Institute for Aerospace Research). The program started in 1990 with first feasibility studies, the design phase was initiated in 1993. The major objectives of the program are to develop a national (INTA, industry, academia, and private sector) capability and to create an environment for state-of-the-art space age technology and research - to mobilize human resources. The emphasis is an affordable technology in the minisatellite and microsatellite segments, along with all the associated activities for all phases of successful space missions. ¹⁶⁸⁶⁾ ¹⁶⁸⁷⁾

The first stage of the MINISAT program concluded with the development and qualification of the MINISAT-0 platform. Phase A of MINISAT-01 started in 1995. - The MINISAT-1 modular satellite family of the program is dedicated mainly to LEO EO mission applications. The third stage of the MINISAT program, the MINISAT-2 family, is an adaptation of the MINISAT-1 family for GEO mission applications. ¹⁶⁸⁸⁾

M.12.1 MINISAT-01

MINISAT-01 is an INTA satellite (platform built by CASA, payload built by INTA), comprised of a low-cost multipurpose bus with a payload consisting of three experiments and a technology demonstrator. The science objective of the mission is the study of background radiation in the extreme ultraviolet spectrum, low energy gamma radiation, and the behavior of liquid bridges in microgravity. The S/C consists of a service module (or bus) and a payload module (payloads up to 300 kg can be accommodated in the architecture). The satellite measures 1145 x 1005 x 1170 mm and has four deployable solar panels (each 60 W, size of

¹⁶⁸⁵⁾B. Iannotta, "SWARM," Smithsonian Air & Space, August/September, 2000, pp. 44-49

¹⁶⁸⁶⁾Paper provided by M. A. Garcia Primo of INTA

550 mm x 800 mm). The spacecraft average power requirement is 60W. Uplink and down-link communication is via S-band, 5W transmitter/receiver at 1 Mbit/s, the on-board data storage capability is 32 MByte. MINISAT-01 is a sun-pointing, momentum-bias (spin) stabilized satellite with a capability to convert to a 3-axis stabilized one by employing torque rod control (three orthogonal torque rods and one momentum/reaction wheel as actuators for attitude control). The pointing accuracy is $\pm 3^\circ$. The attitude is sensed by two two-axis magnetometers and two coarse sun sensors with overlapping FOVs. The S/C bus has a mass of 105 kg, payload mass is 90 kg (total mass of 195 kg). The design life is 4-5 years.

The S/C was launched on a Pegasus-XL vehicle from the Canary Islands (Spain) on April 21, 1997. MINISAT-01 is operated by INTA and tracked via the Maspalomas ground station ($15^\circ 37' 45''$ W, $27^\circ 45' 49''$ N).

Orbit: Circular orbit, altitude = 576 km, inclination = 151° (29° retrograde), period = 96 minutes.

Sensor complement:

EURD (Espectrógrafo Ultravioleta extremo para la observación de la Radiación Difusa - Extreme UV Spectrograph for the Study of Diffuse Radiation), developed by INTA and UCB (University of California at Berkeley). The objectives are to conduct spectrographic observations of the diffuse EUV region of radiation, to study the nature of the interstellar medium, the airglow in the upper atmosphere (atomic oxygen and oxygen lines), and to search for dark matter in the form of massive (about 10 eV), long lived (> 1024 s) neutrinos. The instrument employs two spectrometers. An important feature of these spectrometers is their ability to identify or eliminate systematic effects that have compromised previous efforts to detect diffuse UV radiation. Each spectrometer is equipped with a filter wheel at its entrance slit, which is stepped through four operating positions to evaluate internal background, glare, starlight, and true interstellar plasma emission. These positions include an open position transmitting all wavelength, a metal shield that blocks all radiation and provides a measurement of the internal background, a magnesium fluoride filter giving a measurement of the Lyman alpha radiation, and an aluminum filter that transmits most of the EUV radiation and strongly blocks any scattered Lyman alpha radiation. The EURD instrument is observing continuously during eclipse periods with the S/C pointing into the anti-sun direction.

Spectral band	300-1050 Å
FOV	$26^\circ \times 8^\circ$
Grating	8 cm diameter, 18 cm focal length, holographically ruled 2460 lines/mm
Grating overcoat	long wavelength: silicon carbide; short wavelength: boron carbide
Detector	Multichannel Plate (MCP) with wedge and strip encoding
Detector photocathode	long wavelength: chemically treated; short wavelength: magnesium fluoride
Size (each spectrograph)	40 cm x 40 cm x 13 cm
Mass (each spectrograph)	11 kg

Table 492: Key instrument parameters of EURD

CPLM (Column of Liquid Bridge in Microgravity), developed at the Polytechnic University of Madrid. Objective: to study the behavior of axis-symmetric liquid bridges in microgravity conditions. Accelerations are induced by satellite maneuvers. The CPLM instrument consists of the following components mounted inside a cylindrical container: a test cell with a liquid bridge cell, optical detectors to measure the liquid bridge deformation, motor control to allow the liquid bridge formation and the modification of the liquid bridge configuration through its length, an accelerometer unit to measure the accelerations supported by the liquid bridge, a power supply unit to deliver the appropriate voltages to the different subsystems, a temperature sensor to monitor the CPLM temperature, and pressure sensors to monitor the pressure in the test cell and outside of the test cell. The liquid bridge is oriented

perpendicular to the z axis (sun to satellite direction) and also to the z spin rate direction. It means when the satellite is spinning from -0.375 to +0.375 rpm some axis-symmetric accelerations are induced in the liquid bridge. CPLM is operating about once per week (5 minute cycle).

LEGRI (Low Energy Gamma Ray Imager), developed by a Spanish/British team from the University of Valencia, INTA, CIEMAT, Birmingham University, and RAL (Rutherford Appleton Laboratory). The objective is to demonstrate the technological feasibility of a new generation gamma-ray telescope detector design optimized for low-energy radiation (in the energy range of 10 - 200 keV), using solid-state crystals as detector elements. The actual measuring objective is to detect the gamma-ray radiation emitted by various galactic sources such as neutron stars, binary systems, black hole candidates, and active galactic nuclei.

The initial LEGRI imaging array design employed 100 HgI₂ detectors, a new and emerging detector material, providing an excellent response in the 10-200 keV energy range, with the best presently achieved efficiency/volume ratio. In addition, the material works efficiently at room temperature and exhibits a very high resistance to radiation damage. CIEMAT (Centro de Investigaciones Energéticas y Medioambientales - Environmental and Energetic Research Center) has been working on this material, a production line for such detectors is under development.

The final imaging array design consists of 80 HgI₂ by 20 CdZnTe detectors. The intent is to compare the performances of both detector types, using the same FEE and working under the same background fluxes. - LEGRI is observing in the day part of the orbit mainly and in whatever direction perpendicular to the sun direction.

The LEGRI instrument consists of the following elements:

- A detector unit, comprising a detector plane formed by an array of 80 HgI₂ and 20 CdZnTe elements, the associated front end electronics and a mechanical collimator, all within a mechanical assembly acting as a passive shield.
- A mask unit, located at 540 mm from the detector plane and parallel to it, consisting of a coded mask made by tungsten elements on a honeycomb plate and a support structure.
- A power supply and digital processing units, which act as direct interfaces to PLM for power and data transmission.
- A high voltage supply unit, which provides the high voltages needed to operate the detectors.
- A star sensor, which is used to determine precisely and continuously the attitude of the satellite, allowing for the reconstruction on ground of the gamma-ray images without spatial blurring caused by platform drift or jitter.

ETRV (Experiencia Tecnológica de un Regulador de Velocidad - Speed Regulator Technology Demonstrator), developed by CASA. ETRV is a mechanical speed regulator and deployment mechanism intended to deploy in the future such items as antennas, panels, and booms. The instrument consists of the following elements: a motor and torsion spring; gears to reduce the speed; a momentum wheel to simulate the deployable structure; a pyrotechnic nut to maintain the configuration from launch to the time to fire the pyro and to deploy the dummy mass (momentum wheel); a magnetic Reed switch to measure the angular movement of the momentum wheel and its rates; and associated electronics to manage all the signals. - For the technology demonstration, the speed regulator ETRV must deploy the momentum wheel at a constant rate and with a total deployment angle of 180° in 180 seconds.

M.13 MITA (Minisatellite Italiano di Tecnologia Avanzata)

The Minisatellite for Advanced Technology (MITA), developed by a team of small Italian companies (prime contractor: Carlo Gavazzi Space S.p.A. of Milan - with Contraves Italia-

na, FIAR Spazio, Laben, etc. as sub-contractors), is funded by the Italian Space Agency (ASI). The objective of the MITA satellite project is to design and implement technology (demonstrate the capabilities of the Italian aerospace industry) of a low-cost bus for a wide range of Earth mission applications.

The bus design is modular (composed of tubular elements and closing sandwich panels), based on a cubic-shaped structure in the 100 kg (plus) mass range of a minisatellite. The S/C is three-axis stabilized, it is intended in particular for LEO missions with a lifetime of 5 years (MITA-1 has an expected lifetime of three years due to its low orbital altitude). The bus employs dual-redundant data handling and telemetry/telecommunication subsystem chains (the other subsystems are partially redundant). The attitude control system measures attitude with the following sensors: two monoaxial horizon sensors, a triaxial magnetometer (redundant) and five coarse sun sensors. A momentum wheel and three magnetic coils are used as actuators. Electrical power is provided by two solar panels featuring GaAs solar cells. Each panel is able to produce 200 W (EOL). NiH₂ batteries serve as a secondary energy source during eclipse phases of the orbit with a capacity of 150 Wh. Power conditioning and distribution is performed by a power electronics unit. The thermal control system is passive. ¹⁶⁸⁹⁾ ¹⁶⁹⁰⁾ ¹⁶⁹¹⁾

S/C dimensions	1800 mm x 1400 mm x 700 mm
S/C mass	170 kg
Average power consumption, peak power	80 W, 125 W
Attitude control	Three-axis stabilized, Earth pointing
Pointing accuracy	±1° in each axis (knowledge)
S/C communications	S-band
Data rates: telemetry, telecommand; protocol	512 kbit/s, 4 kbit/s; CCSDS
Mass memory	64 MByte

Table 493: Specification of the major elements of the MITA-1 bus

Communication: The on-board data handling is based on transputer with DSP processor embedded. On-board storage capacity of 64 Gbit. The TM/TC protocol is CCSDS compatible. The downlink is in S-band with a frequency of 2.2 GHz, data rate: 1 Mbit/s, transmitter power: 1 W. The uplink is in S-band with a frequency of 2.1 GHz, data rate: 4 kbit/s.

MITA-1 was launched July 15, 2000 (along with CHAMP) aboard a Russian Cosmos-3M vehicle from Plesetsk, Russia.

Orbit: Circular orbit, altitude = 450 km, inclination = 87.275°.

Sensor complement:

NINA-2 (New Instrument for Nuclear Analysis). NINA-2 is of NINA heritage flown on RE-SURS-O1-4 (launch July 10, 1998). ¹⁶⁹²⁾ NINA-2 is a compact telescope, developed by INFN (Italian National Institute of Nuclear Physics) of Rome, Italy and MEPhI (Moscow Engineering and Physics Institute). The objective is to measure fluxes of charged particles, in particular to detect cosmic ray nuclei of galactic, solar, or other origin from hydrogen to iron, between 10 and 200 MeV/n (contained particles) and 1 GeV/n (outside containment). The silicon detector telescope is composed of 16 X-Y planes, giving information on the energy of the crossing particle and its incident angle. Each of the 32 sensitive elements consists

of two n-type silicon detectors, 60 mm x 60 mm, divided in 16 strips and connected to a supporting ceramic frame under lateral strips (1 and 16). Each couple of detector is glued orthogonal in order to provide X and Y independent view information. The thickness of the detector is $150 \pm 15 \mu\text{m}$ for the first plane, and $380 \pm 15 \mu\text{m}$ for the remaining 15 planes. The geometric factor of the instrument ranges from 8.6 cm² sr for low energy particles to 1 cm² sr for particles crossing the detector. The instrument mass is 40 kg, power = 40 W.

MTS-AMOS (Micro Tech Sensor-Attitude and Orbit Measurement System). An ESA technology sensor for combined attitude and orbit measurements, consisting of three elements: an APS (Active Pixel Sensor) Camera with beamsplitter-optic, a Magnetic Field Sensor, and an Angular Rate Sensor.

M.14 MSX (Midcourse Space Experiment)

The MSX satellite is an observatory-class observation platform and global surveillance system of the US DoD; it is funded and managed by BMDO (Ballistic Missile Defense Organization) with APL (Applied Physics Laboratory of Johns Hopkins University, Baltimore, MD) as the S/C integrator. The primary objectives of MSX are to detect, acquire and track targets and to discriminate lethal from nonlethal objects (detailed characterization and modeling of target objects and their associated phenomenology of the terrestrial, Earth-limb, and celestial backgrounds).

Figure 312: S/C Model of MSX

The MSX satellite is three-axis stabilized consisting of the structure, five primary instrument systems, and the subsystems needed for instrument support and S/C control. The S/C

has a design life of five years, its body measures 150 x 150 x 510 cm, and its mass is about 2700 kg. Power: 1.2 kW from solar array, 28 VDC, 50 Ah NiH₂ battery. - The attitude control system consists of four reaction wheels and three magnetic torque rods. Any three of the four wheels can provide three-axis control of the satellite. Attitude sensors include two three-axis ring laser gyro systems, a star camera, two horizon sensors, five digital sun-angle detectors, and a three-axis magnetometer. The system achieves a real-time pointing accuracy of better than 0.1° and post-processing knowledge of 9 μrad over instrument integration durations of about 1s. - The S/C is operated by APL; its S-band is also monitored by AFSCN (Air Force Satellite Control Network). APL also receives the prime science data and provides processing and archiving for all data. MSX was launched April 24, 1996 on a Delta II vehicle from VAFB, CA.

The MSX communicates on three bands: L-band (1827.8 MHz), S-band (2282.5 MHz), and X-band (8475 MHz). The L-band is used exclusively for commanding and memory loads (data encryption). The S-band has two transponders, diplexers, and antenna pairs for the transmission of 16 kbit/s housekeeping data and either ranging or 1 Mbit/s transmission of compressed or sampled science data. The X-band (two transmitters) transmits 25 Mbit/s prime science data from the S/C data recorders (54 Gbit capacity each). The S-band beacon receiver is a passive radar tracker that can acquire a target with an initial pointing uncertainty of ±5° at a maximum range of 8000 km. It provides calibrated angle tracking with a residual error of 0.1°. ¹⁶⁹³⁾

Some of the sensor data (mostly concerning targets and satellites) will be classified, but the majority are unclassified. These latter data will eventually be released to the general science community after the normal period (~2 years) reserved for exclusive exploitation by the principal investigators.

Orbit: Nearly sun-synchronous orbit, altitude = 898 km, inclination = 99.16°.

Sensor complement: ¹⁶⁹⁴⁾

The suite of state-of-the-art sensor systems include: SPIRIT-III (a cryogenic scanning radiometer and FTIR spectrometer), the UVISI system, SBV, and a suite of instruments to monitor contamination on and around the S/C. MSX is a fully steerable S/C providing a range of pointing capabilities (0.1° pointing accuracy): limb scans, nadir scans, or limb point and stare, to cross-track scans. Of importance to the science community are stellar occultation and daytime limb observations for the retrieval of trace gases: ozone, aerosol, pressure, temperature and NO₂ in the stratosphere.

SPIRIT-III (Spatial Infrared Imaging Telescope), built by SDL (Space Dynamics Laboratory) of Utah State University. SPIRIT-III is the primary sensor system on MSX with the objective to perform midcourse surveillance functions, collect target and background phenomenology data, and to demonstrate advanced cryogenic sensor technologies. The instrument consists of an off-axis re-imaging telescope with a 35 cm diameter unobscured aperture, a six-channel Fourier-transform spectrometer, a five-band scanning radiometer, and a cryogenic dewar/heat exchanger (the dewar cools the telescope, radiometer and spectrometer, the cryogen is expected to last 18 months). Instrument mass = 967 kg; size = 107 cm diameter x 360 cm in length. Note: SPIRIT-I and -II were instruments (FTIR spectrometers only) flown on sounding rockets in the late eighties and in 1991.

The telescope has three sections: the afocal foreoptics, the radiometer re-imaging optics, and the spectrometer collimating optics. The foreoptics use an off-axis all-reflective design. An auto-collimator measures telescope alignment with respect to the S/C attitude system optical bench to an accuracy of 5 μrad. The Fourier-transform spectrometer has six Si:As

detectors operating at 10.5 to 11.0 K. It collects double-sided interferograms in six spectral bands with programmable resolution of 2, 3.9, or 20 cm⁻¹ over sample times of 4.2 s, 2.2 s, and 0.55 s. - The radiometer has five Si:As focal plane detector arrays of 8 x 192 pixels each, operating between 11 and 12 K. It collects data in six passbands with a spatial resolution of 90 μrad. The scan mirror can remain fixed or can operate at a constant scan rate of 0.46°/s with programmable scan fields of regard of 1° x 0.75°, 1° x 1.5°, or 1° x 3°. The radiometer focal plane assembly employs a combination of dichroic and bandpass filters to allow simultaneous measurements in bands A, D and E and or in bands B and C. Table 1363 lists the four operational modes and provides actual values for the radiometer field of regard (FOR). - Earthlimb observations of SPIRIT-III include an experiment to measure chlorofluorocarbons and nitric acid. Channel 5 (10.6-13 μm) of the FT spectrometer collects data in the altitude range from 10 to 40 km. Dominant emissions in this channel include nitric acid, CFC compounds, ozone, and the thermal signature of stratospheric aerosols.

FT Spectrometer Passbands		Radiometer Passbands			
Channel	Passband (μm)	Band	Passband FWHM (μm)	Active Columns (array size)	Sensitivity (NEFD) 10 ⁻¹⁸ W/cm ²
1	17.2 - 28.0	A	6.0 - 10.9	8	1.1
2	2.6 - 4.9	B ₁	4.22 - 4.36	2	10
3	5.8 - 8.9	B ₂	4.24 - 4.45		
4	4.0 - 28.0	C	11.1 - 13.2	4	0.8
5	10.6 - 13.0	D	13.5 - 16.0	4	0.7
6	2.5 - 24.0	E	18.1 - 26.0	2	1.7

UVISI (Ultraviolet/Visible Imaging and Spectrographic Imaging, a suite of nine instruments, designed by APL). The primary objective of UVISI is to collect data on celestial and atmospheric backgrounds; secondary objectives include target characterization and contamination observations in conjunction with the contamination instruments. The UVISI sensor system consists of five SPIM (Spectrographic Imager) instruments and four imagers. The imagers include two WFOV (Wide-Field-of-View) and two NFOV (Narrow-Field-of-View) sensors in the UV and VIS spectrum respectively. Together the SPIMs cover a spectral range from 110 nm (UV) to 900 nm (NIR). - The nine instruments share a common boresight with each other, with the SPIRIT-III IR radiometer, and with the SBV instrument.

Figure 314: Schematic of spectrographic imaging of UVISI SPIMs

Instrument ⁶	Passband Range (nm)	Resolution $\Delta\lambda$ (0.10° slit)	Resolution $\Delta\lambda$ (0.05° slit)	No. of Bins
SPIM1	113-173	0.8 nm	0.5 nm	68, 136, or 272
SPIM2	162-252	1.2 nm	0.9 nm	68, 136, or 272
SPIM3	251-388	1.8 nm	1.5 nm	68, 136, or 272
SPIM4	377-582	2.8 nm	2.1 nm	68, 136, or 272
SPIM5	589-902	4.3 nm	2.9 nm	68, 136, or 272

Table 496: UVISI spectrographic-imager (SPIM) characteristics

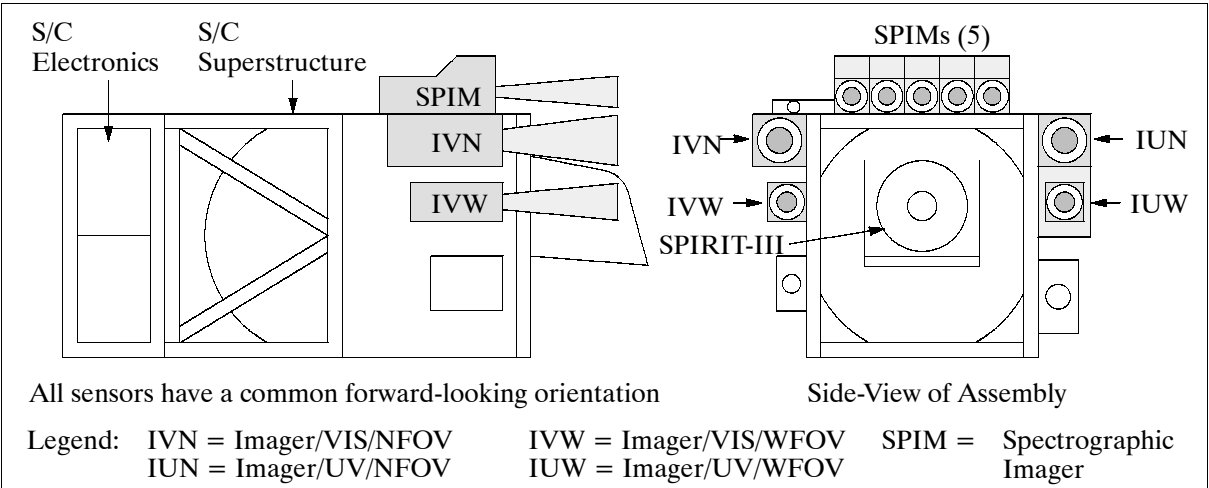

Figure 315: Mounting arrangement of the UVISI sensors on MSX

UVISI SPIMs. All five SPIMs feature an all-reflective off-axis parabolic design (external sunshade, scanning mirror, slit/filter, collimating mirror, dispersive grating, and an intensified CCD focal plane) in which selectable slits provide spectral resolutions between 0.5 nm to 4.3 nm. The SPIM image planes have programmable spectral dimensions with 68, 136, or 272 pixels and programmable spatial dimensions with 5, 10, 20, or 40 pixels.¹⁶⁹⁵⁾ A scan mirror sweeps the slit through a second spatial dimension and generates a spectrographic image once every 5, 10, or 20 seconds. The SPIM CCD detector plane collects an image of the slit length in one direction and spectral information in the other (Figure 134). One spatial dimension is resolved along the slit and the other spatial dimension information is obtained by moving the FOV either 0.05° or 0.1° before recording another observation. It takes about 10 s to complete a $1^\circ \times 1^\circ$ image in either 10 or 20 steps. The five-position slit/filter mechanism provides two slit sizes ($1.0^\circ \times 0.10^\circ$ and $1.0^\circ \times 0.05^\circ$) and various blocking filters that eliminate extraneous spectral orders and long-wavelength contaminants.

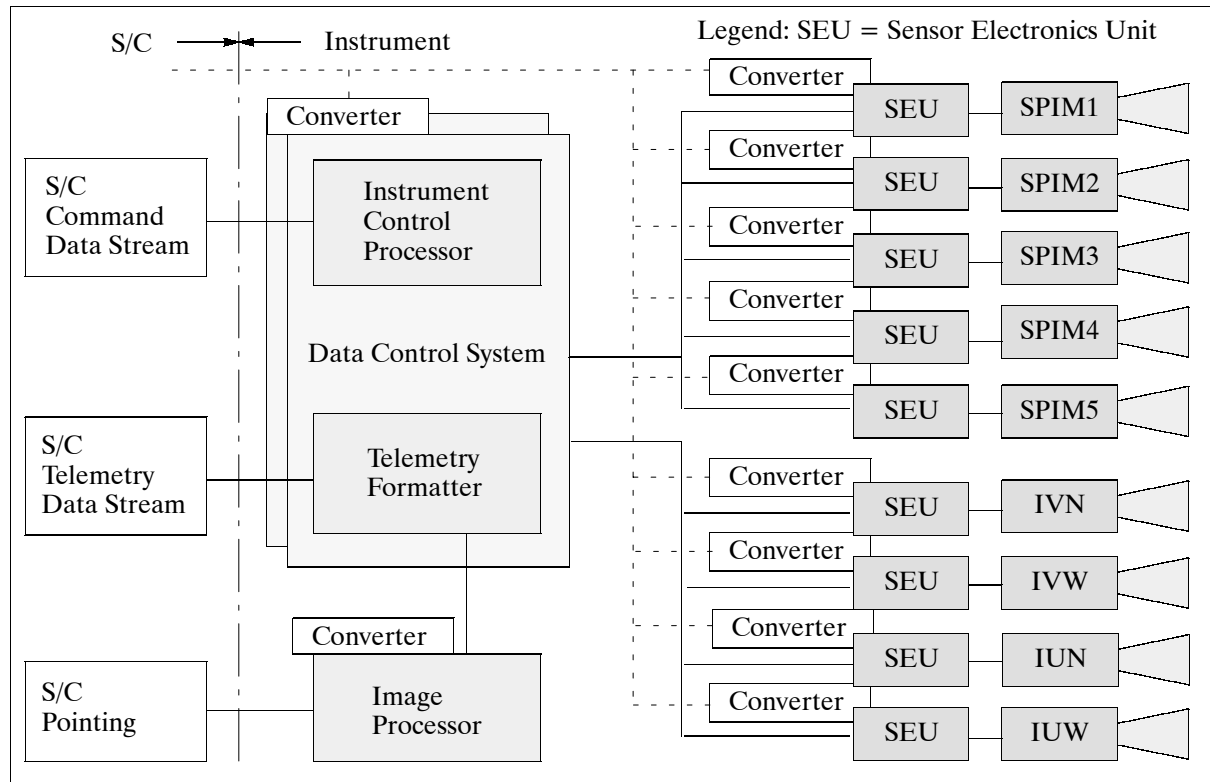

Figure 316: UVISI instruments and major subsystems/interconnections

SPIM electronics perform pixel-summing operations (programmable) on the 40×272 element SPIM focal plane array, yielding 40, 20, 10, or 5 bins in the spatial direction, and 272, 136, or 68 bins in the wavelength direction.¹⁶⁹⁶⁾ The pixel resolution is 14 bit. - With a dynamic range of 10^{11} , UVISI has the capability to obtain data ranging from noontime surface-reflected visible radiation to observations of a diffuse UV celestial background. Objective and applications: generation of spatial/spectral maps of various objects and scenes; prime SPIM observations include the atmospheric dayglow and nightglow, aurora, stars,

¹⁶⁹⁵⁾Note: The spatial resolution of the SPIMs is driven by the point-spread function in one direction (along the slit) and by the point-spread function and the mirror step size in the other direction. For the 0.05° mirror steps one can assume that it is driven by the point-spread function in both directions, and is about 0.85 mrad. The spatial resolution is diminished by using the 0.1° steps or by reducing the number of bins in the readout, by co-adding 2, 4, or 8 adjacent pixels. This is to reduce the bandwidth requirement by trading spatial resolution, spectral resolution and frame rate. The nadir resolution is $0.85 \text{ mrad} \times 900 \text{ km} \approx 770 \text{ m}$. Nadir FOV is 17 mrad ($1^\circ \times 900 \text{ km} \approx 15 \text{ km} \times 15 \text{ km}$).

¹⁶⁹⁶⁾Note: The bins are formed in the SPIM electronics by co-adding 1, 2, or 4 adjacent pixels; this is done to reduce the data bandwidth requirement in cases where UVISI is not the principal instrument, or higher frame rates are needed which can be traded off against resolution. For the case of 136 and 272 bins, the bins overlap; for the case of 68 bins, the bins are noncontiguous.

zodiacal light, and plume contrails. When suitably inverted, SPIM radiance measurements can reveal atmospheric properties such as species concentrations, temperatures, and altitude profiles. SPIM investigations of auroral radiances can provide estimates of fluxes and energies of precipitating particles that cause auroral emissions.

UVISI Imagers. The four imager suite consists of: external sunshade, imaging optics, filter wheel and drive motor, and intensified CCD focal planes. Three of the four imagers employ all-reflective optics. Both NFOV imagers use a Cassegrain design; the UV WFOV imager uses an off-axis three-mirror design. - The commandable filter wheel in each imager houses three bandpass filters on a neutral-density (ND) filter. In case of the visible WFOV imager, a lens is substituted for one of the filters. This lens is used to focus the near-field backscattered emissions from the xenon flashlamp as part of the MSX contamination experiment. The filter bands were chosen for specific objectives. For example, the UV-NFOV 200-230 nm filter is used to observe the NO_y bands in airglow measurements. The UV-WFOV 117-127 nm filter is used for viewing Lyman- α emission from hydrogen in the geo-corona, from auroral hydrogen precipitation, or from outgassing of the SPIRIT-III cryogen. Each imager has a focal plane CCD array of 256 x 244 pixels with 12 bit resolution. The imager nadir resolutions are:

- NFOV: 0.09 mrad x 900 km \approx 80 m
- WFOV: 0.82 mrad x 900 km \approx 750 m

The limb resolutions can be calculated from geometry, given a tangent height.

Instrument	UV-NFOV (IUN)	UV-WFOV (IUW)	VIS-NFOV (IVN)	VIS-WFOV (IVW)
FOV	1.28° x 1.59°	10.5° x 13.1°	1.28° x 1.59°	10.5° x 13.1°
Resolution (IFOV)	90 μ rad	820 μ rad	90 μ rad	820 μ rad
Passband (nm)	180-300	110-180	300-900	380-900
ND filter	10 ⁻³	10 ⁻³	10 ⁻⁴	10 ⁻⁴
WB1 filter	200-230	117-127	305-315	426-429
WB2 filter	230-260	128-138	350-440	529-631
WB3 filter	260-300	145-180	470-640	(lens)

Table 497: UVISI imager characteristics

Figure 317: Schematic diagram of the UVISI focal plane unit

The UVISI image processing system can acquire and isolate likely targets in an image FOV and communicate their positions to the MSX flight processor, which in turn points the satellite in a “closed-loop” fashion. The term “target” may refer to either a point source such as a star, to another satellite, or to an extended source such as an auroral or cloud-top feature. The processor software performs initialization and tracking functions that include filtering, smoothing, thresholding, and centroiding. The image processor seeks targets based on an a priori target description file containing weights for numerous target features such as size, brightness, and location. The image processor then transforms target locations from UVISI pixel coordinates to S/C coordinates and passes them on the MSX flight processor, which performs Kalman filtering of other targeting inputs to select “true” targets for observation.

Figure 318: Optical diagram of the UVISI spectral imagers (SPIMs)

Spectral range	0.3 - 0.9 μm
Spatial resolution (IFOV)	60 μrad
FOV	1.4° x 6.6°
Aperture, focal ratio	15 cm, f/3
Focal Plane Array (FPA, four CCDs)	420 x 1680 pixels
Frame times	0.4 s, 0.5 s, 0.625 s, 1.0 s, 1.6 s, 3.125 s

Table 498: SBV camera parameters

SBV (Space Based Visible, designed by MIT Lincoln Lab) camera. The objective is to collect data on celestial target signatures (stars) in the VIS range and to perform surveillance demonstrations (cataloging of resident space objects). The instrument incorporates a 15 cm aperture off-axis, re-imaging, all-reflective telescope, a thermo-electrically cooled (front-illuminated) bare CCD focal plane, and electronic subsystems. The focal plane consists of four CCDs with 420 x 420 (27 μm) pixels each. SBV instrument mass = 78 kg, power = 68 W.

MSX carries in addition a suite of contamination instruments with the objective to characterize the molecular and particulate environment around the S/C (all APL sensors). This suite includes the following instruments:

- **NMS** (Neutral Mass Spectrometer). A quadrupole RF instrument with two independently programmable filaments which can be operated at either high or low emission currents. It measures species ranging in mass from 1-150 amu (atomic mass units).
- **IMS** (Ion Mass Spectrometer). A Bennett RF positive ion mass analyzer with sampling port oriented towards the ram velocity vector (+X axis) during the park mode of the MSX S/C. It measures ions ranging in mass from 1-60 amu. Gas densities as low as 10^6 molecules/cm³ and 10^3 ions/cm³ can be measured with NMS and IMS, respectively.

- **CQCM** (Cryogenically-cooled Quartz Crystal Microbalance). Five sensors for measuring depositions on the SPIRIT-III primary mirror.
- **KF/KR** (Krypton Flashlamp/Radiometer). KF/KR works in conjunction with the UVI-SI SPIM3 to measure water vapor concentrations.
- **TQCM** (Temperature-controlled Quartz Crystal Microbalance). Four sensors are distributed about the MSX instrument section with the objective to view the mass flux arriving from a particular direction of interest.
- **TPS** (Total Pressure Sensor). Measurement of ambient pressures ranging from 1×10^{-10} to 1×10^{-5} Torr.

Figure 319: SBV telescope schematic

- **XF** (Xenon Flashlamp). Produces an intense VIS photon beam for detection of back-scattered radiation by the UVISI wide field visible imager (IVW). The photon beam is pulsed at 1/2 s, the beam intersects the imager line-of-sight at 200 cm. The imager collects a series of frames of the backscattered emissions, from which the size and velocity of particles as small as $0.5 \mu\text{m}$ can be detected.

M.15 Myriade (CNES Microsatellite Program)

At the start of the 21 century the Myriade program represents the new microsatellite concept of CNES (France), taking advantage of low-cost satellites for technology demonstrations and to serve specific needs of the scientific community. The goal is to provide missions of about 10 MEuro (launch included) at a rate of two missions/year. In general, there are simply more frequent launch opportunities available for microsatellites as secondary payloads on a number of launch vehicles. The objectives are to take advantage of these new enabling capabilities (innovation and introduction of technologies, operations, management methods, building partnerships, etc.). Myriade offers the opportunity for a rearrangement of agency/industry functions such as to relieve CNES of the recurrent provisioning and integration tasks. It is also considered a structure for international cooperation (training for prime contractorship). ¹⁶⁹⁷⁾ ¹⁶⁹⁸⁾

¹⁶⁹⁷⁾ Information provided by Bernard Tatry of CNES

M.15.1 DEMETER

DEMETER (Detection of Electromagnetic Emissions transmitted from Earthquake Regions) is an approved French microsatellite mission (first mission of the CNES microsatellite program referred to as MYRIADE) with the objective to observe geophysical parameters of the terrestrial environment.¹⁶⁹⁹⁾ This involves the study of ionospheric perturbations (measurement of electromagnetic waves and their effects), caused by natural phenomena, such as Earth tremors and volcano eruptions. Of particular interest is the time behavior (occurrence) of these electromagnetic perturbations in relation to Earthquakes. The hypothesis is that they might offer an early warning function prior to eruptions. The participants in the DEMETER project are: CNES, LPCE (Laboratoire de Physique et de Chimie de l'Environnement d'Orléans), CETP (Centre d'étude des Environnements Terrestre et Planétaire) in Velizy/ Saint-Maur, IPG-Paris (Institut de Physique du Globe de Paris) and CESR (Centre d'Etude Spatiale des Rayonnements) in Toulouse. LPCE is responsible for the science payload.

Figure 320: Illustration of Picard (left) and DEMETER (right) satellites

The satellite is of a box-like structure with dimensions of 60 cm x 60 cm x 80 cm. A single solar panel is used for power generation. The S/C is three-axis stabilized with a pointing accuracy of a few degrees. Attitude sensing is provided by a star sensor, attitude actuation is provided by reaction wheels and magnetic actuators. The S/C mass of DEMETER is about 120 kg, the design life is two years.

A launch of DEMETER is planned for mid 2003 as a secondary payload on a Dnepr launcher.

The payload recorder has a capacity of 8 Gbit. RF communications are provided in X-band (frequency = 8.2 GHz) with a downlink data rate of up to 17 Mbit/s. The data modulation scheme is NRZ-L/MDP8-2/3. The CCSDS communication protocol is used.

Orbit: Sun-synchronous orbit, altitude = 700 km, inclination = 98°.

Sensor complement:

IMSC (Instrument Magnetometre Search Coil), or Search Coil Magnetometer of CNRS/LPCE. The objective is to measure the magnetic field components in the frequency range of 10 Hz to 18 kHz. The magnetic vector is measured by the current induced by a coil that is wound around a micro metal bar and by an orthogonal three-antenna system, mounted on a boom at 1 m distance.

IPD (Instrument Detecteur de Plasma), or Plasma Detector Instrument of CNRS/CESR. The objective is to measure the energy spectrum of electrons, at right angles to the magnetic

¹⁶⁹⁹⁾ DEMETER brochure of CNES, provided by Bernard Tatry

field, in the energy range of 30 keV to 2 MeV. The information is needed to estimate the disturbances in the radiation belts induced by earthquakes.

ISL (Instrument Sonde de Langmuir), or Langmuir Probe Instrument of ESA/ESTEC. The instrument is used to measure the total plasma density in the range of 100 to 5×10^6 particles/cm³, the electron temperature in the 500-3000 K range, and the satellite potential in the range of ± 5 V. The instrument consists of two Langmuir probes, one is cylindrical the other is spherical with a 6 cm diameter segmented probe. The plasma density and temperature are determined from the Langmuir probe current-voltage curve.

ICE (Instrument Champ Electrique), or Electric Field Instrument of CNRS/CETP. The objective is the measurement of the vector components of the Earth's electric field in the frequency range from DC to 3 MHz. EFI consists of an antenna system featuring four spherical electrodes placed at the end of 4 m booms.

IAP (Instrument Analyseur de Plasma), or Plasma Analyzer Instrument of CNRS/CETP. The objective is the measurement of ionospheric plasma parameters (density, temperature, and energy distribution). IAP is a two-analyzer instrument.

M.15.2 Microscope

Microscope is an approved French gravity-research microsatellite mission, put forward by ONERA and CERGA (Centre d'Etudes et des Recherches en Geodynamique et Astrometrie) in Grasse, France. The objective is to conduct a fundamental physics experiment, namely to test the first law of thermodynamics (underlying the general theory of relativity). This concept is also known as the EP (Equivalence Principle) test. The best accuracy value of the EP achieved by experiments on Earth is 10^{-13} , the Microscope mission wants to improve this value to 10^{-15} . Leading-edge technologies are implemented, these include: ultra-sensitive accelerometers, ionic thrusters, and simultaneous spin control and drag-free systems.¹⁷⁰⁰⁾

The CNES microsatellite bus consists of a box-like honeycomb-and-plate structure of approximate size: 60 cm x 60 cm x 80 cm. The solar panels (AsGa cells) are body-mounted on three sides of the S/C, providing a power of 100 W (equally shared between the payload and the electric propulsion system). Particular attention is paid to the thermo-elastic behavior of the S/C as well as to possible magnetic disturbances to the test masses. The satellite is spin-stabilized with the spin axis directed normal to the orbit plane. Attitude sensing is provided by a sun sensor and a star tracker. Attitude actuation and drag compensation is provided by DAOCS as described below. In addition, actuation may be provided by magnetorquers and reaction wheels (when needed like in the orbit injection phase). The S/C mass is < 120 kg, the mission design life is one year.

A launch of Microscope is planned for late 2004 on a Dnepr launch vehicle as a secondary payload.

The on-board solid-state recorder has a capacity of 1 Gbit (the total source data rate, including housekeeping data, is about 1 kbit/s). RF communications are provided in S-band with a downlink data rate of 400 kbit/s (max). Satellite operations are conducted at CNES. The science mission center is at ONERA.

Orbit: Sun-synchronous quasi-circular orbit, altitude = 700 km, inclination = 98°.

Sensor/payload complement:

ONERA is the designer/builder of the two similar differential payload accelerometers. These accelerometers are of STAR and SuperSTAR (Super Space Three-axis Accelerome-

¹⁷⁰⁰⁾ P. Touboul, B. Foulon, L. Lafargue, G. Metris, "The Microscope Mission," Proceedings of the IAF Congress, Rio de Janeiro, Brazil, Oct. 2-6, 2000, IAF-00-J1.06

ter for Research mission) heritage flown on the CHAMP and the GRACE missions, respectively. They comprise two concentric electrostatic differential accelerometers. The test mass of each accelerometer is maintained along the three orthogonal axes at the center of the fused silica instrument cage by electrostatic forces. Electrodes, engraved in the cage wall, are used for the capacitive sensing of the mass position and attitude. Both test masses are controlled with respect to the cage frame: the sum of the forces is maintained to a null value by the satellite drag compensation system; the thrusters of the electric propulsion system act to move the instrument silica frame following the masses. The difference of the electrostatic forces is then observed in the orbital path for the search of the EP-violating signal. The electrode configuration allows six-degree-of-freedom measurements and control of each test mass.

Figure 321: Schematic illustration of the electrostatic differential accelerometer

Both differential accelerometer cores are integrated in tight vacuum housings with thermal insulation and magnetic shielding provided. The instrument temperature variation is $<1^{\circ}\text{C}$ per orbit. The entire instrument is positioned at the center of mass of the spacecraft to reduce any torque demand onto the electric propulsion system. The sensitive axes of the accelerometer are oriented in the orbital plane of the S/C x-axis, with the center of the test masses on the rotating axis of the S/C (normal to the orbital plane). The total instrument mass is 25 kg, the power is 25 W.

Operations of the accelerometers: After all initial tests and calibrations, the EP experiment is realized with the first differential accelerometer in inertial and spinning attitudes and with two angular phases along the orbit. The test is concluded with a calibration. The same procedure is repeated with the second differential accelerometer.

Rotational axis of S/C	About y and z or along y, z		About x or along x	
	Max value at DC	Stability at f_{ep}	Max value at DC	Stability at f_{ep}
Angular velocity	10^{-5} rad/s	$10^{-5}\text{ rad/s Hz}^{-1/2}$	10^{-5} rad/s or $2\times 10^{-3}\text{ rad/s}$ (spin)	$10^{-5}\text{ rad/s Hz}^{-1/2}$
Angular acceleration	$10^{-5}\text{ rad s}^{-2}$	$3\times 10^{-8}\text{ rad s}^{-2}\text{ Hz}^{-1/2}$	$10^{-5}\text{ rad s}^{-2}$	$10^{-7}\text{ rad s}^{-2}\text{ Hz}^{-1/2}$
Linear acceleration	$3\times 10^{-9}\text{ ms}^{-2}$	$10^{-9}\text{ ms}^{-2}\text{ Hz}^{-1/2}$	$3\times 10^{-9}\text{ ms}^{-2}$	$10^{-9}\text{ ms}^{-2}\text{ Hz}^{-1/2}$

Table 499: GG velocity and acceleration specifications

DAOCS (Drag, Attitude and Orbit Control System). A FEPP (Field Emission Electric Propulsion)-type system with 8 or 12 thrusters. Four pods of two or three thrusters are installed

on the S/C corners of two opposite faces. One of the pods contains the star tracker. Each thruster provides a thrust range of 15-100 μN controllable in steps of 1 μN . The power consumption for each one of the four pods is about 8 W (mean value on the orbit corresponding to a mean thrust of 15 μN on the orbit). The mass of each pod is around 3 kg (thruster, electronics and propellant).

M.15.3 PARASOL

PARASOL (Polarization and Anisotropy of Reflectances for Atmospheric Science coupled with Observations from a Lidar) is a French science mission, put forward by CNRS/LOA [Laboratoire d'Optique Atmosphérique (University of Lille, France)], with the general objective to study the Earth's atmosphere. The PARASOL mission flies the POLDER instrument as its main payload with the objective to improve the microphysical and radiative property characterization of clouds and aerosols for model improvement. Clouds and aerosols play an important role in direct and indirect radiative forcing of the Earth's energy budget. The study of the dynamic processes and interactions between liquid and solid particles in the atmosphere is therefore a major goal. PARASOL (POLDER) complements PICASSO-CENA (Lidar) and NASA's Aqua and Aura (MODIS, CERES) missions, it also makes use of the CloudSat (CPR) radar data. The instruments form a so-called "train of satellites," all in the same orbits and in a PM sequence (a loosely-coupled constellation), provide a unique opportunity of near-simultaneous observations, by collecting data in different spectral domains (optical and microwave regions) and at various FOVs. ¹⁷⁰¹⁾ ¹⁷⁰²⁾

Figure 322: Illustration of the PARASOL (left) and Microscope (right) satellites

The PARASOL microsatellite of CNES consists of a box-like structure (size: 60 cm x 60 cm x 80 cm) with deployable solar panels. The S/C is three-axis stabilized, providing a pointing accuracy (knowledge) of 0.02°. Attitude sensing is provided by a star sensor, actuation is provided by reaction wheels. The solar power is about 80 W (average orbit value). The S/C mass is 120 kg, the mission design life is one year with two years as goal. A launch of PARASOL is planned as a secondary payload on Ariane-5 in 2004.

A payload mass memory provides a capacity of 16 Gbit. RF communications are provided in S-band (frequency = 2.2 GHz) at a downlink data rate of 400 kbit/s and an uplink rate of 20 kbit/s. In addition, there is an X-band downlink for payload data. The modulation scheme is

¹⁷⁰¹⁾ <http://www-projet.cst.cnes.fr:8060/PARASOL/index.html>

¹⁷⁰²⁾ Information provided by Bernard Tatry of CNES

QPSK. The communication protocol is in CCSDS standard. Mission operations are performed at CNES (MYRIADE Control Center).

Orbit: Sun-synchronous circular orbit, altitude = 700 km, inclination = 98.21°, the local equator crossing time is at 13:30.

Sensor complement:

POLDER (Polarization and Directionality of the Earth's Reflectances), a CNES instrument of ADEOS and ADEOS-II heritage. The objective is the measurement of bidirectional and polarized solar radiation reflected by the atmosphere, and aerosols. POLDER consists basically of a digital staring camera composed of a 284 x 364 pixels CCD detection array, wide-field-of-view telecentric optics ($\pm 51^\circ$ cross-track and $\pm 43^\circ$ along-track) and of a rotating wheel carrying spectral and polarized filters.

POLDER has nine spectral channels, three of which are implemented with polarized filters (total of 15 channels, three channels are needed for each polarized band). The spectral region is from 443 to 1020 nm. For the polarized wavelengths, 3 filters measure the linear polarization of the incoming radiation in three directions separated by 120°. The observed data permit the derivation of the Stokes parameters and the total irradiance. The acquisition of an image sequence takes 20 seconds, enabling the observation of one natural target from different directions.

A scene (image) has a size of about 1440 km (along-track) x 2200 km (cross-track) with a ground spatial resolution of 7 km x 6 km at nadir. POLDER has a mass of about 30 kg, the power consumption = 77 W in imaging mode (mean power of 29 W). The data rate is 880 kbit/s at 12 bit quantization.

M.15.4 Picard

Picard is a CNES solar-terrestrial microsatellite mission with French multi-institutional and international cooperation.¹⁷⁰³⁾ The overall objective is to monitor the solar diameter, the differential rotation and the solar constant and to study the long-term nature of their relations. The mission is named after Jean Picard (1620-1682), a French astronomer, who measured the solar diameter, observed sunspots, and determined the rotational velocity of the sun. Picard was also the first who accurately measured the length of a degree of a meridian (longitude line) and from that estimated the size of the Earth.

The Picard microsatellite consists of a box-like structure (60 cm x 60 cm x 80 cm) with a single solar panel. The platform is three-axis stabilized with a pointing accuracy of 0.01° and a pointing stability of 0.01°. Attitude sensing is provided by a star sensor and/or by the payload telescope, actuation is provided by reaction wheels. Solar power of 80 W (min) and batteries of 9 Ah provide power all along the orbit (including the eclipse phases). The platform mass is 65 kg, the S/C mass is about 110 kg. The mission design life is two years with a goal of six years. A launch of Picard is planned for 2006 on a Russian launcher.

The on-board recorder has a capacity of 1 Gbit. RF communications are provided in S-band. The downlink data rate is 400 kbit/s. Mission operations are preformed at CNES.

Orbit: Sun-synchronous orbit, altitude = 700 km, inclination = 98°.

Sensor complement:

SODISM (Solar Diameter Imager and Surface Mapper), a CNRS/SA (Verrières-le-Buisson, France) instrument in collaboration with ESTEC. The objective is to observe the full image of the solar disk (limb). The instrument consists of a telescope with an aperture diam-

¹⁷⁰³⁾ L. Dame, M. Meissonnier, B. Tatry, "Picard Microsatellite Program," 5th International Symposium on Small Satellites Systems and Services, La Baule, France, June 19-23, 2000

eter of 110 mm. SODISM measures the solar radiation in four spectral bands and two calibration bands (flat field and star field), using two cascading filter wheels (each with five positions). Nominal mode observations are done in the UV band (230 nm), corresponding to a mostly flat UV continuum formed in the photosphere. The visible band (548 nm) is used for the solar diameter measurement. The 160 nm band and the Lyman alpha filters are used for identification of active regions and prominences. Diffusion plates are used to monitor the CCD response and sensitivity (flat field). The detector array employs thinned CCD arrays in a back-illuminated mode of operation to increase the short-wavelength quantum efficiency. The “star field” band is used to image stars. The measurements provide a reference used to calibrate the structural changes in the focus or CCD dimensions which could affect the quality of the sun diameter measure. The instrument design takes great care of component mechanical and thermal stability (materials, structure, alignment, etc). The instrument mass is 17.5 kg.

Measurement parameters	Solar diameter, differential rotation of the full sun
Spectral bands	6 bands: 230, 548, 160 nm, Lyman alpha, flat field & star field
Bandwidth	8 nm for 230 band, 100 nm for 548 band,
Telescope focal length, solar image	2650 mm, 25 mm diameter
Telescope optics	Primary diameter of 120 mm (110 mm are used) Secondary diameter of 34 mm (25 mm are used)
Detector array (EEV-4280 back-thinned CCD)	2048 x 4096 square pixels of 13.5 μm (frame transfer mode, 2048 x 2048 pixels of the array are used)
Guider acquisition range, Guider nominal pointing range Guider servo bandwidths	1.2° ± 30 arcsec 0 to a few Hz (platform), <50 Hz (prime mirror fine guiding)
Quad-cell image displacement	<10 ⁻² π sensitivity
Piezo displacement range	± 6 μm (± 1 arcmin)
Absolute solar shape precision	Better than 10 marcsec (milli-arcseconds)
Relative semi-diameter precision	Better than 1 marcsec

Table 500: SODISM instrument parameters

SOVAP (Solar Constant Variability, Picard) of IRMB (Institut Royal de Météorologie Belgique) or Royal Meteorological Institute of Belgium in Brussels. SOVAP is of SOVA and SOLCON heritage, flown on eight Shuttle flights (EURECA, 1992-93) in the time frame 1983 to 1998 (see Table 38). SOVAP is a differential absolute solar radiometer with the objective to measure the solar constant. The SOVAP radiometric core is formed by two blackened cavities mounted side-by-side on a common heat sink. A heat flux transducer is mounted between each cavity and the heat sink. The difference between the outputs of the two transducers is the differential heat, in which the common part of the thermal surrounding, seen by the two cavities, is eliminated. The instrument mass is 5.8 kg.

Measured parameter, instrument noise	Total irradiance (W m^{-2}), <0.1 W m^{-2}
Number of channels, number of reference voltages	2, 6
Cavity type	Cylindrical, diffuse black
Diameter of precision aperture, slope angle	1 cm, 2.5°
Solar sampling period, duty cycle	3 minutes, 50%

Table 501: SOVAP instrument parameters

Measured parameter (center wavelengths)	Spectral irradiance (W m^{-2}) at 230, 311, 402 and 548 nm
Bandwidth (FWHM)	8 nm (the 402 nm band has a bandwidth of 5 nm)
Number of photometers	12 (3 sets of 4)
Cavity type	Cylindrical, diffuse black
FOV (Field of View), slope angle	2.5°, 0.7°
Diameter of precision aperture	3 mm
Accuracy of aperture area, cross talk	<10 ⁻³ , <10 ⁻⁵

Table 502: PREMOS instrument parameters

PREMOS (Precision Monitoring of Solar variability) of WRC (World Radiation Center) of Davos, Switzerland. The instrument package consists of four “filter radiometers,” the absolute cavity measurement technique is based on the principle of substitution of electrical power for radiative power, but with the preselection of a known and reduced spectral bandwidth. The sun radiation measurements are in four bands in the UV and visible range; two bands (230, and 548 nm) are identical with those of SODISM. Three sets of four photometers are used, one set serves as reference to determine the aging effects. The 230 nm band has a dual function: 1) it monitors the UV flux and 2) it is used to estimate possible degradations of the SODISM CCD detectors. The instrument mass is 4.1 kg.

M.16 NEMO (Navy EarthMap Observer)

The NEMO program (started in 1997) is a cooperative US government/industry satellite program, sponsored by ONR (Office of Naval Research) and DARPA as well as commercial investments, between the Navy’s NRL (Naval Research Laboratory) on the government side as the program manager in partnership with commercial developers, a consortium led by STDC (Space Technology Development Corporation) of Alexandria, VA. In 1999, STDC was acquired by Earth Search Sciences of McCall, Idaho. ¹⁷⁰⁴⁾ ¹⁷⁰⁵⁾ ¹⁷⁰⁶⁾ ¹⁷⁰⁷⁾

The overall objective is the development/demonstration of hyperspectral technology and the collection/processing of moderate-resolution hyperspectral imagery for military and commercial use. The emphasis is on broad-area, synoptic, and unclassified hyperspectral imagery. The prime military interest is to obtain imagery of the coastal regions on a global scale (littoral modeling, shallow water bathymetry, topography, bottom type composition, detection of underwater hazards, water clarity and visibility, etc.), while the civil needs call for imagery supporting such applications as land use management, agriculture, environmental studies, and mineral exploration. Contract agreements call for STDC and its industry partners to provide the commercial satellite bus, selected flight avionics components, launch services, and long-term flight operations. NRL provides the design and integration of the NEMO sensor imaging payload with the commercial satellite bus, bus modifications, the on-board processor, ORASIS (Optical Real-time Adaptive Signature Identification System), and systems engineering. NRL has responsibility for calibration software and calibrated radiances; development of at-launch algorithms including those for atmospheric correction; on-board data compression software and related software for the ground data system; some data processing; and data archiving. The planned products of at-launch algorithms are water clarity (probably diffuse attenuation coefficient at 490 nm), concentration of chlorophyll, absorption coefficient of colored dissolved organic matter, concentration of suspended sediments, bathymetry, and bottom characteristics.

The satellite consists of eight hardware subsystems and a software subsystem that collectively accommodate the payload and meet the mission and science requirements (Table 220). The satellite platform selected is a commercial bus (LS-400) from SS/L. ¹⁷⁰⁸⁾ ¹⁷⁰⁹⁾ The satellite is three-axis stabilized and consists of a trapezoidal main body and two deployable solar arrays. STDC has responsibility for ground data processing system architecture, some data processing and merging, data archiving, and a web-based database interface. The S/C design life is five years (minimum of three year on-orbit mission life).

Subsystem	Short Description
ADCS (Attitude Determination and Control Subsystem)	3-axis stabilized for all modes; 0.07° control Geolocation: 30 m with a Circular Error of Probability (CEP) of 0.9 2 star trackers and 1 inertial reference unit for attitude determination 4 reaction wheels and 2 electromagnetic torquers for attitude control
EPS (Electrical Power Subsystem)	2 gimbale (single axis) solar array panels 4 for 3 redundant power control box 64 Ah nickel hydrogen battery Approximately 1500 W power
RCS (Reaction Control Subsystem)	Monopropellant hydrazine blowdown system 1 propellant tank (76.5 kg capability) 5 x 1N thrusters for orbit correction/orbit maintenance
TCS (Thermal Control Subsystem)	Passive thermal control with heater augmentation Battery and payload panels thermally isolated from bus
Structural Subsystem	Primary structure is a combination of a rigid aluminum tubular frame and aluminum honeycomb shear panels Kinematically decoupled optical bench S/C mass: 496 kg dry; 547 kg wet; payload mass: 292 kg
Mechanisms Subsystem	Optical bench launch restraints Contamination covers for sensors Solar array drive mechanisms for gimbaling arrays Launch vehicle separation Two redundant main electrical umbilical connectors
CT&DH (Command, Telemetry, and Data Handling Subsystem)	On-Board Processing Electronics (OBPE) primary controller: MIL-STD-1750A radiation-hardened processor Payload controller: R3000 processor (12 MIPS) Imagery On-Board Processor (IOBP): multiple Super Harvard Architecture RISC Computing (SHARC) processors in a parallel array Solid state data recorder with a capacity of 56 Gbit
Communications Subsystem	Data downlink in X-band, data rate of 131 Mbit/s; 20 watt; 8025-8400 MHz, with embedded housekeeping telemetry Command uplink in S-band, data rate of 2 kbit/s, 2074.1 MHz Low-rate downlink in S-band, data rate at 1.024 Mbit/s, 2252.5MHz, supports tactical imagery demonstrations
Software Subsystem	On-board task scheduling capability, FDIR (Embedded fault Detection, Isolation, and Recovery)

Table 503: Spacecraft subsystem characteristics

Figure 323: Illustration of the NEMO S/C

A launch of NEMO is planned for 2003. Launch vehicle is TBD.

Orbit: Sun-synchronous circular orbit, altitude = 605 km, inclination = 97.81°, nodal equator crossing at 10:30 AM (ascending node), repeat cycle = 7 days with a 2.5 day global average re-access capability when S/C pointing ($\pm 30^\circ$) in the cross-track direction is used.

Sensor complement:

COIS (Coastal Ocean Imaging Spectrometer), a hyperspectral (ocean color - land surface) imager provided by NRL (built by SAIC). The instrument employs a TMA (Three-Mirror-

off-Axis) anastigmatic design, a 15 cm diameter aperture telescope, a dichroic beam splitter, and two spectrometers (VNIR and SWIR). The overall spectral range of COIS is from 400 to 2500 nm with 10 nm spectral resolution (210 bands). A FOV of 2.86° provides a swath width of 30 km. COIS uses WFOV (Wide Field of View) grating spectrometers. The two spectrometers are:

- A Visible Near Infrared (VNIR) spectrometer that disperses the 400 to 1000 nm radiation into 60 spectral bands (10 nm wide) and onto a Focal Plane Array (FPA). This provides a resolution of 1.0 - 1.5% of the band and 60 spectral bins.
- A Short-Wave Infrared (SWIR) spectrometer that disperses the 1000 to 2500 nm radiation into 150 spectral bands (10 nm wide) and onto an FPA. This provides a resolution of about 0.6% of the band and 150 spectral bins. A cryocooler provides active cooling at 110 K.

Figure 324: Exploded bus view with COIS instrument

Spectral coverage	400 - 2500 nm with a 10 nm spectral resolution (total of 210 spectral bands)
Spatial resolution	30 m or 60 m (for high SNR data products)
SNR (Signal-to-Noise)	>200 for VNIR data (5% reflectance target which is typical of the ocean) >100 for SWIR data at 30% reflectance (typical)
Pointing capability	±30° in the cross-track and along-track directions (body pointing) The pointing is used to increase integration time when sampling in the 30 m mode
Detector arrays	FPA of 1024 x 1024 pixels for VNIR (silicon CCD) and SWIR (MCT detector)
Pixel summing	Pixels are summed by 6 in VNIR and SWIR to achieve the desired spectral resolution
Data volume	Estimated average daily imagery is about 227 Gbit

Table 504: Some performance parameters of COIS

The COIS instrument provides very high SNR environmental products for imaging the low-reflectivity ocean surface. The NEMO platform can implement Ground Motion Com-

pensation (GMC) sufficient to reduce the apparent ground speed by a factor of 5. This provides the required dwell time to give a high SNR at a GSD of 30 m. COIS is also capable of producing 60 meter GSD, high SNR data products without GMC by using spatial binning of the hyperspectral FPAs. - COIS calibration is maintained by on orbit by monthly imaging of the full moon and weekly imaging of uniform ground reference targets. ¹⁷¹⁰⁾

A typical COIS scene is 30 km wide by 200 km in length, with 30 m by 30 m pixel resolution, yielding nine image strips per orbit (number of strips limited by on-board data storage capacity). An alternate pixel size is 60 m x 60 m, yielding a 30 km wide swath as long as 8000 km per orbit.

Parameter	COIS - VNIR	COIS - SWIR	PIC
GSD (Ground Sample Distance)	30 m with 5:1 GMC 60 m with no GMC	30 m with 5:1 GMC 60 m with no GMC	5 m (with or without GMC)
Spectral range	0.4 - 1.0 μm	1.0 - 2.5 μm	0.45 - 0.69 μm
Spectral bands	60	150	1
FOV, swath width	2.86°, 30 km	2.86°, 30 km	2.86°, 30 km
Swath length	200 km at 30 m GSD Continuous at 60 m GSD	200 km at 30 m GSD Continuous at 60 m GSD	Continuous
Aperture diameter	15 cm	15 cm	16.4 cm
Focal length, f/Nr.	36 cm, f/2.4	36 cm, f/2.4	120 cm, f/7.32
Pixel size	18 μm	18 μm	10 μm
Nr. of pixels/band	6	6	N/A
Data quantization	12 bits	12 bits	12 bits
Detector material	Silicon	MCT	Silicon

Table 505: Characteristic parameters of COIS and PIC

PIC (Panchromatic Imaging Camera). The instrument uses an off-axis telescope to simultaneously image the same 30 km swath as the COIS instrument onto a 6000 pixel CCD linear array (PIC data is co-registered with COIS data). The spectral range is from 0.45 - 0.69 μm . The panchromatic imagery has a resolution of 5 m GSD. The moderate COIS GSD matches the spatial scale of natural objects in the littoral zone, while the high resolution PIC provides simultaneous context and sharpening and supports civil land imaging requirements. The 30 km ground swath of COIS and PIC spans the near-shore littoral region of land, beach, and ocean. COIS and PIC use a single optical bench to minimize optical boresight drift. ¹⁷¹¹⁾

Mission operations:

NEMO uses a combination of commercial/industry operations and an existing DoD infrastructure ground segment to provide the user communities (military and civil) with data services. The ground segment consists of the following elements:

- ASOC (Advanced S/C Operations Center), located in Washington, DC area. ASOC is the central hub for all mission planning, S/C operations, and data processing
- TAGS (Transportable Autonomous Ground Stations), located at Fairbanks, AK and elsewhere. Downlinked data is maintained on mass storage devices at the TAGS until final receipt of the IPC is verified.
- IPC (Image Processing Center). The IPCs perform quick-look data processing to level 1B and data archive functions.
- NCC (NRL Control Center). NCC is the science hub for the NEMO program. Also data distribution function for the military side.

Adaptive Spectral Signature Recognition.

The NEMO S/C employs **ORASIS** (Optical Real-time Adaptive Signature Identification System) developed by NRL, an automated and patented end-to-end HSI (Hyperspectral

¹⁷¹⁰⁾M. Corson, "Calibration of the NEMO sensor imaging payload," SPIE Proceedings, Vol. 3437, 1998

¹⁷¹¹⁾A. Myers, "NEMO satellite sensor imaging payload," SPIE Proceedings, Vol. 3437, 1998

Imaging) algorithm and advanced processing system that performs on-board data compression, thereby significantly reducing the capacities needed for on-board storage and for downlink transmission.

ORASIS identifies the spectral signatures corresponding to physical objects in the scene without supervision or a priori knowledge. The approach is to analyze each spectrum in the scene sequentially, discarding duplicate spectra, and working only with the unique spectra. Using convex set methods and orthogonal projection techniques, each observed spectrum is then analyzed in terms of the set of spectra that represent the physically meaningful patterns or end-members that have combined to make the observed spectrum. Matched filters (Filter Vectors) are created, they can be used to de-mix the image.¹⁷¹²⁾

The ORASIS processor, hosted on IOBP (Imagery On-Board Processor), is based on the SHARC (Super Harvard Architecture Computer), it has 32 processors for data handling and a processing capability of up to 2.5 GFLOPS. The on-board processing minimizes subsequent ground processing and data exploitation, and enables the on-board production of data products, such as maps of identified features. An important benefit of ORASIS processing is a **greater than tenfold data compression**, relieving the bottlenecks of on-board data storage, transmission to the ground, and beyond.

M.17 Nimbus

A NASA/GSFC meteorological research-and-development satellite program (parallel to the operational TIROS program) which started in the early 1960s with the prime objective to test new instrument concepts, a secondary objective was to provide atmospheric data for improved weather forecasts. The series grew more into a major Earth sciences program (study of oceans, land surfaces and atmosphere) with successive S/C and with the availability of better sensing instrumentation. The ERTS (Earth Resources Technology Satellite, later renamed to Landsat) program, developed in the early 1970s, is a direct descendent of the Nimbus program.

The basic Nimbus series S/C structure is butterfly-shaped (some call it ‘ocean-buoy shaped’) when deployed in orbit, designed to serve as a stabilized, Earth-oriented platform. It consisted of three major elements: 1) a sensory ring, 2) solar paddles, and 3) the control system housing. The solar paddles and the control system housing were connected to the sensory ring by a truss structure. The Nimbus-1 S/C was nearly 3.7 m tall, 1.5 m in diameter at the base, and about 3 m across with solar paddles extended. The sensory ring at the base of the satellite housed the electronics equipment and battery modules. The lower surface of the sensory ring provided mounting space for sensors and telemetry antennas. An H-frame structure mounted within the center of the torus provided support for the larger sensors and tape recorders. Mounted on the control system housing were sun sensors, horizon scanners, gas nozzles for attitude control, and a command antenna. Pitch and roll stability was sensed by horizon scanners, while a gyroscope controlled stability in the yaw axis. Use of a stabilization and control system allowed the spacecraft’s orientation to be controlled to within $\pm 1^\circ$ for all three axes.^{1713) 1714)}

All Nimbus series S/C were built and integrated by GE Astro Space. The series with their orbits and sensor complements are also listed in Table 374. The Nimbus program, consisting of eight satellite launches, seven of which were successful in achieving orbit, carried a total of 48 instruments and experiments.

Figure 325: The Nimbus-7 spacecraft model

M.17.1 Nimbus-1

The S/C was launched Aug. 28, 1964 on a Thor-Agena-B vehicle from VAFB, CA. Nimbus-1 S/C mass = 375 kg. The satellite was fully operational for 3 1/2 weeks when a failure of the solar-array power system stopped further experimentation.

Orbit: Polar elliptical orbit, perigee = 429 km, apogee = 937 km, inclination = 98.66°, eccentricity = 0.03595, period = 98.42 minutes. Note: A short burn of the Agena rocket resulted in an elliptical orbit instead of the intended circular orbit of 1100 km.

Sensor complement:

HRIR (High-Resolution Infrared Radiometer). HRIR mass = 5.1 kg, power = 4 W. Objective: to map the earth's nighttime cloudcover (to complement the daytime AVCS coverage) and to measure the radiative temperatures of cloud tops and surface terrain. The HRIR instrument consisted of the following basic components: an optical subsystem, an infrared detector (lead selenide photoconductive material), an electronics subsystem, a magnetic tape recorder, and a filter to minimize attenuation effects of water vapor and carbon dioxide. Measurement of thermal radiation in the spectral region of 3.5 - 4.1 μm . IFOV = 1.5° (corresponding to 8 km ground resolution). The radiometer was capable of measuring radiance temperatures from 210 to 330 K. The HRIR system was operational for 3 1/2 weeks.

AVCS (Advanced Vidicon Camera System). The AVCS consisted of three cameras, a tape recorder, and an S-band transmitter. The cameras were mounted on the satellite sensory ring, facing earthward and deployed in a fan-like array to produce a three-segment composite picture. Each camera covered a FoV of 37° with the center camera pointing straight down. The optical axes of the other two cameras were directed 35° to either side. Each of the cameras employed an f/4 lens with a focal length of 16.5 mm. A potentiometer attached to the solar array controlled the lens opening from f/16 when the S/C was over the equator to f/4 when it was near the poles. The 800 scan-line, 2.54 cm diameter vidicon pickup tubes yielded a linear resolution of better than 1 km at nadir from an altitude of 800 km. At this altitude, the camera array produced a composite picture covering an area of 830 by 2700 km. Up to 192 pictures (two full orbits of data) or 64 pictures per camera could be stored on recorder for subsequent playback to an acquisition station. AVCS provided near-global, high-resolution cloudcover pictures ever assembled. Subsequently, the same basic camera system was also used for the TOS/ESSA series program (G.12).

APT (Automatic Picture Transmission). Heritage of APT on TIROS-8 with a launch on Dec. 21, 1963. A vidicon camera and transmitter combination designed to transmit local daytime, slow-scan television pictures of cloudcover conditions to properly equipped ground receiving stations on a real-time basis. The camera used a 108° wide-angle f/1.8 objective lens with a focal length of 5.7 mm. Images retained on the photo-sensitive surface of the 2.54 cm diameter vidicon system were read out at four lines/s to produce an 800 line picture. A 5 W TV transmitter (136.95 MHz) relayed the pictures to local APT stations within communication range. The faceplate of the vidicon had reticle marks that appeared on the picture format to aid in relating the picture to its geographical position on the Earth's surface. At nominal satellite altitude, a picture covered a footprint of about 1660 km x 1660 km with a horizontal resolution of around 3 km at nadir. Over 1600 pictures were obtained in the 3 1/2 weeks of mission lifetime.

M.17.2 Nimbus-2

Nimbus-2 was launched May 15, 1966 on a Trust Augmented Thor-Agena-D vehicle from VAFB, CA. S/C mass = 414 kg. The Nimbus-2 S/C and its sensors performed nominally after launch until July 26, 1966, when the S/C tape recorder failed. Its function was taken over by the HRIR tape recorder until November 15, 1966, when it also failed. Some real-time data were collected until January 17, 1969, when the mission was terminated.

Orbit: Sun-synchronous polar near-circular orbit, perigee = 1103 km, apogee = 1179 km, inclination = 100.35°, period = 108.15 minutes.

Sensor complement:

HRIR (High-Resolution Infrared Radiometer). Identical sensor as flown on Nimbus-1.

AVCS (Advanced Vidicon Camera System). Identical sensor as flown on Nimbus-1. At the orbital altitude of 1100 km, the camera array could produce a composite picture covering an area of 720 by 3400 km.

APT (Automatic Picture Transmission). Identical instrument as flown on Nimbus-1. A picture covered a footprint of 1200 km x 1200 km with a horizontal resolution of > 3 km at nadir. Over 300 APT stations in 43 countries were able to this data.

MRIR (Medium-Resolution Infrared Radiometer). Sensor mass = 9.5 kg, power = 7.5 W. Objective: measurement of the intensity and distribution of electromagnetic radiation emitted by and reflected from the Earth and its atmosphere in five selected wavelength ranges from 0.2 to 30 μm . Data for heat balance of the Earth-atmosphere system were obtained, as well as measurements of water vapor distribution, surface or near-surface temperatures, and seasonal changes of stratospheric temperature distribution. MRIR featured a flat scanning mirror inclined at 45° to the optical axis. The mirror rotated at 8 rpm and scanned in a plane perpendicular to the direction of motion of the satellite. Each of the five channels contained a 4.33 cm diameter folded telescope with a 2.8° IFOV (55 km ground resolution) and a thermistor-bolometer. The collected energy was modulated by a mechanical chopper to produce an ac signal. The signal was then amplified and recorded on magnetic tape for subsequent playback to a ground acquisition station.

Band	Spectral Range	Description
1	6.4 - 6.9 μm	which covered the 6.7 μm water vapor absorption band
2	10 - 11 μm	atmospheric window
3	14 - 16 μm	which covered the 15 μm carbon dioxide absorption band
4	5 - 30 μm	which provided the emitted long-wavelength infrared energy for heat budget estimations
5	0.2 - 4 μm	which yielded information on the intensity of reflected solar energy (albedo)

Table 506: Spectral parameters of MRIR

M.17.3 Nimbus-3

Nimbus-3 was launched April 14, 1969 on a Thor-Agena vehicle from VAFB, CA. S/C mass = 576 kg. Nimbus-3 performed nominally until July 22, 1969, when the IRIS experiment failed. The HRIR and SIRS experiments were terminated on January 25, 1970, and June 21, 1970, respectively. The remaining experiments continued operation until September 25, 1970, when the rear horizon scanner failed. All S/C operations were terminated on January 22, 1972.

Orbit: Polar near-circular orbit, perigee = 1075 km, apogee = 1135 km, inclination = 99.9°, period = 107.4 minutes.

Sensor complement:

MRIR (Medium-Resolution Infrared Radiometer). Identical sensor as flown on Nimbus-2, but with slightly changed spectral ranges.

Band	Spectral Range	Description
1	6.5 - 7 μm	which covered the 6.7 μm water vapor absorption band
2	10 - 11 μm	atmospheric window
3	14.5 - 15.5 μm	which covered the 15 μm carbon dioxide absorption band
4	20 - 23 μm	which covered the spectral region containing the broad rotational absorption bands of water vapor
5	0.2 - 4.0 μm	which yielded information on the intensity of reflected solar energy (albedo)

Table 507: Spectral parameters of MRIR

HRIR (High-Resolution Infrared Radiometer). A modified version HRIR as flown on Nimbus-1 and -2. It used a dual band-pass filter which transmitted reflected solar radiation in the 0.7 - 1.3 μm band as well as emitted thermal radiation in the 3.4.- 4.2 μm band. By

detecting reflected solar radiation in the 0.7 - 1.3 μm band, the radiometer could also map the Earth's cloud cover during the daytime. Radiant energy from the earth was collected by a flat scanning mirror inclined at 45° to the optical axis. The mirror rotated at 48 rpm and scanned in a plane normal to the S/C velocity. The radiation reflected from the scan mirror was chopped at the focus of a 10.2 cm f/1 modified Cassegrain telescope. The modulated energy was then refocused on a lead selenide detector cell that transformed the received radiation into an electrical output. The output was amplified and recorded on magnetic tape for subsequent playback to a ground acquisition station. Using the direct readout infrared radiometer (DRIR) system, nighttime and daytime data could be transmitted by the real-time transmission system (RTTS) to ground APT stations. A ground resolution of 8.5 km could be obtained at nadir. The HRIR measured radiance temperatures between 210 and 330 K to a general accuracy of 1 K.

IRIS (Infrared Interferometer Spectrometer). Sensor mass = 13 kg, power = 16 W, average bit rate = 3.75 kbit/s. Objective: measurement of the vertical structure of the atmosphere and the emissive properties of the earth's surface by measuring the surface and atmospheric radiation in the 5.0 - 20 μm band using a modified Michelson interferometer. Incoming radiation was reflected into the instrument from a plane mirror. The radiation was split into two beams that recombined and interfered after reflection on a fixed mirror and a moving Michelson mirror. The recombined beam was then focused on a bolometer detector. Interference effects resulted from the optical path difference between the two beams as the mirror moved. The moving mirror traveled about 2 mm in 11 s to give an interferogram, which was recorded on magnetic tape. The interferograms were transmitted to an acquisition station, where a Fourier transform was performed to produce a thermal emission spectrum of the Earth. From these spectra, vertical profiles of temperature, water vapor, and ozone, as well as other parameters of meteorological interest, could be derived. The IFOV provided a resolution circle on the ground of 144 km in diameter.

SIRS (Satellite Infrared Spectrometer), built by SBRC. Sensor mass = 41 kg, power = 24 W, average bit rate = 0.1 kbit/s. Objective: indirect determination of the vertical temperature profiles of the atmosphere by measuring the infrared radiation emitted from the Earth and its atmosphere in seven spectral intervals in the carbon dioxide band (11 - 15 μm) and one interval in the atmospheric window centered at 11.1 μm . - A Fastie-Ebert fixed-grating spectrometer was used consisting of the following components: 1) a plane, light-collecting mirror to provide a single Earth-viewing beam fixed in the vertical; 2) a rotating chopper mirror; 3) a spherical mirror; 4) a 12.7 cm diffraction grating with 1250 lines per inch (or 492 lines per cm); 5) a set of eight exit slits with a single interference filter; 6) eight wedge-immersed thermistor bolometers; 7) a blackbody radiation source for calibration, and 8) eight preamplifiers and eight operational amplifiers. FOV = $11.5^\circ \times 11.5^\circ$ centered at nadir (a footprint of about 220 km x 220 km on the ground). Data from the 11.1 μm channel yielded surface and/or cloud-top temperatures. Data from the carbon dioxide band could be used to generate temperature-pressure profiles by a mathematical inversion technique.

IDICS (Image Dissector Camera System). Sensor mass = 11.2 kg, power = 18 W. Objectives: provision of daytime cloudcover photographs. IDICS was a shutterless electronic scan and step tube mounted behind a wide-angle (108°), 5.7mm focal length lens. Scanning and stepping functions occurred continuously while the satellite progressed along its orbital path. The FOV of the optics was 73.6° in the direction of flight and 98.2° in the cross-track direction. The image was focused by the optics on a photosensitive surface of the image dissector tube. A line-scanning beam scanned the photosensitive surface at 4 Hz with a frame period of 200 s. A picture was about 1400 km x 1400 km with a resolution of 3 km at nadir.

IRLS (Interrogation, Recording, and Location System). The objective was to collect and retransmit meteorological, geophysical, and other experimental data from remote data collection stations (platforms) deployed on a global scale. The IRLS could also determine

the location and track the movement of properly equipped objects such as balloons, ocean buoys, and ships to within an accuracy of 2 km.

IRLS consisted of the following components: 1) a 466 MHz receiver, 2) a 401.5 MHz transmitter, 3) decoding and coding circuits, 4) a range detector, and 5) a 20 kByte satellite data memory capable of storing data measurements during each orbit for up to 20 different interrogations. When within range of an acquisition and command station, the satellite command memory was programmed to communicate with selected platforms during the coming orbit. The satellite stored both the address (number) of each platform and the desired time that each should be contacted. At the appropriate time in orbit, the satellite interrogated each platform, measured the satellite to platform distance by determining the round trip propagation time of the RF signal, received the analog data from the platform, converted it to digital form, and stored it. Upon return to the locale of the ground station, the station commanded the satellite to transmit the stored data and to accept new commands for the next orbit. IRLS functioned nominally until Sept. 1970, when the operational capacity was severely restricted by spacecraft yaw problems. All data acquisition ceased on January 22, 1972, when spacecraft operations were terminated.

MUSE (Monitor of UV Solar Energy). The objective was to measure the solar flux, look for temporal variations in the solar UV flux, and to measure the atmospheric attenuation by viewing into the setting sun after the S/C. The instrument had five broad bands in the range of 1150 to 3000 Å with maximum response at 1216 Å, 1600 Å, 1800 Å, 2000 Å, and 2600 Å. MUSE consisted of the following components: five vacuum photodiodes, housed in an electronics package and a sensor package, mounted in the rear of the Nimbus spacecraft. All sensors except the 1216 Å sensor had semi-transparent photocathodes that were deposited on the windows. The 1800, 2000, and 2600 Å sensors had aluminum oxide windows, while the 1216 Å and 1600 Å sensors had MgF₂ and CaF₂ windows, respectively. The five spectral regions were determined by the transmittance of the filter or window materials on the short wavelength side, while the long wavelength cutoffs were produced by the varying degrees of opacity of the different photocathode materials. The solar aspect system measured the angle of incidence of the solar rays. One sample/s was measured. Sensor FOV=90°. Solar acquisition began at 45° prior to the Earth day/night terminator and ceased completely at the satellite day/night transition. The instrument had only an inflight electrical calibration sequence because there were no known suitable UV sources that could provide an inflight optical calibration.

SNAP-19 (Radioisotope Thermoelectric Generator). The objective was to assess the operational capability of radioisotope power for space applications.

Nuclear Auxiliary Power.

M.17.4 Nimbus-4

Nimbus-4 was launched on April 8, 1970 on a Thor-Agena-D vehicle from VAFB, CA. S/C mass = 675 kg. The spacecraft performed nominally until April 8, 1971, when attitude problems started. On April 14, 1971, the spacecraft turned around and flew backwards in orbit. On May 12, 1971, the spacecraft was successfully rotated 180°. The experiments operated on a limited time basis after that time until September 30, 1980.

Orbit: Sun-synchronous near-circular polar orbit, perigee = 1092 km, apogee = 1108 km, inclination = 80.1°, period = 107.2 minutes.

Sensor complement:

IDICS (Image Dissector Camera System). Similar system as flown on Nimbus-3. IDICS data could be transmitted via APT or stored and transmitted to ground acquisition stations. The experiment performed nominally until April 8, 1971. After May 12, 1971 limited data were obtained until February 5, 1972.

THIR (Temperature-Humidity Infrared Radiometer). Sensor mass = 7.6 kg, power = 8.2 W, bit rate = 2 kbit/s. THIR was built by Hughes SBRC. Objective: detection of emitted thermal radiation in two spectral ranges, measurement of daytime and nighttime surface and cloud-top temperatures as well as the water vapor content of the upper atmosphere. The instrument consisted of a 12.7 cm Cassegrain system, a scanning mirror common to both channels, a beam splitter, filters, and two germanium-immersed thermistor bolometers. Incoming radiant energy was collected by a flat scanning mirror inclined at 45° to the optical axis. The mirror rotated through 360° at 48 rpm and scanned in a plane normal to the spacecraft velocity vector. The energy was then focused into a dichromatic beam splitter, which divided the energy spectrally and spatially into two channels (10.5 - 12.5 μm IR window, and 6.5 - 7.0 μm for water vapor). Direct readout infrared radiometer (DRIR) data could be transmitted to APT ground stations for both day and night portions of the orbit. The IR window channel had a ground resolution of about 7 km and the water vapor channel about 22 km at nadir. THIR operated nominally until Jan. 11, 1971. A similar experiment was flown on Nimbus 5, 6 and 7.

IRIS (Infrared Interferometer Spectrometer). Similar system as flown on Nimbus-3. Sensor mass = 17 kg, power = 12 W, bit rate = 3.75 kbit/s. Spectral range of modified Michelson interferometer = 6.25 to 25 μm. The instrument had a FOV of 5° and a spectral resolution of less than 0.4 μm (nominally 1.4 reciprocal cm). The IRIS instrument was turned off on January 25, 1972 to conserve spacecraft power.

SIRS (Satellite Infrared Spectrometer). Similar system as flown on Nimbus-3. Sensor mass = 31.5 kg, power = 30 W. The instrument measured the infrared radiation (11 to 36 μm micrometers) emitted from the Earth and its atmosphere in 13 selected spectral intervals in the carbon dioxide and water vapor bands plus one channel in the 11 μm atmospheric window. The main components of SIRS consisted of: 1) a plane, light-collecting mirror to provide one fixed and two variable Earth-viewing angles; 2) a rotating chopping mirror that served alternately to collect space radiation and Earth radiation; 3) a 6.3 cm diffraction grating with 1250 lines per inch (or 492 lines per cm); 4) 14 slits with associated interference filters; 5) 14 thermistor bolometers; and 6) a blackbody source for calibration purposes. The a scan mirror could observe the ground surface 12.5° to either side of the subsatellite track. FOV = 215 km. The SIRS experiment performed nominally for several months after launch but began to deteriorate in early 1971. The experiment operated on a limited time basis until March 6, 1973.

MUSE (Monitor of UV Solar Energy). Identical system as flown on Nimbus-3.

BUV (Backscatter Ultraviolet). Sensor mass = 14.5 kg, power = 7 W. Objective: to monitor the vertical distribution and total amount of atmospheric ozone on a global scale by measuring the intensity of UV radiation backscattered by the Earth/atmosphere system during day and night in the spectral band of 2500 - 3400 Å. The instrument consisted of a double monochromator containing all reflective optics and a photomultiplier detector. The double monochromator was composed of two Ebert-Fastie-type monochromators in tandem. Each monochromator had a 52 mm x 52 mm grating with 2400 lines per mm. Light from a 0.05 sr solid angle (subtending approximately a 222 km² area on the ground) entered the nadir-pointing instrument through a depolarizing filter. A motor-driven cam step rotated the gratings to monitor the intensity of 12 ozone absorption wavelengths. The detector was a photomultiplier tube. For background readings, a filter photometer measured the reflected UV radiation in an ozone-free absorption area near 3800 Å. Signals from both units were read by separate range-switching electrometers with seven ranges. Cycle time of 6144 s. Each cycle, in turn, was divided into 192 BUV frames of 32 s duration. Calibration by on-board light sources was performed in 26 of the 192 frames. During each of these data frames, the monochromator measured the intensity of the UV radiation in each of the 12 wavelength bands, while the photometer measured the UV intensity in a single wavelength band. The dwell time at each wavelength was 1.8 s, and, during this interval, four analog UV

intensity measurements were taken at 400 ms intervals in addition to an integrated pulse count measurement of the UV intensity and energetic particle flux. Once each orbit, the FOV was changed to monitor the sun or moon directly.

FWS (Filter Wedge Spectrometer). Objective: to determine the radiance from the Earth-atmosphere system as a function of wavelength by measuring the emitted and reflected infrared radiation in the 1.2 - 2.4 μm and 3.2 - 6.4 μm bands. FWS consisted of the following components: 1) a telescope; 2) a rotating disk chopper; 3) a rotating (3.75 rpm) circular interference filter wheel; and 4) a lead selenide detector. The filter wheel was a two 180°-segment (one per passband) 100 layer interference filter with the layer thickness linearly increasing as a function of angular position, causing the bandpass to shift toward longer wavelengths. Incoming radiation was reflected off a surface mirror and was collected by a telescope oriented normal to the earth's surface. The telescope had a 3° FOV toward nadir, and a swath about 57 km. The telescope focused the collected radiation onto the edge of the multi-toothed chopper wheel that chopped the energy at 333 Hz. The energy was refocused onto the edge of the circular variable filter at an aperture that acted as both spectrometer slit and a system field stop. The energy was then reimaged on a lead selenide detector radiatively cooled to 175 K. The incident radiation was sampled 20 times/s, resulting in a spectral intensity plot of 158 points for each passband per revolution. Onboard calibration was accomplished by alternate viewing of the earth and calibration standards by the detector. On June 8, 1970, the FWS suffered a mechanical failure.

SCR (Selective Chopper Radiometer). Sensor mass = 15.3 kg, power = 5 W. Objective: to observe the emitted infrared radiation in the 15 μm absorption band of carbon dioxide. The SCR had six channels, which were arranged in three units of two. The four lower channels were called single-cell channels. The optics of each channel consisted of a cantilever-mounted blade shutter that oscillated at 10 Hz and successively chopped the FOV between Earth and space. The chopped radiation was then passed through a 10 cm path length of carbon dioxide, the pressure being set for each channel to define the viewing depth of the atmosphere. Behind the carbon dioxide path was a narrow-band filter, the centers of which were different for each channel, and a light pipe which focused the radiation on a thermistor-bolometer detector. To obtain adequate height resolution in the upper layers of the atmosphere, the upper two channels operated on a slightly different principle and were known as double-cell channels. The technique consisted of switching the radiation between two half-cells, which were semicircular in shape and of 1 cm path length, and which contained different pressures of carbon dioxide. A movable 45° mirror replaced the oscillating shutter used in the lower four channels. - Inflight calibration was carried out by viewing of an internal reference blackbody of known temperature prior to the view of space. The output of each channel was sampled once every second. The upper two channels had a circular FOV of about 160 km in diameter, and the lower four had a rectangular FOV about 112 km square.

IRLS (Interrogation, Recording, and Location System). Instrument mass = 7 kg, power = 12 W. Identical instrument as flown on Nimbus-3.

M.17.5 Nimbus-5

Nimbus-5 was launched on Dec. 11, 1972 by a Delta vehicle from VAFB. S/C mass = 770 kg.

Orbit: Sun-synchronous polar orbit, perigee = 1089 km, apogee = 1101 km, inclination = 99.9°, period = 107.2 minutes.

Sensor complement:

ITPR (Infrared Temperature Profile Radiometer). Sensor mass = 15.9 kg, power = 16 W, bit rate = 0.24 kbit/s. Objective: to measure the three-dimensional temperature field in the Earth's atmosphere with a spatial resolution of 32 km. The radiometer sensed four intervals

in the 15 μm CO_2 band, one interval in the water vapor rotational band near 20 μm and two spectral intervals in the atmospheric window regions near 3.7 and 11 μm . The ITPR viewed the Earth successively at various angles distributed symmetrically about nadir in a plane normal to the orbital track. Forty-two geographically independent scan spots were taken along a single strip. As the satellite progressed along its orbital path, the radiometer observed 10 such 42-spot strips to form a matrix of independent scan spots. Each matrix was produced in 222 s with the whole scanning sequence repeated every 240 s. Matrix measurements taken in the CO_2 and water vapor absorption bands were used to calculate temperature profiles and total water vapor content in the troposphere and lower stratosphere.

SCR (Selective Chopper Radiometer). Sensor mass = 11.3 kg, power = 15 W. Similar instrument as flown on Nimbus-4. Objectives: to observe the global temperature structure of the atmosphere up to 50 km in altitude, to make supporting observations of water vapor distribution, and to determine the density of ice particles in cirrus clouds. SCR measured emitted radiation in 16 spectral intervals separated into the following four groups: 1) four CO_2 channels between 13.8 and 14.8 μm ; 2) four channels at 15.0 μm ; 3) an IR window channel at 11.1 μm , a water vapor channel at 18.6 μm , two channels at 49.5 and 133.3 μm , and 4) four channels at 2.08, 2.59, 2.65, and 3.5 μm . SCR viewed a 48 km circle on the Earth's surface with a ground resolution of about 25 km.

NEMS (Nimbus-E Microwave Spectrometer). Sensor mass = 22.6 kg, power = 35 W, bit rate = 0.06 kbit/s. Objectives: to demonstrate the capabilities and limitations of microwave sensors for measuring tropospheric temperature profiles, water vapor abundances, cloud liquid water content, and Earth-surface temperatures. NEMS frequencies: 22.235, 31.4, 53.65, 54.9 and 58.8 GHz. The three channels near the 5 μm oxygen absorption band were used primarily to determine the atmospheric temperature profiles. NEMS provided measurements even in cloudcover conditions that normally restrict the usefulness of conventional IR data in such situations. The two water vapor channels near 10 μm permitted the water vapor and cloud liquid water content over oceans to be estimated and also to yield an estimated temperature once the surface emissivity had been calibrated by comparison with direct measurements. The three oxygen channels shared a common signal and reference antenna. Both water vapor channels had their own signal and reference antennas. NEMS viewed a 180 km diameter circle on the earth's surface.

ESMR (Electrically Scanning Microwave Radiometer). Sensor mass = 28 kg, power = 40 W, bit rate = 0.40 kbit/s. Objectives: 1) to derive the liquid water content of clouds from brightness temperatures over oceans, 2) to observe differences between sea ice and the open sea over the polar caps, and 3) to test the feasibility of inferring surface composition and soil moisture. ESMR frequency at 19.36 GHz (1.55 cm wavelength). A phased-array antenna system (83.3 cm x 85.5 cm), deployed after launch, scanned the Earth successively at various angles in cross-track direction, producing a brightness-temperature map of the surface of the Earth and its atmosphere (half-power beam width = $1.4^\circ \times 1.4^\circ$, beam scan angle = $\pm 50^\circ$, polarization = horizontal). The scanning process was controlled by a computer, it consisted of 78 symmetrically distributed independent scan spots extending 50° to either side of nadir. Angular separation of the scan spots allowed for an 8.5% overlap between view positions. ESMR had an accuracy of about $\pm 1^\circ \text{C}$ with a spatial resolution of about 25 km at nadir.

SCMR (Surface Composition Mapping Radiometer). Sensor mass = 25 kg, power = 7 W, bit rate = 0.25 kbit/s. Objective: to measure 1) terrestrial radiation in the 8.3 - 9.3 μm and 10.2 - 11.2 μm intervals, and 2) reflected solar radiation in the 0.8 - 1.1 μm range. Surface composition and sea surface temperatures could be obtained from these measurements. The SCMR had an IFOV of 0.6 mrad, equivalent to a ground resolution of 660 m at nadir. The scan mirror rotated at 10 rps to provide scan lines 800 km wide across the spacecraft track. SCMR operation until Jan. 4, 1973. A modified instrument, heat capacity mapping radiometer, was flown on the Heat Capacity Mapping Mission (HCMM).

THIR (Temperature-Humidity Infrared Radiometer). Similar instrument as flown on Nimbus-4.

M.17.6 Nimbus-6

Nimbus-6 was launched on June 12, 1975 by a Thor-Delta vehicle from VAFB, CA. S/C mass = 586 kg. The complement of advanced sensors was capable of: 1) mapping tropospheric temperature, water vapor abundance, and cloud water content; 2) providing vertical profiles of temperature, ozone, and water vapor; 3) transmitting real-time data to a geostationary spacecraft (ATS-6); and -4) yielding data on the earth's radiation budget.

Orbit: Sun-synchronous circular polar orbit, perigee = 1093 km, apogee = 1101 km, inclination = 100°, period = 107.3 minutes.

Sensor complement:

ERB = Earth Radiation Budget. Sensor mass = 18 kg, power = 30 W, bit rate = 0.50 kbit/s. Objective: measurement of reflected and emitted terrestrial radiation fluxes in conjunction with solar radiation. The results were used: 1) to determine the Earth radiation budget, 2) to determine the angular distribution of terrestrial radiation for various meteorological and geographic regimes, and 3) to correlate measurements made using identical but independent channels calibrated to the same standard.

The multichannel radiometer employed a bi-axial scanning mechanism which enabled measurements to be obtained from the forward horizon to the aft horizon in a 64 s interval. Each axis of the scanning mechanism contained four shortwave channels (0.2 - 4.0 μm) and four longwave channels (4.0 - 50 μm) with a FOV of 0.25° x 5.14°. The channels were oriented in a directional fan to cover 20° to each side of nadir. The 64 s scan period allowed an area to be measured from up to 17 different angles as the spacecraft passed overhead.

Incoming solar radiation from 0.2 - 50 μm was normally monitored in 10 spectral intervals as the satellite orbited over the Antarctic, just before it started its northward trip on the daylight side of the earth. Terrestrial radiation measurements were taken continuously in the 0.2 - 4 μm , 0.7 - 3 μm , and 4 - 50 μm intervals. The measurements were taken in two ways. Four channels, using fixed wide-angle optics (FOV = 133.3°), measured the total outgoing radiation integrated over the entire disk of the Earth. The second set of measurements was obtained from eight high-resolution narrow-angle scanning channels that measured the terrestrial radiation emanating from a relatively small area over a range of zenith and azimuth angles. A similar instrument was flown on Nimbus 7. The solar and wide-angle channels operated successfully and provided good quality data. The scanning channels developed mechanical scan problems in August 1975 and operated only in the nadir position after March 1976.

ESMR (Electrically Scanning Microwave Radiometer). Similar instrument as flown on Nimbus-5. Sensor mass = 36.7 kg, power = 70 W, bit rate = 2.40 kbit/s. Objectives: to measure the Earth's microwave emission to provide the liquid water content of clouds, the distribution and variation of sea ice cover, and gross characteristics of land surfaces (vegetation, soil moisture, and snow cover).

The two-channel scanning radiometer operated in a 250 MHz band centered at 37 GHz. One channel was used to measure the vertical polarization and the other measured the horizontal polarization. The antenna beam array, a 90 cm x 20 cm x 12 cm box-like structure, was mounted on top of the S/C sensory ring and was pointed in the direction of the spacecraft's forward motion and tilted down 45° from the satellite antenna axis. The antenna beam scanned the earth in 71 discrete steps for various angles extending up to 35° on either side of the orbital plane. The deduced brightness temperatures were expected to be accurate to within 3 - 5 K. Spatial resolution was 20 km in the cross-track direction and 45 km in the direction parallel to the subpoint track.

HIRS (High-Resolution Infrared Radiation Sounder). Sensor mass = 13.5 kg, power = 10 W, bit rate = 10.8 kbit/s. Objectives: to provide vertical temperature profiles twice daily on a global basis, to extend up to about 40 km, and to provide information on the water vapor distribution in the troposphere. HIRS measured radiances primarily in five spectral regions: 1) seven channels near the 15 μm CO₂ absorption band, 2) two channels (11.1 and 3.7 μm) in the IR window, 3) two channels (8.2 and 6.7 μm) in the water vapor absorption band, 4) five channels in the 4.3 μm band, and 5) one channel in the visible 0.69 μm region. The sounder consisted of a Cassegrain telescope, scanning mirror, dichromatic beam splitter, filter wheel, chopper, and associated electronics. HIRS scanned the Earth's surface in a plane normal to the spacecraft's orbital path with a maximum scan angle of 30° to either side of nadir to provide data with a spatial resolution of 25 km.

LRIR (Limb Radiance Inversion Radiometer). Sensor mass = 18 kg, power = 36 W, bit rate = 15.68 kbit/s. Objective: to provide calibrated radiance versus altitude profiles by intercepting radiation emanating from an atmospheric path which is tangential to a particular geocentric height. LRIR sensed radiation in four spectral intervals: 1) the 14.6 - 15.9 μm CO₂ band, 2) the 14.2 - 17.3 μm CO₂ band, 3) the 8.8 - 10.1 μm ozone band, and 4) the 20 - 25 μm water vapor rotational band. - Measurements taken in the two CO₂ channels and the water vapor channel were used to calculate global temperature and water vapor profiles in the stratosphere and lower mesosphere. In addition, values of the geostrophic wind up to 1 mb (approximately 48 km) were derived analytically from the deduced temperature profiles. The radiometer included an optical system, a scanning mirror, choppers, and associated electronics and employed an ammonia-methane cooler system for three of the four detector channels. While the deduced temperature profiles had an rms accuracy of 3° at heights above 15 km, the values for ozone were accurate to within 20% at 1 mb. Water vapor values at the same height were within 50%.

PMR (Pressure Modulated Radiometer). Sensor mass = 2.3 kg, power = 3 W, bit rate = 0.01 kbit/s. Objective: to obtain radiometric measurements in the 15 μm CO₂ band at altitudes between 45 and 70 km on a global scale. The PMR comprised two similar radiometer channels, each consisting of a plane scanning mirror, reference blackbody, pressure-modulator cell, and detector assembly. The plane mirror was gold coated and mounted at 45° on a 90° stepping motor so that the FOV of the channel could be directed to space or to the internal reference blackbody for inflight range and zero calibration. The motor was mounted on a pair of flexible pivots so that the mirror could be rotated through $\pm 7.5^\circ$ from its rest position to give the required Doppler scan. Major components in the pressure-modulator cell were a movable piston, a diaphragm, and a magnetic drive coil. The detector assembly consisted of a field lens, a condensing light pipe, and a pyroelectric flake bolometer. Each radiometer had a field of view that was 20° whole-angle across the spacecraft's line of flight and 40° whole-angle parallel to the line of flight. The derived temperature values were within 2 K at 65 km and about 0.2 K near 50 km with a vertical resolution of 10 km.

SCAMS (Scanning Microwave Spectrometer). Sensor mass = 23.4 kg, power = 46 W, bit rate = 0.12 kbit/s. Objective: to map tropospheric temperature profiles, water vapor abundance, and cloud water content to be used for weather prediction even in the presence of clouds, which block conventional satellite infrared sensors. SCAMS is of NEMS heritage of Nimbus-5. SCAMS continuously monitored emitted microwave radiation at frequencies of 22.235, 31.65, 52.85, 53.85 and 55.45 GHz. The three channels near the 5.0 μm oxygen absorption band were used primarily to deduce atmospheric temperature profiles. The two channels near 10 μm permitted water vapor and cloud water content over calm oceans to be estimated separately. The instrument, a Dicke-superheterodyne type, scanned $\pm 45^\circ$ normal to the orbital plane with a 10° FOV. The three oxygen channels shared common signal and reference antennas. Both water vapor channels had their own signals and reference antennas. The absolute rms accuracy of the oxygen channels was better than 2 K, that of the water vapor channels better than 1 K. The dynamic range for all channels was 0–400 K. The ground resolution was approximately 145 km near nadir and 330 km at the scan limit.

THIR (Temperature-Humidity Infrared Radiometer). Sensor mass = 7.6 kg, power = 8.2 W. Similar instrument as flown on Nimbus-4 and -5.

TWERLE (Tropical Wind Energy conversion and Reference Level Experiment). Sensor mass = 12 kg, power = 17 W. TWERLE is a GARP experiment. Objectives: 1) to measure the upper atmospheric winds in the tropics, 2) to study the relative air motion along isobaric surfaces to determine the rate of conversion of atmospheric potential energy into kinetic energy, and 3) to provide direct measurements of various meteorological parameters that served as reference points in adjusting indirect temperature soundings made from satellites. - The experiment consisted of two basic components: 1) approximately 300 constant-level meteorological balloons to yield measurements of winds, temperature, and pressure in the tropics and at southern hemisphere midlatitudes at 150 mb (about 13.6 km altitude), and 2) the Nimbus 6 random access measurements system (RAMS) to provide data collection and location determinations from the balloons. The balloons were equipped with a transmitter-oscillator, solar power supply, digitizer/modulator, and sensors. RAMS merely detected each balloon signal (401.2 MHz) and extracted the carrier frequency, balloon identification, and sensor data. This information, along with time references, was stored in digital form for subsequent relay to a ground acquisition station. The balloon's position and velocity were derived from the relative motion between the platform and the satellite by measuring Doppler shifts in the carrier signal received from the balloon. TWERLE was capable of a location accuracy of 5 km and a platform velocity accuracy of 1 m/s.

T+DRE (Tracking and Data Relay Experiment). This experiment provided the Nimbus portion of a communication link from Nimbus to ATS to a ground station. The purpose of the experiment was to gain information on the use of such a link for range and rate communications (for satellite geodetic purposes) and for data communication from a LEO S/C through a GEO S/C to a ground telemetry station. The instrumentation included an S-band transponder, a command detector/decoder, an antenna programmer, a digital evaluation module, an S-band antenna, and an antenna gimbal assembly. Initial experiment operation was nominal.

M.17.7 Nimbus-7

NASA/GSFC Earth observation spacecraft. NIMBUS-7 was launched Oct. 24, 1978 on a Delta vehicle from VAFB, CA. The S/C was three-axis stabilized and had a mass of 965 kg (832 kg on-orbit dry mass). The attitude control subsystem maintains S/C alignment with the local orbital reference axis to within 0.7° of the pitch axis and 1° of the roll and yaw axis. 1715) 1716)

Application: Oceanography, pollution of the atmosphere, meteorology; measurement of trace gases and particles in the atmosphere; distribution phenomena of air pollution; observation of the ocean surface color and of the temperature; ice observation, in particular in the coastal regions.

Orbit: Sun-synchronous polar orbit, apogee = 954 km, perigee = 941 km, inclination = 99.15° , period = 104.16 minutes, ascending node at 12 noon equator crossing time.

Sensor complement:

CZCS = Coastal Zone Color Scanner (NASA, built by Ball Brothers Research Corp., Broomfield, CO - the predecessor of Ball Aerospace and Technologies Corp.). Instrument mass = 27 kg, power = 11.4 W. Objectives: a 'proof-of-concept' experiment for the measurement of ocean color (chlorophyll concentration, sediment distribution, gelbstoff concentrations as a salinity indicator), and the temperature of coastal waters and open ocean (all parameters were optimized for ocean color sensing).

1715) "The NIMBUS-7 User's Guide," NASA/GSFC, Prepared by The Landsat/Nimbus Project, Aug. 1978
1716) "NIMBUS-7, Observing the Atmosphere and Oceans," NASA pamphlet Dec. 1983

CZCS is a multispectral radiometer (6 bands) utilizing a rotation plane mirror at a 45° angle to the optical axis of a Cassegrain telescope. Band wavelengths: 0.433-0.453 μm (chlorophyll absorption), 0.51-0.53 μm (chlorophyll concentration), 0.54-0.56 μm (Gelbstoff concentration), 0.66-0.68 μm (aerosol absorption), 0.70-0.80 μm (land and cloud detection), and 10.5-12.5 μm (TIR, surface temperature). The mirror scanned 360° but only the 80° of data centered on nadir were collected for ocean color measurements. The instrument viewed deep space and calibration sources during the remainder of the scan. The incoming radiation was collected by the telescope and divided into two streams by a dichroic beam splitter. One stream was transmitted to a field stop that was also the entrance aperture of a small polychromator. The radiance that entered the polychromator was separated and re-imaged in five wavelengths on five silicon detectors in the focal plane of the polychromator. The other stream was directed to a cooled mercury cadmium telluride detector in the thermal region (10.5-12.5 μm). A radiative cooler was used to cool the thermal detector. To avoid sun glint, the scanner mirror was tilted about the sensor pitch axis on command so that the line of sight of the sensor was moved in 2° increments up to 20° with respect to the nadir.

CZCS instrument characteristics: multispectral cross-track scanning radiometer, spatial resolution: 825 m x 825 m (each band) at nadir or IFOV = 0.865 mrad, swath width = 1600 km. Data quantization = 8 bits, data rate = 800 kbit/s. Data products: global maps of chlorophyll concentration, sediment distribution, gelbstoff concentrations as a salinity indicator, and temperature of coastal waters and the open ocean. Prelaunch calibration used an integrating sphere and a blackbody source for the TIR channel. Inflight calibration used an incandescent light source for the first five bands. The TIR channel was calibrated by viewing the blackened housing of the instrument.- The CZCS instrument operated on an intermittent schedule due to overall power demands. The TIR channel failed within the first year after launch. CZCS was operational for eight years before it was turned off in Dec. 1986.

ERB = Earth Radiation Budget. Sensor mass = 32.7 kg, power = 36.2 W, bit rate = 4.5 kbit/s. Similar to the instrument flown on Nimbus-6. Objective: to determine the Earth radiation budget on both synoptic and planetary scales by simultaneous measurements of incoming solar radiation and outgoing Earth-reflected (shortwave) and emitted (longwave) radiation. - The ERB instrument consisted of a 22-channel radiometer containing separate subassemblies to perform the required solar, Earth-flux (wide angle), and scanned Earth radiance (narrow angle) measurements. The systems used optical filters for spectral discriminations, and for uncooled thermal detectors, thermopile detectors in the solar and fixed-Earth-flux channels, and pyroelectric detectors in the scanning channels. The 10 solar channels observed the sun in front of the observatory in the X-Y plane. The solar channels obtained usable solar data only during a period of about 3 minutes in each orbit when the spacecraft was over the Antarctic region. Their full response FOV was 0.18 rad. The solar channel subassembly was pivoted ± 0.35 rad in the X-Y plane to compensate for sun-angle deviation when required. The channel 10c (solar channel) was a model H-F (Hickey-Frieden) self-calibrating cavity thermopile used for monitoring the total solar irradiance in the spectral range 0.2 - 50 μm . The technology for long-term solar radiation monitoring utilized is referred to as ESCC (Electrically Self Calibrating Cavity). The four fixed Earth-flux channels (numbered 11-14) were mounted so that they could continuously view the total Earth disk, and record data at 0.25 s intervals. The eight narrow FOV scanning channels were mounted in the scanning head. The NFOV channels consisted of four shortwave (0.2 - 4.8 μm) and four longwave (4.5 - 50+ μm) channels.

The scanning head was gimbal-mounted in the radiometer unit main frame. The FOVs of the telescopes were asymmetric (4.4×89.4 mrad) and those of the shortwave and longwave channels were coincident. The 89.4 mrad FOVs of the four pairs of channels were not contiguous, but covered only alternate 89.4 mrad angular intervals along the horizon. ERB operation was stopped on Jan. 4, 1994.

LIMS = Limb Infrared Monitor of the Stratosphere. LIMS is of LRIR heritage flown on Nimbus-6. Sensor mass = 68.4 kg, power = 27 W, bit rate = 4 kbit/s. Measurement of verti-

cal gas concentrations and temperature profiles in the stratosphere. Observables: O₃, H₂O, NO₂, HNO₃ and temperature. Channel center wavelengths: 6.25, 6.75, 9.65, 11.35, 15.25 μ m and one broad channel from 13.3 - 17.2 μ m. The LIMS instrument was a six-channel radiometer consisting of two electronic boxes and the radiometer unit (Hg:Cd:Te detectors were used, cooled by a two-stage solid cryogen cooler). Radiance from the Earth's limb entered the OMP (Optical Mechanical Package) aperture, reflected off the scan mirror to the 18 cm diameter off-axis parabolic primary mirror where the radiation was focused and chopped at 945 Hz. The radiation was re-collimated by the secondary mirror and directed through a Lyot stop to a folding mirror and into the detector capsule assembly (DCA). The radiation was then focused through a cadmium telluride lens and through interference filters, which defined the FOVs, and onto an array of discrete mercury cadmium telluride detectors. The detectors were maintained at about 63 K temperature by the cryogen. The LIMS began a scan near 153 km altitude, taking about 12 s to move near 38 km below the solid limb, then retraced its motion upward. After every second scan pair, the scan mirror was placed in a position to observe radiation from a small cavity blackbody for inflight warm calibration after which the instrument viewed space to obtain a cold calibration point.

SAM-II = Stratospheric Aerosol Measurement II (NASA/LaRC). Sensor mass = 17 kg, power = 0.8 W, bit rate = 4 kbit/s. The instrument is a sun photometer that views a small portion of the sun through the Earth's atmosphere during S/C sunrise and sunset. SAM-II measures aerosol extinction and extinction ratio profiles, and stratospheric optical depth as a function of altitude, latitude and longitude. Channel wavelength: 0.98-1.02 μ m. Spatial resolution is 1 km (vertical); swath width is 5 - 40 km vertical. Measurement calibration technique: the Langley technique is used to calculate zero air mass solar intensity. By measuring the intensity of the sun over a several-hour period on a clear, optically stable day and using the calendar day and latitude/longitude of the measurement location, one can plot intensity versus air mass.

The SAM-II instrument package consisted of optics and electronics subassemblies. The optical assembly consisted of gimbals, a flat entrance window (which filters out UV radiation), Cassegrain optics, a flat scanning mirror, sun acquisition sensors, and a sun-photometer detector package. Solar radiation was reflected from the scan mirror into the Cassegrain telescope forming a solar image at the slit plate, which contained two solar edge sensors for monitoring solar limb crossings on either side of the detector aperture. Solar radiation passed through the aperture, was collected by a field lens, passed through an interference filter for wavelength discrimination, and finally measured by a silicon photodiode detector. The optics assembly was gimbaled in azimuth. After acquisition in azimuth, the mirror servo scanned in elevation until the Sun was acquired. The Sun was then scanned back and forth. The photometer viewed a portion of the solar disk with a 0.145 mrad IFOV and a sampling rate of 50 samples/s. SAM-II operation was stopped on January 4, 1994.

Data products: global maps of the concentration and optical properties of stratospheric aerosols as a function of altitude, latitude, and longitude, which prove valuable for studies on radiative transfer and climatic effects; aerosol transport sources and sinks in the stratosphere; seasonal variations and sudden warming phenomena; and volcanic injection phenomena. When no clouds were present in the instrument's IFOV, then tropospheric aerosols were also mapped.

SAMS = Stratospheric and Mesospheric Sounder. Sensor mass = 23.6 kg, power = 20 W, bit rate = 25 kbit/s. Measurement of vertical gas concentrations (H₂O, CH₄, CO and NO) and temperature profiles in the stratosphere and mesosphere. Observation of 'resonant scattering of solar radiation.' Channel wavelengths: nine channels defined by gas cell modulation 4.1 to 15 μ m and 25 - 100 μ m. Radiation from the limb of the atmosphere was incident on a scan mirror in front of a 15 cm aperture telescope. The scan mirror scanned the limb, viewed space for calibration, and viewed the atmosphere obliquely to obtain vertical profiles. There were three adjacent FOVs, each 28 mrad x 2.8 mrad (corresponding to 100 km

by 10 km at the limb). The FOVs were focused onto a field-splitting mirror by the telescope which directed radiation to six detectors. Separation into channels was accomplished through dichroic beam splitters. There were seven pressure modulator cells (PMC), two containing CO₂, the remainder N₂O, NO, CH₄, CO, H₂O. Pressure in the cells could be varied on command by changing the temperature of a small container of molecular sieve material attached to each PMC. The spectral parameters for the H₂O channel were 2.7 μm and 25 - 100 μm. All other channels lay within the range 4.1 to 15 μm. A chopper operating at 250 Hz within the telescope, allowed the measurement of two separate signals from all detectors, one at 250 Hz and one at the PMC frequency. SAMS was operational until April 9, 1985.

SBUV/TOMS = Solar Backscatter Ultraviolet/Total Ozone Mapping Spectrometer. Instrument mass = 20 kg, power = 20 W, bit rate = 4 kbit/s. Measurement of vertical O₃ profiles, total column amounts of atmospheric O₃, solar irradiance, and terrestrial radiances.

SBUV was a double Ebert-Fastie spectrometer and filter photometer, similar to the BUV on Nimbus-4. SBUV used three detectors: a photomultiplier tube (PMT) and a photodiode for the monochromator, and one photodiode for the photometer. Both the monochromator and the photometer have chopper wheels operating at 25 Hz. The SBUV used a depolarizer to eliminate the sensitivity of the grating monochromator to polarization of the backscattered radiation. The instrument's field of view (FOV) at nadir was 0.20 rad. A roughened aluminum diffuser plate viewed the sun for solar-spectral irradiance measurements and for calibration by viewing a mercury-argon lamp. In one mode, SBUV serially monitored 12 selected narrow wavelength bands in the spectral region from 0.250 - 0.340 μm. - The SBUV spectrometer had a second mode of operation that allowed a continuous solar-spectral scan from 0.16 - 0.4 μm for detailed examination of the extraterrestrial solar spectrum and its temporal variations. A parallel photometer channel at 0.343 μm measured the reflectivity of the atmosphere's lower boundary in the same 0.21 rad FOV. Spatial resolution of SBUV = 11.3° in each band. Swath width = 200 km, separated by the 26° longitude interval between successive orbits. SBUV was operational until 1990.

TOMS was a single Ebert-Fastie spectrometer with a fixed grating and an array of exit slits. TOMS step-scanned across the orbital track 51° from the nadir in 3° steps with a FOV of about 0.052 rad. At each scan position, the Earth radiance was monitored at six wavelengths between 0.31 and 0.38 μm to infer the total ozone amount. The TOMS completed a cross scan in eight seconds, with one second for retrace, to record 35 scenes per scan. At each scene, a chopper sequentially sampled all six wavelengths four times. TOMS used the same type of PMT as SBUV, and had a separate mercury-argon lamp for wavelength calibration and a separate depolarizer. TOMS shared the diffuser plate with SBUV. Both SBUV and TOMS had five scanner modes and a shared electronics module. TOMS measured backscattered radiation sampled at six wavelengths from 0.312 - 0.340 μm. Spatial resolution is 3° (scanned through the satellite subpoint and perpendicular to the orbital plane). Swath width = 2700 km. The TOMS instrument failed in May 1993.

Data products: vertical distribution of ozone, global maps of total ozone and 200-mb height fields; incident solar ultraviolet irradiance and ultraviolet radiation backscattered from the Earth. SBUV helps to determine the total amount of atmospheric ozone in a vertical column above the subsatellite point; vertical profile of ozone above the ozone maximum; measurements of ultraviolet solar spectral irradiance and its temporal variability over the 160 - 400 nm range (with a spectral resolution of 1 nm). TOMS exploits the polar orbit to yield global, contiguous maps of total ozone concentrations.

SMMR = Scanning Multichannel Microwave Radiometer. Sensor mass = 52.3 kg, power = 60 W, bit rate = 25 kbit/s. Observation of sea-ice parameters, ocean surface conditions, atmospheric conditions, land parameters, glacial features. Microwave brightness temperatures were observed with a 10-channel (five-frequency dual polarized) scanning radiometer operating at frequencies of 37 (0.81 cm), 21 (1.42 cm), 18 (1.66 cm), 10.69 (2.8 cm), and 6.6

(4.54 cm) GHz. Six Dicke-type radiometers were utilized. Those operating at the four longest wavelengths measured alternate polarizations during successive scans of the antenna; the others operated continuously for each polarization. The antenna was a parabolic reflector offset from the nadir by 42 deg. Motion of the antenna reflector provided observations from within a conical volume along the ground track of the spacecraft. An identical instrument was flown on SEASAT (launch June 28, 1978). SMMR operations on Nimbus-7 ended on July 6, 1988.

THIR = Temperature Humidity Infrared Radiometer (built by Hughes SBRC). Similar instrument as flown on Nimbus-4, -5, and 6. The Nimbus-7 THIR operation ended on Nov. 30, 1987.

M.18 OICETS (Optical Inter-orbit Communications Engineering Test Satellite)

OICETS is a NASDA technology satellite with the objective to conduct, with ESA cooperation, on-orbit demonstrations of high-accuracy pointing, acquisition and tracking technologies (key elements of optical inter-orbit communications), important for future space activities such as global data reception from Earth observation satellites. The OICETS mission goal is to conduct inter-orbit laser communications experiments with ARTEMIS of ESA. The advantages of optical communications are seen in the support of much higher data rates and transmission capacities than in conventional radio links, lower risk of link interference with other optical communication systems (there can be no interference between optical and radio transmissions), as well as in more compact and lighter designs of communication equipment.

The configuration of the overall system for optical inter-orbit communication experiments consists of the following space segment elements: OICETS in LEO, DRTS (Data Relay Test Satellite) of NASDA in GEO, ARTEMIS of ESA in GEO. The ground segment consists of NASDA's TACC (Tracking and Control Center) and domestic ground stations as well as of an ESA ground station (experiments between OICETS and ARTEMIS). OICETS is controlled by TACC via an S-band inter-orbit link, or by an S-band direct link with TACC. The technical challenge of the technology of the optical experiment demonstration between LEO and GEO satellites involves alignment and stabilizing issues, it requires pointing errors of a few μrad by each S/C.

Figure 326: Illustration of the OICETS spacecraft

The OICETS satellite is three-axis stabilized with a box-shaped bus (of dimensions 0.78 m x 1.1 m x 1.5 m) and two solar panels (the S/C has a span of 9.4 m with both panels deployed). The S/C is built by NEC of Tokyo. The spacecraft power is 1220 W (EOL), NiMH batteries of 13 Ah provide power during the eclipse phase of the orbit. S/C mass = 570 kg, the mission life time of about one year. The attitude control subsystem (AOCS) consists of reaction wheels and magneto-rods for actuation, gyros, fine and coarse accuracy sun sensors, and Earth horizon sensors provide the attitude sensing. The attitude determination accuracy is specified within 0.2° (3-sigma). AOCS maintains the attitude of OICETS within specified limits, caused by LUCE movements/perturbations, by exchanging some data with LUCE. The pointing for inter-orbit communication is done at the LUCE level.

A launch of OICETS is planned on a J-1 rocket from the Tanegashima Space Center, Japan, for Feb. 2002.

Orbit: altitude = 610 km (BOL) to 550 km (EOL), inclination = 35°, period = 95 minutes.

Sensor complement:

LUCE (Laser Utilizing Communications Equipment), a NASDA-sponsored instrument built by NEC Corporation. The main objectives of LUCE in-orbit experiments are: ¹⁷¹⁷⁾ ¹⁷¹⁸⁾ ¹⁷¹⁹⁾ ¹⁷²⁰⁾

- To evaluate the performance of optical devices in the space environment
- To evaluate the ATP (Acquisition Tracking and Pointing) capabilities of the system by using planets as targets
- To conduct inter-orbit communication experiments with ARTEMIS (including evaluation of atmospheric effects and micro-vibration effects caused by on-board equipment)
- To conduct optical communication experiments between OICETS and the CRL (Communication Research Laboratory) ground station.

Parameter	Forward link (ARTEMIS-OICETS)	Return link (OICETS-ARTEMIS)
Wavelength	819 nm 801 nm beacon	847 nm
Polarization type	LHCP	LHCP
Data rate	2.048 Mbit/s	49.3724 Mbit/s
Signal format	2 PPM (Pulse Position Modulation)	NRZ
Required bit error rate	10 ⁻⁶	10 ⁻⁶

Table 508: Laser link communication parameters

The optical part of LUCE (LUCE-O) is installed on the anti-Earth panel, the electronics unit of LUCE (LUCE-E) is located inside the S/C. The LUCE power consumption is about 230 W during communications support services.

- LUCE-O consists of three modules: an optical antenna, the optical system, and of two-axis gimbals. The optical antenna is a center-feed Cassegrain mirror telescope. The optical system, located behind the antenna and mounted on a thermally-controlled optical bench, consists of a laser transmitter, a receiver, ATP sensors and mechanisms, relay optics, and some electronics. The optical antenna and the optical system are mounted on two-axis gimbals, referred to as the “coarse pointing mechanism.” The mass of LUCE-O is about 110 kg.
- LUCE-E includes the ATP control electronics and the communications electronics. The mass of LUCE is about 40 kg.

The ATP system performs the followings tasks:

- In the acquisition phase, ATP compensates for the initial LOS (Line of Sight) error, caused mainly by the host S/C (OICETS) attitude error and ephemeris error.
- In the tracking phase, ATP compensates dynamic disturbances caused by the host S/C and the terminal itself within a few micro-radians.
- In the pointing phase , ATP points the beam in the direction of the partner S/C and compensates for relative motion of the S/C during the finite travelling time of the communication beam.

ATP subsystem	Tracking accuracy	$< \pm 2 \mu\text{rad}$ (3 sigma) for acquisition $< \pm 1 \mu\text{rad}$ (3 sigma) for tracking
	Pointing accuracy	$< \pm 3.6 \mu\text{rad}$ (3 sigma) for acquisition $< \pm 2.6 \mu\text{rad}$ (3 sigma) for tracking
	Coarse acquisition and tracking components	Detector: CCD (672 x 488 pixels) Drive mechanism: 2-axis gimbals Actuator: direct drive motor
	Fine acquisition and tracking components	Detector: QD (Quadrant Detector) Drive mechanism: 1-axis mirror drive Actuator: multi-layered piezo-electric
	Receiving beam wavelength	Beacon: 797 to 808 nm Communication: 815 to 825 nm
Transmission subsystem	Laser diode Data rate Modulation	Wavelength: 843 to 853 nm about 50 Mbit/s NRZ (Non Return to Zero)
Receiver subsystem	Detector Wavelength Data rate Modulation	APD (Avalanche Photo Diode) 815 to 825 nm about 2 Mbit/s 2 PPM (Pulse Position Modulation)
Optical antenna	Diameter Wave front error FOV	26 cm (effective) $< \lambda/20$ (rms) $< 1 \text{ mrad}$
MVE (Micro-Vibration Measurement Equipment)	Frequency range Range Resolution	0.5 to 1000 Hz $\pm 100 \text{ mgal}$ $< 50 \mu\text{gal}$
Items of pointing subsystems	Coarse-pointing mechanism	Fine-pointing mechanism
Structure	2-axis gimbals	Pair of independent 1-axis mirror drives
Angular coverage	Azimuth: 10-370° Elevation: 0-120°	$\pm 500 \mu\text{rad}$
Tracking accuracy	$\pm 0.01^\circ$	$\pm 1 \mu\text{rad}$
FOV (Field of View)	$\pm 0.2^\circ$	$\pm 200 \mu\text{rad}$
Bandwidth	2 Hz	200 Hz

Table 509: Specification of the LUCE instrument

The ATP system supports the above functions by a coarse-pointing system, a fine-pointing system, and a point-ahead system. The coarse- and the fine-pointing systems perform the acquisition and tracking tracking of the incoming beam - while the point-ahead system maintains the pointing direction. The coarse-pointing mechanism consists of the two-axis gimbals, two optical encoders, and two direct-drive motors. A CCD detector array (672 x 488) is used as the coarse-pointing sensor for initial acquisition and tracking of the incoming beam. The fine-pointing mechanism consists of two assemblies leading the incoming beam for x- and y-axis respectively. Angular errors of the incoming beam misalignments of $\pm 1 \mu\text{rad}$ are detected in the tracking phase. The point-ahead mechanism uses the same design as the fine-pointing mechanism. Quadrant silicon photo diodes (QD) are used to sense misalignments.

In addition to LUCE, OICETS is carrying MVE (Micro-Vibration Measurement Equipment) to sense the vibration environment of the spacecraft.

M.19 PICOSat (STP)

PICOSat is the name of an off-the-shelf microsatellite for the USAF Space Test Program (STP), in support of DoD space experiments. PICOSat represents a new procurement approach around a proven and low-cost microsatellite bus. In May 1997, a DoD contract was awarded to SSTL of Surrey, UK, calling for the acquisition of a microsatellite with all needed integration services, launch interfaces, on-orbit operations and payload data retrieval and distributions services by SSTL. All satellite experiments are furnished by DoD (managed by USAF/SMC). The mission is officially designated as STP mission P97-1. The PICO-Sat name was derived from the first letter of the initial four experiments.¹⁷²¹⁾

Figure 327: Illustration of the PICOSat spacecraft

The S/C platform is based on the latest version of the ‘Micro-Bus’ of SSTL (the platform, a modular tray design, developed in 1988 and first flown on UoSAT-3 and -4 in 1990). The Micro-Bus platform is a boxlike three-axis stabilized (Earth-pointing) structure with dimensions of 69 cm x 36 cm x 36 cm, comprising the following modules: battery (10 NiCd, 6 Ah), solar power (50 W max, 22 W average), uplink/downlink, telemetry/telecommand, on-board computer (OBC), and attitude determination and control (ADCS). The four outside surfaces are covered with solar panels (GaAs). ADCS employs a combination of passive gravity-gradient stabilization and active closed-loop damping (three-axis magnetorquer which acts against the magnetic field) and boom to maintain pointing within $\pm 1^\circ$ (nadir pointing of $\pm 5^\circ$ in pitch/roll). Attitude is determined by a combination of sun and Earth sensors and a magnetometer. OBC consists of a 80C186 CPU, 16 MByte RAM primary processor and a 80386EX CPU, 32 MByte RAM co-processor. Uplink communication is in VHF-band at 9.6 kbit/s, downlink in UHF-band at 9.6 kbit/s and 384 kbit/s. Both modulations are in CPFSK. The total S/C mass is 67 kg. Design life of one year with a three year goal.

A launch of PICOSat is planned for Sept. 2001 on an Athena-1 vehicle from Kodiak Island, AK. Other payloads on the same launch vehicle are: STARSHINE-3 (NRL), PCSat (Prototype Communications Satellite) of USNA, and SAPPHIRE of Stanford University.¹⁷²²⁾

On-orbit mission control is conducted by the SSTL ground site in Guildford, UK. The US Air Force Academy at Colorado Springs, CO operates a backup ground station for PICO-Sat to increase the amount of experimental data.

Orbit: Circular orbit, altitude = 800 km, inclination = 67°.

Sensor complement: a technology demonstration payload

PBEX (Polymer Battery Experiment), designed and developed at JHU/APL and sponsored by USAF/RL (Rome Laboratory). Objective: first demonstration of the charging and discharging characteristics of polymer batteries in the space environment. PBEX validates the use of lightweight, flexible battery technology to decrease cost and weight for future military and commercial space systems. In PBEX, both electrodes and the electrolyte are made of polymers. The all-plastic battery, composed of nontoxic materials, has the advantage that it can be recharged hundreds of times and can be operated in the temperature range of +50° C to -45° C. PBEX features a sandwich design offering more flexibility than conventional batteries. The anode and cathode are made of a foil-like sheet. The mass of PBEX is 0.4 kg, the size is 14 cm x 14 cm x 2.8 cm. PBEX can be commanded to alternate between charge and discharge cycles. Two charge and two discharge levels are available which can be selected from the ground. During an operational life of 18 months, PBEX will undergo more than 5000 charge/discharge cycles over a temperature range from -20° to +50° C. ¹⁷²³⁾

Parameter	Lead-Acid	Nickel-Cadmium NiCd	Lithium-Ion Li-Ion	Polymer Battery
Specific energy (Wh/kg)	10-35	20-37	100-130	20-90
Vol. specific energy Wh/l	50-80	40-90	300	25-40
Cycle life	200-150	250-2000	100-400	1000
Cell voltage	2.0	1.2	1.4-2.4	1.5-3.1
Discharge profile	Flat	Flat	Sloping	Sloping
Self discharge (%/month)	4-8	10-20	<1	2-5

Table 510: Parameter comparison of rechargeable battery types

IOX (Ionospheric Occultation Experiment) of USAF/SMC with instrument integration by The Aerospace Corporation. ¹⁷²⁴⁾ Objective: to demonstrate ionospheric electron profile monitoring (content and densities) using GPS satellite occultation measurements. IOX is of TRSR (TurboRogue Space Receiver) heritage as flown on SUNSAT and Ørsted with improved codeless performance on 2 of the 8 channels. IOX permits the tracking of 8 GPS channels in parallel in the modes C/A, P1, P2 (if anti-spoof is off) or in C/A, P2 (effectively if anti-spoof is on). The IOX nominal sampling time is 0.1 Hz for navigation data and 1 Hz for ionospheric occultation data (there is also a 50 Hz sampling mode to measure ionospheric scintillation as well as observables in the troposphere). The receiver performs phase measurements of both GPS frequencies L1 and L2, and code pseudoranges. The on-board orbit determination function is not supported by IOX (although some orbit data are provided to the CERTO instrument).

The instrument consists of four elements: a dual-frequency receiver (Allen Osborne), a S/C interface electronics module (built by The Aerospace Corporation), an outboard low noise amplifier/filter (by Delta Microwave), and a dual-frequency GPS patch antenna (BATC). The patch antenna is mounted onto the outer face of one of two dummy sun-sensor blocks that are attached to the nadir-facing instrument platform of PICOSat. The IOX antenna points into the aft direction. Ionospheric observations by IOX are made in concert with ground-based measurements of the CERTO beacon whenever possible. Although ionospheric science is the primary focus of IOX, tropospheric occultation measurements will also be made if telemetry rates permit. The instrument mass is about 3 kg, power is about 10 W, the data rate is 6-50 Mbyte/day if operated continuously.

CERTO (Coherent Electromagnetic Radio Tomography), developed at NRL. The objective is to determine ionospheric electron density by using a three-frequency beacon; coop-

¹⁷²³⁾Information provided by Joseph. J. Suter of JHU/APL, Laurel, MD

¹⁷²⁴⁾Information provided by Paul R. Straus of The Aerospace Corporation, El Segundo, CA

erative ionospheric observations with fixed ground receivers. The instrument is of CERTO heritage flown on ARGOS of DoD (launch Feb. 23, 1999). CERTO provides a global ionospheric map to aid the prediction of radio-wave scattering. This knowledge will improve navigation accuracy and communications capacity for military and commercial systems.

OPPEX (Optical Precision Platform Experiment), developed at AFRL. Objective: to demonstrate 20 dB vibration isolation from S/C to payload using active controls. OPPEX, also referred to as UQP (Ultra-Quiet Platform), aims to provide a 10:1 reduction in vibration isolation over a 100 Hz bandwidth between the spacecraft bus and a science payload. The intent is to reduce the launch cost and to improve the performance of spaceborne sensors.

M.20 PROBA (Project for On-Board Autonomy)

PROBA is microsatellite technology demonstration mission in ESA's General Study Program with the objective to address issues of on-board operational autonomy of a generic platform. The following functional capabilities and/or techniques are to be demonstrated: 1725) 1726)

- Command management coordination of on-board resources and house-keeping functions
- Scheduling, preparation, and execution of instrument observations (coordination of sensor settings, pointing angles, etc.)
- Source data handling functions (data collection, processing, storage, distribution)
- Source data communications management
- Performance evaluation and estimation of drifts, trends
- Failure detection and failure handling procedures

Further (secondary) objectives of PROBA are space environment investigation and Earth observation. The scientific interest relates to the use of the imaging spectrometer CHRIS. 1727)

PROBA was designed/developed by a consortium led by Verhaert Design and Development N. V. of Kruibeke, Belgium and sponsored by OSTC (Federal Office for Scientific, Technical, and Cultural Affairs) of Belgium. The S/C structure resembles a box (60 cm x 60 cm x 80 cm) of conventional honeycomb design with body-mounted solar panels (GaAs) on five sides. The satellite is three-axis stabilized. The ACNS (Attitude Control and Navigation Subsystem) performs autonomous on-board navigation. Attitude measurements are provided by an autonomous star tracker [referred to as ASC (Advanced Stellar Compass), a GPS-based attitude sensor (SRG-20), gyroscopes (one resonating gyro, built by Sagem of France, flies for the first time) and four three-axis magnetometers; attitude control is provided with four reaction wheels and four magnetorquers. All ACNS sensors and actuators are controlled by the ACNS software package (developed at the Université de Sherbrouk) running on the central ERC-32 RISC processor. There is no propulsion capability for orbit correction. S/C power = 90 W (peak) provided by body-mounted GaAs solar cells with integrated diode, a 36 Li-ion cell battery of 9 Ah capacity is used for energy storage. A centrally switched 28 V regulated bus distributes power to all sensors and subsystems. PROBA has a Memory Management Unit (MMU) with a 1.2 Gbit capacity for data storage. S/C mass = 110 kg. The S/C provides nadir and inertial pointing capabilities; along-track body pointing is up to 38°, while cross-track pointing is up to 30°. Yaw steering of up to 24° is only used for calibration purposes. The S/C design life is 2 years.

Figure 328: Illustration of the PROBA S/C

A launch of PROBA is planned on the PSLV launcher of ISRO (secondary payload to TES of ISRO and BIRD of DLR) for Sept. 2001.

Communications: CCSDS-compatible uplink (2-4 kbit/s, PSK/PM modulation) and downlink (up to 1 Mbit/s, transmitter power of 2 W, BPSK modulation) packetized communications in S-band.

Orbit: Sun-synchronous elliptical polar orbit, perigee = 575 km, apogee = 725 km, inclination = 97.7°, period = 101.3 min, repeat cycle = 16 days (approximately), equator crossing time at 10:30 AM on descending node. The pointing capability of PROBA permits a CHRIS imagery repeat cycle of approximately 2 days at mid latitudes.

Sensor complement:

CHRIS (Compact High Resolution Imaging Spectrometer), an AO instrument funded by BNSC of UK and built by Sira Electro-Optics Ltd of Chislehurst, Kent, UK. Objective: collection of BRDF (Bidirectional Reflectance Distribution Function) data for a better understanding of spectral reflectances. CHRIS is the prime instrument of the PROBA mission. The technology objective is to explore the capabilities of imaging spectrometers on agile small satellite platforms. CHRIS provides 19 spectral bands in the VNIR range (410 - 1050 nm) at a spatial resolution of 25 m and a swath width of 19 km. It can be reconfigured to provide 62 spectral bands at a spatial resolution of 50 m. There is a very broad range of application areas, including vegetation mapping, agricultural crop forecasting, forestry, water quality, air quality and pollution monitoring. ^{1728) 1729) 1730)}

The CHRIS instrument design comprises a catadioptric telescope, an imaging spectrometer, and an area detector array at the focal plane of the spectrometer. The focal length of the telescope is 746 mm, the aperture diameter is 120 mm (f/6). All refracting elements in the

¹⁷²⁸⁾ M. A. Cutter, D. R. Lobb, T. L. Williams, R. E. Renton, "Integration & Testing of the Compact High-Resolution Imaging Spectrometer (CHRIS)," Proceedings of SPIE, Vol. 3753, Denver, CO, July 19-21, 1999, pp. 180-191

¹⁷²⁹⁾ M. A. Cutter, D. R. Lobb, R. A. Cockshott, "Compact High Resolution Imaging Spectrometer (CHRIS)," IAA 2nd International Symposium on Small Satellites for Earth Observation, Berlin, April 12-16, 1999, pp. 205-208

¹⁷³⁰⁾ "Exploitation of CHRIS data from the PROBA Mission," Experimenters Handbook, Issue 4, Oct. 18, 1999

design are made of fused quartz. The telescope is axially symmetrical and has only spherical surfaces. The spectrometer uses “prisms” with curved surfaces integrated into a modified Offner relay. The dispersion of the spectrometer varies from about 2 nm to 10 nm across the spectral range, with the highest dispersion at 415 nm and the lowest at the high end (1050 nm) of the spectral range. A pixel registration of better than 5% is provided in the spectral and spatial directions, with resolution limited essentially by the detector pixel size. An area-array CCD detector at the focal plane provides pushbroom imagery. The detector is a thinned, back-illuminated, frame-transfer CCD (1152 rows and 780 columns) - the rows are assigned to separate wavelengths, while the CCD columns are used to separate resolved points in the image. The detector array operates in a frame transfer mode, with image and masked storage zones. The spectrometer fills <200 of the CCD rows, part of the nominally-unexposed area is used to calibrate for stray light and CCD smear effects.

Spectral range	410 nm to 1050 nm
Spectral resolution	1.25 nm to 11 nm
Spectral bands	19 band readout at 25 m spatial resolution, nominal mode for land studies 62 band readout at 50 m spatial resolution, nominal mode for aerosol studies
Spatial resolution	25 m at nadir, integration to 50 m, 75 m, etc.
Image size or FOV	18.6 km x 18.6 km at nadir (748 x 748 pixels)
Radiance range	albedo 1
Radiometric resolution	0.5% at 20% albedo
Body pointing capability	$\pm 30^\circ$ in cross-track and $\pm 50^\circ$ in along-track direction
CCD detector area array	748 nominal resolved elements per swath width (cross-track direction) 576 lines in the along-track direction (about 200 lines are used for spectral resolution - the others are used for smear/stray-light correction) The total frame time for 25 m ground sampling is 12.7 ms
Electronics features	Programmed line integration and dumping on chip for spectr. band selection Pixel integration on chip for spatial resolution control Correlated double sampling (noise reduction circuit) Dynamic gain switch for optimum usage of the ADC resolution 12 bit data quantization (ADC)
Instrument size	about 200 mm x 260 mm x 790 mm
Instrument mass, power	14 kg, about 10 W

Table 511: Some specification parameters of the CHRIS instrument

The CHRIS imagery is processed on-board, i.e. analyzed and compressed, by a TEMIC DSP (Data Signal Processor), a space-qualified TSC 2102OE device, ¹⁷³¹) and stored in MMU (Memory Management Unit), both part of PPU (Payload Processing Unit).

The platform/instrument can be commanded to perform the following functions:

- Target location - requiring roll maneuvers to point cross-track
- Viewing directions for each target in one orbit - requiring pitch maneuvers to point along-track
- Spectral bands and spectral sampling interval in each band
- Spatial sampling interval

Atmospheric science objectives of CHRIS focus on aerosols, which as well as being important for weather and climate, are also a consideration for accurate atmospheric correction of satellite data. Operational plans call for a total of 30 test sites: 15 for aerosol/atmosphere studies, 10 for land surface studies and 5 for coastal studies. Aerosol studies include a number of different continental, marine, urban and desert test sites. Land surface sites include temperate agricultural areas, boreal forests and semi-arid areas.

¹⁷³¹) TEMIC was a daughter of Daimler-Benz until 1997 when it was acquired by Vishay and in 1998 sold to Amtel (with plants in Heilbronn, Germany and Nantes, France)

a) Instrument mass: 2.5 kg, including external Radfets, b) Instrument size: 95 mm x 122 mm x 217 mm, c)
Use of standard OBDH/RTU interfaces, d) Instrument power: 20 - 50 V primary power bus input voltage

Table 512: SREM instrument performance/design parameters

SREM (Standard Radiation Environment Monitor), an ESA/ESTEC instrument of REM heritage flown on STRV-1b and the MIR space station (Oerlikon-Contraves of Switzerland

is the prime contractor of the instrument). The objective of SREM is to measure energetic electrons (0.3-6 MeV), protons (8-300 MeV), and heavy ions, as well as the total accumulated dose, encountered during the mission.

DEBIE (DEBris In-orbit Evaluator), built by Metorex International and Patria Finavitec, both of Oy, Finland. The objective is to monitor sub-millimeter sized particles which impact the detector surfaces - measurement of mass ($> 10^{-14}$ g), impact speed and penetration power. The instrument consists of a central processing unit and up to 4 separate sensor units (each 10 cm x 10 cm) which can be placed on different spacecraft surfaces (two are on the ram side and two on the deep space face). DEBIE uses a combination of impact ionization, momentum and foil penetration detection. The instrument is designed as a standard detector to be flown on different spacecraft and missions with little or no modifications (planned to fly on ISS). DEBIE on PROBA uses two impact detectors located on the panel; one detector is looking in the flight direction, the other detector is looking in the cross-track direction. The DEBIE data is used in risk assessment models and for the design of protective shielding.

Demonstration of Autonomy Technologies:

The attitude control and avionics subsystems accommodate the core technologies for S/C autonomy. The particular subsystems are:

- **SGR-20** (Space GPS Receiver 20), built by SSTL, UK (heritage of UoSat-12 and TMSat). Objective: demonstration of autonomous operations for orbit and attitude determination (alternatively to ASC). The instrument consists of a 24 channel GPS L1 and C/A receiver, and four antennas for position and medium-accuracy attitude determination. The SRG-20 instrument is designed to be tolerant to radiation effects.
- **ASC** (Advanced Stellar Compass), developed and built by DTU (Technical University of Denmark). ASC is already flown on Ørsted, a Danish geomagnetic research microsatellite mission that was launched Feb. 23, 1999 (see also ASC description under Ørsted E.18 and CHAMPE.1). ASC is an autonomous star tracker, the main attitude sensor of PROBA, with the objective to provide full-sky coverage and to achieve a high pointing accuracy (precision of a few arcseconds) for Earth observation. ASC is capable to reconstruct autonomously the S/C inertial attitude starting from the condition “lost in space.” The camera of the star imager is a 752 x 588 pixel CCD device. ASC consists of a camera head unit (CHU) connected to a DPU (Data Processing Unit), i.e. a microcomputer fitted to a frame-grabber. The CHU acquires star images within its FOV, while the DPU provides the processing power to perform image analysis, pattern recognition, data reduction, and communication.
- **PASS** (Payload Autonomous Star Sensor), developed and built in collaboration by Sira Electro-Optics Ltd and MMS (UK) for a demonstration flight on PROBA. The instrument is an autonomous star tracker with a FOV of $19.3^\circ \times 14.4^\circ$, capable of immediate recovery from a “lost-in-space” condition. The PASS elements are: a) an optical head (50 mm focal length, f/2) with a CCD detector array (770 x 576) and an ADC unit (12 bit quantization); b) a DSP-based processor (radiation-tolerant STAR DSP board), which reads relevant pixels from the head buffer, calculates centroids of star events, and hosts the star identification software; c) star identification software, which identifies stars in each camera frame and estimates the pointing direction from this data. PASS provides pointing accuracies of 3 arcseconds in pitch and yaw and 30 arcseconds in roll at update rates of 5 Hz (up to 20 Hz with reduced accuracy). The instrument has a mass of about 2.4 kg, power consumption of 9 W, and standard RS 422 / IEEE 1355 interfaces.¹⁷³²⁾

There are several names for the instrument: a) WASS (Wide Angle Star Sensor), the original name used for the first customer, DERA; b) PASS (Payload Autonomous Star Sensor) is

¹⁷³²⁾ R. Cockshott, D. Purll, N. Fillery, V. Lewis, “The UK Wide Angle Star Sensor (WASS),” Presented at the poster session of the 4th ESA International Conference on Spacecraft Guidance, Navigation and Control Systems, Oct. 18-21, 1999, Noordwijk.

the name used in the PROBA technology demonstration; and c) AST20 (Autonomous Star Tracker 20) is the name chosen for commercial applications.

- **ERC-32 high-performance RISC processor**, funded by ESA, is provided by TEMIC Semiconductors (the DHS uses two of these processors). ERC-32 is a space version of a standard commercial processor, a high-performance radiation tolerant (>80 krad) SPARC V7 processor, providing 10 MIPS and 2 MFLOPS with a floating point unit. A memory controller includes all peripheral functions. The ERC32 computer is able to support a number of on-board processing functions including science data processing. This capability enhances the S/C autonomy with respect to data distribution through the selective use of the downlink and the on-board mass memory.
- **VMC (Visual Monitoring Camera)** is a stand-alone wide-angle digital camera system, based on CMOS APS imaging technology, and designed and built by DSS/OIP and IMEC of Belgium. The camera is modular, offering a choice of various support options with regard to interfaces, detectors, color or grey-scale, and exchangeable optics. VMC accepts image capture and exposure control commands, performs image acquisition, and is capable of storing one image in an on-board buffer to facilitate readout at a lower data rate. In addition, VMC accepts commands from, and transmits imagery to, standard serial digital interfaces such as TTC-B-01 synchronous and RS-422-like asynchronous.

Spectral range	400 - 650 nm, providing color imagery or B&W
Focal length, F-number	12.2 mm, f/5
FOV (Field of View)	40° x 31° - using IRIS-1
Distortion	$<0.5\%$
Resolution	10 cycles/mm in detector plane
Detector size	640 x 480 pixels; 14 μ m pitch (IRIS-1)
Data quantization	7 bits
Image capture speed	200 ms
Image download speed	1 image/s (max)
Operational modes	autonomous or command-interactive operation
Interfaces	Synchronous serial TTC-B-01-like up to 1 Mbit/s, or Asynchronous serial RS-422 up to 3.125 Mbit/s
Power supply	either 28 VDC or 10 VDC
Power consumption	3.0 W (28 V version); 2.0 W (10 V version)
Instrument size (mm)	65 (width) x 60 (height) x 103/108 (depth)
Instrument mass	0.430 kg (excluding mounting bracket)

Table 513: VMC instrument parameters

VMC employs IMEC's IRIS-1 (Integrated Radiation-tolerant Imaging System), a single-chip integrating CMOS imager. IRIS-1 was developed for general purpose imaging applications in space, including visual telemetry, robot vision, planetary imaging, and land/rover imaging. The following functions are integrated on one chip: a focal plane detector array, double sampling readout structures, ADC (Analog Digital Converter), and control/interfaces. VMC flown on PROBA implies a technology demonstration.

- **HRC (High Resolution Camera)**, an ESA/ESTEC instrument built by DSS/OIP of Belgium. HRC is of VTS (Visual Telemetry System) heritage, test-flown on TEAMSAT and XMM (X-Ray Multi-Mirror Mission) of ESA. The objective is to demonstrate a high-resolution imager. HRC is a miniaturized black and white imager with 10 m ground resolution. The telescope is of Cassegrain type with an aperture size of 115 mm and a focal length of 2296 mm. The CCD detector array uses 3D packaging technology. It contains 1024 x 1024 pixels of 14 μ m size. The field of view (along the diagonal of the detector) is 0.504°. Images are digitized to 10 bits before transmission to the spacecraft.

Figure 331: Illustration of the VMC (left) and HRC (right) instruments

- **Mission operations concept.** PROBA software provides considerable flexibility in the allocation of on-board resources and in scheduling of operations when compared to the relatively rigid concepts used in conventional missions. In particular, the following operations functions are being planned for implementation on PROBA:

- 1) **On-board housekeeping:** PROBA monitors autonomously all routine housekeeping and resource management tasks. This includes also the decision-making process in the case of (foreseeable only!) anomalies, i.e. failure detection, failure identification and first-level recovery actions. A summary of the information available on-board is down-linked to the control centre at regular intervals.
- 2) **On-board data management:** PROBA takes care autonomously of all management tasks related to the on-board data handling, storage, and downlinks. The S/C uses a 1 Gbit mass memory for data recording and a tuneable 2 Kbit/s to 1 Mbit/s downlink. As a worst case, two passes of about 10 min every 12 hours are available for downlink of telemetry data (as well as for command uplinks).
- 3) **On-board resources usage:** PROBA takes care autonomously of all management tasks related to the on-board power usage. Any excess power and energy (above the basic spacecraft control requirements during daylight and eclipse phases) is allocated to the instruments and to the spacecraft subsystems supporting the specific operations of the instruments, for instance to the wheels for attitude maneuvers. The allocation is performed on a dynamic basis, resolving task constraints and priorities. Constraints include for each activity the power and data storage area needed, the pointing requested, etc.
- 4) **Instrument commanding:** All preparatory, commanding, and data processing activities related to the instrument operations are performed on-board (after an appropriate initialization period). This includes the planning, scheduling, resource management, navigation, and instrument pointing as well as the downlinks of the processed data. In the case of CHRIS, the main EO instrument, a specific attitude (pointing and rates) of the S/C is required to perform its Earth observation function. The calculations of the relevant slew characteristics are based on a request file (containing the coordinates of the target area and the observation duration) which is uplinked from ground.
- 5) **Science data distribution:** The collected science data are normally downlinked to the (nominal) ground station from where they may be routed automatically or on request

to a user's site using Internet links. Furthermore, it is planned to demonstrate an automatic direct data distribution capability to different user ground antennae upon their requests without human involvement and with minimum possible delay. The optimal downlink times may be uplinked in the request file or calculated on-board.

The ground segment of PROBA is based on a portable ground station, located at Redu, Belgium, and additional support from small stations to validate the concept of distributed users. Users around the world can ask the satellite to take pictures by sending a request through internet. A web server at the ground station handles the request and uplinks it to the satellite, which schedules autonomously and takes the imagery. The picture data are stored in the on-board mass memory unit, they are downlinked during a ground station pass, after which it becomes available to the user.

M.21 RADCAL (Radar Calibration Satellite)

A microsatellite built by CTA Space Systems of McLean, VA for the USAF under the Small Test and Small Launch Vehicle (ST&SLV) program. The satellite is hexagonal in shape with 762 mm diameter, it has a total mass of 87kg. It is passively stabilized to a nadir-pointing attitude by a gravity gradient boom and magnetic nutation dampers (magnetorquers and magnetometer). A prime objective is to provide space-based radar cross-sectional area calibration (via two C-band transponders) for more than 70 military and civilian radars operating in C-band (the S/C position is known to a fair degree of accuracy, thus allowing ground-based users to calibrate their systems by acquiring the RADCAL satellite and comparing their position with the "known" position). A further objective is to demonstrate spaceborne GPS-based attitude determination. RADCAL also carries a peak power tracker and a UHF Store and Forward payload. The design mission life is three years.

The S/C was launched on June 25, 1993 on a Scout launch vehicle from VAFB, CA. Mission design life is 1 year with a 3-5 year goal. The satellite transmits/receives at 306.775 MHz. 1733) 1734)

Initial S/C operations were performed from SMC (USAF/Space & Missile Systems Center at Los Angeles AFB). Since November 1996 RADCAL is controlled from Kirtland AFB, NM (SMC/TEO).

Orbit: Near-circular polar orbit, altitude = 815 km x 765 km, inclination = 89.5°.

Sensor complement:

TANS Quadrex GPS receiver (Trimble Navigation). Objective: to demonstrate post processing attitude determination Two receivers (channels: 6+6, L1 C/A) were modified by Stanford University to measure the differential phase of GPS signals arriving at four micro-strip patch antennas mounted on the zenith face of the vehicle and canted outward 17.5°. The phase differences between each of three slaves and a master antenna are downloaded for post-processing.

SSPSR (Small Satellite Power System Regulator), built by PL. The objective is to test improved methods for battery charging.

M.22 SJ (Shi Jian Program)

Shi Jian (SJ, meaning "practice" or "experimental") is a scientific as well as a technology demonstration minisatellite series of CAST (Chinese Academy of Space Technology)

1733) L. M. Ward, P. Axelrad, "A Combined Filter for GPS-Based Attitude and Baseline Estimation," *Navigation: Journal of The Institute of Navigation*, Vol. 44, No. 2, Summer 1997, pp. 195-213

1734) L. M. Ward, P. Axelrad, "Spacecraft attitude estimation using GPS: Methodology and results for RADCAL,," *Navigating the 90s: Technology, Applications, and Policy*, Proceedings of The Institute of Navigation, National Technical Meeting, Anaheim, Calif., 18-20 January, The Institute of Navigation, Alexandria, Va., pp. 813-825.

which started in the early 1970s. It includes spin-stabilized spacecraft and an a three-axis stabilized spacecraft. An overview of the missions is given in Table 514. For SJ-2, all three spacecraft were launched by a single launch vehicle. The SJ-4 launch was from the Xichang launch site with a Long March-IIa vehicle. ¹⁷³⁵⁾

SJ-4: The objective was to monitor the space environment and its effects. The S/C, built by CAST, has a mass of 397 kg with dimensions: 1.6m diameter and 2.1m high. The main instruments are: Semiconductor high energetic electron detector, Semiconductor high energetic protons, heavy ions detector, Electrostatic analyzer, Electric potential meter, Static Single Events Upset monitor, and Dynamic Single Events Upset monitor.

Spacecraft	Launch Date	S/C Mass	S/C Orbit	Payload
SJ-1 (Shi Jian)	Mar. 3, 1971	221 kg	266 km x 1826 km, I= 69.9°	Particle detectors
SJ-2 SJ-2A SJ-2B	Sept. 20, 1981	250 kg 480 kg 257 kg	232 km x 1598 km, I= 50.9°/5° 232 km x 1615 km, I=69.9° 232 km x 1608 km, I=69.9°	Ionospheric studies and other experiments
SJ-4	Feb. 8, 1994	397 kg	210 km x 36125 km, I=28.6°	Particle detectors
SJ-5	May 10, 1999	298 kg	870 km, sun-synchronous	Particle detectors, etc.

Table 514: Overview of SJ series satellite launches

M.22.1 SJ-5 (Shi Jian - 5)

SJ-5 is a Chinese scientific and technology demonstration satellite. It is the first modern small satellite of China. The satellite platform was developed by CAST, CSSAR (Center for Space Science & Applied Research) of CAS was responsible for the development of the payload and the ground application system. The overall objectives of the mission include:

- Detection of SEU (Single Event Upset) and investigation of the corresponding countermeasures. In addition, dose measurement of the high-energy particles in the space environment
- Demonstration of a space science fluid experiment
- Demonstration of advanced space technology experiments including the operation of multiple-mode attitude control, integrated onboard electronic system, a unified S-band TT&C system, S-band data transmitter, on-board data management system and large-capacity solid state storage.

The SJ-5 spacecraft structure resembles a box with overall dimensions of 1.2 m x 1.1 m x 1.04 m. The total deployed length of SJ-5 is about 5 m. The spacecraft features two modes of attitude stabilization, namely three-axis as well as spin-stabilized attitude control. The spin rate of S/C is between 10-15 rpm during the spin control mode (a comparison of the two control modes is an experiment objective). Operations in spin control mode are conducted about the axis of least inertia. The attitude measurement information is provided by a sun sensor and an infrared Earth sensor. Actuation is provided by a momentum wheel, magnetorquers and a cold-gas propulsion system. The total S/C mass is 298 kg; the payload mass is 58 kg; an average power of 165W is provided by the solar array of 3.4m² in size. NiCd batteries of 17Ah capacity are used for night phase power supply. The S/C design life is three months.

The SJ-5 satellite was launched on May 10, 1999 from the Taiyuan launch site in China as secondary payload together with the primary payload of FY-1/C (meteorological satellite of China) on the LM-4B launch vehicle. User requirements called for the following mission scenario: a) the first three months of the mission were dedicated to the science goals of the mission (these were achieved successfully), and b) the subsequent mission life was dedicated to technology demonstrations. As of spring time 2001 CAST is still able to receive data from SJ-5.

¹⁷³⁵⁾Information provided by Lihua Zhang of CAST, Beijing, China

Figure 332: Illustration of the SJ-5 spacecraft

Orbit: Sun-synchronous circular orbit, altitude = 870 km, inclination = 98.8° , nodal period = 102.35 minutes.

Sensor/experiment complement: There are 11 science experiments onboard, developed by CSSAR and by the Institute of Mechanics (joint program). The experiments or instruments are:

- SEP (Single Event Phenomena) Monitor
- SEP Shielding Experiment Device
- SEU (Single Event Upset) Detector
- SEP synthetical detector
- SEL (Single Event Latch-up) Experiment
- High-energy Proton / Heavy Ion Detector
- High-energy Electron Detector
- PMOS Dosimeter (a radiation dose detector)

The eight instruments are used to measure the SEU effect and the high-energy particle environment. The observation of SEU, the investigation of the countermeasures and the measurement of the radiation in the space charged particle environment are more comprehensive compared with those in the SJ-4. With eight instruments, the investigation of SEU countermeasures includes almost all the methods known today. The measurement range of the energy spectra of the high-energy charged particles is the most completed so far, and the measurement of the radiation total dose is the first ever taken in china .The charges particles distributions in the abnormal area of the south Atlantic and in the subsiding areas of the two poles in the orbit have been obtained for the first time with the instrument developed by CSSAR. The collected data and the research results are significant for improving the design of space electronic instruments, raising the reliability and extending satellite's service life.

The experiments “Solid-state Transmitter” and “Solid-State Memory” are technology demonstrations.

- Space Fluid Experiment Device. A micro-gravity experiment in the field of fluid mechanics. The objective is to investigate the coupling between heat capillary convection and

buoyancy convection, and other phenomena under the condition of micro-gravity. The study of these phenomena and the laws governing them will advance the development of fluids. There are close relations among micro-gravity mechanics of fluids, space material science (crystal growth), space life science (cell breeding) and other disciplines. Multi-layer heat capillary convection is one of frontier subjects in the micro-gravity fluid science research. The technology is very important not only for developing the methods of space crystal material growth, improving the quality of crystals, but also for a better understanding of the characteristics and the mechanisms of the convection movement of the fluid with a free surface or a boundary surface on the ground, which is a fundamental problem in the physics of fluids. This experiment in microgravity fluid mechanics is the first ever carried out by Chinese scientists, and also the most complex one so far.

M.23 SMART-1 (Small Mission for Advanced Research in Technology)

SMART-1 is an approved ESA minisatellite technology mission to the moon (part of the ESA Horizons 2000 Science plan) with the objective to demonstrate innovative and key technologies for scientific deep-space missions. The key objective is to qualify solar electric propulsion (ion drive, but also the peculiar flight dynamics and orbit control concepts) as the primary means of propulsion in deep-space missions, tested in a transfer and gravity-assisted orbital trajectory to the moon.. A mission goal is to spend six months in orbit around the moon, using a suite of instruments to study its composition. Science objectives are to address key questions about the moon: the origin of the Earth-moon system and the role of accretionary processes, long-term volcanic and tectonic activity on Earth’s natural satellite, the thermal and dynamic processes responsible for lunar evolution and the external processes on the moon’s surface such as erosion, and ice deposition. SMART-1 demonstrates also a new approach in terms of implementation strategy (low-cost) and procurement for ESA. 1736) 1737) 1738) 1739) 1740) 1741)

The prime contractor for the SMART-1 platform is the Science Systems Division of SSC (Swedish Space Corporation) of Solna, Sweden. The ASC (Advanced Stellar Compass) of the attitude system is manufactured by DTU, Denmark (heritage of Astrid-2, TEAMSAT, CHAMP, SAC-C, ADEOS-II, GRACE, and PROBA). A launch of the satellite is planned for 2002 as an auxiliary payload on an Ariane-5 vehicle.

S/C is three-axis stabilized	Two autonomous star trackers referred to as ASC (Advanced Stellar Compass), four reaction wheels, four angular rate sensors, eight 1 N attitude control hydrazine thrusters One two-axis gimballed platform for the PPS-1350 system
Solar power	1875 W BOL with multi-junction cascade cells
Batteries	Five Li-ion battery cells, each with 130 Ah
Xenon propellant mass	<82 kg (for PPS-1350)
Communication	Two S-band TT&C transponders, 65 Kbit/s data rate, the mass of the TT&C system is <10kg
S/C launch mass, payload mass	<350 kg, <15 kg

Table 515: Characteristics of the SMART-1 satellite

Orbit: The SMART-1 S/C is intended to reach lunar orbit starting from GTO (Geostationary Transfer Orbit) by using electric propulsion. The overall mission can therefore be divided into the following phases:

1736) G. D. Racca, A. Elfving, A. Marini, et al., “SMART-1 mission description and development status”, Submitted to Planetary and Space Science, MS-No: PSS 79, October 30, 2000

1740) B. H. Foing, G. Racca, A. Marini, et al., “Status of SMART-1 ESA Mission to the Moon,” 31st Lunar and Planetary Science Conference, March 13-17, 2000, Houston, TX
1741) <http://www.ssc.se/ssd/smart1.html>

- Launch and early GTO phase. The standard GTO of Ariane has an apogee of 35781 km and a perigee of 622 km.
- The cruise phase to the moon will last for about 12 months
- Moon capture phase and descent to the operational orbit
- Lunar observation phase. The present baseline plan considers a lunar orbit with an apocenter of 10,000 km and a pericenter of 300 km to 1800 km. A six month observation period in lunar orbit is followed.

Figure 333: Illustration of the SMART-1 S/C

Communication: The downlink data rate is 65 kbit/s or 2 kbit/s. The modulation scheme is PCM/PSK/PM for the low data rate and PCM/SP-L/PM for the high data rate. The ranging signal in the ranging channel of the transponder directly phase-modulates (PM) the down-link carrier. The uplink frequency is 2058.2 MHz, the downlink frequency is 2235.1 MHz.

Sensor/Technology Demonstration Complement:

PPS-1350 (Propulseur Plasmique Stationnaire - or Stationary Plasma Thruster-1350), developed by SNECMA of France (thruster) and ETCA of Belgium (power processing unit). The 1350 label designates the nominal input power (in Watt). The PPS-1350 is an evolution of the SPT-100 (Stationary Plasma Thruster), built by the Fakel Design Bureau in Kalinin-grad, Russia. The demonstration of the electric propulsion and attitude control actuator functions are primary objectives for the SMART-1 mission (the S/C achieves lunar orbit by means of the electric propulsion). The duration to reach the moon after injection into a standard Ariane-V GTO (apogee=35781 km, perigee=622 km), is of the order 12 months. Together with the electric propulsion, a series of gravity assists by the moon are also exploited to reduce the amount of fuel consumed.

Principle of operation of the ion engine which uses Xenon as propellant: Electrons from an external cathode enter a ceramic discharge chamber (10 cm in diameter), attracted by an anode. On their way to the anode, the electrons encounter a radial magnetic field created

between inner and outer coils, causing cyclotron motion around the magnetic field lines. Collisions between drifting electrons and xenon propellant create the plasma. The ions created are then accelerated by the negative potential existing near the exit of the chamber due to the Hall effect. The external cathode acts also as a neutralizer, injecting electrons into the thrust beam to maintain zero-charge equilibrium both in the beam and on the spacecraft. This type of thruster provides a nominal thrust of 70 mN at 16,000 m/s specific impulse (Isp) and 1350 W of nominal input power from the solar array.

EPDP (Electric Propulsion Diagnostic Package), provided by Laben/Proel of Florence, Italy, is a technology payload to study the plasma environment around the SMART-1 spacecraft and the contamination on its external surfaces, when the electric propulsion system is both on and off. EPDP consists of a suite of sensors, comprising a proximity Langmuir probe, a Retarding Potential Analyzer and two Deposition sensors (a Solar cell and a Quartz Crystal Micro-balance). EPDP performs key measurements to characterize the electric propulsion system and its influence on the spacecraft environment. The total mass of EPDP is about 2 kg.

SPEDE (Spacecraft Potential, Electron and Dust Experiment), jointly developed by FMI (Finnish Meteorological Institute), Helsinki, ESA/ESTEC, IRFU (Uppsala Sweden) and KTH (Stockholm, Sweden). SPEDE consists of two electric sensors mounted on the ends of 60 cm booms. These sensors can be driven either as a Langmuir probe or as an Electric Field probe. The instrument complements the EPDP diagnostic package in monitoring the solar electric propulsion, by measuring potential and induced currents by means of a Langmuir probe accommodated on the tips of the booms. It also performs cruise science and lunar orbit science by monitoring the space/time variations of the plasma and electron environment, especially coupled to solar wind effects. The mass of SPEDE is 0.8 kg.

RSIS (Radio Science Investigation Series), a set of radio-science investigations conceived by the University of Rome, Italy. RSIS aims at validating the technique of measuring the rotational state of a celestial body from the orbit (in particular the physical librations in latitude) by combining orbit and attitude determination with accurate imaging. RSIS will test this method on the well-known moon librations making use of the capabilities KaTE Deep-space transponder for precise Doppler and ranging measurements, preparing also for future high precision geodesy and relativity experiment. In addition, RSIS will monitor the dynamic performance of the electric propulsion system, by precision tracking during thrusting periods.

KaTE (X/Ka-band TT&C Experiment), built by Astrium GmbH and managed by ESA/ESTEC. KaTE is an experimental deep-space telecommunication subsystem operating in the X-band (8 GHz) and Ka-band (32/34 GHz) frequencies. KaTE will demonstrate telecommunication capabilities with superior data rate and high accuracy, will characterize the Ka-channel and will perform experiments of all the key TT&C functions (uplinking commands in X-band, downlinking data in X- and Ka-band, ranging, tracking etc.). A new encoding/decoding technique (Turbo code) is also being tested, and possibly also the operation of VLBI (Very-Large Baseline Interferometry). In addition, KaTE supports the RSIS experiment, thereby permitting the characterization of the electric propulsion. With its high-data rate downlinking capability, KaTE will contribute to the transmission of science data from the SMART-1 spacecraft.

D-CIXS (Demonstration of a Compact Imaging X-ray Spectrometer), the design is led by RAL (Rutherford Appleton Laboratory) of UK (the D-CIXS team includes members from the University of Helsinki; University of Sheffield; MP Ae of Katlenburg-Lindau, Germany; IRF of Kiruna, Sweden; and NOAA of Boulder, CO). The objective is to demonstrate a radically new approach to greatly reduce the mass and volume of the instrument. D-CIXS represents a new generation of X-ray imagers for planetary observation, based on the use of an advanced dual microstructure collimator and X-ray detector technologies. D-CIXS includes also **XSM** (X-ray Solar Monitor), provided by the Observatory of the University of

Helsinki, for absolute calibration and solar X-ray flux monitoring. The D-CIXS instrument images high-throughput fluorescence X-rays from the SMART-1 target object, as a means to carry out spatially resolved material analysis of the moon's surface. Mapping of the composition of the moon, in particular key elements like iron, silicon, magnesium, sodium, carbon, and oxygen with a spatial resolution of 30 km in the energy range from 0.5 to 10 keV. This permits to test formation theories of the Earth-moon system. D-CIXS provides the first high-resolution global map of moon-surface chemistry and the relative abundances of the major lunar rock types. The instrument mass is 3 kg including its electronics. ¹⁷⁴²⁾ ¹⁷⁴³⁾ ¹⁷⁴⁴⁾ ¹⁷⁴⁵⁾

Telescope FOV	12° x 24°
Detector array, SCD pixel size	24 SCDs (Swept Charge Detectors), 10 mm x 10 mm
Quantum efficiency	40% @ 0.5 keV to 80% @ 5 keV
Operating temperature	270 K
Energy band, energy resolution	0.5 keV to 10 KeV, 140 eV
Sampling rate	50 Hz
Source data rate	2.74 kbit/s

Table 772: Parameters of the D-CIXS instrument

The spectrometer design is based on “swept charge detectors” (SCD), developed by EEV, Chelmsford, UK, and “micro-collimator X-ray optics.” Each of the 24 detectors has a 10 mm x 10 mm sensitive area with an energy resolution > 200 eV, they operate at near room temperature and have a higher tolerance to radiation doses than conventional CCDs. The other innovative feature of the spectrometer is its “micro-collimator X-ray optics” which ensures that only X-rays from a single well defined direction reach the detectors. The collimator with its associated filters also rejects solar wind particles and radiated heat from the lunar surface.

The XSM (X-ray Solar Monitor), covering the spectral range 1-20 keV, is an auxiliary instrument of D-CIXS with the objective to monitor throughout the whole mission duration the X-ray activity of the sun, and to calibrate D-CIXS measurements when it is pointed to a celestial object, and during the final phase of the mission, to the moon. The electronics of the XSM consists of a) pre-amplifier stages, which are identical in the two sensor units, and b) an electronics board in the main D-CIXS instrument box, which includes further stages of the signal processing electronics.

SIR (SMART-1 Infrared Spectrometer) of MPAe (Max Planck Institut für Aeronomie), Katlenburg-Lindau, Germany. SIR is a technology demonstration instrument with the primary objective to space-qualify and to miniaturize an existing, commercially available, small and very low mass near-infrared (NIR) monolithic grating spectrometer (Carl Zeiss, Jena). SIR is a highly compact monolithic grating point spectrometer, consisting of an optical entrance or ‘slit’ for selecting its view of a target source or area, a collimator which focuses the infrared rays into a parallel beam, a grating which disperses the light and a linear array InGaAs detector which sequentially records the incident light, creating a spectrum. The instrument covers the spectral range of 0.9 to 2.4 micron, the spectral resolution is 60 nm, the field-of-view is about 1 mrad providing 300 m spatial resolution at peri-selene. SIR provides the capability of mineral mapping, including olivine, pyroxene, and feldspar. The total instrument mass is about 2 kg. ¹⁷⁴⁶⁾ The SIR and AMIE instruments have the same alignment allowing simultaneous and complementary observations.

AMIE (Asteroid Moon micro-Imager Experiment). AMIE is developed in the framework of ESA's Technology Research Program in conjunction with CSEM (Swiss Center for Elec-

¹⁷⁴²⁾ http://sci.esa.int/content/doc/10/19216_.htm

¹⁷⁴⁴⁾ M. Grande, et al., “Lunar Elemental Composition and Investigations with D-CIXS X-Ray Mapping Spectrometer on SMART-1,” 31st Lunar and Planetary Science Conference, March 13-17, 2000, Houston, TX

¹⁷⁴⁵⁾ S. K. Dunkin, M. Grande, et al., “The D-CIXS X-Ray Spectrometer on ESA's SMART-1 Mission to the Moon: Science Objectives,” 31st Lunar and Planetary Science Conference, March 13-17, 2000, Houston, TX

tronics and Microtechnology) of Neuchatel, Switzerland (there are AMIE partners in France, Italy, Finland, and Switzerland). The overall objectives are to study the moon's morphology, topography and surface texture. The specific objectives of the tiny camera are to: a) provide imagery of the lunar south pole (Aitken basin), b) to obtain imagery for the study of the permanently shadowed regions of the moon (ice deposits), c) to investigate eternal light (crater rims), and d) to obtain imagery of high latitudes regions (south) mainly at far side of the moon.

The AMIE micro-imager employs a very compact design, a package of dedicated optics, electronics and mechanical interfaces that weighs but 450 grams (all included). This feat has been achieved by using new microtechnology in terms of micro-mechanics, micro-optics and 3D-stack packaging. AMIE features a FOV of $5.3^\circ \times 5.3^\circ$. At closest orbital distance of 300 km (pericenter), a footprint of 27 km x 27 km is provided. The pixel size for the 1024 x 1024 CCD array is therefore 27 m x 27 m at pericenter. The main system functions are:

- To take images with color information
- To keep image data in a memory buffer
- To perform image processing (data compression, image subtraction)
- To allow the downloading of the images by the OBC (On Board Computer)

The AMIE electronics are composed of:

- A microprocessor board (CSEM) for the instrument management
- A micro DPU (Digital Processing Unit) for data compression
- A S/C interface board.

AMIE features also three filters: in the visible (750 nm) and infrared (900, 950 nm), thus providing multispectral data. AMIE will work closely in conjunction with the SIR and D-CIXS instruments. Its infrared filter overlaps and complements the SIR spectrometer (900 nm - 2400 nm) permitting studies of the different lunar rock types. Information obtained by AMIE and D-CIXS will help establish abundance maps of the elements present on the lunar surface.

In addition, AMIE is supporting three other SMART-1 experiments/technology demonstrations:

- LaserLink experiment: involving the demonstration of acquisition of a deep-space laser link from the ESA OGS (Optical Ground Station), located at the Observatorio del Teide at Tenerife, and validation of advanced atmospheric communication technique (sub-aperturing). The OGS transmitter uses a Ti:Sapphire laser pumped by a 28 W Argon laser. The LaserLink experiment will be performed by pointing the spacecraft's AMIE camera towards the Earth. Apart from a laser line filter which covers a section of the CCD imaging array of the camera, there is no specific LaserLink equipment aboard SMART-1.
- Measurement of lunar libration in coordination with the radio-science experiment RSIS (Radio Science Investigation Series).
- OBAN (On-Board Autonomous Navigation). OBAN validates navigation algorithms by planetary body tracking. It makes use of the S/C star trackers and of AMIE images. The overall objective is to test navigation algorithms with respect to their workability in a real-mission environment. The OBAN experiment is designed to function in what is termed an 'open loop', obtaining all the data an autonomous navigation system would require, but instead of being processed onboard, this information is downlinked to be processed on Earth. The experiment involves the spacecraft looking at certain celestial objects or at 'beacons', taking images of them with the AMIE camera. These time-tagged pictures, together with information from the attitude and control system of SMART-1, allows the OBAN ground system to determine the lines of sight to the beacons, and to calculate the precise trajectory. Subsequently all the parameters that

would be required to carry out a correction in the spacecraft's course can be obtained. The picture analysis algorithms and computations are rather complex, but the principles of the experiment are those of elemental triangulation geometry.

M.24 SPORT (Small Payload Orbit Transfer)

AeroAstro of Herndon, VA, has developed the SPORT™ space access capability, enabling small payloads to use low-cost secondary launch opportunities and still reach their desired final orbits. The concept allows small payloads to effectively use a wider variety of launch opportunities, including numerous under-utilized geosynchronous transfer orbit (GTO) slots. Considering the available launch opportunities, it turns out that about 90% of today's the small satellites plan for LEO observations/operations. However, about 90% of the large launch vehicle capacity is destined for GEO. The SPORT concept tries to provide a solution to this asymmetric launch situation with its orbit transfer capability.

The SPORT concept is a flexible orbit transfer vehicle designed to go from intermediate orbits, such as GTO, to final LEO ones (normally from higher to lower orbits) by utilizing a combination of chemical propulsion and aerobraking technology. With aerobraking, SPORT can achieve orbit changes that are many times greater than that achievable with direct propulsion. After using the propulsion system to lower the orbit perigee, the aerobrake gradually slows SPORT via atmospheric drag. After the orbit apogee is reduced to the target level, an apogee burn raises the perigee and ends the aerobraking phase. At the conclusion of the orbit transfer maneuver, either the aerobrake or SPORT can be shed, as desired by the payload. A variety of low-cost core electronics (Bitsy, see M.3), propulsion and power options provide the mission developer with the ability to tailor SPORT to individual needs.

The SPORT system is equipped with a large deployable aerobrake, consisting of an inflatable umbrella (several radially-oriented tubular spars, which harden after inflation, stretch the aerobrake cloth). After about 20-90 days, depending on upon atmospheric conditions and target altitude, the aerobraking phase concludes with a thruster firing at apogee, which raises the perigee above aerobraking altitude. Additional thruster firings are made to trim the orbit to the desired parameters. Upon completion of the orbit maneuver, SPORT can separate from the payload and use residual propellant to lower the perigee so that additional atmospheric drag will deorbit the spent stage. The SPORT/payload system is spin-stabilized during the transfer phase.

Technically, all low LEO spacecraft experience multi-pass aerobraking orbit profiles as they gradually decelerate from atmospheric drag. However, in general, these spacecraft take many years for substantial orbit changes to occur (say, from a 700 km circular orbit). To be useful in an orbit transfer vehicle, this deceleration must be enhanced so that substantial orbit changes occur within time scales on the order of weeks to months, at most. This enhancement can be achieved by increasing the spacecraft profile area by at least one to two orders of magnitude. When deployed, the SPORT aerobrake increases the SPORT profile area by a factor of fifty. - For eccentric orbits such as GTO, only the perigee portion of the orbit experiences significant atmospheric drag. This asymmetrical drag reduces the orbit apogee, while leaving the perigee altitude relatively unchanged. Over time, the cumulative energy loss at perigee produces large altitude changes in the orbit apogee. SPORT is designed to operate with a perigee altitude in the 150 to 200 km range to achieve GTO-LEO aerobraking.

1747) P. W. Gloyer, D. J. Goldstein, "Small Payload Orbit Transfer (SPORT) System: Lowering Launch Cost Without Increased Risk," IEEE Aerospace Conference, Big Sky, Montana, March 10-17, 2001, 0-7803-6599-2/01

1748) P. W. Gloyer, D. J. Goldstein, "Small Payload Orbit Transfer (SPORT) System: An Innovative Approach to Lowering Missions Costs without Increased Risk," Proceedings of the 14th Annual AIAA/USU Conference on Small Satellites, Logan, UT, Aug. 21-24, 2000, SSC00-IV-6

1749) Information provided by Aaron Jacobovits of AeroAstro

A first demonstration flight of the SPORT concept is scheduled with a Malaysian microsatellite of ATSB (Astronautic Technology S B) of Kuala Lumpur (an agreed partner project as of Nov. 2000).¹⁷⁵⁰⁾ A GTO launch on Ariane-5 ASAP (Ariane Structure for Auxiliary Payloads) is planned for 2003 with a subsequent GTO-LEO aerobraking maneuver. Like many countries near the equator, Malaysia's most desired orbit is a low-inclination low-Earth orbit, from which their geographically advantaged location provides revisits on every orbit.

SPORT can go more places than just LEO. With the advantage of the low orbital velocity at apogee, plane changes of 30° or more can be provided, thus extending the region of coverage considerably from GTO injections. Piggybacked to Molniya, SPORT will be capable to insert into sun-synchronous and other polar inclinations.¹⁷⁵¹⁾

M.25 STRV (Space Technology Research Vehicle)

STRV is a multi-microsatellite cooperative technology program, initiated by DERA (Defence Evaluation and Research Agency, UK) in 1992. The prime objective of the program is to provide opportunities for the evaluation of several new technologies. The first two S/C of the mission were launched in June 1994. Two more microsatellites are planned to be launched in 2000, with further missions anticipated beyond these.^{1752) 1753) 1754) 1755)}

M.25.1 STRV-1a and -1b

STRV-1a and -1b are two microsatellites of DERA (funding by MoD) at Farnborough, UK (with contributions from: ESA, BMDO/JPL, USAF/PL), which were launched on ASAP, Ariane-4 flight V64, on June 17, 1994. The objective was to evaluate new technologies in the high radiation dose environment of GTO (GEO Transfer Orbit) - Test of advanced structural materials, radiation hardened computers, sensors, solar cells, and microelectronics. Both S/C are cubical in shape, spin-stabilized at 5 rpm (magnetorquer attitude control and cold gas thruster system, attitude sensing with Earth and sun sensors), with a structure consisting of carbon/peek thermoplastic skinned aluminum honeycomb panels. The GaAs solar cells are body-mounted. In addition, there are 16 NiCd cells providing 46 Whr of power storage. The S/C design life is one year. The RF system conforms to ESA standards using dual redundant transmitters/receivers at S-band. The data transmission (uplink rate: 125 bit/s, 2.025-2.12 GHz, and downlink rate: 1 kbit/s, 2.2-2.3 GHz) uses the CCSDS packet TM/TC concept implementation of ESA with custom chip-sets.

Orbit: Elliptical GTO orbit, perigee = 300 km, apogee = 36000 km, inclination = 7°, period = 10 hours and 35 minutes. The orbit crosses the Van Allen Belts each orbit with a maximum of ionization radiation seen in near-Earth orbit, suffers electrostatic charges close to apogee, and atomic oxygen erosion at perigee.

Mission operations were performed from the DERA/Lasham ground station and the NASA Deep Space Network from June 1994 to June 1996, when routine orbital maintenance of the S/C was passed to LASP (Laboratory of Atmospheric and Space Physics) at the University of Colorado, CO, USA. Note: During the initial orbital period, up to about the

¹⁷⁵⁵⁾<http://www.dra.hmg.gb/html/case/strv/menu.htm>

end of August 1994, STRV-1a experienced in-flight anomalies (low power due to failure of at least one battery cell) resulting in a delay for some experiment operation until September 1994.¹⁷⁵⁶⁾

Despite the very high radiation dose received by the platform systems during the mission, the majority have performed exceptionally well. With one or two small exceptions, the spacecraft electronics were built entirely from military specification components. Although only one receiver on each spacecraft remains usable, the redundancy philosophy adopted has prevented the termination of the mission.

Parameter	STRV-1a	STRV-1b
Total mass	52 kg	54 kg
S/C dimensions	440 mm x 440 mm x 420 mm	
S/C structure	Carbon/PEEK thermoplastic skinned Al honeycomb	
S/C thermal control	Passive	
Power generation and storage	Four body-mounted GaAs solar panels, 46 Whr NiCd battery	
S/C power (at start of mission)	31 W (at 28 V)	33 W (at 28 V)
Power available to payload	19 W (average), 120 W (peak)	
Stabilization	Spin at 5 rpm (provided by the launcher at separation)	
Attitude sensing subsystem	V-slit sun/Earth sensors and analog sun sensors	
Attitude control subsystem (ACS)	Magnetorquer coils & cold gas thruster	Magnetotorquer coils
Onboard computer (OBC)	Dual-redundant GEC/Plessey Mil Std SOS 1750a microprocessor	
Memory	Dual-redundant 128 kBytes SOS RAM, 64 kBytes ROM	
Communications	ESA packet TM/TC CCSDS standard, 12 m antenna at DERA La-sham ground station (26 m DSn antennas)	

Table 516: Overview of STRV-1a and -1b design parameters

M.25.1.1 STRV-1a Sensor/Experiment Complement

AOE (Atomic Oxygen Experiment), provided by DERA and the University of Southampton. Objective: Measurement of atomic oxygen (AO) by silver loss determination in different material specimens - consideration as a future monitoring method of AO environments. AOE is comprised of twelve silver resistance sensors. As silver is converted to its non-conducting oxide the resistance increases. This increase can be measured and converted into silver loss. The erosion resistance of test materials is measured by coating the thin silver films with overlays of the test material. When this coating is breached the silver starts to oxidize, a resistance increase is observed. Knowledge of the fluence experienced and the thickness of the coating enables calculation of the erosion rate. Silver sensors coated with polyethylene, PTFE, carbon, and silica were flown.

BRE (Battery Recharge Experiment), provided by ESA/ESTEC. Objective: Demonstration of control techniques using conventional constant current battery charging, followed by current tapering, instead of simple voltage level triggered end-of-charge cut-off for LEO S/C. Selection of an end-of-charge voltage level to avoid both undercharge and overcharge throughout the lifetime of the S/C.

The basic problem was selecting an end-of-charge voltage level which would avoid both battery undercharge and overcharge throughout the S/C lifetime. BRE was activated in September 1994. The results of the test have implications for S/C power subsystem designers.

CAE (Charge Alleviation Experiment) provided by DERA. Objectives: 1) Demonstration of an active S/C surface charge alleviation system, and 2) Test of several new technologies in orbit, in particular the effects of operation of other S/C subsystems such as that of an ion

¹⁷⁵⁶⁾N. Wells, "Space Technology Research Vehicles (STRV-1a and -1b): Lessons Learned After four Years in GTO," Proceedings of the 4th International Symposium on Small Satellites Systems and Services, Sept. 14-18, 1998, Antibes Juan les Pins, France

propulsion system (UK-10 hollow cathode) and that of a cold gas ACS (Attitude Control Subsystem) on the bulk and differential charging of surface materials.¹⁷⁵⁷⁾

The CAE system is comprised of the following components: (total mass = 3.25 kg, power = 30W during steady-state operation, power = 80 W for initial heater operation of about 30 s).

- Fill and drain valve
- Xenon storage tank
- Five standard series 107 solenoid valves
- Miniature tank pressure transducer
- Plenum tank (100 cm³)
- Miniature plenum tank pressure transducer
- Plenum tank orifice
- Spin-up thrusters and associated pipe work
- UK-10 ion thruster hollow cathode
- Two DC-to-DC power supplies and associated electronics
- Interconnecting pipe work and weld fittings.

The CAE system relies on the ability to produce a diffuse cold plasma of inert xenon gas around the S/C thereby neutralizing the high differential surface potentials. In the CAE design, the diffuse plasma envelope is provided (produced) by the operation of three subexperiments with objectives of their own.

- First flight test of the UK-10 ion thruster hollow cathode assembly.
- First flight test of the xenon gas flow control system, developed for the UK-10 IPS (Ion Propulsion System), with associated solenoid valves, orifices, and valve actuating electronics.
- The provision of a cold gas attitude control subsystem (ACS), a backup for the magnetorquers for control of S/C precession.

SCDE (Surface Charge Detector Experiment) provided by DERA. Objective: Non-contact measurement of surface potentials. The Pockels effect technique (an electro-optical method) was chosen which relies on special crystal properties. The experiment collects charge on a piece of kapton (an insulator) which is exposed to the space environment. Sensing crystals are placed under the kapton, one of the crystals is shielded from electric fields by a thin piece of foil (the monitor). A plane-polarized laser beam is passed through each crystal and analyzed (the strength of the electric field is deduced from the polarization state). The monitor crystal does not respond to the electric field, thus providing a reference. SCDE had a mass of 0.6 kg, power of 2 W, and dimensions of about 100 mm x 150 mm x 30 mm.

CID (Cold Ion Detector). A DERA/MSSL instrument with the objective to measure the energy spectrum of incident, low-energy ions in the interplanetary plasma. A further objective of CID is to act as a diagnostic tool - to directly sense the cold ions produced by the CAE neutralizer. CID is an electrostatic deflection differential energy analyzer consisting of the following elements:

- A collimator accepting a beam of conical shape with a half angle of 5.7°
- An electrostatic energy analyzer with a passband of $DE/E = 0.14$
- A microchannel plate detector which records the impact of the particles.

The CID instrument points perpendicular to the spin axis of the S/C, protruding some 70 mm from the surface.

LPE (Langmuir Probe Experiment), provided by DERA. Objective: Xenon plasma diagnostic instrument for CAE. A conducting surface is biased with a sweeping voltage, attract-

¹⁷⁵⁷⁾ Note: Differential charging of surface material occurs when these materials are electrically isolated, either from the S/C structure or from neighboring surfaces, or when the surfaces are insulators themselves. In these situations charge build-up cannot leak away, resulting in large potential differences between neighboring surfaces.

ing either positive ions or electrons, which are measured as a current in the experiments electronics. The LPE consists of a conducting planar probe of 20 mm diameter with a surrounding guard ring of 100 mm diameter. In the presence of plasma a sheath forms over the conducting surface.

CREDO-II (Cosmic Radiation Environment and Dosimetry Experiment). A DERA/UKAEA experiment with the objective to characterize the radiation dose received by the spacecraft [a) total dose, b) cosmic ray and solar heavy ions, c) protons trapped in the Van Allen belts]. The instrument is the latest of an evolving series which have flown on aircraft [the Concorde (BA) and Boeing-767 (SAS)], on the Shuttle (STS-48, -44, -53, -56, -68, and -63), in sun-synchronous orbit (UoSat-3, since Jan. 23, 1990), and on the USAF APEX satellite (orbit: 359 km x 2544 km, 70° inclination).

CREDO employs a telescope technique to detect coincidences between parallel planes of p-i-n (p-intrinsic-n) diodes to provide directional information and to define the pathlength of particles through the diodes to within 29%. The square diodes (each with a path length of 200 μm , area of 10 mm x 10 mm) are configured in two orthogonal arrays with their axes aligned with two S/C axes. Pairs of diodes are placed in a telescope arrangement with a separation of 1.75 mm, each array consists of four such pairs. - The upper and lower arrays of each telescope system are connected via separate charge amplifier systems into hardware discriminators with thresholds close to 0.33 pC (7.4 MeV) of charge deposited per event. Events are coincident when both discriminator thresholds are exceeded within a 10 μs gate time. Upon sensing a coincident event, the CREDO-II micro-controller performs pulse-height analysis upon the output of one of the planes of each telescope. Fifteen channels of pulse-height analysis are provided. The telescope system does not respond to particles arriving with oblique angles of incidence. Only ions are detected by this arrangement. - Total dose is measured at three locations within the CREDO box using radFET dosimeters. These are MOSFET devices are designed to trap positive charges and shift the threshold voltage of the radFET. Each radFET is co-located with a temperature sensor to permit temperature correction of voltage shift. - Non-coincident events detected by the telescope system are processed similarly, but separately from the coincident events. The detector arrangement is sensitive to protons which can deposit sufficient energy via ionization along oblique paths through the diodes.

RDRS (Radiation Dose Rate Sensor), provided by DERA. Objective: Monitoring of gamma ray bursts.

M.25.1.2 STRV-1b Sensor/Experiment Complement

CVSE (Cryocooler Vibration Suppression Experiment), provided by BMDO and managed by JPL. Objective: To demonstrate and to qualify a new vibration suppressing design by employing piezo materials. (Cryocoolers are used to cool IR or CCD detectors to lower the thermal noise threshold. Since Stirling coolers have a mechanical compressor, there is a significant vibration problem introduced by the cooling of optical instruments). The intent is to use these low-power flight piezo drivers and control systems in zero-g environments.¹⁷⁵⁸⁾

To meet stringent power, weight, and space constraints, the experiment makes use of the tiny 0.2 watt 80 K tactical Stirling coolers (of Texas Instruments). Two different vibration-cancellation actuator techniques are being demonstrated: 1) applique ceramic piezoelectric actuators that are bonded to the coldfinger and stretch the coldfinger to cancel tip motion, and 2) commercial low voltage piezoelectric translators that similarly cancel tip motion by moving the entire cryocooler in three axes. Motion of the coldfinger tip is measured in all three axes to 10 nm accuracy using eddy-current transducers. Two types of control systems are also being demonstrated: 1) an analog control system that uses a bandpass filter to track the drive signal and suppress it, and 2) a unique narrow-band adaptive feed-forward

¹⁷⁵⁸⁾http://www.jpl.nasa.gov/adv_tech/coolers/Integ.htm

system that continually updates a steady-state command signal to each actuator to cancel the tip vibration. Either control system can be used with either actuator.

Using the cryocooler as a vibration source, the response of the satellite was determined from accelerometer data. The translators with digital control reduced the vibration by a factor of about 75.

SEE (Space Environmental Effects) experiments. The overall objective is to measure and evaluate the effects of the high radiation environment on electronic devices. The device sets tested are:

- Neural network integrated circuits
- HIP (Heterojunction Internal Photoemission) infrared sensors
- CMOS (Complementary Metal-Oxide Semiconductor) radiation and SEU (Single Event Upset) monitors

Two identical sets of devices are used, one with minimal shielding to radiation in the spin axis of the S/C, and the other set with significant shielding to provide a basis for comparison. Unfortunately, SEE data were only obtained up to early October 1994 when a system failure occurred.

- **NNE** (Neural Networks Experiment). Objectives: To demonstrate fault-tolerant and graceful degradation characteristics of analog neural network VLSI chips (JPL) in the space environment. For NNE, a special feed-forward “learning” architecture was chosen (signal flow from one layer of neurons to the next through a connecting mesh of synaptic weights) with a suitable pattern recognition problem as a bench-mark for learning.
- **HIP** (Heterojunction Internal Photoemission) Infrared Sensors. The objective of this experiment is to determine if exposure of the HIP sensor to the complex spectrum of incident radiation might result in increased sensitivity. - The experiment measures the dark current to obtain an indication of the radiation damage to the specimen.
- **SEU** (Single Event Upset)/**RADMON** (Radiation Monitor) Experiment. Objective: To develop a small, low-cost, low-power SEU and TD (Total Dose) RADMON using standard CMOS processes. RADMON consists of 16 SRAMs (4-kbit each) designed to detect protons, alpha particles, and heavy ions (SEU-SRAMs). In addition, RADMON contains four p-FETs for detecting total dose (TD-FETs). The SEU-SRAMs and TD-FETs are shielded behind primary and control shields.

REM (Radiation Environment Monitor). Objectives: To study the GTO radiation environment, its spatial, temporal and directional variability for the development of improved models. The results are intended to be used in the design of electronic components for future S/C.

REM consists of two independent shielded silicon detectors (and charge-sensitive amplifiers) with different types of shielding. Energetic particles impacting on the detectors generate pulses which are counted. Each REM detector (300 Tm silicon diode detectors) has 16 channels for pulse magnitude discrimination. The ‘electron detector’ is 25 mm² in surface area with a 3 mm Al shield; the ‘photon detector’ has a surface area of 150 mm², it is shielded by 3 mm Al and an additional 0.75 mm of tantalum. The instrument accumulates energy deposit spectra over varying integration periods, adapted to the speed of the spacecraft and the available on-board memory. These energy deposits can be converted fairly easily into total absorbed dose.

SCTE (Solar Cell Technology Experiment). The objective is to measure the current/voltage characteristics of many new or improved types of solar cells. A total of 47 cell types are exposed to the radiation environment and operated whenever the sun direction is within 5° of the normal to the panel.

M.25.2 STRV-1c and -1d

These are DERA follow-up microsatellite technology missions based on the STRV-1a & -b design (they incorporate a sample ‘multi-function structure’ designed to achieve significant savings in future spacecraft mass and cost).^{1759) 1760)} The overall objectives are to demonstrate emerging technologies on the premise of ‘faster, better, cheaper’ in a collaborative environment of participating institutions. A particular objective is to enhance the capabilities of future communications, navigation, and surveillance systems.

The S/C of STRV-1c/-1d are slightly larger than those of STRV-1a/-1b to accommodate more experiments (otherwise same architecture). The only significant enhancement is the introduction of full dual-redundancy throughout all the platform subsystems.^{1761) 1762)}

S/C total mass, power	100 kg, 65 W (BOL), GaAs solar cells
S/C size	Cube with 700 mm length of each side
Payload mass	25 kg
Battery	NiCd cells providing 59 Whr
Power bus	Regulated 28V \pm 2%
Computers	Military specification 31750a (dual – redundant silicon-on-sapphire)
Platform memory	2 MByte per computer (dual-redundant Military Specification RAM)
Communications	ESA CCSDS Packet TM & TC (with optional encryption on STRV 1d)
Uplink	S-band at 1 kbit/s
Downlink	S-band at 10 kbit/s
Attitude control	Spin stabilized control to \pm 3°. Magnetorquer & cold gas precession thruster maneuvers
Nominal attitude	Sun aspect angle = 90° \pm 10° & orbit normal \pm 10°

Table 517: S/C parameters of STRV-1c/-1d

A simultaneous ASAP (Ariane Structure for Auxiliary Payloads) launch of both STRV spacecraft took place on Nov. 16 2000 on an Ariane-5 launch vehicle from Kourou. The STRV satellites and the AMSAT Phase 3-D satellite were secondary payloads to the PAS-1R (PanAmSat-1R) communications satellite.¹⁷⁶³⁾

Orbit: Elliptical GTO (Geosynchronous Transfer Orbit), perigee = 620 km, apogee = 36,000 km, inclination = 7° (the orbital period exceeds 10 hours).

M.25.2.1 STRV-1c Sensor/Experiment Complement

AOE-2 (Atomic Oxygen Experiment-2), provided by the University of Southampton and ESA. Heritage of STRV-1a. Objective: To characterize and to flight test a novel zinc-oxide sensitive renewable atomic oxygen flux sensor based on semiconducting thin films. These films have the ability to be regenerated after atomic oxygen exposure which offers a significant advantage over the ‘use-once’ silver films used in the AOE-1 flown aboard STRV-1a.

The AOE-2 instrument is designed to measure the flux of atomic oxygen (AO) as the spacecraft enters the Earth’s atmosphere near perigee, typically at an altitude of around 600km. The main aim is to monitor the AO flux at various stages during a perigee pass. This is to be achieved by monitoring the resistance of several metallic and semiconductor thin films upon which the AO is impinging. The metallic (silver) resistance elements were flown on the previous mission (STRV-1a); the secondary aim is to test the new semiconductor resistance elements in the orbital environment and to compare the results obtained with those

¹⁷⁵⁹⁾A. Cant, H. Simpson, “STRV-1c & -d Satellite Architecture Design Document,” March 1998, provided by DERA

¹⁷⁶⁰⁾N. Wells, “STRV-1c & -d Mission Definition Specification,” Feb. 1998, provided by DERA

¹⁷⁶¹⁾N. Wells, R. Blott, “STRV-1c&d Program Update,” Proceedings of the 11th AIAA/USU Conference on Small Satellites, Sept. 15-18, 1997, Logan, UT

¹⁷⁶²⁾<http://www.dera.gov.uk/html/case/strv/high.htm>

¹⁷⁶³⁾N. Wells, Countdown to launch of the first microsatellites qualified for flight on Ariane-5 ASAP,” Proceedings of the 14th Annual AIAA/USU Conference on Small Satellites, Logan, UT, Aug. 21-24, 2000, SSC00-I-7

from the silver elements. In particular, the sensitivity of the semiconductor elements to AO (which will otherwise decrease with time/AO fluence) is to be recovered by heating to approximately 80° C; this takes place periodically during a “refresh” phase.

CDMS (Cosmic Debris and Micrometeoroid Sensor), provided by the University of Kent at Canterbury. Objective: To characterize the debris and micrometeoroid environment of GTO. In particular:

- Measurement of separate components of space debris and micrometeoroids (both as interplanetary a and b meteoroids) in terms of flux distribution
- Definition of the anisotropy of space debris, including altitude distributions and approximate orbital characteristics
- Identification of space debris sources, especially temporal factors
- Exploration of GTO orbit space as a source of micro debris from satellite transfer operations to GEO.

The CDMS consists of two sensor head units mounted externally on the satellite, with one sensor on the top panel (+Z face), and on a spinning face (+Y face), and a control unit located within the satellite. The sensor units combine impact momentum detection on particles (using piezo-electric crystals mounted on the carrier for a thin aluminium foil), with penetration measurement (of the thin foil) and impact plasma detection using plasma sensing wires mounted above and below the foil. The instrument is designed to provide a continuous, in situ measurement of individual impact events. The control unit adds both a time tag and a spin phase tag to the data packet for each impact event. The spin phase is derived using an analogue sun sensor (solar cell) mounted on the +Y face sensor. The pointing direction for each impact event is reconstructed on ground from the event time, spin phase and the spacecraft orbital and attitude data files.

CEASE (Compact Environmental Anomaly Sensor Experiment), provided by AFRL, Hanscom Air Force Base, Bedford, MA. Objective: To demonstrate on-orbit autonomous monitoring of the S/C environment and to provide “alerts” when satellite charging, SEUs or other radiation events are likely. See description under M.29.2.

CREDO-II (Cosmic Radiation Environment and Dosimetry Experiment), provided by DERA, MoD, heritage of STRV-1b. Objective: To monitor those aspects of space radiation which cause single event effects in microelectronic components. The measurements comprise energetic proton fluxes from the inner radiation belt and solar flares, and the linear energy transfer spectra of heavy ions in cosmic rays and solar particle events. The instrument is as a compact, low power monitor housed on a single board. Two telescopes are employed, each comprising two pin diodes of area 3cm² in coincidence, in order to define the arrival directions of the particles and their pathlength through the detector. In one telescope the charge depositions are amplified and pulse-height analyzed to give the linear energy transfer spectra, while in the other the counts above a low threshold are used to monitor the much higher proton fluxes. Counts are accumulated into programmable time bins to reflect the finer resolution required at perigee compared with apogee and to make optimum use of the limited data storage and telemetry.

DDM (Deep Dose Monitor), provided by DRE (Defense Research Establishment, Ottawa, Canada). Objective: To record the space radiation environment absorbed dose behind various thin shields and to estimate the dose due to low energy electrons. The DDM instrument is a small, low power, real-time dosimetry system consisting of four radiation sensitive dual MOSFETs (Metal Oxide Semiconductor Field Effect Transistors) which measure total dose during the mission. Each MOSFET has a unique shield covering the sensitive device to monitor the wide range of doses. The MOSFETs are capable of measuring high energy electrons and protons with dose levels between rad (radiation dose of energy) and Mrad.

GAGE (GPS At GEO Experiment), provided by MoD, DERA, DoD, JPL, and ESTEC. Objective: To characterize the GPS signal availability at selected altitudes up to GEO with

particular emphasis on investigating the feasibility of GPS utilization on GEO satellites. The primary objective is to measure the GPS signal strengths at the L1 and L2 frequencies, to enable the definition of an operational GPS package for future spacecraft in high orbits up to GEO. GAGE consists of a patch antenna and GPS sampling device, known as 'Bit-grabber', both provided by JPL. The device captures the GPS RF environment for short (up to 400 ms), predetermined periods of time and downlinks this information for subsequent processing. The ground segment of GAGE consists of observable extraction and orbit determination software to process the data obtained from the spacecraft and provide the mission results.

GFSE (Gas Flow Sensor Experiment), provided by DERA. Objective: To demonstrate in space a gas flow control and sensing principle (advanced xenon gas flow control and monitoring system) to test the range of UK ion thrusters developed by DERA. The flow sensor uses a thermal technique to measure the flow rate of gas. The gas flows through a small bore stainless steel tube around which is wound two identical coils of wire whose resistance is highly dependant on temperature. A small current is then passed through the wire which heats the coil. - The new system uses a novel thermal flow controller and an accurate, and highly sensitive, flow sensor. These units allow the system to be significantly smaller, cheaper, more flexible and, potentially, more reliable.

LCE (Linear Concentrator Experiment), provided by BMDO, NASA, USAF/PL. Objective: To measure the IV curves and to determine the pointing sensitivity of a new linear concentrator solar cell assembly.

MTB (Microwave Test Bed), provided by MMS, DERA, MoD. Objectives: To evaluate microwave SHF (Super High Frequency) technologies for future military space communication systems. MTB is a single channel transparent SHF (X-band) transponder, built using microwave and electronic components developed under the Matra Marconi Space (MMS) EXPERT satellite project.

PM (Proton Monitor), provided by Thomson & Nielsen Electronics Ltd, Canada, and sponsored by DRE, Ottawa. Objective: To flight-prove a monitor which measures the upset rate due to high energy protons and to compare the results with other on-board monitors and ground-based tests. Secondary objectives include:

- Correlation of the PM proton data with data from other radiation experiments and the AOE-2 experiment
- Correlation of the PM upset monitor data with single event effects/upsets data from other memory devices of STRV-1c
- To distinguish between solar protons, the trapped radiation environment and incident high energy cosmic rays.

The PM instrument consists of a dynamic RAM which is sensitive to proton-induced single event upsets. The experiment is designed to measure both the proton environment and the solar activity.

SCTE (Solar Cell Technology Experiment), provided by Mod, DERA, ESTEC, NRL, USAF/PL, EEV (English Electric Valve Co., UK), heritage of STRV-1b. Objective: To measure the IV curves of up to 47 new solar cell and coverglass technologies. In particular to:

- Demonstrate the use of different types of advanced solar cells in the space environment
- Determine the true absolute electrical performance of the cells
- Compare their relative resistance to the space radiation environment
- Compare actual flight degradations with those predicted from ground testing
- Provide flight data for advanced cells entering production to give satellite program managers confidence of their reliability and suitability for use on large projects.

There are two parts to the experiment: 1) The flight demonstration of advanced cells on the power generating panels of STRV-1c/d. Panel performance data is provided from the solar

array current monitors in the spacecraft power system. 2) The in-flight measurement of the current-voltage characteristics of 38 individual solar cells. The temperature coefficients of some cells are measured throughout the mission.

SMX-1 (Sparc Microprocessor Experiment), provided by MoD, ESA, MMS, DERA and SEI (Space Electronics Inc.) San Diego, CA. The overall objective is to evaluate the ESA ERC32 chip set and advanced processing technologies and shielding experiments in the harsh space environment. SMX-1 consists of the ESA ERC32 chip set and components (some components are shielded). Three RADFETS to monitor the radiation dose on the SMX-1 board. Note: SMX-2, a similar ERC32 board, is flown on STRV-1d in a more shielded location.

SREM (Standard Radiation Environment Monitor), provided by ESTEC, SREM is of REM heritage flown on STRV-1b and the MIR space station.. SREM is also being flown on PROBA. Objective: To map the radiation environment of GTO with high temporal and spatial resolution at post-solar minimum conditions. SREM detects and counts electrons, protons, and cosmic rays with a coarse spectral resolution. The measurement is based on examining the sizes of charge pulses generated by charged particles in silicon diodes polarized in reverse by a high voltage. Two of the three diodes are in-line and operate in 'coincidence', where a charged particle passing through both is detected and identified. SREM also measures the total radiation dose encountered by SREM itself and at different remote locations onboard the satellite, by using RADFETS.

M.25.2.2 STRV-1d Sensor/Experiment Complement

CERTO/PLUS (Coherent EM Radio Tomography & Profiling the Limb with UV Sensors), provided by NRL. Objective: To map the ionospheric electron densities in the satellite's orbital plane and to study the evolution of 1-100 km sized low latitude irregularities using radio/optical tomography techniques. The CERTO/PLUS experiment consists of a three-frequency radio-beacon, antenna and an UV photometer. With these flight instruments and ground radio/telemetry receivers, integrated ionospheric densities are determined near the satellite orbit plane. This provides a two dimensional mapping of the ionosphere which assists in the understanding of the distortion and attenuation of radio frequency (RF) signals caused by naturally occurring ionospheric anomalies.

ECSE (Encrypted CCSDS Space Experiment), provided by MoD, DERA, MMS. Objective: To demonstrate a prototype secure CCSDS packet TM/TC system in an operational environment. a) Demonstration of ESA Packet Telecommand encrypt/decrypt, authentication, validation and anti-replay attack functionality; b) ESA Packet Telemetry encrypt/decrypt functionality, c) Extraction of security management functions onboard the spacecraft and simplified processing of these security management functions. The ECSE ground segment consists of telecommand and telemetry security layer software integrated into the primary STRV TM/TC processor workstation.

ECSE is composed of two segments: a space segment and a ground segment. The ECSE space segment consists of a number of switches, several electronic devices, and interfaces to the Sparc processor with the relevant software loaded.

QWIP (Quantum Well Infrared Photodetector), an infrared camera system provided by JPL and sponsored by BMDO. Objective: To characterize the radiation detection performance of QWIP technology in the spectral range of 11-17 μm by imaging of the moon. The QWIP detector is mounted directly to the 55 K coldfinger of a 1 W tactical cooler (Texas Instruments) using an IDA (Integral Dewar Assembly). The test objectives include determining cooler/battery compatibility and measuring power train efficiency, inrush current levels, and current ripple.

SAS (Satellite Attitude Sensor), provided by CREST (Canada). Objective: To demonstrate the capabilities of a new type of infrared Earth sensor over a range of altitudes from LEO to GEO in a harsh radiation environment on a slow-spinning satellite.

SCL (Spacecraft Command Language), provided by NASA, ICS (Interface Control Systems, US). Objectives: To monitor spacecraft systems.

SCPS (Space Communications Protocol Standards), provided by USAF, NASA, MoD, DERA. Objectives: To demonstrate and test a full space implementation of the Space Communications Protocol Standards.

SMX-2 (Sparc Microprocessor Experiment-2), provided by MMS, DERA, ESTEC. Objective: To demonstrate the ERC-32 Sparc chip-set in a harsh radiation environment and to demonstrate its ability to meet the platform OBC function and to support the experiments: ECSE, SCPS, SCL, and OBPE. The SMX-2 experiment consists of two Single electronic boards with the ESA Sparc ERC32 chip set incorporated into them. SMX-2 has 4 MByte of RAM and 2 MByte of EEPROM. SMX-2 is housed in the same box as ECSE.

Demonstration technologies:

ETB (Electronics TestBed), provided by AFRL, Kirtland AFB, NM and sponsored by BMDO. ETB is a Data Handling System (DHS), providing a general purpose interface between multiple space flight experiments and the spacecraft. The DHS design simplifies some of the complexities by providing a simplified interface for operating the space experiment, recording the results, and communicating the results to the spacecraft. It also reduces the risk to the spacecraft mission by providing a degree of separation between the spacecraft and less-proven new technologies, and it provides a similar degree of separation between experiments.

BEPT (Bradford Engineering Pressure Transducer), provided by Bradford Engineering and sponsored by NIVR. The principal objective is to flight demonstrate BEPT. The instrument is used to measure the pressure in the operational cold gas attitude control system on STRV-1d.

InP/Si Solar Panel, provided by NRL.

GaAs/Ge Solar Panels, provided by ESTEC.

Lithium Ion Battery, provided by BNSC, DERA, AEAT (Atomic Energy Authority Technology, UK).

M.26 TEAMSAT

TEAMSAT (Technology, science and Education experiments Added to Maqsat) is an ESA/ESTEC low-cost satellite demonstrator mission, the first S/C delivered to orbit by the Ariane-5 launcher on its second qualification flight (launch on Oct. 30, 1997 from Kourou). The TEAMSAT spacecraft turned out to be an embedded payload (350 kg) of the Ariane-5 upper instrumented test platform, referred to as Maqsat-H, carrying five experiments provided by various European universities. Very tight experiment development and S/C schedules of only one year (from project proposal to launch) resulted due to the late decision to grab a free-flight opportunity on Ariane 502 (along with the acceptance of all flight constraints) for 'hands-on' experimentation. In the end, over 40 young trainees and students from ten European countries along with experienced ESA engineers were actively involved in the TEAMSAT project. ¹⁷⁶⁴⁾ ¹⁷⁶⁵⁾ ¹⁷⁶⁶⁾

The TEAMSAT S/C structure consisted of a closed aluminum box of octagonal form (0.755 m high and a diameter of 0.944 m) containing the electrical system, the experiments and the

¹⁷⁶⁶⁾ S. Habinc, D. Hardy, P. Sinander, C. Smith, "TEAMSAT's Data-Handling Systems," ESA Bulletin 95, Aug. 1998, pp. 148-151

ejection mechanism for YES. The TEAMSAT mass of 350 kg was part of the Maqsat-H structure. [Total mass of the Maqsat-H platform was 2300 kg; another platform on this flight was Maqsat-B]. TEAMSAT electrical power was provided by three NiCd batteries. Mission operations was provided through ESA/ESOC. From a technology point of view, TEAMSAT's achievements included: ¹⁷⁶⁷⁾ ¹⁷⁶⁸⁾ ¹⁷⁶⁹⁾

- TEAMSAT is the first ESA S/C flown with telemetry and telecommand systems both fully compatible with ESA/CCSDS standards and the first S/C to exploit the adaptive asynchronous telemetry capabilities they support. Use of new chips for telemetry transfer frame generation. Dynamic bandwidth allocation without the use of an on-board computer. First ESA S/C to use the standard packet telecommand protocols.
- Use of a quadrifilar helix antenna for 100 MHz to 3 GHz links. The same system is scheduled to be flown on Metop-1.
- Demonstration of GPS reception from above the GPS satellite constellation.

The TEAMSAT mission ended on Nov. 2, 1997. After three days of intensive operations the available battery energy had been consumed as planned.

Orbit: GTO (Geostationary Transfer Orbit) achieved: Perigee = 525 km, apogee = 27,000 km, inclination = 7.76°, period = 7 hours, 40 minutes.

Sensor/experiment complement:

AVS (Autonomous Vision System), provided by the Danish Technical University (DTU), Lyngby, Denmark. AVS is of ASC (Advanced Stellar Compass) heritage flown on Ørsted. AVS is an advanced star compass which automatically recognizes the star field and tracks non-stellar objects (like satellites, comets or asteroids). AVS consists of two units: a light-weight CCD camera (0.18 kg, 0.4 W) and a DPU (Data Processing Unit) based on 486 technology (0.75 kg, 5 W). The microcomputer of the DPU is radiation tolerant. More than 11,000 stars are stored in memory. AVS is capable of:

- Identifying guide stars in spin-stabilized mode
- Autonomously determine the attitude in a three-axis stabilized or slow spin mode
- Identify non-star objects
- Track or image a detached probe
- Compress image/data for ground analysis

AVS was used in particular during the initial phases of the mission to determine the attitude and orbit of the S/C and to study the autonomous operations during severe radiation dose-rates in GTO. A thin shielding of the AVS was used to achieve a full lifetime dose during the battery-limited lifetime of TEAMSAT. ¹⁷⁷⁰⁾ ¹⁷⁷¹⁾

FIPEX (Flux Probe Experiment), provided by the University of Stuttgart (FIPEX is of TEXUS sounding rocket campaign heritage). The objective is the measurement of atomic oxygen concentration at different orbital altitudes (> 200 km up to 1000 km) to study erosion and degradation of optical surfaces in orbit; the data are also valuable for the verification of numerical models used in re-entry aero-thermodynamics. Oxygen is measured on the principle of electrolysis using a solid electrolyte (potentiometric oxygen sensor). The FIPEX instrument consists of:

- An array of five identical oxygen sensors, used to provide data redundancy and eliminate aerodynamics effects

¹⁷⁷¹⁾ M. Betto, et al., "The Determination of the Attitude and Attitude Dynamics of TEAMSAT," IAA 2nd International Symposium on Small Satellites for Earth Observation, Berlin, April 12-16, 1999, pp. 397-400

- Each sensor head contains an oxygen sensor, a sealed reference gas volume and both a reference pressure and temperature sensor.

The sensors are pre-heated to around 600°C to create sufficient ion conductivity within the electrolyte. The heating is feedback controlled so as to provide temperature stabilization for vacuum operation.

VTS (Visual Telemetry System), an ESA/ESTEC instrument built by MMS (UK), IMEC (Inter-university MicroElectronics Center), Leuven, Belgium and DSS/OIP (Delft Sensor Systems/Optronics Instruments & Products) in Oudenaarde, Belgium. VTS provides a new on-board visualization technology for monitoring S/C activities (solar array deployment, etc.). VTS consists of three cameras and a master unit (up to eight off camera modules may be supported), providing JPEG-compressed (and buffered) image sequences. The master unit is a flight-spec TSC-21020 based DSP computer. Each camera module has a maximum imaging capability of 512 x 512 pixels [using APS (Active Pixel Sensor) technology with associated electronics for camera imaging control], which are digitized to 8 bits. Full-size images can be acquired at up to 1 image/s. APS provides 6 decades of dynamic range. A standard 60° FOV is provided.

A flexible system of controlling imaging sequences is provided in the master unit which includes sub-imaging and interleaving to give higher imaging rates; typically up to 16 images/s. The master unit also stores images (up to 64 full size images, 128 MByte buffer capacity) prior to acquisition by the spacecraft Data Handling System. Image compression is provided to minimize the impact on the spacecraft telemetry downlink. In normal operation two image grades are provided (100:1 and 15:1). Custom compression ratios can be provided based on trade-off of image quality and telemetry bandwidth/downlink periods. The mass of VTS is 1.7 kg.

ODD (Orbiting Debris Device), provided by ESTEC. ODD tested the capabilities of optical and radar instruments on the ground to detect and track objects in space. For this purpose the upper Ariane 502 satellite (Maqsat-H) was covered with contrasting black and white paints of well known properties (75 % white and 25 % black). The other payloads have been left unchanged for comparison and also form part of the experiment.

YES (Young Engineers' Satellite), provided by the Technical University of Delft (Netherlands). YES is a free-flying subsatellite, intended to deploy a 35 km tether attached to an inert counter-balance mass (referred to as TORI), to study the dynamics of tethered satellites. YES is physically the lid of the TEAMSAT box. The YES subsatellite contained additional experiments:

- A GPS receiver was installed to evaluate GPS reception outside the GPS constellation and to provide information on the tether dynamics
- The SF (Scintillating Fiber) detector. The SF nuclear detector module consists of three radiation measuring channels for fiber-optic-coupled SF probes. Detected radiation are fast protons and electrons. A new radiation-hardened experimental SF probe and a doped spinel crystal were flown as the third detector.
- RADFET (Radiation-sensitive Field Effect Transistor) experimentation. Three RADFETs were used to measure the total ionizing dose behind thin shielding (so-called "skin-dose").
- Sun sensors. Seven SAS (Solar Aspect Sensors) measure the S/C attitude. Each of the seven sun sensors consists of two light-sensitive transistors mounted in an aluminium housing. On top of each transistor two baffles are mounted, forming narrow slits through which the transistor is looking out. This makes the FOV wide in one direction (about 90°) and narrow in the other (1 to 2°). As the slits on each sun sensor are perpendicular to each other, the sensors are always looking for the sun in two perpendicular planes. Together, the seven sun sensors have a 360° FOV in all three perpendicular planes through the S/C.

- Accelerometers. Test of new technologies [MNT (Micro & Nano-Technologies)] which are being considered as a possible future way to miniaturize systems and subsystems in space (measurement of vibrations).

Two on-board computers were installed, JORIS (student-designed and programmed) for control of the tether experiment, and a backup PC104 (a small version of a PC providing also the interface to a commercial camera (QuickCam) for imagery acquisition during YES ejection.

In June 1997, the international Steering Committee for Space Debris gave its no-go decision on the deployment of the YES mission's 35 km long tether (posing a high collision and debris risk). As a consequence the tether was not deployed. Nevertheless, a YES separation procedure (without tether) was conducted, the counter-balance mass remained mated to TEAMSAT. The ejection of YES was performed during the 8th orbit on Nov. 2 (ejection speed of 1.7 m/s) in preparation of future flights. Many useful results were obtained despite the restrictions imposed.

M.27 Tether Missions/Experiments

A space tether is a long cable used to couple spacecraft together as they orbit the central body (i.e. Earth).¹⁷⁷² Tethers are usually made of thin strands of high-strength fibers such as Spectra or Kevlar. Any space tethered system is intimately connected to the gravitational force field. Conducting tethers offer the additional capability to interact with the magnetic and electrical force fields.^{1773) 1774) 1775) 1776)}

The tethered system demonstrates gravity gradient attitude control. This is a very low cost attitude control system and if suitable for the mission, typically orients the system to within ± 10 degrees of the vertical, both in and out the orbit plane.

Because the space tether makes it possible to transfer energy and momentum from one object to another, it can legitimately be called a form of space propulsion. There are two general categories of tethers.

Momentum-exchange tethers (nonconductive tethers representing passive propulsion). They allow momentum to be transferred between objects in space, such as two spacecraft (tethers may redistribute momentum of a system from one body to another, but overall momentum is always conserved). The principle is based on the gravity gradient force.

Two objects, separated by a distance but tied together by a tether, are "pulled" apart by the gravity gradient force [this causes vertical (radial) alignment between the two objects]. Due to irregularities in the central body's gravitational field, the nearly radially aligned tether system actually librates, or oscillates, in a pendulum-like motion, about the system's center of mass. This swinging motion may be used to raise or lower the orbit of a tandem system without using any propellant.

- A tethered system release of an end-body from the remaining end-body and tether causes a momentum gain for the released end-body, resulting in a higher orbit for the released end-body orbit and a lower orbit for the remaining end-body and tether.
- A bolo tether rotates end-over-end in the orbit plane. This system could propel a payload attached to one end into a different orbit. The bolo could conceivably catch a payload.

¹⁷⁷⁶) L. Johnson, R. D. Estes, E. Lorenzini, et al., "Electrodynamic Tethers for Space Propulsion," Proceedings of AIAA, Reno, NV, Jan. 12-15, 1998, AIAA 98-0983

- A stationary tether refers to two end-bodies connected by a tether of constant length. The system may be used to drag the lower end-body payload through the higher atmosphere (for sampling) and simultaneously lowering the system's orbit.

Electrodynamic tethers (conductive tethers representing active propulsion and power generation). An electrodynamic tether is essentially a long conducting wire extended from the main end-body (spacecraft). There may be a second end-body to help deploy the bare tether. The gravity gradient field of the "S/C and string system" tends to orient the tether in a vertical position. A tether in Earth orbit interacts with the Earth's magnetosphere due to the relative orbital velocities (in LEO systems the orbital velocity of the tether is greater than the rotational velocity of the geomagnetic field, this force is drag on the tether); the motion of the conductor across the magnetic field induces a voltage along the length of the tether. This voltage can be up to several hundred volts per km.

The interaction of the tether system with the magnetosphere can be used in the design of the system to act either as an "electrodynamic power or thrust system" to boost the orbit of the S/C; or it may be used to act as an "electrodynamic drag system" to lower the orbit of the S/C. The direction of the current flow in or out of an electrodynamic tether system determines if the interaction contributes to drag or to propulsion.

- **Electrodynamic power or tether drag system.** In this case the tether converts the orbital energy of the host S/C into electrical power. The drag force is used to decrease the orbit of the tether and its host S/C. In this design scheme current is produced by the interaction of the tether ends with the external plasma (a current loop consists of the tether, the external plasma, and the ionosphere). The collection of electrons from the plasma creates a net positive charge. This means that when electric power is generated by the tether for on-board use or simply for dissipation, it is generated at the expense of orbital energy.
- **Electrodynamic thrust tether system.** In this case, an EMF (Electromotive Force) acts to induce an electric potential along the tether system; the tether is used to boost the orbit of the host S/C. This concept requires power to be injected into the tether system from an on-board power supply, causing the system to gain altitude. The tether interaction with the Earth's magnetic field provides a "push" resulting in an orbit boost of the S/C.

A side effect of tether current flow is the production of electromagnetic waves (ULF, ELF, VLF) into the ionosphere, resulting from the electron transfer from the tether back into the plasma. This feature may give rise to use the tether also as an antenna.

Mission (Agency)	Launch (Timeframe)	Orbit	Tether Length	Comment
Gemini-11(NASA)	Sep. 11-15,'66	LEO	30 m	Spin-stabilized, 0.15 rpm
Gemini-12(NASA)	Nov. 11-15,'66	LEO	30 m	Local vertical, stable swing
H-9M-69	1980	Suborbital	500 m	Partial deployment
S-520-2	1981	Suborbital	500 m	Partial deployment
Charge-1	1983	Suborbital	500 m	Full deployment
Charge-2	1984	Suborbital	500 m	Full deployment
ECHO-7	1988	Suborbital		Magnetic field aligned
Oedipus-A (NRC/ NASA,CRC, CSA)	Jan. 30, 1989	Suborbital	958 m	Spin-stabilized, 0.7 rpm (Canada/USA)
Charge-2B	1992	Suborbital	500 m	Full deployment
TSS-1 (STS-46) (ASI/NASA)	Jul. 31-Aug. 8, 1992,	LEO	< 270 m	Electrodynamic tether, partial upward deployment and retrieval of tether
SEDS-1 (NASA)	Mar. 29,1993	LEO	20 km	Nonconducting tether, downward deployment, swing and cut
PMG (DoD) Plasma Motor Generator	Jun. 26, 1993	LEO	500 m	Electrodynamic tether, upward deployment, tether current in both directions. Demonstration of hollow cathode plasma contactors for current collection and emission

Mission (Agency)	Launch (Timeframe)	Orbit	Tether Length	Comment
SEDS-2 (NASA)	Mar. 9, 1994	LEO	20 km	Local vertical stable, downward deployment
Oedipus-C (NRC/NASA,CRC, CSA)	Nov. 6, 1995	Suborbital	1 km	Spin-stabilized, 0.7 rpm (Canada/USA)
TSS-1R (STS-75) (ASI/NASA)	Feb. 22-Mar. 9, 1996	LEO	19.6 km	Electrodynamic tether, severed prior to full deployment
TIPS (NRO/NRL)	May 12, 1996 Jun. 20, 1996 deployment	LEO	4 km	Long life tether (tracking of one year)
YES (Technical Univ. of Delft)	Oct. 30, 1997	GTO	35 km	YES (of TEAMSAT) was not deployed to avoid a collision with other S/C (M.26)
STEX/ATEX (NRO/NRL)	Oct. 3, 1998 Jan. 16 1999 deployment	LEO	6 km	Nonconductive tether, planned demonstration of tether system stability and control. However, a deployment malfunction caused an experiment failure
PICOSAT1.0 of the Aerospace Corporation	Jan. 27, 2000 on OPAL of Stanford	LEO	30 m	PICOSAT1.0 was ejected OPAL on Feb 6, 2000. The system of two S/C operated for 3 days when battery power decayed.
PICOSAT1.1 of the Aerospace Corporation	July 19, 2000 on MightySat II.1 of AFRL	LEO	30 m	PICOSAT1.1 will be ejected from Mightysat II.1 one year after launch (in Sept. 2001) to test storage effects on the system.
METS (MIR Electrodynamic Tether System)	2001	LEO	5 km	First practical application of non-rocket propulsion in space
ProSEDS (NASA)	2001	LEO	25 km	Upward deployment (producing drag and electrical power)
TSE (ESA)	2002	LEO	35 km	Demonstration of ISS sample return

Table 518: Chronology of tether missions

The drag feature of tethers may be used to deorbit a body (a malfunctioning or out-of-service satellite). A multitude of low-cost applications can be designed around tether systems besides propulsion (such as communications, atmospheric studies, gravity experiments, power generation, etc).¹⁷⁷⁷⁾

History: The first two tethers (each 30 m in length) flew in 1966, during the Gemini-11 and -12 manned orbital missions. Orbital tether experiments began again in 1980 and have continued through the present. Tether missions in the 1990s have included several important milestones, such as: (see also Table 518)

- First retrieval of a tether in space (TSS-1, 1992)
- Successful deployment of tethers 20 km long (SEDS-1, 1993)
- First operation of an electrodynamic tether (PMG, 1993) with current driven in both power mode and thrust mode.

M.27.1 ASTOR (Advanced Safety Tether Operation and Reliability)

ASTOR is a proposed Shuttle hitchhiker payload (HH-S) of NASA/MSFC and the Michigan Technic Corporation, Holland, MI. The objective is to demonstrate the performance of ETD (Emergency Tether Deployment). ETD is designed to overcome the safety hazard caused by snags during tether deployment. ASTOR itself consists of three elements: the satellite upper unit, the satellite lower unit, and the tether. Each unit is hexagonal in shape with a length of 66 cm and 46 cm in diameter. The mission involves ejection of HH-S and deployment of ASTOR. ETD provides for accurate control and deployment of the tether.¹⁷⁷⁸⁾

M.27.2 BOLAS (Bistatic Observations with Low Altitude Satellites)

BOLAS is a proposed Canadian/USA satellite technology mission (tethers, microsatellites, the use of GPS, etc.) with CSA and NASA/MSFC as contributing partners (the BOLAS mis-

¹⁷⁷⁷⁾<http://www.tethers.com>

¹⁷⁷⁸⁾<http://www.airseds.com/astor.html>

sion team includes institutes, Canadian and US universities, and industry). As of 2000, the BOLAS mission is postponed indefinitely due to funding problems.

Sensor complement:

HF Receiver, provided by CRC (Communications Research Center).

SII (Suprathermal Ion Instrument), provided by the University of Calgary.

TECHS (Thermal Electron Capped Hemisphere Spectrometer), provided by SwRI (Southwest Research Institute), San Antonio, TX.

GPS Receiver, provided by the University of New Brunswick.

M.27.3 METS (MIR Electrodynamic Tether System)

Another electrodynamic tether, nicknamed Firefly, is expected to be attached to the MIR space station to reboost the altitude decaying MIR, thereby adding more years to its lifetime. The METS initiative/study was sponsored by FINDS (Foundation of the International Non-Governmental Development of Space) and carried out by Energia Ltd. and Tether Applications Co. of San Diego, CA. If successful in 2001, this will be the first practical application of non-rocket propulsion in space. METS is mounted on the EVA ladder at the end of the Kvant-2 module. The tether consists of a 5 km anodized aluminum wire deployed downward from MIR. The tether is kept nearly vertical by gravity gradient effects acting on the wire and a 200 kg ballast mass at the end of the wire. The 1 km section of tether furthest from MIR is bare metal and this strip will begin collecting electrons that are moving within the Earth's magnetic field. As the electrons move along the wire toward the space station, a hollow cathode emitter mounted on MIR will spray them back into space, completing the circuit and letting a current flow. This will result in a net force increasing the station's orbit speed. ^{1779) 1780)}

M.27.4 OEDIPUS

Various Canadian organizations (NRC, CRC, CSA) have successfully deployed two tethered systems from sounding rockets. These suborbital missions for "Observations of Electric Field Distribution in the Ionospheric Plasma - a Unique Strategy" were accomplished as OEDIPUS-A in January 1989 and OEDIPUS-C in November 1995.

OEDIPUS-C has two spinning payloads connected by a 1,174 m tether. The scientific objectives addressed natural and artificial waves in the ionospheric plasma. The mission provided perspectives on plane and sheath waves and their interaction with space plasma. The science experiments were also designed to help to understand how charged particles associated with aurora affect satellite transmissions. ¹⁷⁸¹⁾

M.27.5 PMG (Plasma Motor Generator)

PMG is a tether payload of a DoD satellite that was launched as a secondary payload on a Delta-2 launch vehicle on June 26, 1993. The objectives of PMG were to test: 1) the performance of the HCA (Hollow Cathode Assembly) to provide a low impedance bipolar electrical current between a S/C and the ionosphere, and 2) demonstrate the functions of space propulsion and electrical current generation (and current reversal in tether using a bias voltage). The PMG consisted of four basic elements: FEP (Far-End Package), NEP (Near-

¹⁷⁷⁹⁾J. Oberg, "Saving MIR With A Rope Trick," IEEE Spectrum, July 2000, Vol. 37, No. 7

¹⁷⁸⁰⁾<http://www.finds-space.org/METS.html>

¹⁷⁸¹⁾A. Jablonski, F. Vigneron, G. Tyc, and H. G. James, "OEDIPUS-C Mission Tether Dynamics Results," paper presented at the Tether Technology Interchange Meeting, MSFC, Sept. 9-10, 1997, NASA/CP-1998-206900

End Package), an electronics box called SEDS (Small Expendable Deployer System), and PDP (Plasma Diagnostic Package) of NASA/LeRC. The tether was 500 m in length and consisted of a number 18 AWG (American Wire Gauge) Teflon-insulated copper wire. After third-stage separation, the PMG was left in an elliptical orbit (193 km x 869 km, inclination = 25.7°). The FEP was ejected upward with an initial velocity of 2-3 m/s. Each HCA was equipped with a 1 liter gas bottle, on/off solenoid, gas metering block power supplies to produce a weekly ionized xenon cloud. Both end platforms carried a 28 V silver cell battery for a nominal lifetime of 3-6 hours. ¹⁷⁸²⁾

The PMG current showed to be fully reversible, operating either as a generator system with electron current flow down the tether, or as a motor with electron current driven up the tether. The induced EMF was measured with total voltage biased from +150 to -90 V, and also with the bias turned off by using only the induced EMF.

M.27.6 ProSEDS (Propulsive Small Expendable Deployer System)

A NASA/MSFC tether demonstration experiment, planned to fly in June 2001. ProSEDS is based on the SEDS deployment scheme, with the objective to deploy an electrodynamic tether from a Delta-II rocket's third stage (launching a GPS satellite) to achieve about 1 N drag thrust for stage deorbiting. The tether is composed of 10 km of nonconducting Spectra tether for ballast and to begin the deployment and 5 km of aluminum wire (1.2 mm diameter) covered with thermal coatings next to ProSEDS. Normally, these stages slowly spiral back to Earth over the next half year as atmospheric drag nibbles away at their speed. By generating an electrical current, ProSEDS will turn itself into an electromagnetic brake. An orbital decay of at least 5-15 km in altitude per day is expected with this deorbiting technique. It's not quick compared to a retrorocket, but it is much faster than natural decay. And it's being done without the use of any propellant. ^{1783) 1784) 1785)}

Orbit: circular orbit, altitude = 400 km, inclination = 35°

M.27.7 SEDS (Small Expendable Deployer System)

SEDS is a NASA/MSFC tether experiment demonstration program, developed by MSFC and by Tether Applications Co. of San Diego. Two flight experiments (nonconducting momentum-exchange tethers) have been flown as Delta secondary payloads on the second stage of GPS satellite launches. Each SEDS sub-satellite was deployed by means of a deployer system. ¹⁷⁸⁶⁾

SEDS-1, launched March 29, 1993, was a 20 km downward deployment with the objective to demonstrate the use of a tether to place a payload in a deorbit trajectory (study of reentry after the tether was cut). The Delta second stage was in an elliptical orbit (195 km x 705 km, inclination of 34°), the tether deployment was initiated at apogee. Telemetry was obtained from the deployer through the Delta second stage telemetry system and from the tether end-mass via an S-band transmitter. The deployment took about one orbit and the tether brake was applied. The tether with its end-body payload swung to local vertical at which time the tether was cut at the deployer end and the end-body, trailing the tether, reentered the atmosphere and burned to destruction off the coast of Mexico. The reentry was video taped by a team of observers.

SEDS-2, launched on March 9, 1994, was also a 20 km downward deployment, but the mission objective was to demonstrate the use of a modified SEDS to deploy and stabilize a teth-

er system along the local vertical. The orbit of the second stage was circular at an altitude of 350 km. The tether was not intentionally cut and instrumentation on both the deployer end and end-body measured performance for several hours until battery depletion. System stability was within 4°. The tether was cut by a micrometeoroid or space debris about 5 days after launch. Approximately seven km of tether remained attached to the second stage until reentry into the atmosphere two months later. ¹⁷⁸⁷⁾ ¹⁷⁸⁸⁾

Figure 334: Illustration of SEDS on the Delta second stage

For both payloads, the end-body instrument package was designed and built by LaRC. It consisted of a three-axis tensiometer, a three-axis magnetometer, and a three-axis accelerometer. The end-body measured tether system performance and end-body attitude.

M.27.8 STEP-AIRSEDS

STEP-AIRSEDS (Space Transfer Using Electrodynamic Propulsion - Atmospheric Ionospheric Research Small Expendable Deployer System) is a proposed electrodynamic tether mission of NASA, designed and built by the Michigan Technic Corporation, Holland, MI. The objective is to demonstrate new technologies (mitigation of orbital debris) including an electrodynamic tape tether and a deployer that can retract the tether. This 1,000 kg satellite is required to conduct boost, de-boost, plane-change and station-keeping operations during the mission. The satellite operates in an altitude range between 350 km and 1,100 km for a minimum of one year. It is targeted for a launch in 2004. Currently, The Michigan Technic Corporation is conducting the Phase B development of the satellite.

M.27.9 STEPS (Station Tethered Express Payload System)

STEPS is a NASA/MSFC project in the SBIR Phase II program to increase sample return opportunities between regular service flights to ISS (of Shuttle, Soyuz, or Raduga). The

¹⁷⁸⁷⁾H. F. Smith, "The First and Second Flights of the Small Expendable Deployer System (SEDS)," *Proceedings of the Fourth International Conference On Tethers In Space*, Science and Technology Corp., Hampton, VA, Apr. 1995, pp. 43-56.

¹⁷⁸⁸⁾<http://ixiab8.larc.nasa.gov/seds/>

STEPS design uses a return capsule of 78 cm diameter with a payload capacity of 100 liter. STEPS is both deorbited and oriented for reentry by a 2.5 kg expendable tether. The tethered deorbit and kite-tail-orienting effect before reentry were both demonstrated on the SEDS-1 (Small Expendable Deployer System) mission in March 1993.¹⁷⁸⁹⁾

The STEPS deployer is a small easily reloadable version of the SEDS deployer. It is part of a reusable ejector/deployer assembly that remains on the Station (ISS). The empty capsule plus its tether weigh 10 kg and take only 30 liter of storage space. The ejector/deployer stow has a volume of 20 cm x 40 cm x 100 cm.

A STEPS precursor flight is planned as a Delta secondary payload. It is intended to test the heat shield, modified SEDS deployer, tether control law, and a soft mid-air recovery technique.

M.27.10 TiPS (Tether Physics and Survivability)

TiPS is a low-budget quick reaction experiment (a secondary payload) sponsored by NRO [National Reconnaissance Office (of DoD, USA)]. It was launched May 12, 1996 on a DoD satellite from VAFB, CA (Titan-4 vehicle), and deployed on June 20, 1996 [built and operated by NCST (Naval Center for Space Technology) of NRL]. The experiment objective is to increase knowledge about gravity-gradient tether dynamics and the long-term survivability of tethers in space. A deployment sequence jettisoned the TiPS satellite from a host vehicle and then separated its two end-bodies from each other (initial separation velocity of 5.1 m/s).^{1790) 1791) 1792)}

The TiPS payload consists of two end-bodies (of box-like shape, each covered with 18 laser retroreflectors), with a total mass of 54 kg [37.7 kg for the larger box (dubbed ‘Ralph’)¹⁷⁹³⁾ and 10.8 kg for the smaller upper box (dubbed ‘Norton’), tether mass of 5.5 kg], were separated by four km of a nonconducting tether. The cylindrical shape of the tether is due to strands of Spectra woven around yarn. Ralph contains a SEDS (Small Expendable Tether Deployer System) box from NASA which in turn contains all the electronic components (telemetry system, turn-count recorder, and temperature sensors). The telemetry system is powered by a non-rechargeable battery, which operated for the first eight hours of the satellite’s life after deployment. Telemetry generated during the separation of the two end-bodies confirmed full tether deployment. NRL, NASA and an international network of SLR (Satellite Laser Ranging) stations (in addition ground-based radar data and optical data from several telescopes) provided global tracking of the system for the duration of one year (history of the librational and rotation motion dynamics).

Retroreflectors are mounted on the exterior surfaces of both Ralph and Norton, for long-term passive monitoring of the tethered system. End-body discrimination is accomplished by coating the retroreflectors of Ralph to reflect only one of the two transmitted laser wavelengths. The uncoated retroreflectors on Norton reflect both transmitted wavelengths.

Orbit: Near-circular orbit, mean altitude = 1022 km, inclination = 63.4°, period = 105 min.

The TiPS orientation is controlled by gravity gradient forces. The passive TiPS satellite orbits the earth with a nominal vertical orientation, with Ralph closest to the earth. About this nominal orientation, the tethered system undergoes libration. The various tracking information was used to determine the orbit and attitude of the tethered system. The most signif-

M.27.11 TSE (Tether System Experiment)

TSE is a proposed ESA tether project, initiated in 1997. The study is carried out by an international project team, led by Kayser-Threde GmbH of Munich, Germany. The launch of the TSE demonstration mission is planned for 2002. The objectives of the TSE mission are to: ¹⁷⁹⁴⁾

- Demonstrate the operation of a tether-deployment mechanism suitable for ISS sample return and the ability to operate properly in the ISS (International Space Station) environment
- Test a robust tether-deployment control strategy for re-entry initiation, and demonstration of an accurate landing scheme of future sample-return capsules
- Demonstrate the critical technologies associated with the re-entry capsule of an ISS tethered sample return system
- Collect experimental data on system dynamics to support the validation of models used for tether-deployment simulations.

The TSE design is conceived as a low-cost mission using existing hardware whenever possible. The mission scenario calls for the TSE subsatellite to be installed on a Russian Prog-

¹⁷⁹⁴⁾J. G. Izquierdo, H. Rozemeijer, S. Müncheberg, "The Tether System Experiment - Preparing for ESA's First Tether Mission,," ESA Bulletin No 102, May 2000, pp. 139-143

ress cargo vehicle, conducting a service mission to ISS. The ejection of the subsatellite from Progress and tether deployment is planned to occur after completion of the service mission in a safe distance away from ISS.

The tether deployment strategy consists of two phases: In the first phase, the tether is deployed to 3 km vertically downward of Progress to stabilize the capsule and to reduce sensitivity to ejection errors. After synchronization with the target landing site, the second phase is initiated with the full deployment of the tether to 35 km length. At the end of deployment, the tether motion is stopped by a brake, causing a swing-back into the direction of the local vertical. The tether is cut by the deployer system at a predefined instant (close to the local vertical), resulting in a momentum exchange (sling shot) that releases the subsatellite onto its re-entry trajectory, with the tether in tow.

Thirty minutes later, the subsatellite reaches the Earth’s upper atmosphere and decays above the Pacific Ocean. From activation to burn-up, the subsatellite collects experiment data such as position and velocity (GPS receiver), angular rates and accelerations (IMU), and temperatures. The information is transmitted to the tether deployer system on-board Progress for storage and subsequent downlink.

System mass	143 kg (total)
Tether deployer and electrical subsystems	60 kg
Subsatellite	42 kg
Experiment container	41 kg
TSE dimensions (without container)	1265 mm x 588 mm x 588 mm
Power consumption	88 W during tether deployment
Tether type	Dyneema 4 x 400 denier (momentum exchange tether)
Tether diameter, length	0.5 mm, 35 km

Table 520: Technical data of TSE

The tether deployer system provides the following functional support:

- Tether storage during launch and pre-experiment phases
- Ejection/acceleration of the subsatellite at initiation of the TSE release
- Tether guidance throughout the experiment to prevent tether damage
- Monitoring of tether system behavior
- Control of tether release (tether tension and velocity)
- Tether cutting in nominal and non-nominal modes
- Reporting of status information to the data handling system

The actual TSE deployment was preceded by a test campaign (in 2000) with a breadboard system to cover all aspects of functional system testing.

M.27.12 TSS (Tethered Satellite System)

TSS is a cooperative program of ASI and NASA for a reusable multi-disciplinary facility to conduct space experiments in Earth orbit. The system consists of a satellite, a conductive tether (approx. 20 km long) and a deployer in the Shuttle’s cargo bay.

Background: The TSS program traces its birth to 1974 when Guiseppe Colombo of Padua University (Italy) came up with the idea of using a long tether to support a satellite from an orbiting platform. Later in the 1970s, G. Colombo and Mario Grossi of the Smithsonian Astrophysical Laboratory (SAO), Cambridge MA, proposed a mission to study the possible scientific applications for long tethers in space. A NASA-ASI memorandum of understanding was signed in 1984, in which NASA agreed to develop a deployer system and tether and ASI agreed to develop a special satellite for deployment.

- **TSS-1.** The first TSS mission was conducted on STS-46, July 31 - Aug. 8, 1992. The objective of the TSS-1 mission was to demonstrate the feasibility of deploying and control-

ling long tethers in space, and to evaluate some of the unique applications of the TSS as a tool for research by conducting exploratory experiments in space plasma physics. An electrically conductive satellite, a sphere of 1.6 m diameter with a mass of 518 kg, was deployed; it was tethered to the Orbiter by a conductive tether (2.54 mm diameter using Kevlar and Nomex with 10 strands of 34 AWG copper wire and a Teflon sheath). A maximum upward separation of 267 m between the Orbiter and satellite was achieved. Several unsuccessful attempts were made to extend the tether to its full planned extension of 20 km. Deployed operations lasted nearly one full 24 hour period - then the tether was retrieved. Even though the primary mission goals were not achieved many interesting results were obtained.

The **SETS** (Shuttle Electrodynamic Tether System) was one of several instrument packages included in TSS-1. It includes five instruments, a flight computer, and a power interface box. **TCVM** (Tether Current Voltage Monitor) measured the tether current and voltage. **FPEG** (Fast Pulsed Electron Gun) provided removal of negative charge from the Orbiter electrical ground. The **CCP** (Charge Current Probe) used a dual-sensor combination to measure the differential changes in the vehicle potential and return current from the ionosphere to the Orbiter structure. The **SRPA/LP** (Spherical Retarding Potential Analyzer and Langmuir Probe) instrument determined the thermal plasma characteristics relative to the ionosphere. **AMAG** (Aspect Magnetometer) measured the magnetic field in the Orbiter's payload bay.

- **TSS-1R.** A reflight mission, TSS-1R, flew on STS-75 Feb. 22 - March 9, 1996. The TSS-1R mission suffered a broken tether (the cable suddenly snapped near the top of the deployment boom, it was burned through by an electrical arc prior to maximum deployment of 20 km). Tether dynamics were verified up to a length of 19.6 km providing a total of five hours of deployed electrodynamic measurements (largest man-made electrodynamic structure placed in orbit so far). Additional TSS-1R satellite payload instruments were: a triaxial accelerometer and a current meter, and the 2.4 m extendable instrument booms.

Both TSS missions confirmed concept validation of long gravity-gradient tethers; moreover the data gathered during the second mission confirmed the possibility to use the system for the conversion of orbital energy to electrical energy.^{1795) 1796)}

M.28 TOPSAT

TOPSAT is a UK collaborative small-cost satellite mission of DERA (QinetiQ), SSTL, RAL and InfoTerra, funded by the UK Ministry of Defense (MOD) and by the BNSC (British National Space Centre) small satellite initiative (Mosaic). The overall objectives are to demonstrate the capabilities of small spacecraft on a high-resolution imaging mission, including an end-to-end ground segment with services for a commercial user community (direct user access, innovative solutions). In this setup, the mission is designed and managed by DERA (QinetiQ), SSTL (Surrey Satellite Technology Limited) is building and integrating the microsatellite bus, RAL (Rutherford Appleton Laboratory) is developing the imaging instrument, while InfoTerra is responsible for data distribution (rapid delivery) and the marketing services. The data is also being used by institutional users (government agencies, military, etc.). The demonstration mission is planned for one year. There will be an evaluation in terms of all aspects of performance.

The spacecraft structure of SSTL employs a truncated pyramid design which offers a high volume efficiency in multiple launches and more solar power. TOPSAT is three-axis stabi-

¹⁷⁹⁵⁾ N. Stone, et al., "A Review of Scientific and Technological Results from the TSS-1R Mission," paper presented at the Tether Technology Interchange Meeting, MSFC, Sept. 9-10, 1997, NASA/CP-1998-206900

¹⁷⁹⁶⁾ B. Strim, M. Pasta, and E. Allais, "TSS-1 vs. TSS-1R," *Proceedings of the Fourth International Conference On Tethers In Space*, Science and Technology Corp., Hampton, VA, Apr. 1995, pp. 27-42

lized. Attitude is maintained by reaction wheels, the momentum is being off-loaded through magnetorquers. The reaction wheel/magnetorquer combination provides also a S/C pointing capability of $\pm 30^\circ$. Attitude is sensed by Earth and sun sensors. A high-precision three-axis gyro permits the offtrack and pitch compensation maneuvers required of the mission and image rectification if needed. An attitude stability of 0.002° is provided for image acquisition (1.5 s), the control accuracy is $\pm 0.2^\circ$ with a knowledge of $\pm 0.1^\circ$ in all axes. A GPS receiver provides orbit determination and on-board clock updates. Solar power of 55 W (orbital average) is provided by three body-mounted solar panels (GaAs cells). NiCd batteries provide 168 Wh of power storage capacity. The command and data handling subsystem employs the 80386 processor architecture providing a semi-autonomous control of the satellite. The spacecraft has a mass of about 125 kg. The design life is one year, although there are no life limiting factors in the design (e.g. fuel). A launch of TOPSAT is planned as a secondary payload in 2003. ^{1797) 1798) 1799)}

Orbit: Sun-synchronous circular orbit, altitude = 600 km, inclination = 97° , period = 100 min, 10:30 local equator crossing time. A four day target revisit capability is provided.

RF communications: An on-board storage capability in Flash memory of up to four full and uncompressed scenes (= 2 Gbit) is provided. Standard VHF and UHF subsystems are provided. The VHF uplink is used for spacecraft commanding including file transfer. The UHF downlink is used for telemetry. In addition, there is an X-band downlink for the high-rate image data dumps with a data rate of 25 Mbit/s developed by DERA (QinetiQ). Mission operations are provided by QinetiQ. Two mobile ground stations will be used, one at QinetiQ and one at BURS (Bradford University Remote Sensing), UK. An S-band tracking beam is provided to enable spacecraft tracking with the mobile ground stations.

Sensor complement:

HIROC (High Resolution Optical Camera), developed by RAL. The objective is to provide panchromatic (2.5 m resolution) and multispectral imagery (5 m resolution) over a wide swath. The optical system employs a folded focal length of 1680 mm and a collecting aperture of 200 mm diameter. A three-mirror off-axis, aspheric design is used to provide flat image projections free of first order aberrations. Two of the mirrors are off-axis sections resulting in an obstruction-free aperture system. The design features a nearly diffraction-limited wide FOV (Field of View) of 1.4° in the cross-track direction and a sufficiently wide FOV in along-track to accommodate a number of detector array configurations (pushbroom operation). The telescope, the optics, all sensors and their associated front-end electronics are mounted on a CFRP (Carbon Reinforced Polymer) optical bench providing the needed stiffness, low thermal expansion, and alignment qualities. The FPA (Focal Plane Assembly) uses two separate CCDs, one for each channel (i.e., PAN and MS image detection). TDI (Time Delay and Integration) is provided through pitch compensation (by rotating the spacecraft counter to the satellite track velocity vector), increasing the integration time of the imagery and enhancing the SNR (TDI by motion compensation). The objectives call for up to 8 times TDI with an SNR of 50 in the prime band. The system is designed for a 90% probability of achieving 15% MTF at the Nyquist frequency after manufacture, assembly, integration and launch and including factors for the optical system, detector sampling, temporal sampling, jitter and smear.

The camera is mounted externally to the spacecraft platform, it uses heaters and MLI blankets to maintain temperature within limits. It is mounted to the platform using blade flexures that accommodate some difference in thermal expansion between the platform and payload that may otherwise warp the camera. Three internal, non-structural baffles protect

the system from stray light. A further baffle covers the top of the monocoque and provides an attachment point for an aperture cover.

Spectral range of panchromatic band	0.5-0.7 μm
Spectral range of multispectral bands	0.4-0.5 μm , 0.5-0.6 μm , and 0.6-0.7 μm
Pan detectors	Kodak 6000 element array (Si) at 7 μm pitch
Multispectral detectors	Kodak 3x 2000 element array (Si) at 14 μm pitch
Spatial resolution	Pan = 2.5 m, MS = 5 m
Swath width	Pan = 15 km, MS = 10 km
Maximum scene length	About 30 km
FOR (Field of Regard)	Body pointing capability of $\pm 30^\circ$ in two axes
On-board data compression	The DERA data handling unit (DHU) provides a DSP which can be programmed with different image handling techniques
Instrument mass	<30 kg including FPA, electronics, thermal control, aperture cover and power conditioning
Instrument power	30 W operational, 10W standby (thermal control)
Instrument size	70 cm x 55 cm x 35 cm

Table 521: Specification of the HIROC instrument

Figure 336: Illustration of HIROC optics (left) and the TOPSAT S/C (right)

M.29 TSX-5 (Tri-Service Experiments Mission 5)

A US DoD mission of AFRL (Kirtland AFB) within STP (Space Test Program) with the objective to operate two experimental payloads - **STRV-2** (Space Technology Research Vehicle-2) and **CEASE** (Compact Environmental Anomaly Sensor Experiment) - for a period of six months with a one year goal. TSX-5 was launched June 7, 2000 on a Pegasus XL vehicle over the Pacific, some 80 km west of VAFB (OSC's L-1011 jumbo jet - dubbed Stargazer - dropped the launch vehicle and payload from its belly).

The STRV-2 spacecraft structure, built and integrated by OSC of Dulles, VA, uses a bus of the STEP (Space Test Experiment Platform) program heritage (a nominal 95 cm point-to-point 12-sided structure). The all-aluminum structure consists of a honeycomb core plate with sheet metal panels mounted to milled longerons or stringers. The 0.82 m long STRV-2 payload is mounted to the top of the spacecraft structure. The S/C subsystems include: EPS (Electrical Power Subsystem, C&DH (Command and Data Handling), communications, and an attitude determination and control subsystem. The electronic components of the

subsystems and the CEASE experiment are mounted internal to the S/C on the -x or wake oriented core plate. The S/C mass is 249.5 kg.

Orbit: Elliptical orbit of 410 km x 1750 km, inclination = 69°.

Figure 337: The TSX-5 S/C model

M.29.1 STRV-2 (Space Technology Research Vehicle-2)

STRV-2, sponsored by BMDO and DERA (UK), is a multi-national, highly integrated suite of experiments designed to push the envelope of space-based imaging technology, satellite vibration suppression, and material science. The prime objectives include demonstration of operation of optical instruments (MWIR and Lasercom) on a low-cost, non-precision platform, downlinking of data via Lasercom, obtaining infrared background data in selected wavelength bands at low and high altitudes, and assessing performance of candidate components in the space environment. Additional objectives of STRV-2 are the testing of the following experiments: ACCESS, SAMMES, VISS, and ETB; they include characterization of the space environment (radiation, micrometeoroid and debris), vibration isolation and suppression, assessment of contamination transport and effects aboard a low-cost satellite, and the demonstration of a modular architecture for autonomous command, control and data handling. The minimum success criteria for STRV-2 include collection of infrared background data for phenomenal analysis, demonstration of a laser communication downlink, demonstration of vibration isolation and suppression technology, and collecting six months data on the space environment and its effects on candidate components.¹⁸⁰⁰⁾

All the data obtained from the BMDO STRV-2 experiments, applicable to the design and operation of civilian and commercial spacecraft, are made available to scientific investigators for analysis and interpretation.

Sensor/experiment complement:

MWIR (Medium Wave Infrared Imager), a DERA instrument with a mass of 23 kg and power consumption of <60 W. The instrument main features are:

- The optics of the Dall-Kirkham reflective telescope comprise: a 200 mm aperture primary mirror, a secondary mirror and a refractive relay lens system to provide a fully

¹⁸⁰⁰⁾<http://www.te.plk.af.mil/stp/tsx5/strv2/strv2.html>

cold shielded thermal imagery. A filter wheel, containing 6 filters, is used to select the required waveband. The contains two relative calibration sources. They are imaged at the pre- and post-image instant to give a “flat field” calibration across the focal plane.

- An FPA (Focal Plane Assembly) of two staggered CMT arrays, each of size 2 x 512 elements, the detectors are separated in the along-track direction. The instrument operates in a dual pushbroom fashion, obtaining two near-simultaneous images in parallel.
- A Stirling cycle cryocooler, developed by Texas Instruments Inc., provides 1 W of cooling to the FPA; the operating temperature is 80 K. This is a COTS design, the STRV-2 mission represents its first use on a spaceborne platform.
- Carbon fiber composite telescope structure of DERA.
- Control electronics, pre-amplifier and memory of DERA.

The imager filter wheel carries filters for spectral ranges from 4.3 to 5.15 μm and 5.4 to 6.0 μm and a reference source system. The imager is designed for nadir Earth viewing; however, the 5.4 to 6.0 μm band is in the water absorption region, hence unable to see to the ground. The detector arrays produce a ground resolution of 35 m. - DERA acquires MWIR data to evaluate the instrument’s capability to detect aircraft movement (non-afterburning aircraft from space using passive detection). At the resolution of 35 m, most aircraft will still be sub-pixel in size. This means that the thermal contrast may not be visible in the natural variation of the background radiance or clutter. The two near-simultaneous images are co-registered and subtracted from each other to reduce this clutter. The resultant “frame-differenced” image removes the background features.

Measurements are made to determine the detectable limits for a variety of backgrounds (ocean, urban, rural). The data provide missile designers information necessary to develop effective detection/tracking algorithms. A secondary objective of the MWIR experiment is to collect earth background data as a function of seasonal variation.¹⁸⁰¹⁾

Lasercom (Laser Communication Experiment), developed by Astro-Terra, Inc.. The prime objectives are to demonstrate high data rate laser communications between a satellite and other platforms, and to establish the practicality and benefits of free-space laser communications. Secondary objectives are to downlink stored data from the MWIR instrument at data rates between 50 and 100 Mbit/s and to demonstrate data rates in a repeater mode between 270 - 1000 Mbit/s.

ACCESS (All Composite Experiment Spacecraft Structure). The objective is to demonstrate the performance of composite spacecraft, and show the advantages relative to conventional designs.

SAMMES (Space Active Modular Materials Experiment System), developed by Physical Sciences Inc. The objectives are to: a) demonstrate the utility of on-board monitoring of spacecraft subsystem performance, including the effects of contamination and the ambient environment; b) to obtain environmental degradation data for selected spacecraft materials and components in lower MEO orbit; c) to improve the quantitative knowledge of the energetic radiation environment in lower MEO orbit. SAMMES is designed to provide long-term, time-variant engineering performance data on materials exposed on the exterior of spacecraft and to quantify the phenomena of contamination deposition and effects.

VISS (Vibration, Isolation, Suppression and Steering System). VISS is an AFRL instrument, a self-contained precision vibration control device designed to provide an ultra-quiet environment for sensitive optical sensors, laser transmitters, and other detection and measurement devices. VISS is designed to isolate a precision payload from spaceborne disturbances using passive isolation in combination with voice coil actuators. VISS is a platform which is mounted to a satellite bus via six actuators arranged in a hexapod (Stuart platform) configuration. In the low-frequency range, the passive design is supplemented by a voice-coil-based system mounted in parallel to the D-strut. This portion is actively controlled to

¹⁸⁰¹⁾ S. J. Cawley, S. Murphy, A. Willig, P. S. Godfree, “The Space Technology Research Vehicle 2 Medium Wave Infrared Imager,” Proceedings of the 3rd International Symposium of IAA, Berlin, April 2-6, 2001

provide vibration isolation (in all six degrees of freedom) from the satellite to the payload (optics, etc.), suppression of vibration generated within the payload (cryocooler, etc.), and steering about any or all of the three rotational axes. The objective is to achieve the following goals: >20 dB vibration isolation, >20 dB vibration suppression, $\pm 0.3^\circ$ steering of the payload at a rate of 2 Hz. The payload for VISS in the STRV-2 configuration is the DERA-built MWIR telescope. Accelerometer data is recorded to determine the system performance.¹⁸⁰²⁾

ETB (Engineering Test Bed). This includes the MDIM (Meteoroid and Debris Impact Monitor) and the Meteoroid Impact Sensor of BMDO. ETB enables demonstrating the durability of advanced micro-electronic components and COTS (Commercial Off-The Shelf) devices in the space environment. ETB provides system designers with an opportunity to test device designs proposed for incorporation in future space systems.

MDIM (Meteoroid and Debris Impact Monitor) of NASA/LaRC (an element of the SEE program). The objective is to monitor populations of small-mass particles as a function of altitude. The MDIM experiment is of OMDC (Orbiting Meteoroid & Debris Counting) heritage flown on the Clementine S/C. MDIM utilizes 48 MOS detectors which are mounted on the exterior of the STRV2 spacecraft. When space debris or meteoroids impact the detector, the sensor location and time of impact is stored and down linked for data analysis. From this information, space debris flux and directionality can be assessed.¹⁸⁰³⁾

M.29.2 CEASE (Compact Environmental Anomaly Sensor Experiment)

CEASE, sponsored by AFRL, Hanscom Air Force Base, Bedford, MA, is an environmental scanner, providing the S/C with essential knowledge about the surrounding space. CEASE uses this flight to prove its near spacecraft environmental assessment capabilities. The overall objectives are to develop and demonstrate on-orbit, autonomous, compact, light weight, low-power instrumentation to monitor the environment around a spacecraft, and to provide alerts whenever the environment is likely to cause any of the following anomalies: surface charging, deep dielectric charging, single event upsets (SEU's), or radiation dose effects.

The instrument also provides on request detailed data on particle fluxes incident on the spacecraft over the 72 hours prior to the request. This feature allows the S/C operator, once an anomaly has occurred, to have sufficient data to analyze and understand the cause of the anomaly. CEASE's output can be used to distinguish between natural effects and those caused by other (possibly hostile) actions. By on-board analysis of its measured space-environment data using decision making algorithms in its microprocessor, CEASE provides alerts/warnings in terms of a series of ascending order flags, indicating the likelihood and severity of the forthcoming anomalies.¹⁸⁰⁴⁾

The instrument has a size of 10 cm x 10 cm x 8.2 cm, a mass of 1 kg, and power consumption of <1.5 W. An RS-422 or 1553B interface is used. The instrument is flown on the following missions: TSX-5, STRV-1c, and DSP.

Part N University/Student-Developed Satellites & Payloads

During the 1990s, satellite and payload development projects have become the program of choice for challenging (multi-year) training courses in quite a few engineering departments at universities throughout the world. The intent is always to enrich the student training program, to stimulate interest in a problem-solving multi-disciplinary technical environment, to be imaginative and resourceful, and to take some risks – with ample and essential help from mentors and partners (industry, institutional, or otherwise). Cooperation on many levels and active participation/publication within the international space science community are important ingredients in the overall objectives of research and development. In some instances, project-sharing among engineering departments of several universities is being practiced in order to handle the demanding and complex project goals in a certain time frame. In general, a good amount of enthusiasm and lots of volunteer work by all parties involved are needed to bring such low-cost program activities to maturity – an invaluable amount of professionalism is gained for all students in such programs. Some of the student-involved projects are presented here.

One of the biggest problems of small satellite building is to get a launch opportunity as a secondary payload with some primary payload. Many things have to be considered for such a piggyback flight, including the orbit and the price tag.

Note: The UoSAT program of SSTL [Surrey Satellite Technology Ltd (University of Surrey, UK)] with its many microsatellite missions is included in Part D under D.40.

The documentation of UNP (University Nanosatellite Program), sponsored by DoD (AFRL, DARPA), NASA and US industry, and consisting of ten university teams, could not be completed due to a lack of information. I managed a draft description of about 15 pages. But in the constellation of military-sponsored programs, my review and information requests were generally simply ignored by AFRL contacts as well as by most university contacts. - The UNP initiative is only one aspect of AFRL's TechSat 21 (Technology Satellite of the 21st Century) program which was started in 1998. The overall idea is to explore distributed mission concepts of clustered micro- and nanosatellite constellations, able to cooperate and to share resources and functions (processing, communications, payload, and/or observation and mission functions) with each other, in order to perform the functions of a larger single satellite. In the time frame Dec. 1998 to spring 1999, UNP (University Nanosatellite Program) selected 10 universities to participate in the development of university-class nanosatellites. In this concept, AFRL is providing the launches (Shuttle) for the nanosatellite constellations. NASA/GSFC is providing advanced crosslink communications and navigation hardware along with flight algorithms to demonstrate formation flying. Numerous industry partners are also supporting the universities with hardware, design expertise, and test facilities.

UNP includes the following projects (launches are projected for 2002):

- 1) ION-F (Ionospheric Observation Nanosatellite-Formation). A three-satellite mission consisting of: USUSat of Utah State University (USU), Logan, UT; DawgStar of the University of Washington (UW), Seattle WA; and HokieSat of Virginia Polytechnic Institute and State University (VT), Blacksburg, VA.
- 2) 3CSat (Three Corner Satellite). A three-satellite mission of Arizona State University (ASU), Tempe, AZ; University of Colorado (CU), Boulder, CO; and New Mexico State University (NMSU), Las Cruces, NM.
- 3) Emerald (Electromagnetic Radiation and Lightning Detection). A two-satellite constellation of Stanford University, Stanford, CA, and Santa Clara University, Santa Clara, CA.
- 4) CPM (Constellation Pathfinder Mission). Boston University (BU), Boston, MA.
- 5) Solar Blade Heliogyro Nanosatellite. Carnegie Mellon University (CMU), Pittsburgh, PA

N.1 ASUSat-1 (Arizona State University Satellite 1)

ASUSat-1 is a student-designed, built, and operated nanosatellite mission of ASU at Tempe, AZ, sponsored by industry and government. The objectives call for an Earth imaging and technology demonstration mission, as well as an audio transponder service for the amateur radio community. The ASUSat project started in 1993, went through several different launch opportunity versions and configurations, and a long waiting period before the satellite lifted from the ground. A launch took place on Jan. 27, 2000 (UTC, as a secondary payload to JAWSAT, OPAL, FalconSat and OSCE) on a OSC Minotaur vehicle from VAFB, CA. ASUSat-1 was the first S/C deployed from JAWSAT.

The S/C design employs a composite 14-sided structure (almost a cylinder with 25 cm in height and 32 cm in diameter), capped by two composite bulkheads (one fixed, the other removable). The solar cells (GaAs) are body-mounted to the drum-shaped outer surface and to the top bulkhead (70%). ASUSat-1 is an Earth-pointing, three-axis stabilized S/C, using a deployable gravity-gradient boom (2 m) with a small tip mass (135 grams). Damping is provided by a new **fluid-damper** design, referred to as the “ball-within-a-ball concept.” The inner ball has three substantially different inertias, causing it to align itself always with the gravity and velocity vectors. The movement of this ball within the fluid dissipates sufficient energy to damp the S/C oscillations within a reasonable amount of time. A small (backup) torque coil is also integrated into the S/C, capable to reposition the satellite in the event of an uncontrollable flip-over. Attitude information is provided by clusters of sun- and Earth sensors. For this purpose, sixty tiny sensors are mounted into the exterior S/C surface. Each sensor cluster houses three VIS sensors for sun radiation detection and one IR sensor for Earth radiation detection. Periodic readings from these sensor clusters and their known positions provide an attitude determination with an accuracy of about $\pm 10^\circ$ for each axis. A GPS receiver (Trimble Navigation) provides position and velocity measurements. S/C mass = 5.9 kg, solar power = 8-14 W [a 6-cell Sanyo NiCd battery pack (5 Ah) is used for eclipse operations], passive thermal system. The OBC is built around the Intel 80C188EC embedded processor. 1805) 1806) 1807) 1808)

Communications: 5 W transmitters/receivers. Transmission in digital mode for TT&C services, in analog mode for all AMSAT services. Use of HDLC frame protocol (packet) at 9.6 kbaud with GMSK (Gaussian Minimum Shift Keying) modulation for all services.

- TT&C services: Bi-directional RF links between S/C and ground station at ASU. The on board transmitter uses direct frequency modulation of a 436.5 MHz carrier using the modem's output to produce narrow band frequency modulation (NBFM).
- AMSAT services: The uplink frequency for voice communication is 145.990 MHz. The downlink frequency is 436.7 MHz.

Orbit: Circular sun-synchronous (terminator) orbit, altitude = 750 km, inclination = 100° , period = 99 minutes.

Status: After a successful launch, ASUSat-1 telemetry was sporadically received at various stations around the world, in particular by amateur radio ground stations. The first contact confirmed that the S/C had been successfully deployed and was functioning in orbit. During initial passes, the ASUSat students successfully commanded and controlled the satellite. Initial systems checkout confirmed that the communications, commands, power regulation, data acquisition, and structures/deployment subsystems were performing as expected. The last report received from ASUSat1 was by the SUNSAT team (Stellenbosch University,

1808) <http://nasa.asu.edu/asusat/>

South Africa) at fourteen hours into the mission. This reception included a telemetry frame that confirmed that the satellite did indeed have a critical problem in the power system. Unfortunately, this problem prevented the solar arrays from supplying power. Predicted lifetime of the satellite on battery power alone was estimated to be fifteen hours.

With only two telemetry frames available for analysis it was not possible to draw any firm conclusions. Even with such a short mission, the ASUSat team has gathered an immense amount of experience and insight into the building, launching and operation of a satellite.

Sensor complement:

ASUSat Imager. The instrument package consists of two Dycam modular cameras. Each camera has its own electronics board (processor and 1 MByte of memory), taking snapshots on command. They are also able to provide compression and storage services. The cameras feature a 2-D CCD detector array (496 x 365), providing a resolution of about 0.5 km from a 550 km orbital altitude (FOV=18°). Camera-1 uses a red pass filter and operates in the spectral range of 600 - 800 nm (VNIR), providing color imagery. Camera-2 uses a short pass filter in the spectral range of 420 - 550 nm (VIS), providing gray-scale imagery. The two cameras are daisy-chained inside a single anodized alumina housing (about 5 cm x 6.5 cm x 16 cm) with a total mass of about 0.5 kg. Imagery applications are in vegetation indexing, coastal mapping, water-body penetration, etc.

ASUSat technology demonstrations include: the mostly composite satellite structure, the student-designed array of attitude determination sensors, the Trimble GPS unit, the Maxon transmitter, the gravity gradient deployment mechanism, gravity gradient fluid damper, satellite deployer, and the student-designed CPU and power boards.

N.2 BREM-SAT 1

BREM-SAT 1 is a microsatellite built by the German University of Bremen's Center of Applied Space Technology and Microgravity (ZARM) in cooperation of OHB System of Bremen under the sponsorship of the German Space Agency (DARA). The satellite was deployed from a GAS (Get Away Specials) container on Shuttle flight STS-60 (Feb. 3-11, 1994). Deployment occurred on Feb. 9, 1994 with a standard door assembly and a modified GAS Carrier Ejection System. The S/C had a 12-sided cylindrical structure with a diameter of 48 cm and a height of 52 cm, total mass of 63 kg. The S/C was spin-stabilized with an average spin of 1 rpm (use of magnetic torquers and a momentum wheel for stabilization), attitude measurement with a star sensor, sun sensor, and magnetometer. The exterior was covered with solar cells, average power = 25-40 W. Two battery sets provided energy during the nighttime portion of the orbit. OBC: T-800 processor with 1 MByte RAM and 512 kByte EEPROM.

The scientific mission objectives were to measure heat conductivity, obtain residual acceleration forces, estimate the in-orbit on-board microgravity quality, investigate the density distribution and dynamics of micrometeorites and dust particles in low-Earth orbit, map atomic oxygen, measure the exchange of momentum and energy between the molecular flow and the rotating satellite, and measure pressure and temperature during satellite re-entry. 1809) 1810) 1811) 1812)

S/C communication: VHF communication in uplink (137 MHz) and downlink (145 MHz), with data rates of 1.2 kbit/s in the uplink and 9.6 kbit/s in the downlink. Modulation: bi-

phase modulation in the downlink and FM/FSK in the uplink. The satellite's four antennas are omnidirectional. Downlink power of 2 W, uplink power of 5 W.

BREM-SAT 1 was operated by the ZARM tracking station (4-6 passes per day - total of 1114 contact periods) for over a year. It reentered the atmosphere on Feb. 12, 1995. In addition, there was a backup station at Iowa State University and several mobile stations for reentry data reception.

Orbit: The initial orbit was that of STS-60, altitude = 360 km, inclination = 57°.

Sensor complement:

The BREM-SAT 1 mission consisted of three phases. A total of six experiments were conducted during these phases.

- Microgravity phase. Defines the orbital phase on-board the Shuttle prior to BREM-SAT 1 deployment.
- Orbital phase. Defines the free-flying phase of BREM-SAT 1.
- Reentry phase.

Experiment-1: Measurement of heat conduction of light-viscous fluid mixtures.

Experiment-2: Acceleration measurements (absolute and rest acceleration) during reentry. A set of commercially available one-axis analog micro-g accelerometers of type Q-Flex QA-1400 (Sundstrand) were tetrahedron-mounted and arranged normal to each other in a way as to measure accelerations in three axis (the major S/C axis and accelerometer axis were intentionally displaced for reasons of redundancy).

Experiment-3: Measurement of cosmic dust/micro-meteoroid distributions. The instrument has the name of **MDC** (Munich Dust Counter) and is a cooperation of the Institute of Space Technology at the Technical University of Munich and ZARM of the University of Bremen. Objective: Measurement of impact charges and deduction of particle mass, velocity, and approximate flight direction. MDC consists of an impact box with a target area and two side-mounted charge collectors, biased by positive and negative high voltages, generating an electric field. This electric field separates the impact plasma into positively and negatively charged components. The negatively charged components of the plasma (electrons, negative ions) are accelerated toward the positively biased collector, while the positive ions are accelerated toward the negatively biased collector. Charge-sensitive amplifiers convert the input charge into an output voltage.

MDC was mounted on the outer cylinder of the S/C, offering a FOV of $\pm 76^\circ$ for particle collection, with the spin axis oriented toward the north pole of the ecliptic. This configuration provided measurements in the ecliptic plane. ¹⁸¹³⁾

Experiment-4: Aerodynamic reentry measurements - pressure densities. The measurement of normal and tangential pressures was obtained with strain gauges.

Experiment-5: Aerodynamic reentry measurements - Patterson pressure, heat flow, pressure and temperature of the satellite surface. Use of 14 Ni-Cr-Ni thermo-elements.

Experiment-6: Measurement of atomic oxygen. ¹⁸¹⁴⁾ **OXFLUX** (Oxygen Flux, an ESA-provided instrument). The OXFLUX detector consists of two coated QCM (Quartz Crystal Micro-balances) with the associated electronics and interfaces. ¹⁸¹⁵⁾ OXFLUX is located underneath MDC in the plane of the velocity vector. The instrument is connected to the

¹⁸¹⁴⁾ H. P. Willemsen, M. v. Eesbeek, "OXFLUX, Atomic Oxygen Sensor on BREM-SAT 1," Executive summary of the Final Report of Contract ESA No 9037/90/NL/JG

¹⁸¹⁵⁾ Note: QCM measurements are based on the principle that the resonance frequency of a crystal controlled oscillator varies inversely proportional to the mass change of the crystal. Hence, a QCM may be used to measure the erosion of a pre-deposited coating under exposure to an atomic oxygen environment.

OBC by a 5 V RS-232 serial interface (data rate = 9.6 kbaud). The two crystal oscillators transmit their frequency signals of approx. 10 MHz to the two 16-bit counters. The frequency is measured every second. The temperatures at each crystal are measured continuously with a resolution of 0.5° C. The atomic oxygen flux can enter the detector cavity when the angle between the ram-direction and cavity opening is between $\pm 16.7^\circ$ (view factor). OX-FLUX measurements were obtained throughout the free-flying period of BREM-SAT 1.

Parameter	Value	Parameter	Value
Crystal frequency	approx. 10 MHz	Total fluence measured	$2.5 \cdot 10^{20}$ O-atoms
Measuring range	approx. 65 kHz	Crystal temperature	$\pm 50^\circ$ C
Resolution	1 Hz	Resolution	0.5° C
Instrument mass	0.557 kg	Instrument size (mm)	110 x 110 x 60

Table 522: Specification of the OXFLUX detector

N.3 CHIPSat (CHIPS Satellite)

CHIPSat is a mission of UCB (University of California at Berkeley, PI: M. Hurwitz), supported by NASA’s UNEX (University-class Explorer) program, with the objective to obtain spectral sky maps of the scientifically critical EUV (Extreme Ultraviolet) band between 90-260 Å. The CHIPS full-sky survey helps to determine the electron temperature, ionization conditions, and cooling mechanisms of the so-called “local interstellar bubble,” a cloud of hot gas surrounding our solar system that extends about 300 light-years from the sun.¹⁸¹⁶⁾

Background: The CHIPS (Cosmic Hot Interstellar Plasma Spectrometer) project was selected by UNEX in 1998. The CHIPS mission (i.e. the instrument) was initially proposed as a secondary payload aboard a FAISat communications S/C. This approach was dropped in favor of a small spacecraft with a single instrument payload. Thus the CHIPS project mutated to CHIPSat.

Figure 338: Illustration of the CHIPSat spacecraft

¹⁸¹⁶⁾W. Marchant, E. Riddle Taylor, “Status of CHIPS: A NASA University Explorer Astronomy Mission,” Proceedings of the 14th AIAA/USU Conference on Small Satellites, Logan, UT, Aug. 21-24, 2000, SSC00-V-6

CHIPSat¹⁸¹⁷⁾ is a dedicated microsatellite built by SpaceDev, Inc. for UCB/SSL (Space Sciences Laboratory). CHIPSat is a three-axis stabilized S/C using 4 momentum wheels, three torque coils, two sun sensors, magnetometer, a moon sensor, and rate sensors to provide an attitude pointing accuracy of about $\pm 2^\circ$. The S/C is nominally sun-pointing with complete freedom to yaw about the solar array normal vector allowing the CHIPS instrument to obtain a full-sky survey within six months, while avoiding pointing the instrument at the sun, Earth, moon and the orbital Ram direction. The design permits access to all points on the celestial sphere within the one year mission lifetime. The S/C structure employs a milled aluminum transition adapter and aluminum honeycomb panels with facesheets for structural integrity. Power (106 W EOL) is provided by body-mounted solar arrays using dual-junction GaAs/InP/Ge solar cells, NiCd batteries are used during solar eclipses. In addition, small keep-alive arrays are positioned on the other five sides of the S/C providing enough power to run critical subsystems regardless of the S/C attitude. A passive thermal system is used for CHIPSat. The C&DH (Communications and Data Handling) subsystem employs a single-board computer (Motorola Power PC 750 CPU, memory, and I/O for distributed processors). The S/C mass is 85 kg, the design life is 18 months (one year mission).

The RF communications are in S-band. The data rates are: 4 kbit/s in the uplink, the downlink supports data rates of up to 1 Mbit/s. Modulation: the uplink is PM carrier, suppressed carrier BPSK on a subcarrier; the downlink uses suppressed carrier BPSK. The TCP/IP and UDP/IP (User Datagram Protocol/Internet Protocol) protocol suite is used to communicate all data between the S/C and the ground user directly. Data is received, archived, and monitored at MCC (Mission Control Center) at SpaceDev and then sent to SOC (Science Operation Center) at UCB/SSL.¹⁸¹⁸⁾

The UDP/IP is protocol is selected for real-time monitoring and real-time commanding (it de-couples both directions) and presents much less overhead. The setup permits the reception of engineering and status packets (telemetry) in case the uplink isn't working. Conversely, the setup permits also to command "into the blind" by uplinking UDP packets in case the telemetry isn't working.

Note: The UDP service of the TCP/IP protocol permits to send discrete packets of information called "datagrams" that aren't guaranteed to get there and may arrive out of order depending upon their routing through the IP system. A two-way communication isn't needed in this setup because the data are broadcast. So, if a guarantee is needed that at least some packets get through, even if one direction of the communication link fails, then UDP may be used. - TCP deals with making sure that all the packets arrive and are in the correct order. TCP implies a two-way connection and a higher level of communications overhead to assure that all the packets arrive and are in the correct order.

A launch of CHIPSat is planned as a secondary payload to a NAVSTAR GPS satellite on a Delta-2 rocket in April 2002.

Orbit: circular orbit, altitude of 190 km x 1200 km (initial) and 600 km (final), inclination = 38° . - Note: The 190 km x 1200 km orbit is the initial orbit in which the Delta-2 2nd stage, with CHIPSat still attached, is left when the 3rd stage separates. But then, the 2nd stage is fired twice again, first to lower the apogee, then about 45 minutes later, to raise the perigee. Only then does CHIPSat separate from the 2nd stage.

Sensor complement:¹⁸¹⁹⁾

CHIPS (Cosmic Hot Interstellar Plasma Spectrometer) is a low-cost instrument with high sensitivity and spectral resolution in the spectral band near 170 Å, built at UCB/SSL. The science objectives are to carry out EUV spectroscopy to determine how the million degree

¹⁸¹⁷⁾ <http://chips.ssl.berkeley.edu/chips.html>

¹⁸¹⁸⁾ Courtesy of Will Marchant of UCB/SSL

¹⁸¹⁹⁾ <http://chips.ssl.berkeley.edu/instrument.html>

gas-cloud surrounding our solar system, cools. - The CHIPS instrument uses an array of grazing-incidence optics to achieve a peak resolving power of $f/150$ for diffuse emission in a field of view (FOV) of $5^\circ \times 26.7^\circ$ (the gratings are aligned in one dimension on the sky). Light enters the spectrograph through the array of six entrance slits (channels). The entrance apertures are narrow slits, each covered by a rotating mechanism with closed, narrow, and wide settings to protect the interior from contamination during launch. The gratings disperse and focus the diffuse extreme ultraviolet radiation onto a single detector through a filter assembly. The detector is a planar, photon-counting MCP (Micro Channel Plate) with a crossed delay line anode. In-band photon locations are determined from the anode, which converts the light into analog electronic pulses.

Note: The use of variable line-spaced gratings in instruments is of EUVE and ORFEUS (Orbiting Retrievable Far and Extreme Ultraviolet Spectrograph) instrument heritage. The ORFEUS payload flew twice with the ASTRO-SPAS missions on STS-51 (Sept. 12-22, 1993) and on STS-80 (Nov. 19 - Dec. 7, 1996). The NASA satellite EUVE (Extreme Ultraviolet Explorer) was launched June 7, 1992.

Parameter	Value	Parameter	Value
Entrance slits	0.027 cm x 6 cm	Nr. of spectral channels	6
Grating graze angle	14°	FOV (Field of View)	5° x 26.7°
Groove density	1625-1900 mm ⁻¹	Bandpass	90 - 260 Å
Grating curvature	148 cm	Spectral resolution	45-155 ($\lambda/\Delta\lambda$)
Grating dimensions	8 cm x 6 cm x 1.2 cm	A _{eff} x Ω	(1.3-8.8) x 10 ⁻⁴ sr
Optical coatings	Rhodium	Payload mass	<25 kg (spectrograph) 10 kg (electronics box)
Detector area	5.0 cm x 6.0 cm	Payload power	21.2 W (average) 30 W (peak)
Photocathode	NaBr	Attitude control	±2°
EUV filters	720 Å Polyimide; 500 Å Boron, 1000 Å Al; 300 Å C	Data rate	>16 MByte/24 hours

Table 523: CHIPS instrument performance parameters

Figure 339: Schematic concept of CHIPS

N.4 CX-I (Citizen Explorer-I)

CX-I is a microsatellite mission of the Colorado Space Grant Consortium (CSGC), designed and built by students at the University of Colorado in Boulder, CO (project partners/sponsors are NASA, and industry such as Ball Aerospace, Boeing, Lockheed Martin, Analytical Spectral Devices Inc., CIRES, etc.).^{1820) 1821)} The spacecraft objectives are to advance radio communications and to determine atmospheric ozone levels by measuring direct, reflected and transmitted sunlight at various wavelengths. The following overall mission goals are pursued:

- The educational objectives are to: a) directly downlink science and S/C data to participating K-12 schools worldwide, b) enable receipt of data at schools with low-cost ground stations (<\$800), c) provide the means for students to share data over the internet, d) provide a means for K-12 students to take an active part in data collecting and analysis with student-built ground instruments.
- The technology objectives are to: a) demonstrate S/C autonomy and the ability to evolve and migrate autonomy, b) demonstrate the “beacon mode” communications concept.
- The science objectives are to: a) provide global total ozone observations, b) provide a network of UV monitoring sites, c) provide observations of aerosol optical depth to assist in modeling surface level UV flux.

Figure 340: Illustration of the CX-I spacecraft

The S/C employs an aluminum plate construction as a basic platform for all instruments and components. CX-I uses a gravity-gradient-boom design (passive stabilization with a 4 m long deployable boom and a tip mass of 2 kg, pointing in the zenith direction) to keep the satellite facing the Earth in the same direction at all times. Additional attitude control is provided by three orthogonal magnetic coils. The attitude is sensed by two 2-axis magnetometers and a fine sun sensor. In addition, a set of six coarse sun sensors is mounted on all sides of the satellite providing full spatial coverage. S/C power is provided by four sur-

¹⁸²⁰⁾E. Hansen, “Advancing Radio Communications technology with the Citizen Explorer Mission,” Presented at the AMSAT Conference, New Orleans, Oct. 1998

¹⁸²¹⁾<http://citizen-explorer.colorado.edu/index.html>

face-mounted solar panels; the panels are comprised of triple-junction GaAs cells with an efficiency of 23%. A peak-power tracking system is used to maximize the solar panel efficiency. A NiCd battery stack (1.5 Ah capacity) is employed for energy during orbital eclipse phases. The C&DH (Command and Data Handling) subsystem is based on a standard PC/104 architecture. C&DH has also the capability to store on-board data. The microsatellite has a mass of 45 kg, power = 40 W at 30 V (average power of 27 W), design life = 1 year.

A launch of CX-I is planned for early 2003.

Communications: CX-I is equipped with two transmitters, a receiver, and a modulator/demodulator. AMSAT communication standards are used. Data are transmitted in UHF-band at a frequency of 436.759 MHz in downlink at a data rate of 9.6 kbit/s. Mission operations are conducted by students at MOCC (Mission Operations Control Center) of the University of Colorado, Boulder.

Orbit (requested/desired): Sun-synchronous circular orbit, altitude = 705 km, inclination = 98.7° period = 99 minutes, descending nodal crossing time of 10:15 AM.

N.4.1 On-board Sensor Complement

The science sensor complement consists of two flight instruments and two hand-held ground instruments. The flight instruments include a spectrophotometer (informally termed “speck”) that measures UV radiation, and a photometer that measures visible reflectance. The ground instruments include a UV detector and an aerosol meter. Data from the four instruments complement each other to provide information about ozone levels in the stratosphere.

Figure 341: Schematic illustration of radiation path optics in the Speck instrument

SPECK (Spectrophotometer). The objective is to measure atmospheric reflected radiation in the UV spectral range of 280-350 nm. The instrument consists of an aperture with a FOV of 6.9° , a broadband visible light filter, two lenses, a light trap, a grating, a mirror, and a 35-element (pixel) detector. Radiation entering the aperture is passed through a broadband filter which is opaque for visible light. The beam is then collimated by a lens system and dispersed by a grating into 16 bands (or channels), reflected off a UV-coated flat mirror, and

detected by a 35-pixel linear diode array. Speck provides observations in 5 of the 6 channels used by TOMS. The channels between 280-340 nm are used for total column ozone monitoring; the 340-350 nm channels measure the albedo. The on-board data is quantized to 16 bits. Instrument mass = 1 kg, power = 2 W, data rate = 2.56 kbit/s.

Photometer. The objective is to measure visible atmospheric reflectance around 550 nm. The instrument consists of an aperture, lens, filter, and a photodiode. The light passes through a bandpass filter which allows only the visible light through and is detected with a photodiode. The photometer measures visible (yellow-green) light reflected off the Earth's atmosphere or surface. The data of the photometer are used to identify cloud tops and ice/snow versus dry land, ocean, and vegetation reflectance.

N.4.2 Ground Instruments

Ground truth data are collected by a network of participating student observers. There are two hand-held instruments used by the CX-I project. The first is an aerosol detector that can either be purchased from CSGC (Colorado Space Grant College) or built by a website instruction set. The second instrument is an UV detector. The UV detector must be purchased directly from Sunsensor, Inc. The information produced by the two hand-held instruments is used, in conjunction with the satellite data, to create global maps of ozone coverage.

Sunsensor UV-Detector. This is a bandpass photometer using a UV-sensitive photodiode detector. A band-pass filter is integrated onto the surface of the detector so that only UV light (in the 290-314 nm range) contributes to the signal.

Aerosol Detector. The objective is to measure the aerosol content in the atmosphere by measuring solar intensity (visible light range). The aerosol detector measures the intensity of green light, which is used to determine the number of aerosol particles in the atmosphere.

N.4.3 Technology Demonstrations

Beacon mode operations. A new spacecraft operations/communications concept, called the "beacon mode," is being demonstrated. The technique provides a way to operate a spacecraft and monitor its health without extensive day-to-day attention by ground controllers. Instead, the S/C uses an onboard software package, capable of monitoring onboard health functions and making autonomous decisions and/or alerting ground control. The objectives of CX-I beacon mode are to demonstrate the following concepts:

- A summarization of S/C status with a limited number of messages to indicate its need for contact with the ground.
- The ability and interest of amateurs and K-12 students to participate in space missions and to extend the traditional MOCC functions. The functions include:
 - Monitoring and evaluation of S/C health and status by amateurs and K-12 students
 - The receipt of these messages by participating amateurs and K-12 students and relay of these messages to the MOCC.
 - The relay of telemetry data received at a participating school to the MOCC.
- A significant reduction in time that a MOCC needs to be staffed
- The applicability of this concept to other missions (of NASA and the commercial world).

The beacon mode experiment was designed by a team at the University of Colorado, with help from experts at JPL.

On-board autonomy and autonomy migration. These technologies consist of:

- An intelligent onboard system capable of monitoring health and status and alerting other onboard software.

- Onboard scripts to determine if an alarm is valid based on context checks
- Actions generated by onboard scripts including the selection of the appropriate beacon message for downlink, reconfiguring of the S/C, and/or safing the S/C.
- Data summaries to enable ground users to diagnose the situation.

These key technologies are part of the CX-I design. Several mission simulations are scheduled where a select set of schools and amateur sites are participating in mission simulations to train users and to verify all functions/components in an end-to-end environment.

On-board autonomy is accomplished through the use of several software tools/techniques: a) SCL (Systems Control Language) performs onboard control and monitoring; b) Scripts, written in SCL by students, accomplish the data summaries used in the Beacon Mode; c) Rules and constraints, written in SCL by students, provide on-board autonomy - or the ability to detect situations and to automatically respond to these situations.

PPP (Point-to-Point Protocol). The objective is the use of off-the-shelf computer networking protocols to communicate with the S/C over the RF link. The TCP/IP protocol running of PPP is being used for CX-I, i.e., CX-I piggybacks the TCP/IP PPP packets onto standard amateur radio packets to change the asynchronous nature of PPP packets to the synchronous nature of packet radio.

N.4.4 Data Distribution Scheme and User Involvement

CX-I data and data products are communicated/distributed via the internet with all participating parties (schools, citizens, and other users). MOCC maintains a website of satellite data, processed data, and composite maps of the atmosphere built up from user contributions, ground measurements, etc. Users at participating schools are able to share data with other users and to generate regional and global maps of the atmosphere and of UV radiation.

N.5 FS-1 (FalconSat-1)

FalconSat-1 is the first of a series of small satellites, designed, built and operated by cadets at the US Air Force Academy, Colorado Springs, CO. The overall science objective of the mission is to determine the effects of S/C charging in the LEO environment. Other objectives are to demonstrate/validate the S/C design and to provide a hands-on experience for all students involved.^{1822) 1823)}

The S/C structure is nearly cubical in shape with dimensions: 46 cm x 46 cm x 42.5 cm. The solar arrays are body-mounted providing 24 W of power, in addition there is a battery with 10 NiCd cells (4.4 Ah). The bus design features a stack assembly into which the subsystems are mounted. The S/C is spin-stabilized at about 10 rpm pointing toward nadir (a minimal pointing of $\pm 25^\circ$ is required in the direction of S/C velocity vector). Attitude is measured by a three-axis magnetometer; a torque rod functions as an actuator, damping is provided by hysteresis rods. The launch vehicle imparts an initial spin on S/C separation. In addition, nylon solar radiation paddles are used to maintain the initial spin rate. The mass of the microsatellite is 50 kg.

A launch of FalconSat-1 took place on Jan. 27, 2000 (UTC) with a converted Minuteman-II missile (Minotaur) from VAFB, CA.. The Minotaur of OSC is a four-stage vehicle with the first and second stages being Minuteman-II stages; the two upper stages come from OSC's Pegasus launcher. FalconSat-1 was part of the JAWSAT multi-payload adapter and

¹⁸²²⁾R. Chari, "Pre-Flight Characteristics of the US Air Force Academy's FalconSat-1," Proceedings of the 13th AIAA/USU Conference on Small Satellites, Aug. 23-26, 1999, Logan UT, SSC99-VII-8

¹⁸²³⁾<http://www.usafa.af.mil/dfas/Research/FalconSat1/falconsat1.htm>

launched with the following satellites: ASUSat-1, OPAL (PicoSat, Artemis, StenSat), OSCE, MASat, and JAWSAT (see N.7).

S/C communications are provided in UHF (downlink) at 400.475 MHz and in VHF (uplink) at 148.030 MHz. The data rate for transmit and receive is 9.6 kbit/s. The signal modulation scheme employs GMSK. - Status: The FalconSat-1 spacecraft failed after about a month in orbit, apparently due to a power failure.

Orbit: Sun-synchronous orbit, altitude = 750 km, inclination = 100°, period = 99 minutes.

Sensor Complement:

CHAWS-LD (Charging Hazards and Wake Studies - Long Duration experiment). The objective is to measure electric charge characteristics of the S/C. Voltage and current sensors, made of sheets of stainless steel (and an electric circuit board stacked together with aluminum and Teflon spacers), are installed on the four sides of the S/C. As FalconSat moves through the space plasma, it creates a wake region behind it, in which primarily electrons accumulate. Hence, the electrically isolated sections of the voltage sensors on the wake side are negatively charged. The current sensors reject electrons and collect ions from the space plasma, providing a current that is correlated to the ambient plasma density. The relative amount of current collected by each sensor provides in addition information about the S/C attitude relative to the plasma flow. Data measurements can be made at 5 or at 10 Hz. A series of measurements is taken over the course of one or more orbits. - One voltage and one current sensor are center-mounted at side of the S/C. The surface of the voltage sensors, exposed to the plasma, is the metalized surface of the circuit board. The exposed surface of the current sensors is an electro-formed stainless steel mesh. The data collected from each sensor are stored in the memory of the flight computer. They can be transmitted to the ground during station passes.

N.6 NanoSat

NanoSat is a low-cost technology demonstration nanosatellite of INTA (Instituto Nacional de Tecnica Aeroespacial), the Spanish Space Agency. INTA partners in the project are the universities and students of: UPM (Universidad Politecnica de Madrid) and CNM (Centro Nacional de Microelectronica' de Barcelona). The overall objective is to get involved and familiarized with all aspects in the development of micro- and nano technology: a) on the spacecraft and instrument level, b) to demonstrate new types of magnetic and solar sensors, c) to space-qualify new ASIC designs and components, d) to allow store-and-forward communications, and e) to obtain hands-on experience with NanoSat operations and to conduct experimentation in the space environment.¹⁸²⁴⁾

The satellite is spin-stabilized. The S/C structure consists of two hemispheres (top and bottom), each one has one hexagonal and six trapezoidal shaped sides. The overall structure approximates roughly a sphere. The satellite has the following subsystems: PDU (Power Distribution Unit), OBDH (On-Board Data Handling), Communications and Experiments. Power (17 W average) is provided by surface-mounted solar cells. NiCd batteries provide 4.8 Ah of energy for eclipse operations. The OBDH provides all S/C control, processing functions and experiment interfacing (based on Motorola's microprocessor MC68332, 4 MB of storage capacity, 8 kB PROM, 512 kB EEPROM, 768 kB of protected RAM). The S/C uses a magnetometer for attitude sensing. The communications subsystem employs omnidirectional antennas. Two digital modems are implemented for experimentation purposes; one uses a single DSP chip, the other is based on an ASIC design. The UHF band (387.1 MHz downlink, 400 MHz uplink, GMSK modulation and Viterbi encoding) is

¹⁸²⁴⁾A. Martinez, I. Arruego, M. T. Alvarez, J. Barbero, et al., "Nanosatellites Technology Demonstration," Proceedings of the 14th Annual AIAA/USU Conference on Small Satellites, Logan, UT, Aug. 21-24, 2000, SSC00-II-2

used for all data communications with the ground. The downlink data rate is 24 kbit/s. The satellite mass is about 13 kg. All ground station access is based on the TDMA protocol using a Slotted Aloha access version.

Figure 342: Illustration of the NanoSat spacecraft

A launch of NanoSat is planned for 2003 on an Ariane-5 vehicle (as an ASAP launch) from Kourou.

Orbit: Sun-synchronous orbit, altitude = 645 km, inclination = 98°, period = 97 minutes.

Sensor complement/experiments:

Solar sensors: Porous silicon-based (PS) photodiodes are used with the objective to: a) test the performance of solar cells based on PS-layer technology, and b) provide a means of sun aspect angle sensing for spin control. Since the output signal of each solar detector is proportional to the cosine angle of incidence of the solar radiation, the S/C spin axis determination is made by using the output from three out of six PS-based solar sensors positioned at known locations of the outer S/C surface. This method permits a nutation angle determination to within 5°.

Magnetometer. The objective is the measurement of the Earth's magnetic field (magnitude and direction). The magnetic field measurements have a resolution of 1 mGauss scalar in the range of ± 0.1 Gauss. The instrument has a total mass of 220 grams (200 g control electronics) and a power consumption of <2W.

N.7 JAWSAT (Joint Airforce Academy / Weber State University Satellite)

The JAWSAT mission is a collaboration between the United States Air Force Academy (USAF) and the Center for Aerospace Technology (CAST) at Weber State University in Ogden, Utah. The JAWSAT project was initially designed (1994) with a pulsed-plasma thruster to train Air Force Academy cadets. In its new dedication (April 1998), JAWSAT is mainly functioning as a multi-payload adapter for the following satellites: ¹⁸²⁵⁾ ¹⁸²⁶⁾ ¹⁸²⁷⁾

- ASUSat-1 (Arizona State University Satellite-1)

¹⁸²⁵⁾ J. L. Smith, D. Richards, M. Wood, G. Sharp, W. Clapp., "The JAWSAT Mission: Final Report and Lessons Learned," Proceedings of the 14th AIAA/USU Conference on Small Satellites, Logan, UT, Aug. 21-24, 2000, SSC00-V-4

¹⁸²⁶⁾ <http://cast.weber.edu/jawsat/jawsat.html>

¹⁸²⁷⁾ <http://www.osss.com/>

- FalconSat of the USAF Academy, Colorado Springs
- OPAL (Orbiting Picosat Automatic Launcher) of Stanford University with the following picosats:
 - PicoSat of the USAF (DARPA), Aerospace Corporation (2)
 - Artemis of Santa Clara University (3)
 - StenSat (1)
- OCSE (Optical Calibration Sphere Experiment) of AFRL
- MASat (Miniature Amateur Radio Satellite)
- JAWSAT of Weber State University

JAWSAT includes two other payloads which remain attached to the S/C structure. These are: PEST (Plasma Experiment Satellite Test), provided by NASA/MSFC, and ACP (Attitude Control Platform) of Weber State. This includes the efforts of several universities, local aerospace companies, the Air Force Academy, the Air Force Research Laboratory, and NASA.

The JAWSAT **MPA** (Multi-Payload Adapter) technology, in a sense “a mass-transport” capability to space, was developed at CAST of Weber State University and built by OSSS (One Stop Satellite Solutions) and of Ogden, UT. The objective is the deployment of a number of small satellites. The design elements/features of MPA are:

- Complete three-axis attitude determination and control
- Lightweight isogrid space frame
- Flight computer with EDAC memory module
- Onboard multi-channel imaging system
- Onboard power system with battery charge regulation

Figure 343: Illustration of the JAWSAT MPA spacecraft model

MPA for JAWSAT consists of six waterjet-cut aluminum isogrid pieces assembled in a “windmill” design, a frame of 71 cm x 71 cm x 76 cm (the isogrid space frame is composed for four vertical panels, a top and a bottom panel that can be arranged in a number of configurations). MPA can be quickly and easily proportioned for multiple applications and payloads. JAWSAT is three-axis stabilized. Since attitude determination and control are fundamental

to this mission, JAWSAT is equipped with several systems for attitude determination and a 3-axis stabilization system. The overall S/C structure has dimensions of: 90 cm x 90 cm x 107 cm, its mass is 230 kg, 80 W of average power are provided from solar panels.

Note: The small satellites of normally cubic shape are also being referred to “cubesats” (a generic name). In the same context the MPA, a platform to integrate multiple payloads, is also referred to as a CubeSat launcher.

The ACP (Attitude Control Platform) of CAST uses tiny reaction wheel canisters (4), and a magnetometer; ACP is used to orient JAWSAT during the deployment of its payloads. ACP may also be used for a free-flying satellite with all the attributes needed to operate a mission. On this testbed spacecraft, a number of attitude sensors are available for comparison and possible integration.

JAWSAT was launched on Jan. 27, 2000 (UTC) with an OSC Minotaur vehicle (a converted surplus Minuteman-2 motor combined with the upper stages of the Pegasus-XL booster) from the commercial California Spaceport at Vandenberg, operated by SSI (Spaceport Systems International).¹⁸²⁸⁾ All satellites were deployed successfully from the JAWSAT mothership.

Orbit: Circular sun-synchronous (terminator) orbit, altitude = 750 km, inclination = 100°, period = 99 minutes.

JAWSAT payload complement:

DPA (Deflection Plate Analyzer). DPA is flown as part of **PEST** (Plasma Experiment Satellite Test), provided by NASA/MSFC, on JAWSAT. The objective of PEST is to study plasma (electrically charged gases), at orbital altitudes. DPA uses an new analysis technique that can measure multiple ion streams and determine the intensity, flow direction, and energy and mass distributions for each stream. The space test requires comparing the DPA with instruments that have been successfully used in space many times.

OCSE (Optical Calibration Sphere Experiment) of AFRL.¹⁸²⁹⁾ OCS is a 3.5 m diameter kapton/aluminum balloon that is designed to orbit the Earth for up to two years. The highly-reflective silver-colored balloon was built by L'Garde, Inc. of Tustin, CA. The overall objective is to further refine the ability to track high-flying satellites. The Air Force uses its SLR (Satellite Laser Ranging) network of ground stations to periodically track OSCE. - The balloon was deployed from a tiny canister shortly after orbit injection and inflated.

N.8 NavGold

NavGold¹⁸³⁰⁾ is a project of the University of Colorado at Colorado Springs (UCCS) involving the design, development, launch, and operation of two nanosatellites. The objectives of NavGold include the establishment of an on-orbit test bed for demonstrating and validating critical nanosatellite technologies that enable formation flying. Some specific objectives are:¹⁸³¹⁾ ¹⁸³²⁾

- To demonstrate autonomous relative-navigation accuracies of < 100 m, with a goal of 10 m accuracy or better

¹⁸²⁸⁾ S. Schoneman, S. J. Buckley, G. Stoller, L. M. Marina, C. B. Morris, “Demonstration of a New Smallsat Launch Vehicle: The Orbital/Suborbital Program (OSP) Space Launch Vehicle Inaugural Mission Results,” Proceedings of the 14th AIAA/USU Conference on Small Satellites, Logan, UT, Aug. 21-24, 2000, SSC00-I-1

¹⁸²⁹⁾ <http://www.lgarde.com/programs/ocse.html>

¹⁸³⁰⁾ The name NavGold is derived from Navigation, emphasizing the relative navigation focus of the project, and Gold, one of the colors of the University of Colorado at Colorado Springs.

¹⁸³¹⁾ D. Sipple, J. Torley, F. Chavez, et al., “NavGold – An On-Orbit Test Bed for Experiments in Formation Flight,” Proceedings of the 13th AIAA/USU Conference on Small Satellites, Aug. 23–26, 1999, Logan UT, SSC99–II–5

¹⁸³²⁾ <http://mae.uccs.edu/fdcl/navgold/home.html>

- To demonstrate autonomous relative-position maneuvering and stationkeeping capability with relative position accuracy equal or better than 100 m
- To demonstrate autonomous relative-attitude maneuvering and stationkeeping capability with a relative attitude accuracy of $< 2^\circ$.
- To provide an educational, multidisciplinary team-building experience.

The S/C structure consists of a hexagonal prism with a diameter of 45 cm and a height of 31 cm. Each of the satellites is three-axis stabilized by an attitude control system. Attitude is sensed by digital sun sensors, a three-axis magnetometer and a horizon sensor (all developed at CU). The accuracy of each sensor is about 0.5° . Four magnetic torque rods and cold gas thrusters are used as actuators. Power of 18 W is provided by surface-mounted GaAs solar arrays. There are NiCd batteries (15 cells) for the eclipse phase of the orbit. Regulated power distribution is provided. A mission life of 3-5 months is expected prior to rapid orbital decay. The S/C mass is about 14 kg.

A Shuttle launch in 2003 is planned using the HES (Hitchhiker Ejection System).

A cold gas thruster system is used as on-board propulsion system, consisting of a propellant tank and six thrusters. The mass of the system is about 1.5 kg. The truster system is used for attitude control as well as for orbit maneuvers.

Orbit: Circular orbit, altitude = 400 km, inclination = 51.6° , period = 92 min.

Navigation, Guidance, and Control (NGC):

NGC is the primary payload package consisting of the attitude sensor suite and the actuator/propulsion elements.

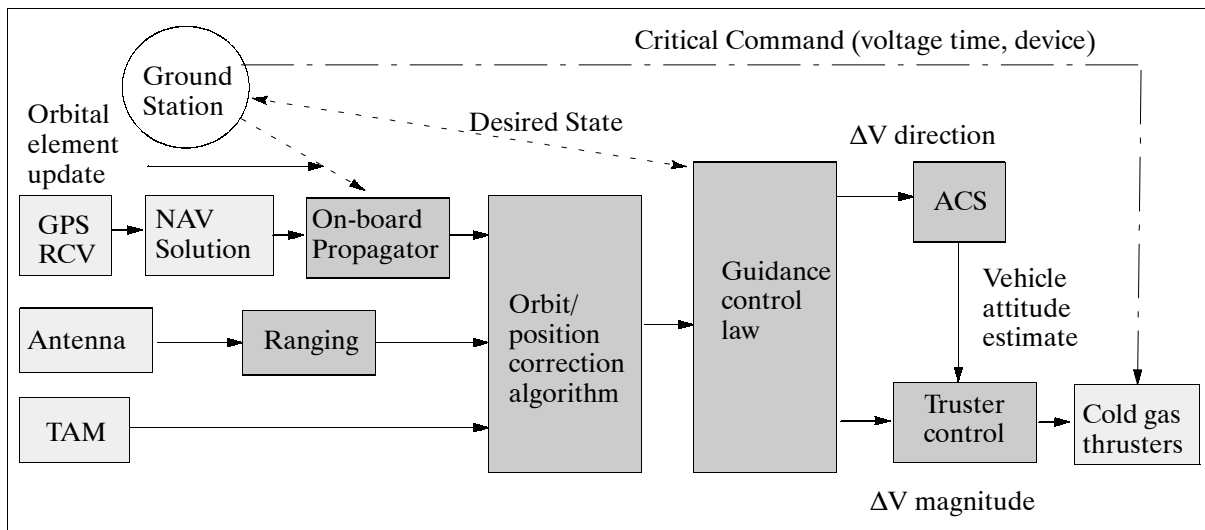

Figure 344: Block diagram of navigation and guidance function

Relative navigation in formation flight: ¹⁸³³⁾

Formation flight involves the use of an active control scheme to maintain the relative states of the formation flying satellites. The leader-follower concept is chosen for the two nanosatellites of NavGold (other possible types of formation flight are: a) same ground track, and b) side by side), representing the simplest configuration of in-orbit-plane formation flight. In this formation, the orbital elements of each S/C are identical except for the true anomaly.

All S/C maneuver experiments are to be performed autonomously. This involves the following classes of maneuvers:

¹⁸³³⁾F. Chavez, D. K. Schmidt, "Formation Flying and Relative Navigation - A Nanosatellite Research Mission," Proceedings of the 23rd Annual AAS Guidance and Control Conference, Feb. 2-6, 2000, Breckenridge, CO, AAS 00-061

- Relative re-positioning. - a) relative phasing maneuver (increase/decrease in relative separation or phase angle), and b) relative attitude maneuver (increase/decrease in relative attitude separation)
- Relative position stationkeeping
- Relative re-orientation
- Relative orientation stationkeeping.

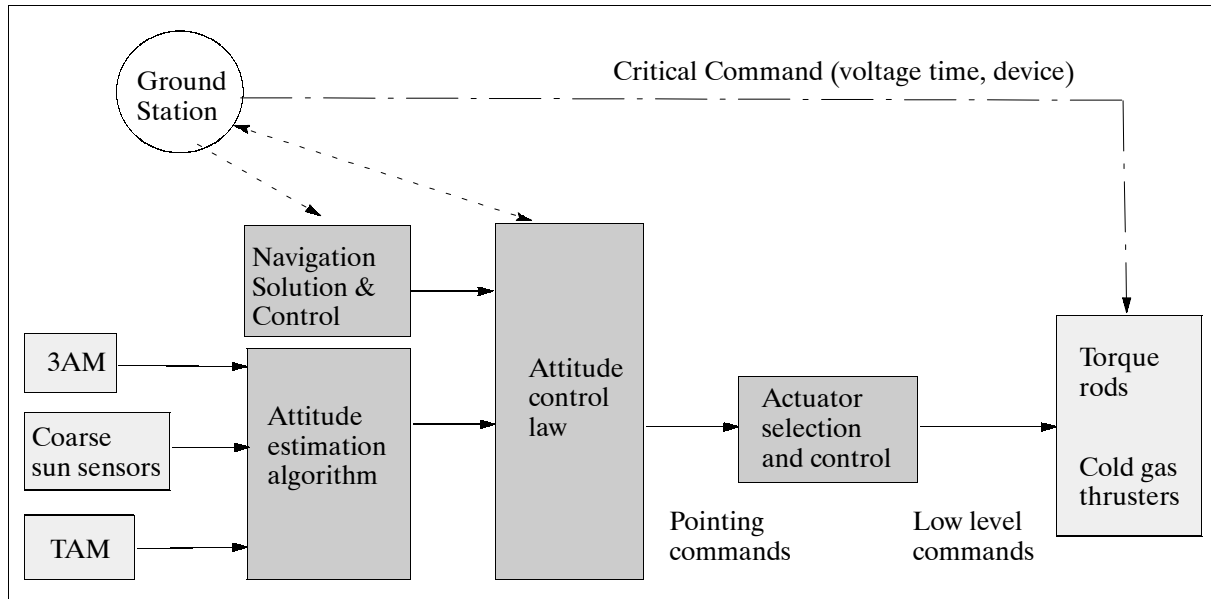

Figure 345: Block diagram of attitude determination and control function

Communications architecture:

- 1) S/C to ground station (TT&C) communication. The link utilizes the UHF-band according to US radio amateur assigned frequencies. The downlink data rate is 9.6 kbit/s.
- 2) Inter-satellite communication. The link utilizes the UHF band. Operations of this link are non-concurrent to ground transmissions of the leader S/C to avoid link interference. The link performs two functions: a) to relay status of the “follower” S/C to the “leader” S/C, b) to provide relative S/C ranging measurements. The data of the inter-satellite link includes GPS information, payload status, bus status and range based beacon data.

Control architecture of the constellation

The selection of an appropriate augmented GPS receiver system is under consideration as of 2001. Augmentation refers to a parallel measurement technique to GPS, such as tonal ranging in which a pseudo-random code is transmitted on an RF crosslink between the two spacecraft.

N.9 Munin

Munin is a joint nanosatellite pilot project between IRF (Swedish Institute of Space Physics), students at Umeå University (RYP), students at Luth (Luleå University of Technology), the former institutions are located in Sweden, and SwRI (The Southwest Research Institute) in San Antonio, Texas, USA. The scientific objective of Munin is to collect data on the auroral activity on both the northern and southern hemispheres (and distribution of electrons, ions and neutral particles), such that a global picture of the current state of space weather activity can be made available on-line.

The name of the satellite comes from Nordic mythology: “The ravens Munin and Hugin flew out and brought back news from every corner of the world. Sitting on the God Odin’s shoulders, they whispered all the news in his ears. Munin represented the memory and Hugin the intelligence... and they were his embodied soul...”

Figure 346: The Munin S/C model (only one solar array is shown)

The satellite is of size 21 cm x 21 cm x 22 cm, it uses a passive magnetic stabilization system, a permanent magnet holds the satellite aligned along the geomagnetic field lines (like a compass needle). Since the S/C does not require high precision pointing, the attitude problem of restoring torque is solved by the use of a permanent magnet. Average pointing accuracies of $\pm 5^\circ$ are achieved.¹⁸³⁴⁾ There are no actuators and traditional orientation sensors for attitude control. There are also no moving parts, such as deployable booms, etc. The S/C attitude is determined by the Kiruna ground station from the following inputs: a) current measurements of the six solar arrays which cover each side of the S/C body, b) the data of two single-axis on-board magnetometers which measure the \mathbf{H} vector, and c) images of the Earth’s limb and of stars by a CCD camera. The passive magnetic attitude stabilization system of Munin, developed by IRF in cooperation with the Keldish Institute of Applied Mathematics, Moscow, employs a magnetic hysteresis damper.¹⁸³⁵⁾¹⁸³⁶⁾

The satellite is covered with solar cells (Si) on all surfaces, which provide enough power when the satellite is in sunlight and recharge a battery (lithium-ion) for power during eclipse periods. S/C mass = 6 kg. On-board data storage of 2 MByte of RAM. The data is down-linked with a radio modem [a TEKK KS-1000 UHF transceiver at 405.55 MHz downlink and 449.95 MHz uplink, data rate between 4.8 - 19.2 kbit/s] during passes over the Kiruna

1834) M. Ovchinnikov, V. Pen’kov, O. Norberg, S. Barabash, “Attitude Control System for the First Swedish Nanosatellite “Munin,” *Acta Astronautica*, Vol. 46, No 2-6, 2000, pp. 319-326

1835) http://munin.irf.se/frames/technology_index.html

1836) O. Norberg, W. Puccio, J. Olsen, et al., “Munin: A Student Nanosatellite for Space Weather Information,” *Proceedings of the COSPAR Colloquium on Scientific Microsatellites, “Microsatellites as Research Tools,”* Tainan, Taiwan, 1997

ground station (68° N, 20° E). It is made available to all on Internet immediately after reception for space weather forecasts (auroral oval, geomagnetic storms, etc.). Munin was launched as a secondary payload on a Delta 7320-10 launcher from VAFB on Nov. 21, 2000 (primary payloads were EO-1 and SAC-C).

Orbit: Elliptical polar orbit of 705 km x 1700 km, inclination = 98.2° (for Munin only, the other two S/C are separated and put into a sun-synchronous orbit at 707 km altitude).

Sensor complement:

MEDUSA (Miniaturized Electrostatic Dual-tophat Spherical Analyzer), a joint instrument (of Astrid-2 heritage) provided by SwRI and IRF-K. MEDUSA is a combined electron and ion spectrometer. Objective: simultaneous measurement of electrons and ions with energies up to 18 keV/q with a resolution of 16 energy sweeps/s for electrons, and 8 sweeps/s for ions. Particles are measured in 16 sectors in the plane of acceptance, which is aligned with the Earth's magnetic field. Particles enter the spectrometer aperture at any angle in the plane of incidence, electrons and ions are then deflected into their respective spectrometer unit by a spherical electrostatic analyzer. The particles hit a microchannel plate after being filtered in energy in the electrostatic analyzer, the hits are counted by preamplifiers connected to registers, and the hits per sample interval are then further processed by the data processing unit (DPU). The mass of MEDUSA is 0.6 kg, the power consumption is 1000 mW.

DINA (Detector of Ions and Neutral Atoms), a solid-state neutral particle detector of IRF (heritage of PIPPI on Astrid-1). The objective of DINA is to extend the measurements of the precipitating ions to the higher energy range 20 - 500 keV complementing the MEDUSA experiment (also measurement of ENA). The instrument consists of two sensors with an aperture of 5° x 30° each (angular resolution: 2.5° x 25°). The sensor DINA-0 is looking at 180° pitch angle, DINA-90 is looking at 90° pitch angle. The mass of DINA is 0.340 kg, the power consumption is 500 mW. DINA performs alternate measurements of ions and energetic atoms. Mass identification is performed by (Delta E) / E detectors). For the energy range 20 - 100 keV, the front detector provides integral flux of all masses.

Over the northern hemisphere DINA-0 provides measurements of the ion precipitating flux during the auroral oval crossing. While the S/C moves through the polar cusp, DINA-90 makes measurements of ENA (Energetic Neutral Atoms) flux from the exosphere at one local time sector. Over the southern hemisphere DINA-0 pointing down in the southern hemisphere is aimed to detect outflowing ENA in the precipitation region. The information about input ion flux can be obtained from the DINA-90 measurements because the precipitating ion distribution can be considered approximately isotropic.

N.10 NUSAT (Northern Utah Satellite)

NUSAT is a collaborative satellite project designed and built by students at Weber State University (Ogden, Utah) with outside participation from academia (Utah State University, New Mexico State University), industry, and government agencies. The objective and primary mission was to solve a timely problem of FAA (Federal Aviation Agency), namely to calibrate antennas from orbit used for the purpose of air traffic control radar antenna pattern mapping.^{1837) 1838)}

The NUSAT S/C structure consists of a 26-sided multi-hedron with a size of 49 cm in diameter and a mass of 68 kg. Power is provided by solar panels and a 10.5 V battery. NUSAT was deployed from a modified GAS (Get Away Specials) canister on Shuttle flight STS-51B

¹⁸³⁷⁾J. L. Smith, et al., "Low-Cost Attitude Determination and Control for Small Satellites," Proceedings of the 10th Annual AIAA/USU Conference on Small Satellites, pp. 1-20, Sept. 16-19, 1996

¹⁸³⁸⁾<http://cast.weber.edu/nusat/index.html>

(Spacelab-3 mission, April 29 - May 6, 1985) along with GLOMR (Global Low Orbiting Message Relay), a DARPA payload developed by DSI (Defense System Inc.). However, GLOMR failed to eject from the GAS canister on this flight. The mishap hindered NUSAT to support its very mission objectives. The NUSAT microsatellite orbited Earth for 20 months (reentry in Dec. 1986) and demonstrated that satellites could be built small, simple, and at low cost for special applications.

Orbit: Altitude = 411 km, inclination = 57°, period = 90 minutes.

NUSAT Experiment:

Conventional antenna calibration methods involved antenna signal tracking of the setting sun for long periods of time. The NUSAT project was to demonstrate a new antenna calibration technique of FAA antennas based on the following principle: Since a satellite moves across the sky much faster than the sun, and since it can respond to signals on the ground, antennas anywhere on the ground can be calibrated in only a few minutes as opposed to the several hours that it would take to use the sun. FAA antennas would then be free to resume monitoring aircraft.

N.11 OPAL (Orbiting Picosat Automatic Launcher)

OPAL is a student-designed microsatellite of SSDL (Space Systems Development Laboratory) at Stanford University, Stanford, CA. The objective is to test the feasibility of launching several picosatellites (daughterships) from a mothership microsatellite. The picosats and the mothership, OPAL, are instrumented with magnetometers to measure their attitude relative to the magnetic field. The intent is to simultaneously sample a volume of space for denser magnetic field measurements. OPAL uses a mechanical launching system to eject six hockey-puck sized picosats. OPAL's secondary payload consists of a suite of miniature accelerometers and a fluxgate magnetometer. The OPAL design was started in 1995 and was completed in May 1999. ^{1839) 1840) 1841)}

The OPAL S/C structure resembles a hexagonal prism, consisting of 4 hexagonal horizontal trays connected by 4 vertical rods. The space between the trays is used by each subsystem to place its components. The components are mounted in aluminum boxes, the boxes are fastened to the trays. The trays are surrounded by 6 side panels, which double as structural members and solar array surfaces (GaAs and Ge). Solar cells are also mounted on the outside of the top and bottom trays. All panels and trays are made out of 6 mm aluminum honeycomb, except for the bottom tray, which is 12 mm thick to support the carrier attachment and to be able to handle the heavier launch loads. Some S/C parameters: body height = 23.5 cm, radius = 21 cm, total mass = 25 kg. The on-board computer consists of a Motorola 68332 microcontroller (16 MHz, 1 MB RAM). Power storage is provided by NiCd batteries (1.2 V, 5 Ah). Power is regulated to 5V and 8V, the average power consumption is 2.4 W (12 W max). Secondary power is provided by NiCd batteries. Note: An attitude control system was not implemented since the mission objective did not require any attitude control. However, the attitude can be estimated from the magnetometer readings as well as from the solar panel currents.

Communications: OPAL has four 1/4 wavelength monopole antennas (each about 17.5 cm) which are placed on the top and bottom panels (right-hand polarized). OPAL uses packet radio transmissions over amateur radio frequencies (uplink/downlink at 420-450 MHz,

¹⁸³⁹⁾J. Cutler, G. Hutchins, R. Twiggs, "OPAL: Smaller, Simpler, and Just Plain Luckier," Proceedings of the 14th AIAA/USU Conference on Small Satellites, Logan UT, Aug. 21-24, 2000, SSC-VII-4

¹⁸⁴⁰⁾D. S. Clarke, M. T. Hicks, et al., "Picosat Free Flying Magnetometer Experiment," Proceedings of the 10th Annual AIAA/USU Conference on Small Satellites, Sept. 16-19, 1996

¹⁸⁴¹⁾<http://ssdl.stanford.edu/opal/index.html>

transmitter of 2.2 W, AX25 protocol, data rate = 9.6 kbit/s). The IP (Internet Protocol) is used between users and the OPAL ground system.¹⁸⁴²⁾

Figure 347: Illustration of the OPAL microsatellite

A launch as a secondary payload to JAWSAT, ASUSat-1, OPAL (StenSat, PICOSAT1.0, Artemis), OCSE, and FalconSat, on an OSC launch vehicle (Minotaur) took place on Jan. 27, 2000 from VAFB, CA. OPAL was attached to the multi-payload adapter built by OSSS of Ogden, UT. In addition to OPAL, three other free-flying satellites (ASUSat-1, OSCE, and FalconSat) were attached to the adapter and deployed within minutes of reaching orbital altitude.

Status: OPAL achieved its primary mission goal, all six picosats were successfully deployed (ejection was confirmed by telemetry), the component testbeds are fully operational. Extended mission operations focus on long-term characterization of the bus and component (magnetometer) testbeds. After launch and initial operation, OPAL has been designated as: OPAL OSCAR-38 (OO-38) by AMSAT, the Radio Amateur Satellite Corporation.

Orbit: Circular sun-synchronous orbit, altitude = 750 km, inclination = 97.5°, nodal crossing at 6 AM/6 PM.

N.11.1 Sensor/payload complement

OPAL has three payloads: a) the Picosat Launcher and Payload as an end-to-end demonstration of a mothership/daughtership mission architecture and technology (the objective is to explore distributed sensing in space), b) the Accelerometer Testbed, and c) the Magnetometer Testbed. - OPAL mission operations are conducted from the SSDL ground station.

Background: The original OPAL mothership system was designed as an FFM (Free-Flying Magnetometer) mission, sponsored by JPL. In this version, the daughterships carried precision magnetometers and were similar in shape to a hockey puck. A lack of funding terminated this approach. - New sponsors were found for the picosatellite mission. The launcher was redesigned to suit the new requirements.

¹⁸⁴²⁾J. Cutler, G. Hutchins, C. Kitts, R. Twiggs, "Infrastructure for Internet-Based Operations," Proceedings of the 14th AIAA/USU Conference on Small Satellites, Logan, UT, Aug. 21-24, 2000, SSC00-IX-4

Picosat Launcher and Payload. ¹⁸⁴³⁾ OPAL carried and ejected a total of six picosatellites: StenSat (1), PICOSAT1.0 (2), and Artemis (3). The picosat launcher consists of a total of four picosat launch tubes. Each is capable of holding two short (7.5 cm x 10 cm x 2.5 cm) or one long (7.5 cm x 20 cm x 2.5 cm) picosat. Six picosats flew on OPAL, four short and two long.

A latched door with a dual-release mechanism was used to eject the picosats (single shot release and replacement of actuators). The firing was ground commandable.

Accelerometer Testbed. Objective: Test of COTS instruments in space. Three accelerometer types, working on different measurement principles, are being tested, consisting of: a micromachined capacitor, piezoelectric crystal, and magnetic inductor.

- Capacitive sensor: The ADXL05 from Analog Devices measures changes in capacitance in a circuit etched on a silicon die.
- Piezoresistive sensor: The PCB 336M27 from PCB Piezotronics uses the piezoelectric properties of a quartz crystal to provide a measurement of acceleration (sensitivity of 1 mgal).
- Inductive sensor: The Geophones (GS-11D & GS-30CT) from GeoSpace Corporation use coil's motion with respect to a magnet to generate a signal.

Two accelerometers of each type were flown in the testbed. A stimulation source was provided to exercise the accelerometers. Characterization of the accelerometers is defined as determining short-term sensor degradation due to launch and initial exposure to the space environment.

Magnetometer Testbed. Objective: to measure OPAL's attitude (S/C alignment within 2°). A miniature 3-axis fluxgate magnetometer designed by Applied Physics Systems (model APS533). The magnetometer is enclosed in a fiberglass package and is very compact (19 mm diameter x 4 cm long cylinder, 18 grams of mass). It provides direction information to better than 0.1°, while consuming only 200 mW. It generates three voltages proportional to the magnetic field in three perpendicular directions, with an accuracy of $\pm 0.1\%$. Resolution of the magnetometer is limited by OPAL's 12 bit A/D conversion. The magnetometer can be read with a frequency of up to 1 kHz.

Characterization of the magnetometer is defined as determining short-term magnetometer degradation due to launch and initial exposure to the space environment. Also, determination of the long-term magnetometer performance degradation due to extended exposure. The magnetometer performance is measured by comparing the vector magnitude of the Earth's magnetic field as measured by the sensor to the predicted vector magnitude of standard geomagnetic modeling software.

N.11.2 StenSat

StenSat is a picosatellite (260 cm³ in volume, mass = 0.235 kg), developed by a group of amateur enthusiasts in the Washington DC area. The satellite structural components consist of an aluminum chassis (of size 10 cm x 7.5 cm x 2.5 cm), a magnet, top and bottom printed circuit board solar cell panels, two internal printed circuit boards (receiver/transmitter and controller), and black and white paint. One NdFeB disk magnet provides alignment and attitude control. The painting of different sides of one of the dipole antennas with black and white paint introduces a slow radiometric spin. Power is supplied by the top and bottom panel of six GaAs solar cells. Further subsystems are controller, sensors and antenna.

¹⁸⁴³⁾ Note: The three picosats are the main payload of OPAL, a technology demonstration project funded for JPL. The ultimate goal of this project is to be able to launch hundreds of picosatellites from a mothercraft in low Earth orbit - to obtain simultaneous measurements of the magnetic field over a large volume. Each picosat could measure the magnetic field and then transmit the data back to the mothercraft.

The picosatellite is used by amateur radio operators world wide. It operates as a single channel mode "J" FM voice repeater. The uplink frequency is 145.84 MHz and the downlink is 436.625 MHz. StenSat periodically transmits 1200 baud AX.25 for broadcasting telemetry. Additionally, amateur radio operators are able to "PING" the satellite by transmitting a six digit DTMF command to the receiver uplink.¹⁸⁴⁴⁾

Status: StenSat was released from the OPAL launcher on February 10th. Unfortunately, no confirmed signals have been received.

N.11.3 PICOSAT1.0

The PICOSAT1.0 mission of the USAF (sponsored by DARPA) was developed and built by the Aerospace Corporation, El Segundo, CA. PICOSAT1.0 is a free-flyer technology demonstration mission consisting of two tethered PICOSATs with the following objectives:

- To demonstrate the basic functional elements of a low-power LEO "swarm" or formation PICOSAT array
- To communicate from space using node-type radios and to report the results of MEMS-switched tests.

The two PICOSATs, tiny boxes of size: 25 mm x 75 mm x 100 mm, each with a mass of 0.275 kg, were ejected from OPAL's spring-loaded launcher on Feb. 6, 2000, in sight of the SRI (Menlo Park) ground station. Each PICOSAT uses a small, battery operated, very low power radio with a cross-link capability. The PICOSATs are referred to by their nodal names as PICO21 and PICO23. The communication system of each PICOSAT employs a receiver/transmitter system featuring: a) a spread-spectrum DCT (Digital Cordless Telephone) chip set, a COTS product of Conexant, b) a CPU/RF board design. The system is operated at 64 mW output transmit power. The store and forward communication protocol is a random-access packet system operating at a frequency of 915 MHz spread-spectrum (20 channels) with a data rate of 80 kbit/s. The satellite computer is a 6502 system (Rockwell Science Center, Thousand Oaks, CA) with a simple operating system for data collection, system management and the network protocol. Each PICOSAT is powered by three tiny Lithium Thionyl Chloride batteries with a capacity of 1 Ah each for a total of 3 Ah and a voltage of 3.65 V. The simplicity of the PICOSAT design does away with such standard spacecraft components as attitude sensors and a propulsion system.

The tether system of PICOSAT1.0, of 32 m in total length, uses a polyethylene 3-braid thread which contains 26 gold wire dipoles along its length, tuned to 430 MHz and 1 GHz. The tether was released from a tether spool right after the PICOSAT1.0 ejection from OPAL. The tether objectives are: a) to enhance system detection (the tether system serves as a dipole, enlarging the radar cross section of the assembly for a more distinctive signature and thus permitting ground detection), b) to keep the PICOSATs within range of each other (32 m max) for communication reasons (with each other and to the ground). A sensor board on each PICOSAT has a chip containing 4 MEMS RF switches (a 100 V charge pump on the sensor board is needed by the switches) that are operated in space after deployment. An A/D converter measures the resistance across each switch every time a switch occurred and records the results.

Status:¹⁸⁴⁵⁾ In retrospect, the tether release mechanism worked nominally, communication was established between each PICOSAT and the ground. The ground station was able to call PICO21 or PICO23, upload instructions and download housekeeping data (temperature and MEMS switch test results). The crosslink capability was also tested, communicating from the ground indirectly with PICO23 via PICO21. Detection of the PICOSAT1.0 system from a ground-based radar system, referred to as SSN (Space Surveillance Network),

¹⁸⁴⁴⁾<http://users.erols.com/hheidt/>

¹⁸⁴⁵⁾ Information provided by Ernest Y. Robinson and by David A. Hinkley of the Aerospace Corporation.

was verified. The radar tracking provided also ephemeris data for orbit determination. The PICOSAT1.0 mission lasted until Feb. 9 when battery power decayed.

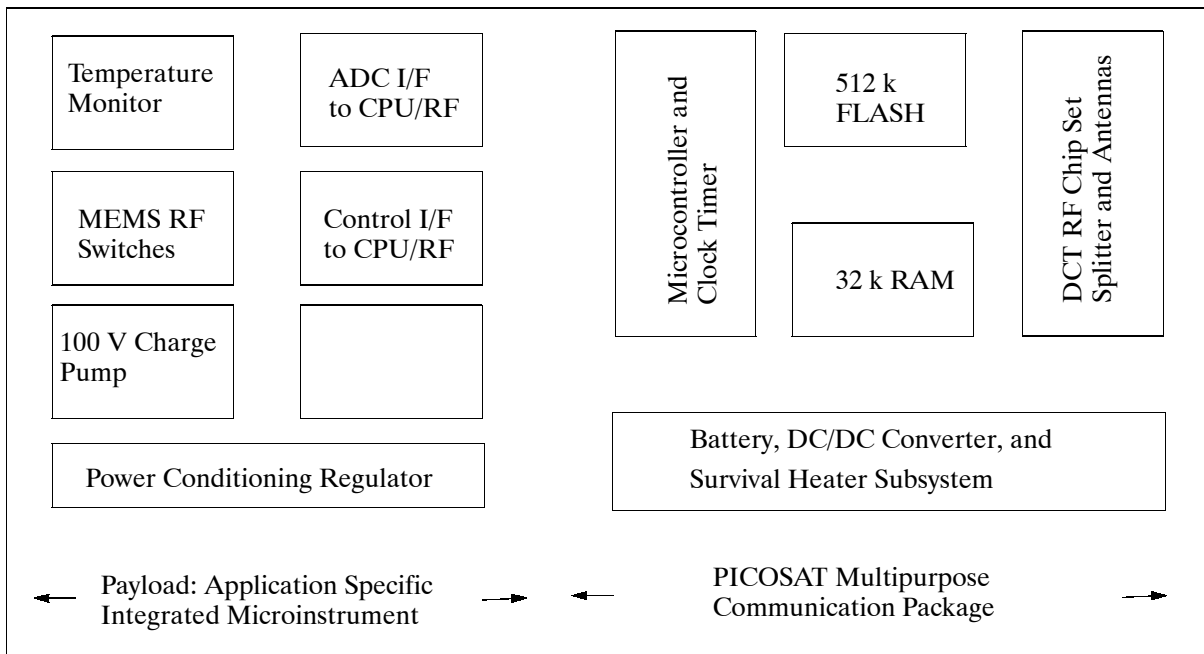

Figure 348: PICOSAT1.0 system block diagram

Figure 349: Illustration of major PICOSAT1.0 components for a single spacecraft

N.11.4 Artemis

Artemis is a set of three picosatellites provided by undergraduate engineering students of Santa Clara University, Santa Clara, CA. The mass of Artemis is < 1kg by utilizing a commercial microprocessor, transmitting on amateur radio frequencies from the picosatellite to ground, and using commercial off-the-shelf batteries to power the picosatellite. The pri-

mary mission of the OPAL picosatellite payload is to provide an end-to-end mission demonstration of mothership and daughtership technologies. ¹⁸⁴⁶⁾ ¹⁸⁴⁷⁾ ¹⁸⁴⁸⁾

The structure of two Artemis picosats is of size: 20 cm x 2.5 cm x 7.5 cm with a mass of 0.611 kg. The two picosats consist of the following subsystems:

- VLF (Very Low Frequency) Receiver. The VLF receiver board is the main payload aboard Artemis. The objective is to research the effects of lightning on the outer ionosphere. Measurements are taken by using the VLF radio signals traveling between the ground and the S/C. Lightning discharges and the effects on the Earth's near space environment can be recorded with the VLF receiver. The VLF receive frequency range is 0.1-12 kHz, with 5 kHz considered typical of a lightning strike. The two picosatellites have different VLF thresholds, namely 100 mV and 10 mV respectively. Measurements are taken simultaneously by both picosatellites. Comparison of the data permits the extraction of the occurrence and amplitudes of horizontal and vertical lightning.
- Power is provided by GaAs solar cells and two NiCd batteries, rated at 1.25 V and 800 mAh.
- A microcontroller provides the necessary functionality to check for adequate battery supply, read sensors, read and log pulses from the VLF receiver, transmit using FSK modulation, and receive commands sent from ground.
- Attitude is determined by four VNIR phototransistors, mounted perpendicular to each other. Rubber ferrite magnets are used as actuators to control the spin axis, aligning it relative to the Earth's magnetic field.
- The communications subsystems transmits and receives over amateur radio frequencies. The data rate is 1.2 kbit/s.

The third picosat, named JAK, was a simple beacon transmitter designed to test the ground reception ability of spaceborne picosat broadcasts.

Mission operations: The picosatellites deploy their communication and VLF antennas after ejection from the mothership OPAL. Both picosatellites broadcast their call-signs once per minute for tracking purposes. Upon a command reception, the CPU initiates the VLF experiment by enabling the VLF receiver. The experiment is carried out in one minute during which the CPU counts the number of pulses the receiver detects above the threshold voltage. The measured data are downlinked in the next (and follow-up) broadcast until the next command is received.

Status: JAK was ejected with StenSat on Feb. 10 (they were stored in the same launch tube). No reception of JAK's beacon signals was confirmed. The limited battery life of JAK ended soon all communication attempts. The two VLF picosats were released on Feb. 12, 2000. However, no signals could be confirmed.

N.12 PANSAT (Petite Amateur Navy SATellite)

PANSAT (Petite Amateur Navy SATellite) was designed and built at the Naval Postgraduate School (NPS) in Monterey, CA. as an educational project for officer students. It is a low-cost microsatellite for messaging or relay services. The overall objective is to demonstrate digital communications using direct-sequence spread-spectrum and store-and-forward packet radio technology. The S/C design is kept very simple. There is neither an attitude control system nor an on-orbit propulsion system. This makes PANSAT a tumbling S/C. The

¹⁸⁴⁶⁾M. F. Breiling, C. Y. Hu, et al., "The ARTEMIS Project: Picosatellite-Based Missions to Study VLF Phenomenon," Proceedings of the 13th AIAA/USU Conference on Small Satellites, Aug. 23-26, 1999, Logan UT, SSC99-VIII-3

¹⁸⁴⁷⁾<http://screem.engr.scu.edu/artemis/>

¹⁸⁴⁸⁾A. Valdez, C. Hu, C. Kitts, et al., "The Artemis Project: Picosatellites and the Feasibility of Smaller, Faster, Cheaper Approach," Proceedings of the IEEE Aerospace Conference, Snowmass, Co, March 6-13, 1999

microsatellite has a total mass of 57 kg. It was launched as a Hitchhiker (HH) payload on Shuttle flight STS-95 (Oct. 29, 1998; use of HH Pallet Ejection System).¹⁸⁴⁹⁾

Orbit: LEO orbit, altitude = 555 km, inclination = 28.4°

Communications payload:

A UHF operating center frequency of 436.5 MHz is used, a bit rate of 9600 bits per second and 4 MByte of message storage. Amateur radio ground stations are able to utilize PANSAT for store-and-forward communication and to test spread-spectrum communications. In addition, PANSAT provides many potential applications for low-cost communications. The low probability-of-intercept is an important feature for the military in downed-pilot-rescues. The pilot could obtain his/her location through a GPS system and uplink the information to the orbiting satellite at low risk. Examples of civilian uses include emergency rescue and communication to remote areas. A modified amateur satellite ground station is needed to communicate with PANSAT. The NPS ground station utilizes off-the-shelf software, is microcomputer controlled, and is equipped with a spread-spectrum modem. The NPS ground station is similar to a typical amateur radio user station, except it has spacecraft command capability. The NPS ground station is also utilized as a classroom instructional laboratory.

N.13 SAPPHIRE (Stanford AudioPhonic Photographic IR Experiment)

SAPPHIRE is a graduate-student project within the framework of SQUIRT (Satellite Quick Research Testbed) in SSDL (Space Systems Development Laboratory) at Stanford University. The overall objective is to design, construct and operate a microsatellite. Sapphire's primary mission is to space-qualify a micromachined infrared sensor (PI: T. Kenny).

The S/C structure consists of four stacked aluminum honeycomb trays, one to a subsystem (from bottom: Power, Communications, CPU, and Sensors), with eight external panels (six sides, top and bottom) upon which the solar cells are mounted. The entire hexagonal cylinder, fully loaded and on the launch interface, has a mass of about 19.6 kg. Solar cells (GaAs) provide 16 W of peak power (8 W average). Eclipse power is provided by ten NiCd "D" cells in series.

Figure 350: Illustration of the SAPPHIRE satellite

The ADC (Attitude Determination and Control) subsystem follows in the footsteps of the early Oscar satellites (AMSAT) to provide a "controlled tumble" with a spin of about 1/3 to 1/2 rpm. Four permanent (ALNICO-V bar) magnets are aligned with the vertical S/C z-axis

¹⁸⁴⁹⁾ <http://www.sp.nps.navy.mil/pansat/pansat.html>

(providing the primary means of attitude control), forcing the S/C to line up with the local North direction of the Earth's magnetic field. This in turn generates near-nadir pointing in the northern hemisphere (the top face of the S/C is pointing to nadir), a prerequisite for the camera system. In the southern hemisphere, the top face of the S/C looks to the horizon, while the bottom face of the S/C is pointing toward nadir, giving the IR sensors full view of the Earth in this region. [As the latitude of the S/C increases, the S/C pitch angle increases causing SAPPHIRE to "flip" over at each pole crossing]. - A minute spin moment (torque) is induced by the four turnstile transmit antennas on the outside of the S/C, which are painted black on one side, white on the other, to create a spin effect about the Z axis.¹⁸⁵⁰⁾ Hysteresis rods are placed perpendicular to the Z-axis to damp nutation about that axis as well as to create a maximum spin rate. S/C attitude is sensed by Earth sensors.

Communication: The subsystem uses modified Hamtronics kits. The transmitter broadcasts with 2 W of power at 437.100 MHz (UHF). The receiver is at 145.945 MHz (uplink in VHF). Data is transmitted at 1200 baud and uses AFSK encoding, the AX.25 packet protocol, and standard Mode J Amateur Satellite frequencies. The voice downlink utilizes frequency modulation and operates at variable speeds.^{1851) 1852)}

The SAPPHIRE project started in 1994 (it is in effect the first spacecraft designed and fabricated by SSDL). It was flight-readied in 1998, and is planned to be launched as a secondary payload in Aug. 2001 (PICOSat, STARSHINE-3, PCSat) on Athena-1 from the Kodiak Launch Complex on Kodiak Island, AK.

Orbit: circular orbit, altitude = 500 km, inclination = 67°.

Sensor complement:

THD (Tunneling Horizon Detector). Objective: to test a new infrared sensing technique for Earth horizon detection on microsatellites. The THD experiment uses a micromachined IR detection system of JPL on-a-chip, employing the electron-tunneling principle, and operating at room temperature. The sensor is constructed with roughly 1 micron of separation between the membrane and tip. To pull the membrane close enough to enable tunneling currents, an electrostatic force is created by applying a large voltage (100s of Volts) between the membrane and the deflection electrodes. An external circuit controls this "deflection voltage" to maintain a constant tunneling current.

THD is a fixed narrow-FOV horizon detector. Its primary output is an analog signal that triggers on the Earth/space and space/Earth horizon crossings. The THD assembly contains a TIS (Tunneling Infrared Sensor) with 2 independent sensing elements and corresponding electronic circuitry. THD is sensitive to the entire infrared spectrum with an average sensitivity of 1,500 V/W. The assembly is fastened to the payload tray and looks out a slit aperture from the side of the spinning S/C, perpendicular to the spin axis ("scanning" is provided by the spinning S/C). The slit aperture limits the FOV to 6° in the transverse spin plane and to 22° in the vertical plane. The tunneling element outputs are proportional to the level of variation in incident infrared radiation on TIS and consist of a 3.0 V signal + 1/400 of the tunneling high voltage + the tunneling signal disturbance.

Digital Camera. A commercially available B&W CCD camera (model "Fotoman Plus" of Logitech). The objective is to obtain imagery in the northern hemisphere of about 1 km spatial resolution. The capabilities of the digital camera include JPEG image compression, storage in DRAM of up to 32 (496x360) images with 8-bit gray scale in compressed form. A compressed image has a volume of about 23 kbytes. The Digital Camera has a mass of 0.450 kg and an average power consumption of 2 W.

¹⁸⁵⁰⁾ Note: The solar pressure creates a minute, however constant torque, resulting from black and white painted antennas

¹⁸⁵¹⁾ <http://aa.Stanford.EDU:80/~ssdl/>

¹⁸⁵²⁾ R. Twiggs, M. Swartwout, "SAPPHIRE - Stanford's First Amateur Satellite," AMSAT-NA 16th Space Symposium, Vicksburg, MS, Oct. 16, 1998

Voice Synthesizer. The objective of the “Digitalker” is to test and illustrate a new communication approach which might be of interest to the Amateur Radio community. There are certainly also some applications seen in the field of education. The Digitalker can be received by radios (hand-held or whatever) when the satellite is overhead, capable to “talk” to an audience, giving for instance a lesson on a particular subject. The on-board voice synthesizer is based on the commercial V8600 Speech Synthesizer of RC Systems with some modifications by the student team.

Telemetry Experiment. A pseudo-payload, designed by students, with the objective to assess attitude determination by using the solar panels as a differential sun sensor.

N.14 SEDSAT-1 (Students for the Exploration & Development of Space)

SEDSAT-1 is a microsatellite of the University of Alabama in Huntsville, AL (UAH). The objectives are to 1) provide hands-on experience for students in the full lifecycle development of space systems, 2) advance the state of the art in low-cost attitude stabilization and control for microsatellites, 3) collect space performance data on advanced electronics technologies, 4) collect and distribute imaging data, and 5) provide packet S&F communications service for the amateur radio community. The project is supported by NASA, DARPA, and industry. A launch of SEDSAT-1 took place October 24, 1998 as a secondary payload on JPL's DS-1 mission.

The box-shaped S/C has dimensions of 30 cm on each side. The structure consists of honeycomb-machined aluminum panels forming a nearly solid cube. The solar cells are in integral part of the external panels (five sides are covered with solar cells. The S/C is stabilized by an active control system using three mutually perpendicular magnetorquers as control actuators (test of new control algorithms). The OBC is of type 80186 with a 1 MByte ECC SRAM and 32 MByte DRAM solid state disk. In addition, there is a transputer-based image processor (Inmos T805) with integral frame grabber and 128 MByte of solid state memory. S/C mass = 36 kg, power = 30 W (depending on mode). SEDSAT-1 operation relies on 16 NiMH (Nickel Metal Hydride) recharge batteries (each rated at 1.5 V) during the eclipse periods of the orbit. A total of six antennas are installed on SEDSAT-1; three are fixed and three are deployable antennas. The S/C design life is three years.

Orbit: Elliptical orbit, perigee = 556 km, apogee = 1042 km, inclination = 31.5°. Note: The orbit is not optimal, but there was no better choice to obtain as a secondary payload.

Sensor/experiment complement:

SEASIS (SEDSAT Earth Atmospheric and Space Imaging System). SEASIS consists of two camera systems, PAL and Telephoto, and an image processor (Inmos T805) with corresponding subsystems (I/O devices, control logic, digitizers, buffers, mass memory, etc.). The overall objective is to use one camera for an attitude determination experiment, to collect imagery of the Earth's surface with the second camera, and to make the data available to a large user community via the Internet. The two cameras are mounted perpendicular to each other, observing in the S/C x-axis and y-axis (the z-axis is nadir pointing). Both digital camera systems are Sony products, employing a 2-D CCD array detector assembly (Si detectors), and featuring a 12-filter interferometric filter wheel between the optical train and the camera imaging chip (i.e., CCD array). Five spectral bands at 10 nm bandwidth are defined at the following center wavelengths: 440, 540, 610, 670, and 777 nm. The source data of each camera system is output in NTSC format (B&W) with a resolution of 768 x 484 pixels (data rate of 20 Mbit/s from each data stream) and stored into mass memory. Both cameras can be operated in parallel (snapshot imagery). Control is provided for camera operation including filter wheel selection. The fixed mounting of the cameras into the S/C structure permits observation (of the Earth's surface) by the mechanism of body-pointing. The S/C is turned into the desired direction.

Camera operation. Only a single spectral band at a time can be used for observation. The normal operating mode takes a snapshot in each band while moving the filter wheel (sequential collection of “multispectral” data). Snapshots at up to two hertz can be taken.

- Camera-1 is a digital video camera featuring a Panoramic Annular Lens (PAL) with a FOV of 360° and $\pm 40^\circ$ on optical equator. Objective: demonstration of wide-angle attitude determination and wide-area Earth observation. The PAL system is always pointed at the Earth’s horizon, imaging a panoramic “doughnut” (a ring-sized shape) projected onto the camera. The PAL images are then used with corresponding algorithms for attitude determination.
- Telephoto camera. The instrument features a 50 mm focal length lens. With Telephoto pointed at nadir, the Earth appears centered on the equator of the PAL camera, providing attitude information of the S/C relative to Earth as well as relative to the Earth/sun system. The spatial resolution on the ground is between 100 - 300 m for the orbital altitudes of 500 - 1000 km. A corresponding image scene has the size of 100 km x 140 km. Data quantization is 12 bit.

A further objective of the Telephoto camera is to detect lightning activity by counting the lightning strikes through a timed series of images. The filter is centered at a wavelength of 777 nm for this observation mode.

Ground truth. SEASIS observation imagery is paralleled by several **PGAMS** (Portable Ground-based Atmospheric Monitoring System) stations in the continental USA, permitting synchronous measurements of atmospheric parameters in up to 512 wavelength bands. The SEASIS filters were selected to match the PGAMS bands for some of the most interesting atmospheric absorption bands.

Mode-A Transponder. Objective: to provide analog relay capabilities to the amateur radio community. Data is received at 147 MHz and reflected at 29 MHz. In addition, an FSK transmitter is provided on this link, permitting send-only communication at 300 baud. It is intended for transmission of S/C housekeeping data.

Mode-L Transponder. Objective: to provide digital packet store-and-forward capabilities to the amateur radio community. Data transmission rates in uplink and downlink at 9.6 and at 57.6 kbit/s. The uplink frequency is in L-band at 1.2 GHz, the downlink frequency is in UHF at 430 MHz.

Technology experiments include testing of NiMH batteries and specialized electronic parts.

N.15 Sputnik-II

Sputnik-II is a nanosatellite, a commemorative functioning replica of the original Sputnik (40th anniversary), built by French high-school students from the l’Aeroclub of France (radio transmitter) and staff from the Russian Aeronautical Federation (structure). The project was funded by various sponsors in the space industry. Sputnik-II was deployed from the MIR space station during an EVA by Russian cosmonauts Anatoly Solovyov and Pavel Vinogradov on November 3, 1997. Sputnik-II is 1/3 scale of the original with a mass of 3 kg.
¹⁸⁵³⁾ ¹⁸⁵⁴⁾

The initial orbit of Sputnik-II was identical to the MIR orbit at deployment, namely a 383 km x 391 km orbit inclined at 51.6°. The satellite carries a low-power (100 to 200 mW) 2 m VHF-FM beacon transmitter operating on 145.820 MHz that emits a pulsating tone with duty cycle of 5, with 1.3 kHz frequency as a function of the internal temperature of the

¹⁸⁵³⁾ <http://www.ee.surrey.ac.uk/SSC/SSHP/nano/nano1997.html>

¹⁸⁵⁴⁾ <http://www.oceanes.fr/~fr5fc/angspoutnik.html>

spacecraft, similar to the original Sputnik. The antenna polarization is circular, however no satellite attitude control exists to control the polarity sense. Its lifetime in orbit is expected to be between one and two months as it employs non-rechargeable batteries. Orbital lifetime is expected to be about 18 months. The SSHP author still observed the satellite near the 20th November. The spacecraft was reported to be spinning rapidly (8-13 rpm), and finally stopped transmitting on December 29, 1997 (55 days of radio transmission). Sputnik-II decayed on May 21, 1998.

N.16 STARSHINE (Student-Tracked Atmospheric Research Satellite for Heuristic International Networking Equipment)

STARSHINE is a US cooperative program of small optically reflective spherical student satellites, designed and built by NRL/NCST (Naval Center for Space Technology). They are being deployed by NASA from Hitchhiker canisters in Space Shuttle cargo bays, as well as from an Athena unmanned launch vehicle, into highly inclined low earth orbits at a rate of once every year or so.^{1855) 1856) 1857)} The principal objectives of project STARSHINE are educational and motivational. If students help “build” the spacecraft (by polishing its mirrors), they should be more excited about tracking it and using it to measure upper atmospheric density and the response of that region of the atmosphere to solar storms. - Self-contained mirror polishing kits, containing two mirror blanks each, were prepared by project volunteers and mailed to 1050 schools around the world. Nearly 1800 mirrors were polished by 25,030 students in some 700 schools in 18 countries.

N.16.1 STARSHINE-1

STARSHINE-1 is an optically reflective small passive satellite with no moving parts or electrical components. It is spherical with an outer diameter of 47.5 cm, the S/C mass is 39 kg. The shell is made of aluminum, the exterior is covered with 878 aluminum mirrors that are 25 mm in diameter. The Starshine structure consists of the following basic components: two hemispherical domes (two top dome has 499 mirrors, the bottom dome 399 mirrors), and an equatorial disk (to join the two hemispheres).

STARSHINE-1 was launched by Shuttle flight STS-96 (launch May 27, 1999 - deployed June 5, 1999), with the objective to provide educational observations for students around the world. More than 1,000 schools across America and the world have helped construct the satellite and participated in the project. Although only slightly larger than a basketball, STARSHINE-1 is covered by almost 900 highly polished mirrors that make it visible from the ground. It was released from Discovery on June 5, 1999, near the end of the STS-96 mission after the Shuttle had left ISS (International Space Station).

Orbit: The initial orbit of the STARSHINE after release was 387 km in altitude and 51.6° in inclination (decaying circular orbit), orbital period of 90 minutes.

Satellite operation: The twinkling satellite was visible to the naked eye against the star background, during certain recurring morning and evening twilight periods, to observers around the world between the latitudes of $\pm 60^\circ$. Student observers around the world recorded the position, of the tumbling (sunlight reflecting) satellite and provide this information to the project's website. They measured right ascension and declination at precise times by reference to known stars, and they were also recording the precise time of their observations by the use of stopwatches synchronized with international time signals. Some observers used

¹⁸⁵⁵⁾ B. Braun, C. Butkiewicz, J. Vasquez, G. Moore, “The Starshine Satellite From Concept to Delivery in Four Months,” Proceedings of the 13th Annual AIAA/USU Conference on Small Satellites, Aug. 23-26, 1999, Logan UT, SSC99-I-7

¹⁸⁵⁶⁾ <http://www.azinet.com/starshine/index.html>

¹⁸⁵⁷⁾ Information provided by Gil Moore, Director of the STARSHINE project

GPS receivers to measure the latitude, longitude and altitude of their observing sites. They posted their observations and station locations on the STARSHINE web site to permit computation of the classical elements of the satellite's orbit by the angles-only-method of Laplace. The changes in the decaying orbit were used to calculate the density of the upper atmosphere. Student investigations were also made to the effect as to how the density of the upper atmosphere varies with solar activity.

Figure 351: Illustration of STARSHINE spacecraft

It turned out that Starshine did initially not tumble as expected after deployment from HES (Hitchhiker Ejection System). The rate of visible flashes produced by the mirrors varied from once per 15 seconds to once or twice per pass. The situation improved in the latter phases of the mission as the satellite descended into the atmosphere (the denser air causes a torque on the S/C). Re-entry of STARSHINE-1 occurred on Feb. 8, 2000 when it was consumed by aerodynamic heating at an altitude of about 80 km above the Atlantic Ocean off the coast of Brazil. The project STARSHINE observers webpage is at NASA/HQ under: <http://spacekids.hq.nasa.gov/starshine/>

N.16.2 STARSHINE-2

As of early 2001, STARSHINE-2 is under construction to be deployed from STS-108, an Endeavour mission to ISS in October 2001. The 858 mirrors that will cover the outside surface of this satellite have already been polished by students in 26 countries. These mirrors have been coated with a scratch-resistant, anti-oxidizing layer of Silicon Dioxide by optical technicians at the Hill Air Force Base. At NRL, the mirrors are installed onto the spacecraft. The satellite has the same size and mass as STARSHINE-1. This time around, it also contains a special cold-gas spin system to rotate the satellite at 5°/s to enhance the rate at which sunlight will flash from its mirrors. In addition, the satellite carries twenty laser retro-reflectors, distributed evenly across its surface, to permit tracking by the International Satellite Laser Ranging Network.

N.16.3 STARSHINE-3

The structure of STARSHINE-3 is a sphere of 94 cm in diameter and a mass of 91 kg (micro-satellite class). It is covered with 1000 student-polished mirrors; in addition, twenty laser retro-reflectors are mounted on its surface. The spacecraft is built and integrated by NRL with assistance from Calhoun Community College in Decatur, Alabama, and the C. F. P. Paul Rousseau school in Drummondville, Canada. STARSHINE-3 is of higher technical sophistication featuring a nano-g drag accelerometer of SwRI (Southwest Research Insti-

tute), and an experimental integrated power supply, consisting of combined solar cells and thin film batteries provided by NASA/GRC. The power is needed for two-way RF communications (amateur standard) between the ground and the spacecraft, consisting of a telemetry transmitter, a command receiver, a rechargeable battery, a secondary solar array, signal-conditioning circuitry, and an antenna. The data is transmitted to ground receiving stations at the University of Alaska, Fairbanks, the US Naval Academy, Annapolis, MD, Santa Clara University in Santa Clara, CA, and to numerous amateur radio stations around the world. The downlink is in UHF-band.

A launch of STARSHINE-3 is targeted for Aug. 31, 2001 on an Athena-1 vehicle from the Kodiak Launch Complex on Kodiak Island, Alaska. The entire launch payload consists of four small satellites: STARSHINE-3, PICOSat, a technology demonstration microsatellite of DoD/AFRL, PCSat (Prototype Communications Satellite) a microsatellite designed and built by Midshipmen of the United States Naval Academy (USNA), Annapolis, MD, and SAPHIRE (Stanford AudioPhonic Photographic IR Experiment) of Stanford University. The launch of all satellites represents also the inauguration of launch services from this site.

Orbit: circular orbit, altitude = 500 km, inclination = 67°. The higher orbit implies also a longer lifetime of the satellite in the order of several years.

N.17 STEDI (Student Explorer Demonstration Initiative)

The STEDI program is an USRA-managed (Universities Space Research Association) cooperative initiative (a competitive pilot program) among US universities to define, build and operate small and low-cost spacecraft and sensors as part of the civil space program. The overall STEDI objective is to give US universities an opportunity to conduct research in space - through cooperative agreements - which is related to scientific disciplines, eg., astrophysics, Earth sciences, life and biomedical sciences and applications, microgravity sciences and applications, solar system exploration, and space physics. STEDI is funded by NASA. There are three phases to the STEDI program:

- 1) Phase 1: Mission definition
- 2) Phase 2: Mission implementation
- 3) Phase 3: Mission operations and data analysis

In February 1995 two university teams were selected from many applicants by USRA to implement their particular proposals (phase 2); in addition a third team was selected to act as backup. The University of Colorado at Boulder is one team in this scenario with the SNOE (Student Nitric Oxide Explorer) mission; the other team is headed by Boston University, with a satellite project named TERRIERS (Tomographic Experiment using Radioactive Recombinative Ionospheric EUV). The backup team is headed by the University of New Hampshire at Durham with the CATSAT mission (Cooperative Astrophysical and Technology Satellite).

N.17.1 SNOE (Student Nitric Oxide Explorer)

The SNOE spacecraft and its instrument complement are being designed, built, and operated at the University of Colorado at Boulder [Laboratory for Atmospheric and Space Physics (LASP); PI: Ch. Barth; student involvement in all aspects of the project]. There is also collaboration with Ball Aerospace, NCAR, JPL, and Arapahoe High School of Littleton, CO. The science objectives of SNOE are to measure nitric oxide density in the terrestrial lower thermosphere (90-200 km) and to analyze the energy inputs to that region from the sun and magnetosphere that create this compound and cause its abundance to vary dramatically. The S/C is a compact hexagonal modular structure, 0.95 m high and 1 m across its

widest dimension. S/C mass = 115 kg; spin rate = 5 rpm normal to the orbit plane; attitude knowledge provided by horizon crossing indicators, magnetometers and GPS; attitude control with torque rods and nutation damper; passive thermal control; power = 35 W; data rate = 6 MByte/day. The science data are made available to the science community. The mission design life is one year. The SNOE S/C was launched on a Pegasus XL vehicle (along with Teledesic LLC's T1 satellite - the world's first commercial Ka-band LEO satellite) on Feb. 26, 1998. The launch originated from VAFB, CA. 1858) 1859) 1860) 1861) 1862)

RF communications are provided in S-band. The S-band system consists of a transmitter, receiver/demodulator, hemispherical antennas, coupler, RF switch, and filter. The down-link data rate is 128 kbit/s, the modulation is PCM/PSK/PM. The uplink data rate is 2 kbit/s NRZ-M using PCM/PSK/PM modulation. The communications protocol employs the CCSDS standard. Mission operations for SNOE are being performed at LASP of the University of Colorado at Boulder with tracking and communication services provided by NASA.

Orbit: Sun-synchronous polar circular orbit, altitude = 556 km, inclination = 97.5° , equator crossing at 10:30 AM.

Figure 352: The SNOE S/C model

Sensor complement:

UVS (Ultraviolet Spectrometer). A limb-viewing instrument with the objective to measure the densities of nitric oxide in the altitude range of 50-200 km by observing the (1,0) and (0,1) gamma bands. UVS is of SME (Solar Mesosphere Explorer, see K.20) heritage; it con-

sists of an Ebert-Fastie spectrometer, an off-axis telescope, and two Hamamatsu PMT detectors. The spectrometer has a focal length of 125 mm and uses 3600 lines/mm mechanically ruled plane grating, which produces a dispersion of 2.15 nm/mm at the detectors. The grating in the spectrometer is set to place the (1,0) gamma band (215 nm wavelength) on one detector and the (0,1) gamma band (237 nm wavelength) on the other detector. Both channels have a sensitivity of ~ 1.1 counts/second/Rayleigh. - UVS is mounted with its optical axis perpendicular to the S/C spin axis. Its telescope images the entrance slit of the spectrometer on the limb. The image of the slit is 7 km high (resolution). The integration time is 28 ms for 2x spatial oversampling.

AP (Auroral Photometer).¹⁸⁶³⁾ AP is a two-channel broadband nadir-viewing instrument with the objective to observe UV emissions from the aurora and to determine the energy deposited in the upper atmosphere by energetic auroral particles. The channels (A and B) consist of two Hamamatsu PMT detectors, a US window/filter for each channel, and a FOV limiter. FOV = 11° (full cone) for each channel. Spectral range observed = 125-180 nm for channel A and 135-180 nm for channel B. The sensitivity of channel A at 130.4 nm is ~ 70 counts/second/Rayleigh; the sensitivity of channel B at 135.6 nm is ~ 27 counts/second/Rayleigh. - The AP instrument is mounted with its optical axis perpendicular to the S/C spin axis. The integration time for each channel is 187 ms, providing 32 samples per channel per spin.

Figure 353: Illustration of the SNOE instruments

SXP (Solar X-ray Photometer).¹⁸⁶⁴⁾ A sun-viewing instrument with the objective to measure the solar soft X-ray flux within a FOV of $\pm 35^\circ$ of the local zenith direction in the spectral range of 2-31 nm. Each of the five photometer channels contains a silicon photodiode detector; the wavelength selection is accomplished by thin metallic films deposited directly onto the diode surface. The integration time is 62.5 ns. A small two-axis sun sensor is co-aligned with SXP to measure the solar incidence angle for the instrument.

BGSR (microGPS - Bit Grabber Space Receiver). The receiver is provided by JPL for orbit determination of SNOE (cooperation with the University of Colorado at Boulder). Instrument size: 6.3 cm x 11.5 cm x 5 cm, mass = 0.68 kg, power = 2.1 W (while operating, but 0.02 W on orbit average). The GPS orbit is determined about three times per orbit for short time intervals, otherwise the receiver is in hibernation. The information is used for post-factum ground orbit determination.

N.17.2 TERRIERS

The TERRIERS (Tomographic Experiment using Radioactive Recombinative Ionospheric EUV) satellite project is a collaboration between Boston University (Center for Space Physics), Aero Astro of Herndon, VA, University of Illinois at Urbana-Champaign (UIUC), NRL, MIT's Haystack Observatory, USAF Phillips Laboratory (Hanscom Field, Bedford, MA), and Cleveland Heights High School. The primary goal of the mission is to obtain individual 2-D (altitude-latitude) profiles of ionospheric electron density using EUV (Extreme Ultraviolet), visible and radio instruments. A further step in the analysis is to use these individual cuts (similar to CAT scan projections) to construct eventually a global 3-D image of the ionosphere. The overall approach permits detailed studies of solar and geomagnetic storms for a better understanding of the ionospheric structure and its relationship to external forces. D. Cotton of Boston University is the overall PI of the TERRIERS program.

TERRIERS is a spin-stabilized S/C with a spin rate of 10 rpm who's design is based on HETE. Satellite mass = 122 kg, total payload mass = 49 kg, S/C power = 21 W (average), design life = 1 year. The S/C was launched May 18, 1999 by a Pegasus XL launch vehicle off the coast of California (the aircraft started from VAFB, CA). Another satellite on the same launcher was MUBLCOM (Multiple Path Beyond Line of Sight Communications), a demonstration satellite for DARPA of DoD. [The objective of MUBLCOM is to demonstrate a unique new capability to provide space-based digital voice and data communications to combat forces or commercial users that were previously considered out of range of standard radio communications systems.]¹⁸⁶⁵⁾

Orbit: Sun-synchronous circular polar orbit, altitude = 550 km, inclination = 97.5°, ascending node at 9 AM, period of about 96 minutes.

Mission and payload operations for TERRIERS are being performed by students at the Payload Operations Center of Boston University. The S/C is serviced by one ground station; all communications are in S-band.

Status: After orbit injection the TERRIERS S/C failed to orientate itself to allow the solar panels to work fully and its battery lost power after launch. A review board found that a wiring error caused the spacecraft's attitude control to malfunction and its solar panels to point away from the sun.

Sensor complement:

TESS (Tomographic EUV Spectrograph System). TESS is the prime instrument package of the TERRIERS payload.¹⁸⁶⁶⁾ The objective is to image the strength of radiative EUV emission profiles in the ionosphere with good spatial (50 km) and spectral resolutions (20 Å). The overall system consists of five spectrographs, four identical nightglow instruments (for redundancy and added sensitivity), and one spectrograph for daytime operation, featuring a smaller aperture slit to reduce sensitivity and to increase spectral resolution (10 Å). Each spectrograph is referred to as a SEIS (Single Element Imaging Spectrograph). The instrument features a diffractive optical design combining the spectral qualities of a Rowland-mount spectrograph with the imaging capabilities of a Wadsworth-mount spectro-

graph with a unique toroidal diffraction grating. The detectors employed are MCP (Micro Channel Plate).

Figure 354: The TERRIERS S/C model

Parameter	Night (day) value
Number of spectrographs	4 (1) SEIS
Spectral range, spectral resolution	800 - 1400 Å, 10 - 20 Å
Slit size	0.5 mm (0.1 mm) x 40 mm (10 mm)
Grating	Toroidal
surface figure	3200/mm
line density	30 mm x 75 mm
blank size	25 mm x 65 mm
ruled area	150 mm x 290.4 mm
radii	900 Å
blaze wavelength	Si C
reflective coating	
Detector type	MCP with wedge strip
photocathode	KBr
format	0.20 mm x 0.20 mm (256 x 256 pixels)
FOV	10° x 10° with 0.5° spatial resolution across the limb

Data volume	~ 340 Mbit/day
On-board data storage	20 MByte in memory storage with error correction (2 systems)

Table 524: TESS parameter specification

GISSMO (Gas Ionization Solar Spectral Monitor).¹⁸⁶⁷⁾ The instrument is an optics-free solar EUV spectrometer with the objective to measure solar EUV emissions in the spectral range from 7 to 40 nm. The instrument design features a gas cell in which solar EUV photons ionize neon, producing an ion and a photoelectron of energy equal to the ionizing photon's energy minus the ionizing potential of neon. The subsequent measurement of the photoelectron's energy, coupled with a knowledge of the neon's cross section for photon absorption, yields information about the original photon's energy and flux. - The spectral resolving power ($\lambda/\Delta\lambda$) of the GISSMO spectrometer varies from 25 to 50, depending on photon energy. The instrument sensitivity remains constant over large (solar cycle) time scales - normally a problem for conventional instruments.

BEACON. BEACON is an on-board dual-frequency transmitter (150/400 MHz frequency), developed by NRL, with the objective to measure electron density profiles through the upper atmosphere in conjunction with a ground-based network of radio beacon receivers. This ground network is provided and operated by NRL, UIUC and by Phillips Laboratory with the intent to observe electron densities from line-of-sight TEC (Total Electron Content) measurements.

Photometers. Two lightweight photometers, each with a FOV of 0.4° in diameter, will be flown aboard TERRIERS. One photometer will measure atomic oxygen emissions at 630 nm (to obtain photoemission profiles); the second instrument is intended to measure the off-line signal to obtain an estimate of background radiation. Both instruments use interference filters and integrated photon detectors consisting of channeltron detectors and associated electronics.

N.17.3 CATSAT (Cooperative Astrophysical and Technology Satellite)

CATSAT is a small satellite mission designed and built by the University of New Hampshire (UNH, Durham, NH) with support from the University of Leicester (Leicester, UK), sponsored by USRA (Universities Space Research Association and NASA in the STEDI (Student Explorer Demonstration Initiative) program. Its scientific mission is to study the nature and distribution of cosmic gamma-ray bursts by observations in the soft X-ray band down to energies of 500 eV. Its technology mission will be to demonstrate that an all university team can construct, launch, and operate a mission of this extent. ¹⁸⁶⁸⁾ ¹⁸⁶⁹⁾ ¹⁸⁷⁰⁾

The S/C is three-axis stabilized with an orbital zenith and solar reference position accuracy of $\pm 5^\circ$. CATSAT is a minisatellite with a boxlike structure of dimensions: 100 cm x 100 cm x 103 cm, S/C mass = 168 kg, power = 90 W. The attitude system employs a biased momentum system; a redundant set of reaction wheels with magnetic torque coils for momentum dumping and backup (the torque coils are used to offload the reaction wheel de-spin to prevent saturation, hence: 'momentum dumping'). Attitude measurement is provided by two three-axis magnetometers, two coarse and two fine sun sensors and two horizon sensors, providing $\pm 5^\circ$ control and $\pm 1^\circ$ of attitude knowledge. TT&C communication uses S-band in the uplink and downlink using CCSDS protocols. The uplink is PM modulated at 4 kbit/s, the downlink uses BPSK modulation at 16 kbit/s or 1 Mbit/s. The science data volume is about 50 MByte/day and is downlinked about twice per day. Planned design life is one year

with a goal of two years of operation. A launch is planned for Dec. 2001 on a Delta-II 7310 from VAFB in a dual payload configuration with NASA's ICESat mission.

Orbit: Sun-synchronous dawn/dusk orbit, altitude = 590 km, inclination = 94° , equator crossing at 6 AM on the ascending node.

Figure 355: The CATSAT S/C model

Sensor Complement:

SXR = Soft X-Ray spectrometer. The objective is to measure burst spectral information in the energy range from 500 eV to about 15 keV. The instrument uses APD (Avalanche Photodiode) detectors, material = Si, size = 1.7 cm^2 , with a 300 eV FWHM energy resolution near 1 keV. SXR consists of seven modules each containing 16 APDs and collimated to a 1 steradian FOV (the detectors are arranged in four groups of four on each module which are jointly collimated to yield a FOV of about 1 steradian. The pointing directions for the modules are offset so that together they view nearly 2π steradians). The instrument detectors are radiatively cooled to -40°C ; the energy loss information is recorded in seven separate spectra at a resolution of one second.

The use of APDs for direct soft x-ray detection is a new application for the devices, which are usually used to detect optical emission, and represents a key enabling technology for low-cost missions. APDs are constructed from high purity n-type silicon wafers that are doped to form a p-n junction. A very high reverse bias (about 1.5 kV) is applied across the diode so that charge carriers liberated by x-ray interactions in the silicon migrate into the depletion region, and are rapidly accelerated, generating a cascade of electron-hole pairs as they collide with silicon atoms.

Parameter	Value	Parameter	Value
Detector type	Silicon (ADP)	Energy range	0.5 to 20 keV
Operating temperature	-30° C	Energy resolution	E/D E > 1 at 500 eV
Quantum efficiency	> 80% at 2 keV	Active area	> 190 cm ²
Maximum count rate	10 ⁴ cts s ⁻¹	Limiting burst fluence	about 10 ⁻⁶ ergs cm ⁻² s ⁻¹
Angular resolution	23.6°	Total FOV	about 2 pi steradians

Table 525: Parameters of the SXR instrument

Parameter	Value	Parameter	Value
Detector type	4 cm f x 1 cm CaF ₂ (Eu) + 3" f PMT	Operating temperature	0° C
Energy range	15 to 380 keV	Energy resolution	E/D E > 3 at 30 keV
Quantum efficiency	> 80% at 2 keV	Active area	80 cm ²
Maximum count rate	10 ⁵ cts s ⁻¹	Limiting burst fluence	about TBD ergs cm ⁻² s ⁻¹

Table 526: Parameters of the HXR instrument

HXR = Hard X-Ray spectrometer, built by UNH. The objective is to measure burst spectral distribution in the energy range from 15 to 380 keV. The instrument uses four independent CaF₂ scintillation detectors of size: 7.6 cm in diameter x 1 cm, viewed by PMTs (of 7.6 cm diameter) with 20% FWHM resolution at 60 keV. The four detectors are located on the corners of the SXR assembly and are canted at 45° so that altogether they observe 2pi steradians of sky centered on the zenith direction. The energy loss information is recorded in four separate spectra at a one second time resolution.

DGS = Directional Gamma-ray Spectrometer. The objective is to measure the burst spectral information in the 250 keV to 5 MeV energy range. The sensors are NaI scintillators 7.6 cm x 7.6 cm in size, viewed by PMT detectors with 7% FWHM energy resolution at 662 keV. The instrument consists of three closely packed detectors located near the mass center of the spacecraft. Burst directional information is obtained by self shielding (i.e., the detector response function makes it possible to calculate the direction of the incident radiation with the help of a shadow technique applied to the particular geometric arrangement of the three detectors). The energy loss information is recorded in four separate (three singles and one multiple) spectra at sampling rates of one second.

There are two ground stations for CATSAT operations, one at UNH and one at the University of Leicester, UK.

N.18 SUNSAT (Stellenbosch University Satellite)

SUNSAT-1 is an advanced microsatellite program (start in 1992), developed by graduate students of the Department of Electrical and Electronic Engineering at Stellenbosch University, Stellenbosch, South Africa (Stellenbosch University is located about 50 km east of Cape Town).^{1871) 1872)} The overall objective is to demonstrate proven and new technologies in the fields of remote sensing, spacecraft control, the solid Earth sciences, and to provide services (mail box, speech and data relay experiments) to the AMSAT community. The S/C structure features a tray-based design of proven flexibility. The trays are sandwiched (stacked) between base and top plates of the S/C structure, containing all subsystems and payload instruments. The dimensions of the box-like S/C are: 45 cm x 45 cm x 62 cm; S/C mass = 64 kg; power = 30 W from body-mounted solar panels and rechargeable NiCd batteries; design life = 5 years; two on-board computers and an attitude processor.

¹⁸⁷¹⁾G. W. Milne, A. Schoonwinkel, et al., "SUNSAT - Launch and first Six Month's Orbital Performance," Proceedings of the 13th Annual AIAA/USU Conference on Small Satellites, Aug. 23-26, 1999, Logan Utah, SSC99-1-4

¹⁸⁷²⁾A. Schoonwinkel, G. W. Milne, et al., "Pre-Flight Performance of SUNSAT, South Africa's First Remote Sensing and Packet Communications Microsatellite," Proceedings of the 10th Annual AIAA/USU Conference on Small Satellites, Sept. 16-19, 1996

Figure 356: SUNSAT-1 S/C model in operational configuration

Figure 357: SUNSAT-1 instrumentation on zenith-pointing face

SUNSAT is stabilized with a gravity-gradient boom (2.2 m boom with a 4.2 kg tip mass consisting of 8 laser retro-reflectors, a star sensor and a magnetometer). The S/C is pointing toward nadir. Attitude actuators are: 3-axis reaction wheels (to provide fine-pointing during imaging), 3-axis magnetic torquer coils (continuous control capability). Attitude sensors are: 3-axis fluxgate magnetometer, 2-axis horizon sensor (CCD array, to obtain pitch and roll to an accuracy of 0.02°), a fine slit sun sensor (CCD array, to obtain yaw information to an accuracy of $<0.1^\circ$), a second star sensor to measure a star positions with accuracies of <12 arcseconds. A small S/C spin is provided during normal operations; however, not during imaging periods.

SUNSAT's communications employ the store-and-forward concept and the PACSAT protocol suite to provide the services for amateur radio communications (VHF, UHF, L- and S-bands), data downlinking (VHF, UHF, S-band), data collection (VHF, UHF), and spacecraft control. Different frequencies are at times required for different services. The power amplifiers have 5 W output at VHF and S-band and 10 W output at UHF. The S-band downlink permits QPSK modulation.

SUNSAT-1 was launched on a Delta-II vehicle from VAFB, CA on Feb. 23, 1999 as a secondary payload along with the Ørsted satellite of Denmark. The prime satellite was ARGOS of DoD. SUNSAT has been allocated the Amateur designation of SO-35 (SUNSAT Oscar 35) and is supporting Amateur radio FM repeater operations in South Africa and the USA.

Orbit: Sun-synchronous orbit, altitude = 857 km x 655 km, inclination = 96.4° .

Sensor complement:

HRI (High Resolution Imager). A three-color CCD imager, developed jointly by Stellenbosch University, CSIR (Council for Scientific Research, South Africa), and KAIST (Korean Advanced Institute of Science and Technology). The imager consists of a single 10 cm diameter optical tube assembly, comprising a lens system, penta-prism with dichroic color splitter, three vertically mounted linear CCD detectors (TC104 of Texas Instruments with 3456 pixels/line) and their clock drivers and output buffers. The optical tube is mounted diagonally across the bottom of the S/C on bearings, and can be rotated by a stepper motor. Stereo images are taken with the optical tube horizontal and normal to the velocity vector (forward or backwards pitching of up to 24° to obtain various stereo base/height ratios). Images to the left or right of the ground track can be taken by placing the optical tube parallel to the velocity vector. A 64 MByte RAM enables an image to be stored for subsequent downlinking. The spectral band selection is identical to that of TM of the Landsat missions (LS-2, -3, and -4). A ground pointing accuracy of the imagery within 1 km is the goal.

Imagery from a PAL TV camera is transmitted in real-time via S-band to a ground station at Stellenbosch. The HRI downlink is via the VHF and UHF transmitters, because of a malfunction of the high-speed modem, HRI transmission could not occur in S-band, as planned originally.

The reaction wheels of the attitude control system provide 3-axis stabilization during imaging periods. Fast target pointing (body pointing of the S/C) is accomplished with an axis-rotation algorithm.

Parameter	Value	Parameter	Value
Spectral band 1	0.52 - 0.61 μm	Lens focal length	570 mm
Spectral band 2	0.61 - 0.70 μm	Aperture diameter	100 mm
Spectral band 3	0.76 - 0.87 μm	Spatial resolution	15 m (800 km orbit)
Linear CCD detectors	3 x TC104 (one/band)	Swath width	51 km (800 km orbit)
Nr. of pixels/detector	3456 (active), 3490 total	FOV	3.715°
Sensor pixel size	10.7 μm	Line scan rate	400 lines/s
Total data rate	70.5 Mbit/s	Quantization	8 bit

Table 527: Summary of Imager parameters

TRSR (TurboRogue Space Receiver). A NASA/JPL-provided advanced GPS receiver (TurboRogue, built by Allen Osborne Associates) to perform experiments in atmospheric, ionospheric, and gravity mapping. The receiver is designed to overcome many of the anti-spoofing difficulties experienced by a GPS receiver on TOPEX/Poseidon. The receiver performs phase measurements of both GPS frequencies L_1 and L_2 , and derives pseudoranges from these measurements. The dual-frequency occultation technique employed measures retarded signals (atmospheric propagation delays) which permit the derivation of atmospheric profiles of density, pressure, and temperature (or moisture) in an altitude range from 85 km to the ground. The co-location of the GPS receiver and the satellite laser retro-reflector permit a check of the two reference frame systems for GPS and SLR geodesy.

- Objectives for atmospheric mapping: to improve occultation measurements of the troposphere to measure temperature (resolution of 1°C) and water vapor. Continuous GPS operations in occultation mode provides over 300 globally distributed measurements per day.
- Ionospheric objectives: continuous monitoring of the ionospheric structure. TurboRogue measures the arrival times of the GPS signals at two frequencies. Hence, the electron content of the ionosphere is measured in terms of the differential arrival times of these two signals.
- Geodesy and gravity objectives: the GPS and SLR systems of SUNSAT are being used for precise orbit determination. There are also plans to monitor the long wavelength gravity field and its variation in time.

MIS (Meteoroid Impact Sensor) of NASA/LaRC within the SEE program. The objective is to monitor the meteoroid and small mass man-made debris population. The experiment, which utilizes MOS detectors, is similar in concept and design to OMDC (Orbiting Meteoroid & Debris Counting) experiment flown on the Clementine spacecraft. When space debris or meteoroids particles impact the sensor, then the sensor location and time of impact is stored and down linked for data analysis. From this information, space-debris flux and directionality can be assessed.

Magnetometer. The magnetometer (provided by Hermanus Observatory, South Africa), collocated with the star camera in the tip mass of the gravity boom, provides a complementary measurement of the magnetic field to the Ørsted geomagnetic satellite.

Laser retroreflector. The passive laser retroreflectors (boom and S/C-mounted, provided by NASA/GSFC) offer SLR (Satellite Laser Ranging) measurements from many ground stations. The design features eight encapsulated retroreflectors inserted in a ring configuration azimuthally about the tip mass.

N.19 SURFSAT (Summer Undergraduate Research Fellowship Satellite)

SURFSAT-1 is a student summer project at the California Institute of Technology and 14 other universities in cooperation with JPL (NASA funding). The project began in 1987 with six students, each summer a new group of students took over, through 1994 a total of 61 students participated. The objective was to design, build, launch and operate a low-cost, low-power microsatellite for the purpose of testing the performance of space communication in Ka-band at frequencies of approximately 32 GHz. A further objective is to test NASA's VLBI ground stations (the stations communicate with two VLBI spacecraft in orbit: Japan's VSOP and Russia's RadioAstron). Surfsat-1 was launched November 4, 1995 on a Delta II vehicle as a secondary payload on the Radarsat satellite from Vandenberg AFB, CA. ¹⁸⁷³⁾

The microsatellite consists of two aluminum devices, each the size of a box of 30 cm edge length, which remain attached to the 2nd stage of the launch vehicle as it orbits the Earth.

¹⁸⁷³⁾http://sgra.jpl.nasa.gov/html_surfsat/SURFSATHomePage.html

The Surfsat-1/Delta 2 system is gravity gradient stabilized. Power is provided by body-mounted solar panels providing about 15 W orbit average power. The boxes are electrically connected by an interconnecting wire harness. Surfsat-1 contains low power radio beacons and transponders, radiating over hemispherical antennas in three microwave bands, for testing new NASA ground-tracking facilities. Three omni antennas (two on the primary box, one on the secondary box) are used for uplink and downlink communication. Three independent command detector units are used to control the operational state of the S/C. The satellite uses passive thermal control. The S/C has no propulsion system, batteries or attitude control/determination.

Orbit: Near circular polar orbit, perigee = 1000 km, apogee = 1400 km, inclination = 98.6°

Payload complement: Solar-powered mW-level microwave beacons and transponders with hemispherical coverage. Each “box” carries a transponder. The primary transponder operates at X-band and Ka-band. The secondary transponder operates at Ku-band. Both transponders radiate milliwatt (mW) level signals through the omni antennas.

- Coherent beacons for deep space communication tests: 10 mW at 8.4 GHz (X-band), 1 mW at 32 GHz (Ka-band)
- 10 mW output coherent microwave transponders (7.2 GHz up and 8.4 GHz down) for space VLBI (Very Long Baseline Interferometry) for RadioAstron (S/C of Russia)
- 20 mW output coherent microwave transponders (15.3 GHz up and 14.1 GHz down) for space VLBI tests for VSOP
- Three independent X-band command detector units for determining S/C states: On/Off, Acquisition/Normal, Ka-band/Ku-band
- Three (X-band, Ku-band, and Ka-band) short corner-mounted stub antennas with hemispherical coverage.

N.20 TechSat/Gurwin-II

TechSat/Gurwin-II¹⁸⁷⁴⁾ ¹⁸⁷⁵⁾ ¹⁸⁷⁶⁾ is a microsatellite, built by the Haifa-based Technion (Israel Institute of Technology) with industrial and government support (the S/C is also referred to as TechSat-1B). The Earth-pointing satellite was launched on July 10, 1998. A Russian Zenit-2 vehicle carried the Resurs-O1-4 satellite and five piggyback payloads (IRIS-1, TMSAT, TechSat/Gurwin-II, FASat-Bravo, and SAFIR-2) from the Baikonur Cosmodrome into orbit.¹⁸⁷⁷⁾

Status: The spacecraft is operational and functioning as of June 2001. All its subsystems were tested under various operational conditions. Of the payload complement, SOREQ and SUPLEX offered non-stop operations; two instruments (ERIP and XDEX) were periodically turned off; OM-2 failed after 10 months of operations; while SLRRE, the laser retro-reflector, was only used in the initial phase of the mission.

Background: TechSat is a microsatellite family of Asher Space Research Institute (ASRI) of Technion. As a university, Technion is involved in the development of space-qualified systems based on advanced and innovative technologies. TechSat is an academic program at Technion, it is also supported by Israel industry. The TechSat development started in 1993. TechSat-1a, a technology demonstration microsatellite (50 kg), was launched March 23, 1995 on a Russian Start launcher (a newly converted Russian intercontinental ballistic missile) and experienced a launch failure.

¹⁸⁷⁴⁾ Note: The microsatellite is named in honor of Joseph and Rosalind Gurwin whose long-term support for space research at Technion enabled the TechSat mission.

¹⁸⁷⁵⁾ Information provided by R. Waller of Technion.

¹⁸⁷⁶⁾ <http://www.technion.ac.il/shell/Research/Space—Institute.html>

¹⁸⁷⁷⁾ M. Guelman, F. Ortenberg, A. Shiryaev, R. Waller, “Microsatellites for Science and Technology: Gurwin-TechSat in-flight Experiments Results,” Proceedings of the 3rd International Symposium of IAA, Berlin, April 2-6, 2001, pp. 67-70

The TechSat/Gurwin-II satellite is of cube shape with a size of 445 mm x 445 mm x 445 mm. It is three-axis stabilized, it has a momentum wheel and three magnetorquers as actuators, a three-axis magnetometer as attitude sensors; all attitude instruments have a total power consumption of about 3 W. The power consumption for all housekeeping functions is less than 10 W (including transmitters, receivers, on-board computer, and power conditioning. Initial attitude stabilization (after injection) used “Coarse Cruise” algorithms that utilize magnetometer data only with pointing accuracies within 5°. This was followed by the “Fine Cruise” phase. The solar cells are mounted on four sides of the six outer aluminum panels (a NiCd battery is provided for eclipse operations). The fifth panel, pointing toward Earth, includes antennas, the retroreflector, the UV spectro radiometer (OM-2) and a camera. The sixth panel is opposite the Earth-pointing panel 5; it is not exposed to the sun and therefore does not include solar cells. The structure plays a major role in the thermal design. The heat flows from the solar illuminated panels to all parts of the structure that are used as radiators. The S/C mass is 48 kg, the total payload mass is 6.6 kg, power = 20 W. The S/C design life is one year.

Satellite operations are conducted from a ground station at Technion. The S/C features a digital store and forward multi-user system, compatible with existing store and forward facilities already in use on microsatellites (use by the international amateur radio electronic community). Communication is realized via receive and transmit antennas. Three uplinks in the 145 MHz VHF band (2 m), three uplinks in the 1270 MHz L-band (23 cm), and one downlink in the 435 MHz UHF-band (70cm). Data is transmitted at two available rates: 1200 bit/s and 9600 bit/s. At 1200 bit/s the carrier modulation is BPSK (downlink) and FM (uplink). At 9600 bit/s the carrier modulation is FM (downlink & uplink).^{1878) 1879)}

Orbit: Sun-synchronous circular orbit, altitude = 820 km, inclination = 98.8°, period = 101 min, local time of equator crossing is at 10 AM in descending node.

Sensor complement:

OM-2 (Ozone Meter-2). Objective: Measurement of the ozone concentration in the Earth’s atmosphere (vertical distribution of ozone and the total ozone amount in the nadir direction). Study of latitudinal, seasonal and planetary-scale ozone variability. OM-2 is a UV spectroradiometer with a total mass of 1.80 kg (optical head of 1.55 kg and the microcontroller of 0.25 kg), “a tiny SBUV instrument,” measuring in the spectral range of 252 - 340 nm. The instrument uses a filter-wheel photometer that measures the SBUV (Solar Back-scattered UV) radiance.

Spectral region	252 - 340 nm
Number of spectral bands	7 fixed wavelengths with 1.0 nm bandwidth located at: 252.0, 273.5, 283.0, 292.2, 301.9, 320.0, 340.0 nm
Measurement height of atmosphere	0 - 55 km
Swath width	170 km
Spatial resolution (IFOV), vertical resolution	170 km x 70 km, 5 km
Precision of ozone density profile determination	10-15%
Instrument mass, power	1.80 kg, 3 W

Table 528: OM-2 parameter definition

The optical sensor head consists of the following subsystems: a single lens objective, a filter wheel, a set of apertures, a baffle, and a photomultiplier detector (Rb₂Te, 26 mm in diameter). The mounted objective has an aperture of 10 cm in diameter and an effective focal length of 80 mm. OM-2 conducts sequential measurements of SBUV radiation in seven wavelengths (each of 1 nm width), the sampling time is 30 ms. A total measurement se-

¹⁸⁷⁸⁾<http://techsat.internet-zahav.net/>

¹⁸⁷⁹⁾<http://www.technion.ac.il/pub/projects/techsat/asher/asri.html>

quence lasts 5 s. The total footprint size is 70 km (along-track) x 170 km (cross-track), the corresponding FOV is 3° x 12°. The data volume of one day of contiguous measurements is about 50 kByte after data compression. ^{1880) 1881)}

Spectral range	0.5 - 0.8 μ m
Spatial resolution	52 m along-track x 60 m cross-track
Image size	25 km (along-track) x 31 km (cross-track)
Size of CCD detector array	12 mm
SNR	50 dB
Light sensitivity	0.5 lux
Exposure	1/60 to 1/1000 seconds
Instrument mass, power, data rate	1.0 kg, 4.5 W

Table 529: Instrument parameters of ERIP

ERIP (Earth Remote-Sensing Imaging Package). Objective: Collection of snapshot pan-chromatic imagery in the vicinity of ground stations. The instrument consists of a CCD video camera unit (VCU) and an Image Processing and Control card (IPC). ERIP uses a Nikon objective, $f=135$ mm, and a PUL NiX CCD TM-720. On command, a video image is captured, digitized, compressed and stored in an image buffer for later transmission. The compressed image data is transferred to the OBC (On Board Computer) and transmitted to the ground station, where the captured image is decompressed and displayed. Each image contains about 250 kByte of data, or about 60 kByte after compression.

SOREQ (Single Event Monitor for Detecting Protons and Heavy Ions in Space). Objective: measurement of the solar charged particle environment (protons and heavy particles) for a better understanding of the changing radiation environment (interest in the hazardous nature of the environment to long-term effects on S/C electronic systems). SOREQ measures SEU (Single Event Upset) and SEL (Single Event Latch-up) occurrences in six HM65162 (2k x 8 SRAM) devices. [Note: single-event latch-ups manifest themselves in a sudden increase of power consumption.] The devices are arranged in two groups, allowing for the examination of chips from different date codes having different sensitivities. The TechSat computer initializes, twice per minute, a read-write circle (about 1 ms in duration) and serially reads the shift register. This enables mapping of events with a resolution of about 2°. The instrument mass is 0.23 kg, its power consumption is < 30 micro W. ¹⁸⁸²⁾

SUPLEX (Superconductivity Experiment). ^{1883) 1884)} Objective: Conduction of a series of operational tests of the instrument in flight - consideration for later use of power generation. The superconducting device is based on thin film technology (developed at the Physics Department of Technion) made of $Y_1Ba_2Cu_3O_7$. It uses superconducting filters to separate the channels. The experimental assembly on-board TechSat comprises the HTS (High Temperature Superconductor) device, a cryocooler and electronic instrumentation. An automatic electronic technique is used to measure the transition temperature and critical current in the superconducting state. Cyclic measurements (about 15 minutes) are conducted once a week. The device is mounted into an insulating housing, and is thermally attached to a K-508 miniature cryocooler of Ricor, Ltd., Kibbutz Ein-Harod Ihud, Israel. The overall

instrument mass is 0.63 kg, the power consumption is 12 W. The nominal cooling power is 0.5 W at 77 K.

XDEX (X-Ray Detector Experiment). Objective: 1) test of high performance, sensitive X-ray detectors (CdZnTe) with high energy resolution; 2) test of a focal plane array where photon counting and signal processing can be performed and stored; and 3) test of degradation of the detectors/focal plane array assembly in a high-energy particle environment. The instrument consists of solid-state detectors, a sensitive preamplifier, a microcontroller and memory. The experiment is a step towards development of an X-ray telescope based on CdZnTe detectors. The instrument mass is 1.6 kg.

SLRRE (Satellite Laser Ranging Retroreflector Experiment). Objective: High-precision laser ranging measurements from the ground for orbit determination (5-10 cm range). SLRRE is a passive on-board experiment consisting of an array of laser retroreflectors, corner-cube mounted on the Earth-viewing panel (panel 5) of the microsatellite. The SLRRE mass is 0.65 kg.

N.21 TUBSAT (Technical University of Berlin Satellite)

TUBSAT is a low-cost and fast-turnaround microsatellite program series defined, designed and built by TUB (Technical University of Berlin, with DLR funding). The objective is to explore technical capabilities in microsatellite design (in particular in the field of attitude determination) and space-related applications. The following fields of study are of particular interest:^{1885) 1886)}

- S&F (Store & Forward) communication techniques in conjunction with DCS (Data Collection Systems)
- Test of attitude control systems
- Test of disaster monitoring technologies

Satellite	Payload Class	S/C Mass	Launcher	Launch Date
TUBSAT-A	S&F communications	35 kg	Ariane-4	July 17, 1991
TUBSAT-B	Earth observation	45 kg	Tsyklon	Jan. 25, 1994
TUBSAT-N, N1	S&F communications	8 kg, 3 kg	SHTIL	July 7, 1998
DLR-TUBSAT	Earth observation	45 kg	PSLV	May 26, 1999
MAROC-TUBSAT	Earth observation	40 kg	Zenit	2001

Table 530: Overview of the TUBSAT program

N.21.1 TUBSAT-A

The microsatellite has a cube structure with dimensions of 38 cm x 38 cm x 38 cm and a mass of 35 kg. It is three-axis stabilized, control is provided by three magnetorquers and a magnetometer. Attitude is sensed by star and sun sensors. The objectives are to study S&F techniques and to test an attitude control system. TUBSAT-A was launched piggyback July 17, 1991 from Kourou by Ariane V44/ASAP together with ERS-1 and three other microsatellites [UoSAT-5 (SSTL), SARA (French University), DATA-X (OSC)]. As of 1/1996 TUBSAT is operating nominally.

Orbit: Sun-synchronous polar orbit, altitude = 780 km, inclination = 98.42°, equator crossing time at 10:30 AM.

S&F communication is provided in VHF-band (143.075 MHz) at a data rate of 1200 baud. The satellite uses an ALOHA-type access system for ground communications; it transmits a

¹⁸⁸⁵⁾ Information provided by U. Renner of TUB

¹⁸⁸⁶⁾ U. Renner, "Small Satellites at the Technical University of Berlin," IAA 2nd International Symposium on Small Satellites for Earth Observation, Berlin, April 12–16, 1999, pp. 253–256

set of telemetry data plus one kByte of text data every 4.5 minutes. On-board storage capacity is 32 kByte. Typical experiments are with lightweight (hand-held) ground stations such as manned expeditions in arctic and antarctic regions, tracking of drifting buoys and location experiments with animals (deer). TUBSAT is operated by a single ground station at TUB; it comprises a steerable cross-polarized yagi-antenna and standard radio amateur receive and transmit equipment.

Status: TUBSAT-A is fully operational as of June 2001 (10 years in orbit as of July 17, 2001).

N.21.2 TUBSAT-B

A microsatellite with dimensions of 38 cm x 38 cm x 50 cm and of 45 kg mass with the objective of Earth imaging. The S/C is three-axis stabilized with three reaction wheels. Attitude is sensed by star and sun sensors. TUBSAT-B was launched on January 25, 1994 as a secondary payload(together with Meteor-3-7) by a Russian Tsyklon launcher from Plesetsk.

Orbit: Polar orbit, altitude = 1250 km, inclination = 82.3°.

On March 5, 1994 contact with TUBSAT-B was lost after 39 days of successful operation. Transmission frequency in VHF-band (143.075 MHz) at data rates of 1200 and 2400 baud.

Sensor:

A video camera system in the VNIR spectral range capable of taking snapshots of the ground. System parameters: Zeiss Jena telescope with 1 m focal length (folded optics), aperture = f/5.6, CCD array: Thomson-CSF, 288 x 384 pixels. FOV = 0.35° x 0.5°; spatial resolution = 23 m x 30 m.

N.21.3 TUBSAT-N (Technical University of Berlin Satellite-Nano)

TUBSAT-N and -N1 are two communication (data collection) nanosatellites of the Technical University of Berlin (Institute of Aeronautics and Astronautics) which were tandem-launched July 7, 1998 on a Russian SS-N-23 military launch vehicle (also referred to as SHTIL).¹⁸⁸⁷⁾ The submarine launch, from the Delta-IV class nuclear vessel 'Novomoskovsk' of the Northern Fleet, took place in the western Barents Sea (in the vicinity of Murmansk). Both satellites were separated from the launch vehicle's payload capsule after orbit injection. The launch represents the world's first underwater/space launch of a satellite into Earth orbit on the basis of a commercial service. Both satellites are used for mobile communications with the following objectives and service provision (a consistent extension of the TUBSAT-A package):¹⁸⁸⁸⁾

- Demonstration of low-cost access to space without performance reduction
- Bidirectional data transfer between autonomous environmental stations and the satellite (e.g., drifting buoys in the ocean, arctic and antarctic meteorological stations, etc.)
- Tracking of medium-sized and large mammals
- Worldwide positioning and deactivation services of stolen cars and support of very mobile communications.

TUBSAT-N has the shape of a small box with dimensions of 320 mm x 320 mm x 104 mm; its mass is 8.5 kg. A carbon fiber structure was chosen for both satellites for stiffness and lightweight design (passive thermal stabilization). Implementation of a single-board design, functional integration of modules/subsystems (e.g., TT&C with communication module), there is no physical separation between platform and payload. The ACS (Attitude Control

¹⁸⁸⁷⁾ Note: SS-N-23 is the NATO designation for the Russian RCM 54 missile, built by the Makeyev State Rocket Center of Miass (a town in the Ural Mountains).

¹⁸⁸⁸⁾ R. Schulte, "TUBSAT-N, A Global Communication Satellite System, Based on Nanosatellites," Proceedings of the 4th International Symposium on "Small Satellites Systems and Services," Sept. 14-18, 1998, Antibes Juan les Pins, France

Subsystem) consists of a CCD star sensor, a 3-D magnetic compass, two magnetic coils and a reaction wheel. Note: ACS on TUBSAT-N is simply flown as an experiment to space qualify the star sensor and the reaction wheel (mobile communication with omnidirectional antennas does not require such attitude control). Electrical power is provided by 9 NiCd battery cells of 5 Ah. They are charged by two strings of solar cells (34 cells per string) with cell dimensions of 6 cm x 4 cm. The solar cells are mounted on the top and bottom surface of the box. TUBSAT-N has an on-board storage capacity of over 6000 messages at 134 bytes in length. The messages are transferred several times per day to the TUB ground station.

TUBSAT-N1 is of same design but somewhat smaller (dimension: 320 mm x 320 mm x 34 mm; mass = 3 kg; 9 NiCd battery cells of 2.8 Ah). The design life for each S/C is seven years. The solar generator consists of two parallel strings with 36 cells on each side with cell dimensions of 4 cm x 2 cm. Nine NiCd cells of 2.8 Ah provide battery power.

The tandem launch of the two satellites represents a demonstration of the launch and separation technology of the SS-N-23 launch system. In addition, the communication coverage of the overall system is improved and redundancy provided by the two-satellite configuration.

Orbits: elliptical orbits, both satellites are in the same orbital plane, apogee = 780 km, perigee = 404 km, inclination = 78.9°.

Status of mission: Due to relatively low orbital perigees the satellites ended their service lives; TUBSAT-N1 after about one year of operation, and N after two years of operation. The lower mass of N1 (3.0 kg) was more affected by the drag forces than the N spacecraft (8.5 kg) with more than double the mass of N1.

Communication configuration for data collection:

TUBSAT-N uses four independent communication channels (two VHF, two UHF), all with FFSK modulation (optional GMSK). TUBSAT-N1 uses two UHF communication channels, all with FFSK modulation (optional GMSK). Data collection function: Access to the satellites is via MP-TDMA (Modified Preassigned - Time Division Multiple Access). The satellite antenna radiation pattern is sufficiently omnidirectional to guarantee a link budget in any direction. The S/C UHF and VHF transmitter power is 10 W.

A mobile communications terminal in the ground segment consists of the following components: 16-bit CPU, RAM and FLASH memory, real-time clock, DC/AC converter for GPS receiver, FFSK or GMSK ASIC and a UHF/VHF transceiver, based on YAESU (manufacturer) chip sets. Several I/O pins, a serial communications interface and eight analog channels provide connection to external devices (e.g., LCDs, keyboards, measurement devices, etc.). With the knowledge of position, time and orbital parameters of the satellite, provided at each contact, the mobile terminal is able to calculate the upcoming contact times with the space segment for elevations above 5°. Each terminal has predefined time slots for communicating with the satellites (including update orbital parameters). The data collection rates between S/C and terminal are either 1200 or 2400 baud. An additional downlink transmitter with 9.6 kbaud and GMSK modulation is used to transmit the collected messages to the central ground station.

The two nanosatellites collect also data from a number of Lagrangian buoys that are automatically submerged to depths of 2500 m to measure salinity and other parameters, they only rise to the ocean surface after predefined measurement periods for the purpose of data transmission.

N.21.4 DLR-TUBSAT

A joint venture between TUB and DLR, Berlin Adlershof. The prime objective of the mission is to test a newly developed attitude control system (S/C attitude recovery from hiber-

nation); a secondary objective is to test a TV camera system to demonstrate disaster monitoring. The microsatellite is three-axis stabilized, it has dimensions of 32 cm x 32 cm x 32 cm and a mass of 45 kg. The bus consists of four aluminium shells, one for each subsystem. The first shell contains ACS (Attitude Control Subsystem), the NiH₂ batteries and the TT&C subsystem are part of shell number two. The payload is part of the third shell, and OBDH (On-Board Data Handling), along with an S-band transmitter, is contained in the fourth shell. 1889) 1890) 1891)

Attitude is sensed by the camera assembly; the actuators consist of three reaction wheels (TUB design) and three fiber optic laser gyros providing a pointing knowledge accuracy of ± 1 arcsecond. The agile S/C is pointable into any direction and able to stabilize itself on short notice within a few seconds. Tracking modes for inertial pointing (S/C attitude) and/or target pointing (Earth observation) are supported. In its normal standby (hibernation) mode, the S/C tumbles in its orbit at rates of about 0.1 rpm. An acquisition sequence starts with a rate reduction command, followed by a coarse sun acquisition maneuver. This may be followed by a TV transmission.

A S/C passenger launch took place on an ISRO PSLV launcher from the SHAR lunch site, India, on May 26, 1999 (along with IRS-P4 as the primary payload and KITSAT-3 as another secondary payload).

Orbit: Sun-synchronous polar orbit, altitude = 720 km, inclination = 98.28°, period = 99.3 min.

Status: DLR-TUBSAT is fully operational as of June 2001.

Sensor complement:

Camera Assembly. The system (a Sony CCD array system with Nikon optics) consists of three commercially available TV cameras: a wide-angle camera with 16 mm focal length with a black-and-white chip, a standard-angle optic with 50 mm focal length and color CCD chip, and a narrow-angle camera (a tele lens) with 1000 mm focal lens and black-and-white chip. The objective is to provide a snapshot imaging capability of medium or high-resolution ground scenes of locations stricken by disaster (hazardous or unexpected environmental events such as wild fires, floods, and earthquakes). Each camera head of the camera assembly can be selected as the active one. All cameras are aimed in the same direction (nadir direction by default), but offer different fields of view (image sizes). One of the three cameras may provide imagery at any time (16 mm camera by default). The camera system automatically adjusts its gain to prevailing illumination conditions. A body-pointing capability is provided by ACS of the S/C, allowing the camera assembly to look at targets anywhere up to the horizon. The camera assembly has a video output as well as a digital output. Both of them can be selected to feed the S-band transmitter. The analog signal is coded as a standard FM PAL signal which may be received by a 3-m antenna dish and standard equipment. The digital data is bi-phase level encoded with a transfer data rate of 125 kbit/s. A 1.2 m antenna dish is sufficient for reception.

Spacecraft operation: The S/C is normally operated from a single ground station at TU Berlin (TT&C operations in UHF-band, the UHF transceiver receives and transmits data at a rate of 1200 baud, FFSK modulation). Most of the time (certainly over 95%) the satellite is orbiting in standby mode, slowly tumbling (a few rotations per orbit); all on-board systems are in hibernation (including ACS) to save power; only the UHF receiver is listening for potential commands. In case of an event, the S/C attitude may be restituted within a few minutes. However, this wake-up capability requires the S/C to be in view of a commanding UHF station. TUB has portable UHF ground stations from its TUBSAT-A experience to handle such events; it is also relying on the use of existing infrastructures of the remote sensing community.

Parameter	16 mm camera	50 mm camera	1000 mm camera
CCD array size	750 x 580 pixels	750 x 580 pixels	750 x 580 pixels
Pixel size	8 μm x 8 μm	8 μm x 8 μm	8 μm x 8 μm
IFOV		9.2×10^{-3} degrees	0.46×10^{-3} degrees
FOV		$6.9^\circ \times 5.336^\circ$	$0.345^\circ \times 0.267^\circ$
Nadir image size (1000 km altitude)	110 km x	120 km x 92.8 km	6 km x 4.6 km
Nadir ground resolution (IFOV)	370 m x 370 m	120 m x 120 m	6 m x 6 m
Focal length, f/number	16 mm	50 mm, f/1.8	1000 mm, f/11
Spectral range	Panchromatic	Panchromatic	Panchromatic

Table 531: Definition of Camera Assembly

There is no on-board storage capability for video data from the Camera Assembly. Real-time transmission of the video data is in S-band (frequency = 2.206 GHz, bandwidth = 8 MHz, data rate at 128 kbaud using analog video, the beamwidth of the S-band antenna is 70°) to a ground station in the vicinity of the event. Video transmission beyond the TU Berlin ground station has to be negotiated on a case-by-case basis. A possible alternative for video data reception coverage may also be found in the widespread use of portable commercial S-band transmitter systems and their corresponding receiver systems. The S-band transmitter system on DLR-TUBSAT happens to be of the same type as those regularly used in TV coverage of sports events, such as in the helmet of a downhill skier.

N.21.5 Maroc-TUBSAT

Maroc-TUBSAT is a cooperative microsatellite project between CRTS (Centre Royal Tele-detection Spatiales) of Rabat, Morocco, and the Institute of Aeronautics and Astronautics

of the Technical University of Berlin (TUB). In this joint venture, the Moroccan side is responsible for the development of the payload and launch of the satellite while the German side provides the satellite bus. The overall objectives of the mission are in Earth remote sensing (in particular with regard to vegetation detection at medium-scale resolutions), and in the field of store-and-forward communications for mobile localization. A further goal is to develop attitude control strategies for high-resolution Earth observations.¹⁸⁹²⁾

The project selected an adaptation of the existing TUBSAT-C bus, a three-axis stabilized box structure of size: 320 mm x 340 mm x 362 mm. The main elements of the bus are: the attitude control module, the power module, and the payload module. The modular design provides functional freedom and flexibility during all phases of development. S/C power is provided by four surface-mounted solar cells (60 W max) and by 4 NiH₂ batteries with a capacity of 12 Ah. The attitude control subsystem (ACS) employs a star sensor (inertial attitude determination), a three-axis magnetic field sensor, and three fiberoptics gyros for attitude sensing. In addition, single solar cells on the surface-mounted solar panels are used for coarse sun direction determination. Attitude actuation is provided by three reaction wheels and magnetic coils. The S/C mass is 47 kg.

A launch of Maroc-TUBSAT is planned for Nov. 2001 on a Zenit-2 launch vehicle from the Baikonur Cosmodrome, Kazakhstan. The prime payload is Meteor-3M-1. Secondary payloads on the flight are the Badr-2 satellite of Pakistan, Maroc-TUBSAT of CRTS, the Compass spacecraft of IZMIRAN, Moscow, and REFLECTOR (US/Russia).

Orbit: Sun-synchronous circular polar orbit, mean altitude = 830 km, inclination = 98.85°, period = 102 minutes; local time of ascending node is 9:15 AM.

RF communications: Store-and-forward communications of TT&C data in UHF and VHF (AMSAT standard) are provided at data rates of 1.2 kbit/s (uplink and downlink, FFSK modulation). The RF output power is 3.5 W for UHF and 5.0 W for VHF. The payload data is transmitted in S-band (BPSK modulation, FEC, 2 W RF output) at data rates of up to 250 kbit/s. Spacecraft operations are conducted at (TUB, CRTS), ground stations are at TUB and at CRTS.

The mission scenario of spacecraft activity/operations is event-driven as practiced on DLR-TUBSAT. This implies that Maroc-TUBSAT spends most of its time in hibernation mode. Event recognition (time) or a command for a ground station cause the spacecraft to return to observation mode. - The following general start-up and acquisition sequence describes the steps involved in S/C recovery/initiation from the hibernation mode (ACS is off) into an operations mode for recording specific areas of the Earth by the payload camera:

- At a preprogrammed event time turns the ACS on. This causes a reduction in tumbling motions by a rate damping process, provided by the closed-loop system of gyros (3) and reaction wheels (3). The residual motion amounts to <0.5°/s.
- In the event that the star sensor is blinded by Earth or the sun, a slew maneuver is enacted to align the sensor to a star (information is provided by the solar cells and by orbit model inputs). The star sensor is now capable to determine the inertial attitude of the system.
- Meanwhile, the ground station software compares the current S/C position with the intended acquisition time. It seeks a minimum solution for the three different slew maneuvers (controlled by the gyros).
- The predefined attitude of the S/C is reached after slew maneuver completion. The pointing accuracy in this mode is better than ±0.05° (limited only by the star sensor performance).
- The hibernation mode is turned on again by the operator after observation and data transmission of the pass are completed. The batteries are recharged in hibernation mode.

¹⁸⁹²⁾“MAROC-TUBSAT, A Microsatellite for Earth Observation,” TU-Berlin, Ref. 2 EB-MT-R01

Sensor complement:

EIC (Earth Imaging Camera), developed at RAL, UK (same camera as on BADR-2). The instrument optics have a focal length of 72 mm with f/6 number. Observations are performed in the visible/near-infrared range. A filter is used for the near-infrared range. The FOV is $\pm 8.5^\circ \times \pm 8^\circ$, providing an image size of about 190 km x 144 km at a resolution of 250 m. A CCD matrix array of 770 x 576 pixels is used (of EEV, Chelmsford, UK, pixel size of 32.5 μm) is used with frame transfer of imagery. The nominal integration time for a snapshot is 28 ms. A 12 bit data quantization is used.

Star Sensor (of ACS). The instrument consists of the following elements: A CCD array camera, optics with 16 mm focal length and f/0.95, analog electronics and a microcontroller for star tracking, a microcontroller for star recognition (relative and inertial attitude determination), a RS422 serial interface to the host computer, a mechanical interface for mounting and heat transfer, and a power supply. The CCD array is of size: 288 x 384 pixels with frame-transfer capability (8 bit data quantization). The microcontroller uses a star catalog of 6000 stars and a pattern recognition database. The FOV of the sensor is $21^\circ \times 31^\circ$, an inertial pointing accuracy of $\pm 0.02^\circ$ is provided. The instrument has a mass of 0.68 kg, power = 5 W, data rate = 38.4 kbit/s.

N.22 UniSat (University Satellite)

UniSat is an experimental microsatellite project of the University of Rome (Universita di Roma “La Sapienza”, Scuola di Ingegneria Aerospaziale). Education and hands-on experience of students and faculty in the field of aerospace engineering is the overall theme of the program (involving a number of Italian universities), funded by the Italian Government MURST (Ministry of University and Technological Research) and by ASI (Italian Space Agency). In the framework of the UniSat program, a laboratory for satellite design and construction and an amateur ground station called SPIV (San Pietro in Vincoli), were established at the University of Rome. ¹⁸⁹³⁾ ¹⁸⁹⁴⁾

The UniSat-1 development phase started in 1997 at GAUSS (Gruppo di Astrodinamica dell’ Universita degli Studi “la Sapienza”), sponsored by ASI in cooperation with other Government Research Centers and with industry. The S/C body structure consists of an octagonal prism, 40 cm in diameter and a height of 25 cm. The modular tray design employs five Al/Al honeycomb plates, kept together by four stainless steel bars. Eight lateral panels with surface-mounted solar panels make up the external surface of the spacecraft. The satellite is spin-stabilized at 5 rpm with the spin-axis normal to the orbital plane. Attitude is sensed with two three-axis magnetometers and the use solar panels as a sun-sensing system. Actuation is provided by an active magnetic control system for spin-axis orientation and for spin rate control. One equatorial coil is used for spin-axis orientation and two transverse magnetic coils are used for spin-up/spin-down maneuvers. An average power of 10 W is provided by the solar panels. In addition, NiMH batteries of 2.4 Ah capacity are used for eclipse operations. The OBC (On-Board Computer) consists of a distributed network of microcontrollers (master/slave architecture) providing flexibility and reliability. UniSat-1 has a mass of 12 kg, qualifying almost as a nanosatellite. The S/C design life is one year.

The RF communications are implemented according to AMSAT standards with VHF (145.848 MHz) in uplink and UHF (436.450 MHz) in the downlink using the AX.25 packet protocol at data rates of 9.6 kbit/s. The UHF transmitting antenna consists of four dipoles providing circular polarization. The VHF receiving antenna is a dipole.

¹⁸⁹⁴⁾ <http://pcgauss5.ing.uniroma1.it/entra/attivita/attivita.htm>

Figure 359: Illustration of the UniSat spacecraft

A launch of UniSat-1 took place on Sept. 26, 2000 from the Baikonur Cosmodrome on a Dnepr launch vehicle. UniSat-1, along with MegSat of Italy and TiungSat 1 of Malaysia, and SaudiSat-1A and -1B of SISR (Saudi Institute for Space Research), was launched in a multiple launch configuration (no primary payload). UniSat-1 is being operated by students.

Orbit: circular orbit, altitude = 650 km, inclination = 65°, period = 98 minutes.

Technology experiments:

The power subsystem represents two experiments; one involves a solar panel environment test, the second experiment involves a functional NiMH (Nickel Metal Hydride) battery test. The new batteries offer a much better capacity/mass ratio than conventional NiCd batteries. - The OBC distributed network architecture is a proof-of-concept test.

N.23 WeberSat

WeberSat is a joint project of CAST (Center for Aerospace Technology) at Weber State University in Ogden, Utah with AMSAT-NA (Radio Amateur Satellite Corp. - North America), a scientific, non-profit organization of amateur radio operators that have been active in building small satellites for a number of years.¹⁸⁹⁵ In the late 1980s, AMSAT-NA asked CAST to participate in the fabrication of four microsatellites. For their contribution, CAST received ownership one of the four microsatellites which was named WeberSat. The four microsats were launched Jan. 21, 1990 on the Ariane ASAP from Kourou, French Guiana on Ariane flight V35 (Spot-2 was the primary payload). All microsats were spin-stabilized and offered store-and-forward amateur packet communications. WeberSat operated nominally until 1998. The AMSAT name of WeberSat is WeberSat-Oscar 18.

WeberSat is a small microsatellite, equipped with five radio receivers, two transmitters, a color video camera, spectrometer, and a micrometeorite impact detector. The S/C structure is a cube of size: 22.2 cm x 22.2 cm x 31.75 cm. The solar panels are surface mounted providing 6 W of average power in combination with NiCd batteries. The S/C mass is 12.25 kg. WeberSat is spin-stabilized, attitude is controlled by a gravity-gradient boom.

Communications: L-band AM receiver for Amateur radio, video S&F (Store & Forward).

Orbit: Sun-synchronous polar orbit, altitude = 800.0 km, inclination = 98.58°, equator crossings at noon and midnight.

¹⁸⁹⁵) <http://cast.weber.edu/webersat/index.html>

Sensor complement:

Color Video Camera. The CCD camera has a resolution of 700 pixels by 400 lines (a snapshot image provides a coverage of about 200 km x 270 km), and can be viewed with Weberware software running on a personal computer having adequate graphics display capability. Digitized NTSC video from the camera is assembled into packets that are sent as unnumbered information UI frames. Ground stations must receive this data over several passes to capture a complete image. Each image contains about 200 kilobytes of data. An on-board 1265 MHz ATV uplink receiver allows ground stations to load WeberSat's memory using a groundbased video camera for later transmission by the spacecraft. WO-18 can also transmit CCD images on 70 cm using an analog "turbo" mode that is much faster than using the AX.25 packet downlink. However, no interference protection is afforded by the analog transmission mode since information received in this form does contain a checksum.

Visual Light Spectrometer. A light spectrometer employing an NEC linear CCD measures the spectrum of sunlight reflected from the atmosphere.

Micrometeorite Impact Detector. A piezoelectric Particle impact detector measures the micrometeorite environment.

Part O Reference Data and Definitions

The following table contains the “EO” missions (in alphabetical order according to mission acronym) that were launched after the 3rd edition was published in early 1996. Excepted are Shuttle launches and GPS/GLONASS launches, each of these series has its own launch table in this volume. There is no claim for completeness.

Mission	Launch Date	Comment
ACE	Aug. 25, 1997	Advanced Composition Explorer, NASA/GSFC
ACRIMSAT	Dec. 21, 1999	NASA minisatellite to monitor the amount of total solar energy
ADEOS	Aug. 17, 1996	Advanced Earth Observing Satellite, NASDA,
ARGOS	Feb. 23, 1999	DoD technology satellite, launch from VAFB
ARTEMIS	July 12, 2001	ESA communication/technology spacecraft, Ariane-5 launch
ASTRID-2	Dec. 10, 1998	Swedish solar-terrestrial energy transport mission (IRF-K)
CBERS	Oct. 14, 1999	Chinese/Brazil imaging mission
CHAMP	July 15, 2000	Challenging Minisatellite Payload (GFZ/DLR)
Cluster-1	June 4, 1996	ESA, launch failure (4 spacecraft)
Cluster-2	July 16, 2000 Aug. 9, 2000	ESA, two S/C were launched at a time ESA, two S/C were launched at a time
Coronas-F	July 31, 2001	Russian and NKAU (Ukraine) solar physics mission
CRISTA-SPAS-2	Aug. 7-19, 1997	STS-85
Deep Space-1	Oct. 24, 1998	First mission with ion propulsion, NASA/JPL
DMSP, 5D-2 F-14	Apr. 4, 1997	USAF launch from VAFB
DMSP, 5D-3 F-15	Dec. 12, 1999	launch aboard a Titan 2 rocket from VAFB,
EarlyBird	Dec. 24, 1997	EarthWatch controllers lost contact with the S/C on Dec. 28, '97
EO-1	Nov. 21, 2000	Earth Observing-1 of NASA
Equator-S	Dec. 2, 1997	MPI Garching, DLR
EROS-A	Jan. 22, 1998	West Indian Space Ltd., Cayman Islands, Shavit launcher failure from Palmachim, Israel
EROS-A1	Dec. 5, 2000	Commercial imagery of ImageSat International
ETS-VII	Nov. 27, 1997	Technology mission of NASDA
FAISAT-2V	Sept. 24, 1997	Data collection, communication
FASat-Bravo	July 10, 1998	Microsatellite of Chile built by SSTL (secondary payload to RE-SURS-O-4)
FAST	Aug. 21, 1996	NASA/GSFC mission within SMEX
FORTE	Aug. 29, 1997	Fast On-Orbit Recording of Transient Events, LANL, SNL
FY-1C	May 10, 1999	China (along with SJ-5)
FY-2B	June 10, 1997	GEO weather satellite of China (CASC)
FY-2 (Fen Yun-2)	June 26, 2000	GEO weather satellite of China (CASC)
Genesis	Aug. 8, 2001	NASA, Solar wind sample return mission
GFO-1	Feb. 10, 1998	GEOSAT follow-on Satellite, US Navy
GOES-10	Apr. 25, 1997	NASA launch on Atlas-1 vehicle from Cape Canaveral
GOES-11 (-L)	May 3, 2000	NASA launch of NOAA weather satellite
GOES-12 (M)	July 23, 2001	NASA launch of NOAA weather satellite on Atlas-II vehicle from VAFB
Helios-1B	Dec. 3, 1999	Military reconnaissance S/C of France, Italy and Spain, Ariane-4 launch, Clementine (built by SSTL) was a secondary S/C
IKONOS-1	Apr. 27, 1999	Space Imaging, launch failure
IKONOS-2	Sept. 24, 1999	Space Imaging
IMAGE	March 25, 1999	DOE S/C launch from VAFB
INSAT-2D	June 3, 1997	GEO meteorological/communication satellite of ISRO
INSAT-2E	April 2, 1999	GEO meteorological/communication satellite of ISRO
Interball-2	Aug. 29, 1996	Auroral Probe of Interball (Molniya-M launch from Plesetsk) Magion-5 as subsatellite
IRS-1D	Sept. 29, 1997	ISRO
IRS-P3	Mar. 21, 1996	ISRO
IRS-P4	May 26, 1999	ISRO, referred to as OceanSat-1, along with KITSAT-3 and DLR-TUBSAT

Mission	Launch Date	Comment
JAWSAT	Jan. 26, 2000	Weber University, secondary payloads: FalconSat, ASUSat-1, OPAL, StenSat, PICOSAT-1, -2, Artemis
KITSAT-3	May 26, 1999	KAIST (Korea) secondary payload to IRS-P4 of ISRO
KOMPSAT-1	Dec. 21, 1999	Cooperative minisatellite technology-training program of KARI with TRW, EOC (Electro-Optical Camera) and OSMI (Ocean Scanning Multispectral Imager) instruments
Landsat-7	April. 15, 1999	NASA S/C with ETM+ imaging instrument
Lewis	Aug. 23, 1997	NASA, The Lewis S/C reentered the atmosphere Sept. 28, 1997. The Clark mission was cancelled in Feb 1998 due to cost overruns and launch delays
MegSat-0	April 28, 1999	Italian data collection satellite
Meteosat-7	Sept. 3, 1997	ESA/EUMETSAT
MightySAT-1	Dec. 4, 1998	AFRL technology S/C, launched as HH payload on STS-88, Dec. 14, 1998
MightySat II.1	July 19, 2000	AFRL technology S/C with ten technologies and FTHSI
MINISAT-01	April 21, 1997	INTA of Spain,
MITA	July 15, 2000	MITA (Minisatellite Italiano di Tecnologia Avanzata)
MSX	April 24, 1996	DoD satellite launch from VAFB
MTI	Mar. 12, 2000	DOE satellite launch from VAFB
MTSAT	Nov. 15, 1999	NASDA, launch failure
Nadezhda	June 28, 2000	Russian search and rescue satellite in COSPAS-S&RSAT series
NEAR	Feb. 17, 1996	NASA S/C launch on a Delta vehicle from Cape Canaveral. Flyby of asteroid 433 EROS on Dec. 23, 1998. Next rendezvous with EROS in mid-Feb. 2000
NOAA-15 (-K0)	May 13, 1998	NOAA weather satellite (POES series)
NOAA-16 (-L)	Sept. 21, 2000	NOAA weather satellite
Munin	Nov. 21, 2000	IRF (Sweden) nanosatellite, secondary payload to EO-1
Odin	Feb. 20, 2001	Swedish satellite for astronomic and atmospheric research
Oersted	Feb. 23, 1999	DTU of Denmark S/C, measurement of the Earth's magnetic field
OKEAN-O-1	July 17, 1999	Ukrainian/Russian satellite
Orbview-2 (SeaStar)	Aug. 1, 1997	Orbimage of OSC, Dulles, VA; SeaWiFS sensor for ocean color data
ORFEUS-SPAS-2	Nov. 19 - Dec. 7, 1996	STS-80
POLAR	Feb. 24, 1996	NASA/GSFC solar-terrestrial mission
Priroda	April 23, 1996	Russia, module of MIR station
QuickBird-1	Nov. 20, 2000	Earthwatch, commercial imaging, launch failure
QuikSCAT	June 19, 1999	NASA/JPL, wind measurements
RESURS-F	Nov. 18, 1997	launch from Plesetsk
RESURS-F-1M	Sept. 28, 1999	RKA
RESURS-O1-4	July 10, 1998	RS satellite launched from Baikonur on a Zenit-2 vehicle Secondary payloads: LLMS/IRIS, TMSat (Thailand), TechSat/Gurwin-II (Israel), FASat-Bravo (Chile), SAFIR-2 (OHB), WESTPAC (Australia)
REX-2	March 9, 1996	DoD S/C launch on a Pegasus vehicle from VAFB
ROCSAT-1	Jan. 27, 1999	First S/C of Taiwan with an ocean color sensor
SAC-A	Dec. 4, 1998	CONAE, Argentina, launched as HH payload on STS-88
SAC-B	Nov. 4, 1996	CONAE, Argentina, Pegasus XL launch failure
SAC-C	Nov. 21, 2000	CONAE, NASA, launched as secondary payload to EO-1
SACI-1	Oct. 14, 1999	INPE, secondary payload to ZY-1 of CASC
SCD-2	Oct. 23, 1998	Data collection satellite of INPE
SCD-2A	Nov. 2, 1997	INPE, VLS launch vehicle failure from Alcantara
SEDSAT-1	Oct. 24, 1998	Secondary payload to DS-1, S/C of Univ. of Alabama
Shenzhou	Nov. 20, 1999	Chinese test launch for manned space flight
SMEX/FAST	Aug. 21, 1996	NASA/GSFC, (Fast Auroral Snapshot Explorer)
SMEX/TRACE	Apr. 2, 1998	NASA/GSFC, (Transition Region and Coronal Explorer)
SNAP-1	June 28, 2000	SSTL technology S/C
SNOE	Feb. 25, 1998	University of Colorado at Boulder

Mission	Launch Date	Comment
SPOT-4	March 23, 1998	CNES, a new instrument “VEGETATION” is flown
SRTM	Feb. 11-22, 2000	NASA/DLR/ASI mission (Shuttle Radar Topography Mission)
STEDI/SNOE	Feb. 26, 1998	(Student Nitric Oxide Explorer), NASA, Univ. of Colorado on a Pegasus XL vehicle from VAFB, CA
STEX/ATEX	Oct. 3, 1998	DoD payload launched from VAFB with tether experiment
STARSHINE	May 27, 1999	Student satellite on STS-96
STRV-1c/d	Nov. 16, 2000	DERA satellites
SUNSAT	Feb. 23, 1999	Student-built satellite of Stellenbosch University, SA
TDRS-H	June 30, 2000	NASA Data Relay satellite
TEAMSAT, YES	Oct. 30, 1997	ESA technology demonstrator payload on Ariane-5 test flight
TechSat/Gurwin-II	July 10, 1998	Technion Israel Institute of Technology, Haifa, Israel
Terra (EOS/AM1)	Dec. 19, 1999	NASA S/C with MODIS, ASTER, etc.
TERRIERS	May 18, 1999	Boston University/NASA
TiungSat-1	Sept. 26, 2000	Microsatellite of ATSB, Kuala Lumpur, Malaysia (built by SSTL)
TMSat	July 10, 1998	Microsatellite of Thailand built by SSTL
TOMS-EP	July 2, 1996	NASA S/C, Ozone measurements
TRACE	April 2, 1998	NASA/GSFC mission in the SMEX (Small Explorer) program
TRMM	Nov. 27, 1997	NASDA/NASA (Tropical Rainfall Measuring Mission)
Tsinghua-1	June 28, 2000	Tsinghua University, Beijing - Imaging Demonstrator Mission Three S/C in Cosmos launch from Plesetsk (SNAP-1, Nadezhda (Hope) and Tsinghua-1
TSX-5	June 6, 2000	DoD with STRV-2 payload package and CEASE
TUBSAT-N+N-1	July 7, 1998	Data collection satellites of TU Berlin
DLR-TUBSAT	May 26, 1999	Earth observation, TU Berlin
UniSat	Sept. 26, 2000	Dnepr launch from Baikonur with SaudiSat-1A/1B (SISR), UniSat, MegSat, and TiungSat 1 of Malaysia
UoSat-12	Apr. 21, 1999	First minisatellite of SSTL
WESTPAC	July 10, 1998	Australian research S/C of Electro Optic Systems Pty Limited (EOS)
ZY-1 (Zi Yuan-1)	Oct. 14, 1999	ZY-1 (Resource) was launched on a Long March 4B vehicle from the Taiyuan Satellite Launch Center.
ZY-2	Sept. 1, 2000	Chinese CZ-4B launch vehicle with the Zi Yuan 2 remote sensing satellite from the Taiyuan launch facility.

Table 532: EO satellite launches since submission of 3rd edition to the publisher (Feb. 1996)

Mission	Launch Date	Comment
Aqua (EOS/PM-1)	Dec. 2001	NASA satellite on Delta-2 launcher from VAFB
CBERS-2	Dec. 2001	CAST (China) and INPE (Brazil) satellite from Taiyuan
DMSP-16	Nov. 2001	US DoD weather satellite, Titan-2 launch
ENVISAT	Nov. 2001	ESA, Ariane-5 launch from Kourou
GRACE	Nov. 2001	US-German dual-minisatellite mission
HESSI	Oct. 2001	NASA solar physics mission, Pegasus XL launch
ICESat/CATSAT	Dec. 2001	NASA launch on Delta-2 from VAFB
Jason/TIMED	Dec. 2001	NASA launch (Delta-2-7925) from VAFB
METSat	Oct. 2001	ISRO (India) from SHAR (replacement of INSAT-2E)
Meteor-3M-1	Nov. 2001	Russian weather S/C along with BADR-2, Compass, etc.
OrbView-4/ QuikTOMS	Sept. 2001	OrbImage and NASA S/C on Taurus launch vehicle from VAFB
PICOSat/Star-shine-3	Sept. 2001	Launch on Athena-1 vehicle from Kodiak Island, AK - including Sapphire of Stanford, PCSat of USNA, and Bitsy-SX
QuickBird-2	Oct. 2001	EarthWatch imaging satellite, Delta-2 launch from VAFB
TDRS-I	Oct. 2001	NASA Tracking and Data Relay Satellite
TES, PROBA, BIRD	Oct. 2001	ISRO prime payload TES with secondary payloads: PROBA of ESA and BIRD of DLR

Table 533: EO satellite launches projected for 2001

O.1 Definitions, Concepts, Summaries

Remote Sensing

Remote sensing, in the broadest sense, is the measurement or acquisition of information of some property of an object or phenomenon that is not in physical contact with the object or phenomenon under study. Remote sensing instruments, such as optical imagers or radar sensors, acquire information about an object of interest by detecting and measuring the changes that the object imposes on the surrounding electromagnetic field. For instance, in the case of visible and near-infrared (VNIR) sensors the reflected sunlight is used to acquire information about the chemical composition and physical structure of the object being observed. In the case of thermal infrared and passive microwave sensors, the emitted field is used to acquire information about the thermal properties as well as the composition of the object. In the active microwave region, information about the object's physical structure and electrical properties is acquired by analyzing the reflected field when the sensor illuminates the object with a well-defined generated field of electromagnetic waves.

Electromagnetic energy in its broad spectrum is the supreme messenger, the basis for all remote sensing. It conveys information about its source (structure, position, speed, temperature), about the medium it traverses, and about the medium it intercepts (by absorption and/or reflection). This information is coded by pattern, color, and intensity.

There are four elements of a radiation-based remote sensing system:

- 1) The radiation source (i.e., the sun, radar). In Earth observation the sun is the radiation source most commonly exploited. A radar system uses its own illumination source in the microwave region of the electromagnetic spectrum.
- 2) The transmission path (i.e., atmosphere, vegetation canopy). Atmospheric attenuation may cause some or all of the radiation to be absorbed or scattered. The transmission path length is a function of the geometric location of the source, target and sensor.
- 3) The target (i.e., surface area such as soil or water, a resolution cell such as a volume of the lower atmosphere). The target is the instantaneous object of observation of a sensor.
- 4) The sensor (i.e., multispectral scanner, film, radiometer, etc.). The instrument (usually flown on a platform) detecting and measuring the radiation of the target.

O.1.1 Remote Sensing across the Electromagnetic Spectrum

Electromagnetic waves interact with matter by a variety of mechanisms which are related to the composition and structure of the object. These mechanisms modify the wave characteristics (spectral, content, polarization intensity, direction, etc.) in such a way that the object properties can be identified. The emission or absorption spectral lines of a gas in the infrared spectrum will uniquely identify the nature and concentration of its constituents as well as its temperature. The reflectance spectral lines of a solid in the visible and near-infrared may allow the identification of its chemical composition, and, to some extent, its crystalline structure.

The depolarization and spectral reflectivity of the radar echo from a surface provides information about the roughness structure, geometric structure, morphology, and dielectric constant of the surface and immediate subsurface. The time of arrival and spectral contents of the radar echo allow a location of position of the reflecting object and its speed to extremely high accuracy (few cm in location and few cm/s in speed). The intensity of the black-body radiation field in the thermal and microwave regions allows the derivation of the thermal properties of the object.

O.1.2 Types and Classes of Remote Sensors and Sensing Data

The survey of spaceborne and airborne instruments represents a great variety of sensor types that need an ordering scheme for a better understanding and overview by the reader. There are many ways of sensor classifications (some of them are trivial or simply problem specific), for instance by:

- the type of application (field of research or operation such as: meteorology, atmospheric research, solid Earth, climatology, biosphere, etc.)
- the type of primary observation targets (oceans, land, coastal regions, ice sheets, or atmosphere.
- the observed frequency range (UV, optical, infrared, microwave, etc.),
- the type of sensing mechanism (passive or active source),
- the type of instrument (imager, altimeter, sounder, spectrometer, radiometer, etc.)
- the type of measurement precision (resolutions)
- etc.

Another classification scheme can be derived from the type of information being sought (Ch. Elachi, see Ref. 1896)). If we consider for instance the three fundamental information parameters as being: spatial, spectral, and intensity information, each located diametrically at the extremities of a triangle, as illustrated in Figure 360, then a number of basic relationships and commonalities are self-evident or may be directly extracted.

The primary sensor types are allocated in the triangle to the primary information parameters. The measurement of two prime parameters results in an instrument type (like an imaging spectrometer) which is located somewhere between the two extremities and is also designated accordingly. There are already attempts to combine all three fundamental information parameters into a single instrument, such as MISR (Multi-Angle Imaging Spectro-Radiometer) in EOS. Not everything can be characterized and explained by this method, but the scheme illustrates the fundamental principles involved, even beyond the fancy naming conventions of some sensors. ¹⁸⁹⁶⁾

Figure 360: Overview of sensor class relationships

¹⁸⁹⁶⁾ Charles Elachi, "Introduction to the Physics and Techniques of Remote Sensing," John Wiley & Sons, 1987, Chapters 1-1 and 8-8.

1) Spatial Information

Spatial information throughout the spectrum (2-D or 3-D) is acquired with an imager (this may be a camera, a mapper, a scanner, etc. or combinations thereof). The major application is in topographic mapping.

- a. Optical imaging techniques¹⁸⁹⁷⁾ (optical systems are limited by cloud cover, etc.)
- Stereophotogrammetry - photographic methods have the advantage of very good geometric resolutions; the disadvantages are in the handling of the film material, the data require geometric corrections, detection of reference points and conversion of brightness into digital information
 - Electromechanical line scanner - 2-D images are acquired line by line by scanning a mirror across track. Where the swaths of two adjacent subsatellite tracks overlap, stereo pairs are obtained. For polar orbiting satellites, overlappings are normally small near the equatorial regions and large over the polar regions. Examples: MSS and TM (of Landsat)
 - Electronic line scanner - in this method an array of CCDs (Charge-Coupled Device) is used instead of a single detector and scanning mirror. The advantages are: absence of moving elements, longer integration times per pixel, and better geometric performance. The disadvantages: the number of detectors is limited, which limits the resolution. Examples: HRV (Spot), MSU-E, etc.
 - Stereo line scanner - Three lines of semiconductors are arranged in the focal plane of the pushbroom scanner perpendicular to the direction of flight. The three lines scan simultaneously in forward-, down-, and aft-direction. Three images of the same scene are acquired from the same swath. The stereo images are taken simultaneously. Example: MOMS-02.

- b. Sounding techniques - Sounders are used for field measurements to map subsurface structures, or to map atmospheric profiles of temperature, composition and pressure as a function of altitude. Nadir sounders scan across the satellite suborbital track to provide good horizontal resolution (in the suborbital plane), but they usually have poor vertical resolution. Limb sounders look at the horizon (the limb) and scan vertically, producing good vertical resolution but poor horizontal resolution (see Figure 363).

The effect of the electromagnetic wave interactions on the Earth's atmosphere are relatively complex due to the multiplicity of mechanisms: scattering, absorption, emission and refraction. The atmospheric sounding technique is based on the fact that carbon dioxide (CO₂) is the same percentage of the total composition of the atmosphere at all altitudes - this is called the constant mixing ratio. The atmosphere has an emissivity that varies with wavelength from about 0% at 10 μm to about 100% at 16 μm . An infrared sounder with about five channels in the region from 11-16 μm probes the radiation of the atmosphere to different depths. Since the emissivity is high at 16 μm , only the top of the atmosphere is sensed by the 16 μm channel. The 11 μm channel, however, senses the radiation from all altitudes. The other channels are somewhere in between.

All sounders examine either the emission or backscattered radiation spectrum within a narrow field of view.

In the case of emission, the radiation source is the atmosphere itself. The sensor measures the spectral characteristics and intensity of the emitted radiation. If atmospheric parameters are measured, a down-looking geometry (nadir) is used for the spacecraft sounder.

In the scattering technique, the approach is to measure the characteristics of the scattered wave field in the direction (or directions) away from the incident wave direction. The source can be the sun or a star.

¹⁸⁹⁷⁾See chapter 5 in 'The Interdisciplinary Role of Space Geodesy,' Springer Verlag, 1987, pp. 164-165

Some sounding techniques/applications are:

- Temperature sounding - measurement of radiance variation as a function of frequency near a spectral line. For instance, the temperature is measured by examining a small part of the CO₂ spectral band at 15 µm or microwave emission from O₂.
- Composition sounding - identification of atmospheric constituents (by spectral techniques)
- Pressure sounding - technique: columnar absorption measurements of a homogeneously mixed gas constituent
- Density sounding - technique: refraction profile measurements
- Sounding of atmospheric motion (wind fields) - technique: measurement of the spectral line shift by the Doppler effect.

In the occultation techniques, the approach is to measure the changes that the atmosphere impinges on a signal of known characteristics as the signal propagates through the atmosphere. The signal source can be the sun, the moon, a star, or a man-made source. Usually a limb-looking geometry is used to sound the upper atmosphere by occultation or by emission.

Another sounding technique is called Lidar (see chapter O.8.5). This is an active technique, similar to radar. A laser pulse is generated and transmitted outward. The light is scattered back from the atmosphere. A time-gated detector senses the return. Since the sensor is not active immediately after the generation of the pulse, the detector is not 'blinded' by the backscatter from the mirror. In fact, since it is only active for a very brief period of time (the pulse length), it senses the return from only a small portion of the atmosphere at a specific range. Light travels about 0.33 m in 1 ns; thus, segments of the atmosphere in the order of 1 m in depth can be probed this way. The use of several wavelengths permits a limited amount of constituent identification.¹⁸⁹⁸⁾

c. Altimetry

In a number of applications, the information required is strongly related to accurate distance measurements or to the 3-D spatial characteristics of a surface of an object. This is the wide area of topographic measurements with the use of altimeters.

- Radar altimeters (nonimaging radar sensors) use the ranging capability of radar sensors to measure the surface topographic profile (parallel to the subsatellite track). There are beam-limited altimeter types as well as pulse-limited altimeters.
- Scanning Laser Altimetry (see lidar ranging techniques under O.8.5). In the across-track scanning technique 3-D topography can be acquired by a series of neighboring profiles. Beam scanning can be achieved electronically by using a phased array antenna or mechanically by scanning the antenna or by spinning the spacecraft.
- All spaceborne radar altimeters to date have been wide-beam systems, limited in accuracy by their pulse duration.¹⁸⁹⁹⁾ Such altimeters are useful for smooth surfaces (oceans), but are ineffective over relatively high relief continental terrain. - A fundamental problem in narrow-beam spaceborne radar altimetry is the physical constraint of antenna size. Large antennas are required for small radar footprints.

d. SAR (Synthetic Aperture Radar) Mapping

SARs generate microwave images of a surface. By using the overlapping images from adjacent tracks, one can produce stereo images. However, observation of the two overlapping tracks must occur from the same side. SARs have the disadvantages of high data reduction cost and poor vertical resolutions.

¹⁸⁹⁸⁾ Encyclopedia of Physical Science and Technology, Academic Press, 1987

¹⁸⁹⁹⁾ NASA 'Topographic Science Report,' 1988, p. 46

e. **Radar Interferometry**

The radar interferometer applies to two radar receiver units and a baseline across track. The phase differences as a function of location are used for direct measurement of the elevation of the backscattering surface.

2) **Spectral Information**

Spectral information is acquired with a **spectrometer** (examples: Fourier Transform Spectrometers, grating instruments, Fabry-Perot instruments, or gas correlation spectrometers). Spectrometers are used to detect, measure and analyze the spectral content of the incident electromagnetic field. This information plays a key role in identifying the chemical composition of the object being sensed (for instance atmospheric constituents). In the case of atmospheric studies, the spatial aspect is less critical than the spectral aspect due to low spectral variation in the chemical composition. In the case of surface studies, both spatial and spectral information are essential, leading to the need imaging spectrometers (see chapter O.6).

The selection of the number of spectral bands, the bandwidth of each band, the imaging spatial resolution, and the instantaneous field of view leads to trade-offs based on the object being sensed, the sensor data-handling capability, and the detector technological capabilities.

Figure 361: The imaging spectrometry concept

3) **Intensity Information**

In a number of applications the information needed is mainly contained in the accurate measurement of the intensity of the spectrum over a wide region.

- Radiometers - measurement of radiative intensities (flux, polarization, thermal properties, temperature profiles of the atmosphere and of sea surfaces, etc.). Imaging radiometers are used to spatially map the variation of these parameters.

- Scatterometers - are used in active remote sensing to accurately measure the backscattered field when the surface is illuminated by a signal with a narrow spectral bandwidth. Measurement of surface roughness.
- Polarimeters - these are a special type of radiometer. They are used for applications in which the key radiative information is embedded in the polarization state of the transmitted, reflected, or scattered wave. The polarization characteristic of reflected or scattered sunlight provides information about the physical properties of planetary atmospheres and other target signatures.

Remote Sensor Types	Part of Spectrum utilized	Remarks/Use Note: 1 Å = 10 ⁻¹⁰ m; 1 µm = 10 ⁻⁶ m
Scintillation Counters Gamma-ray spectrometers Geiger counters	<0.03 - 0.100 Å	Measurement of emitted natural radiation by gamma-ray detectors or Geiger counters
Scanners with photomultipliers Image orthicons and cameras with filtered IR film > 2900 Å	100 Å - 0.4 µm	Records incident natural radiation. Imaged ultra-violet spectroscopy available.
Cameras Using conventional B&W and color film Using infrared film (B&W and IR color)	4,000 - 7,000 Å (0.4 - 0.7 µm) 6,000 - 9,000 Å (0.6 - 0.9 µm)	B&W film for high spatial detail Improved spatial detail through contrast. Greater reflectance gradients useful for vegetation surveys
Multispectral units	3,000 - 9,000 Å (0.3 - 0.9 µm)	Individual narrow band scenes available with multi-camera systems
Lidar Laser radar	4,000 - 11,000 Å (0.4 - 1.1 µm)	Monochromatic active systems for measuring backscattered radiation from the atmosphere (particles)
Radiometers	Usually IR and microwave bands	Generally measures total radiation in a wide band in the infrared or microwave regions. Imagery obtained by scanning techniques.
Photometers	4,000 - 7,000 Å (0.4 - 0.7 µm)	Measures luminous flux in various bands of the optical region for distribution, color, etc.
Spectrometers	In any spectral region	Narrow-band data available sequentially - Electromagnetic radiation amplitude vs frequency
Solid State Detectors Single detectors, Line arrays Matrices	1 µm - 1 mm	Single detecting element used in scanners, radiometers. 1-D and 2-D arrays for sequential data gathering.
Radars	1 mm - 0.8 m	Narrow band active systems. Both analog and imagery available.
Radiometers (microwave)	1 mm - 0.8 m	Passive systems. Both analog and imagery available.

Table 534: Survey of remote sensor types and their applications¹⁹⁰⁰⁾

O.2 Some Aspects of Radiometric Instrument Calibration

In remote sensing, radiometry or spectroscopy is the measurement of radiation that is incident upon a sensor's receiver/detector after having passed from a target source through an intervening medium to the sensor. The objective of such a measurement is to characterize the source, in terms of its size, shape, location, composition, temperature, and maybe other parameters of interest. Target attributes can be inferred from the instrument response based upon adequate calibration.¹⁹⁰¹⁾

For the limited case of noncoherent and noninterfering radiation, the target can be characterized in terms of three nearly independent measurement domains:

¹⁹⁰⁰⁾ Manual of Remote Sensing, Second Edition, American Society of Photogrammetry, 1983, p. 41

¹⁹⁰¹⁾ C. L. Wyatt, "Radiometry," in Encyclopedia of Physical Science and Technology, Vol. 11, 1987, pp. 738-749

- spatial (geometric extent of measurement)
- spectral (distribution of energy flux as a function of wavelength or frequency)
- polarization (orientation of the electromagnetic vector)

The sensor calibration must reflect the sensor response in these measurement domains. The calibration objective is to determine a functional relationship between the target source flux and the sensor output signal. This relationship is also referred to as sensor 'responsivity.' Inherent to sensor responsivity is the complete characterization of the instrument (such as IFOV, spectral bandpass, time constant, polarization, sensor subsystems, the signal conditioning, throughput of the instrument, etc.).

The quality of the measurement is the most difficult problem of calibration. Optically pure measurements are only approximated with practical instruments, which are always non-ideal. Consequently, the interpretation of field data is subject to some uncertainty and is often dependent upon assumptions that must be made about the target. Some of the measurement problems/objectives in the measurement domains are as follows:

- The sensor is bombarded by unwanted flux that originates from outside the instrument field of view (such as radiation contributions from the Earth's atmosphere, or from the sun, or from other background sources). Objective: The sensor output for a 'spatially pure measurement' is a function of the radiant flux originating from the target within the sensor IFOV and is completely independent of any flux arriving from outside this region (see Figure 362 for a general scenario).
- The sensor is also bombarded with unwanted flux that is out-of-band that is, outside the spectral region of interest. Objective: The sensor output for a 'spectrally pure measurement' is a function of the radiant flux originating from within the sensor spectral bandpass and is completely independent of any flux arriving at the sensor from any spectral region outside the bandpass.
- The flux originating from the target may be polarized. The sensor may be sensitive to the polarization of incident flux. Objective: The polarization characteristics may be considered as target attributes for discrimination against the background, or they may be related to physical properties of the target.

A major (ideal) objective of the calibration of a sensor type (radiometer, etc.) is to make the measurements independent of the instrument. This means that when a particular physical entity is to be measured at different times and places or with different instruments, the results should always be the same. It also means that attributes inferred by the measurements are target attributes and not instrument attributes.

Unfortunately, the complexity of the physical conditions of the instrument and source parameters existing at the time of measurement make this ideal of calibration somewhat difficult, if not impossible, to obtain. A basic rule of good performance is that the calibration should be conducted under conditions that reproduce, as completely as possible, the conditions under which the measurements are to be made.

A common practice for spectral-response comparison is the use of a calibration source. Obviously, a sensor in orbit cannot be calibrated as extensively as the same sensor in the laboratory, but high-quality sensors have generally built-in standards (along with well-defined calibration procedures), which permit a periodic comparison at least for the primary measured values. Depending on the quantity to be calibrated, such a 'standard' may turn out to be an external source of known reference (star, moon, sun, etc.) or an internal source, a blackbody or a calibration lamp (e.g., a high-temperature gray-body source).

Often temperature variations around the orbit may affect the spectral stability of the instrument. In such cases, spectral calibration needs to be repeated from time to time by either looking onto a built-in source with well known spectral features or by evaluating well known features in the spectrum itself. Calibration sources can be small semiconductor laser-diodes or atomic line-lamps such as low-pressure Hg or PtCrNe lamps. Optical instruments work-

ing in the visible or ultraviolet range of the spectrum often use the well known Fraunhofer-structures in the solar spectrum for spectral calibration.

If absolute radiometric accuracy is important, then spaceborne measurements may also be checked against underflying airborne measurements that are made with the same sensor type.¹⁹⁰²⁾

Figure 362: Generalized scenario of radiative contributions in remote sensing

O.2.1 GNSS Radio Occultation Sounding

Note: The term GNSS (Global Navigation Satellite System) is used here because the method applies equally well to signals/receivers of the GPS and GLONASS constellations.¹⁹⁰³⁾ A new approach to the field of radio occultation (limb sounding) techniques was introduced with the use of the GPS receivers as a science instrument in Earth observation - to perform atmospheric sounding measurements, gravity measurements, and ionospheric sounding measurements.¹⁹⁰⁴⁾ - This new receiver occultation technique was introduced with GPS/MET on Microlab-1 (launch April 3, 1995) - tracking on C/A code, P code, and carrier phase.

High resolution atmospheric soundings can be retrieved, when the radio path between a LEO GPS receiver and a GPS satellite traverses the Earth's atmosphere. The GPS signals experience refractive bending and retardation in the atmosphere. Accurate receiver measurements of carrier phase changes permit to determine the atmospheric refractive index as a function of altitude. Pressure and temperature profiles can then be derived using the gas law.

¹⁹⁰²⁾ Courtesy of J. M. Palmer, University of Arizona, Tucson; published in: J. M. Palmer, "Calibration of satellite sensors in the thermal infrared," 108 / SPIE Vol. 1762 Infrared Technology XVIII, 1992

¹⁹⁰³⁾ S. Riley, N. Howard, E. Aardoom, P. Daly, P. Silvestrin, "A Combined GPS/GLONASS High Precision Receiver for Space Application," Proceedings of ION GPS-95, Sept. 12-15, 1995, Palm Springs, CA, pp. 835-844

¹⁹⁰⁴⁾ Note: The radio occultation technique was initially invented in the early 1960s by NASA/JPL in its planetary exploration programs to Venus, Mars and later to the outer planets.

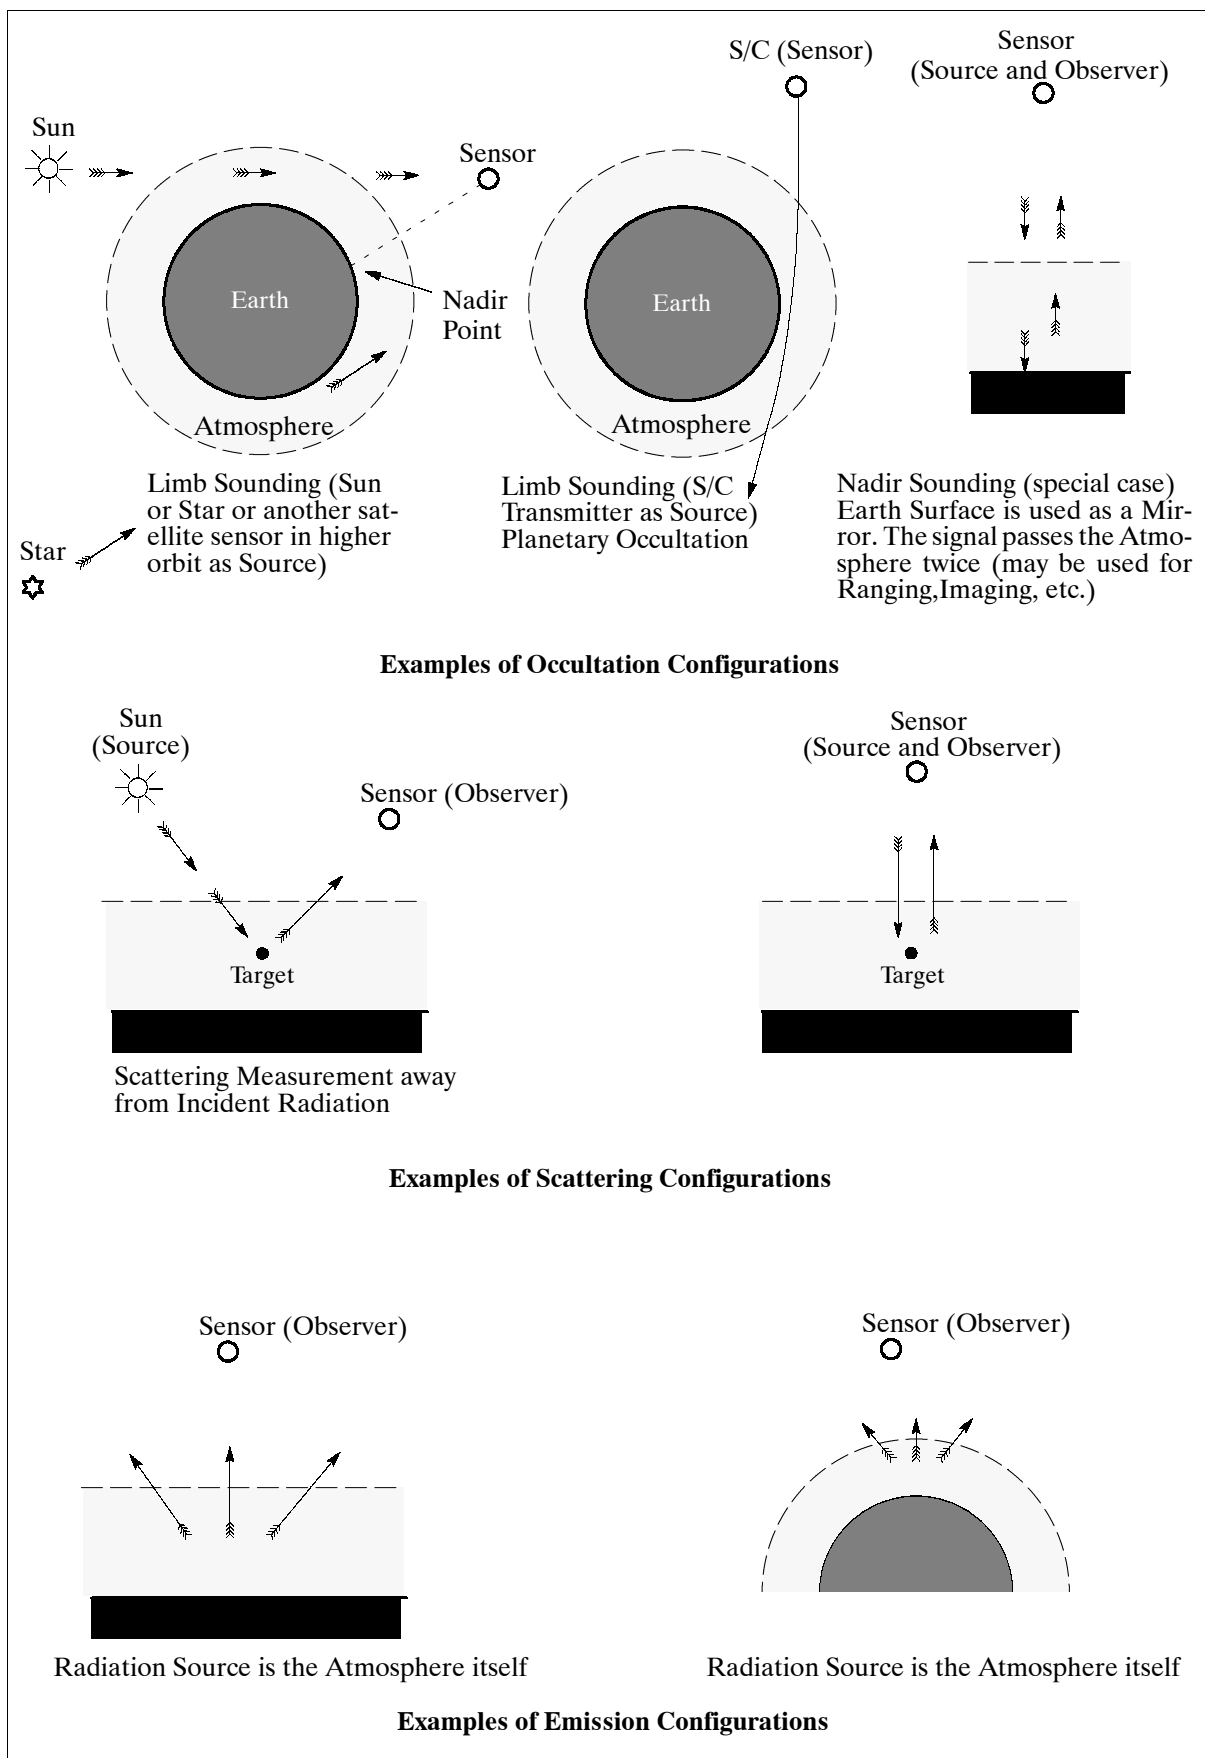

Figure 363: Different configurations for atmospheric sounding ¹⁹⁰⁵⁾

When the path of the GPS signal begins to transect the mesopause at about 85 km altitude, it is sufficiently retarded so that a detectable delay in the order of 1 mm in the dual frequency carrier phase observations is obtained by the LEO GPS receiver. As the signal path descends through successively denser layers of the atmosphere, the delay increases to approximately 1 km at the Earth's surface. Thus the atmosphere creates a unique signal with over six orders of magnitude in dynamic range. - GPS/MET temperature retrieval accuracies of better than 1K have been demonstrated in the altitude range of 10-30 km during the proof-of-concept phase of the mission with vertical resolutions of better than 1 km.

The possibility to extend these measurements into the troposphere (below 10 km) and into the upper stratosphere (up to about 45 km) is the subject of worldwide research. A single orbiting GNSS receiver can observe hundreds of such occultations per day. Hence, the all-weather radio occultation technique has the potential of providing an abundance of data for a wide range of applications, in particular for the fields of operational meteorology and climatology.

The GNSS radio occultation technique relies on precise time delay measurements. This method is generally not as involved with calibration problems usually associated with the other radiative sounding techniques. Hence, more independence of calibration gives radio occultation sounding a further advantage for the collection of long-term data sets.

O.2.2 Correction/Calibration Methods for Sensor Data

Once the functional relationships between the target source flux and the sensor output signals are known, then this knowledge can be applied for data correction in the ground processing algorithms.

- **Atmospheric correction.** Applied to sensor data in order to separate and eliminate the atmospheric path radiance contribution from the ground-reflected signal (i.e., surface contribution, also referred to as ground radiance). Path radiance is energy that may originate from the surface outside the 'field of view'; it is scattered into the beam by the atmosphere. In the visible region and at shorter wavelengths, Rayleigh scattering caused by density fluctuations in atmospheric gases is the dominant contributor to path radiance. Light scattered by particles or aerosols creates both path radiance as well as extinction.

The algorithms employed are based on model assumptions about the atmospheric state and on supplementary measurements. So far only approximate methods are available. Much effort is given to the development of strict algorithms. The application of atmospheric correction (the atmospheric path radiance contribution of the signal is eliminated by 'masking') to sensor data permits the experienced user to compare different data sets of the same sensor (and/or of different sensors), measured at different times and different locations (mosaicking).

- **Geometric correction.** The removal of sensor, platform, or scene-induced geometric measurement errors in such a way that the data conform to a required projection. This process involves the creation of a new digital image by resampling the input digital data. - Geometric correction is performed by giving each pixel of the image the correct place on Earth. This process is known as **geocoding**, i.e. matching pixel coordinates with the proper Earth coordinates in the required projection.
- **Radiometric correction.** Processing techniques on sensor data to calibrate and correct the particular radiometric measurement errors of the sensor detectors. A typical error that may affect the actual radiation measurement of a sensor is the brightness intensity variation across the image plane. For sensor data in the optical range, the far-side data is usually brighter than near-side data, thereby reducing the contrast of the image; for SAR data, however, the opposite is true, e. g. the near-side data is brighter than the far-

side data. Another error source may result from the fact that an output signal of a particular detector cell is not exactly proportional to the brightness intensity of the input signal. - All radiometric corrections are performed on the digital gray values of the pixels of an image, resulting in 'calibrated gray values.'

O.2.3 Electron-scanned Imaging Devices

Electron-beam imager system (vidicon, return-beam vidicon). ¹⁹⁰⁶⁾ A TV imaging technique, employed in the very early period of the space age (a framing system), consisting of the following elements: foreoptics, shutter, photoconductive surface (detector), electron gun, and beam-deflection system. The optical beam of the instrument focuses the image on a photoconductive surface in a fashion similar to that in a photographic system. However, the back side of photoconductive surface is negatively charged by the electron-scan beam prior to shutter opening. After shuttering, the image is retained as a charge pattern on the photoconductive surface. An electron beam is then used to produce an electrical signal by scanning the back side of the photoconductive surface. - The resulting signal of scan beam location is synchronized with the measurement value (signal coming off the transparent conductor) permitting reconstruction of the image. ¹⁹⁰⁷⁾ ¹⁹⁰⁸⁾

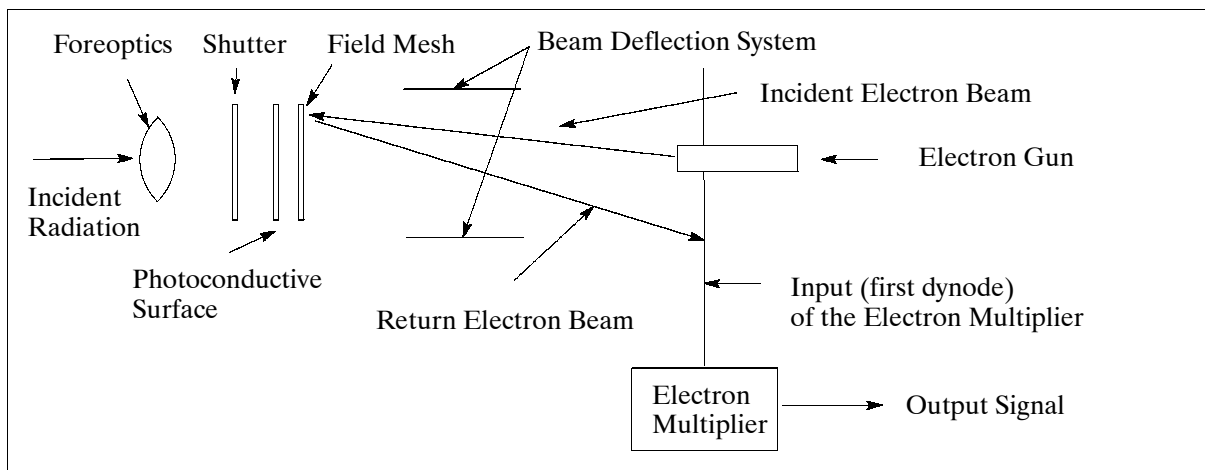

Figure 364: Schematic illustration of an RBV system

The RBV (Return-Beam Vidicon) also uses a photoconductive surface as a detector. However, in this arrangement, the electron beam is reflected from the back side of the photoconductive surface (weaker signal). The intensity of the electron beam, discharged from the electron gun, varies with the intensity of the light. The values of the intensity are then converted into digital information.

The RBV system instantaneously imaged an entire scene, (had greater inherent cartographic fidelity than imagery acquired by the early Landsat MSS sensor), and contained a reseau grid in the image to facilitate geometric correction of the imagery. This resulted in an array of tick marks that were precisely placed in each image.

O.3 Scanners

Many imaging instruments employ a scanning mechanism in order to cover a wide field of view in object space while utilizing narrow FOV (Field- Of View) telescope optics. The size

¹⁹⁰⁶⁾ Note: The name "vidicon" was coined in the early 1950s at RCA Laboratories to distinguish the electron-beam tubes from the photoemissive tubes.

¹⁹⁰⁷⁾ P. H. Swain, S. M. Davis, "Remote Sensing: The Quantitative Approach," McGraw-Hill, 1978, pp. 106-107

¹⁹⁰⁸⁾ P. K. Weimer, et al., "The Vidicon Photoconductive Camera Tube," Electronics, May 1950, pp. 70-73

and mass of instrument scanning mechanisms are determined geometrically by the telescope's aperture size and the desired object space field of view. Other factors, such as the need to view calibration reference sources, can also have a significant effect on the size of scanning subsystems.

A scanning system for the collection of imagery is a complex arrangement of optical, mechanical, electrical and electronic subsystems. Since the field of scanning applications is very broad, only those scanner systems are considered, that pertain to the classes of Earth observation instruments like imagers, imaging spectrometers, and imaging radiometers. The scanners listed in the following chapters are of solid-state technology.

The method of body pointing is yet another scanning alternative and is in particular suitable for single-sensor small satellites. Body pointing implies that the entire S/C (along with its imaging instrument) is pointed into the desired direction. The technique of body pointing may be employed to extend the regular FOV into a particular side-viewing direction to cover an occasional event of interest. With an agile S/C, body pointing may also be used in the along-track direction (forward and backward pointing on a cyclic basis) to collect imagery for stereo applications. It should be pointed out, however, that the body-pointing technique puts additional demands on the attitude control system of the satellite as well as on its power system.

O.3.1 Line Scanners

In remote sensing terminology a **line scanner** is a (nonphotographic) device that forms instantaneous exposure geometries between a target and a detector, with the sensor optics in between, thus forming an image by the successive addition of picture elements. The feature of 'scanning' adds picture elements in one direction (the cross-track direction), thereby increasing considerably the width of the observation path [this is different from 'sounding,' which considers only a line or surface (plane) observation of the immediate orbital path]. The received radiation is then dispersed into its spectral components (bands) using prisms, gratings, dichroics, or filters. An array of detectors senses the dispersed radiation. The signal from each detector is then amplified, processed and stored (on-board recorder).

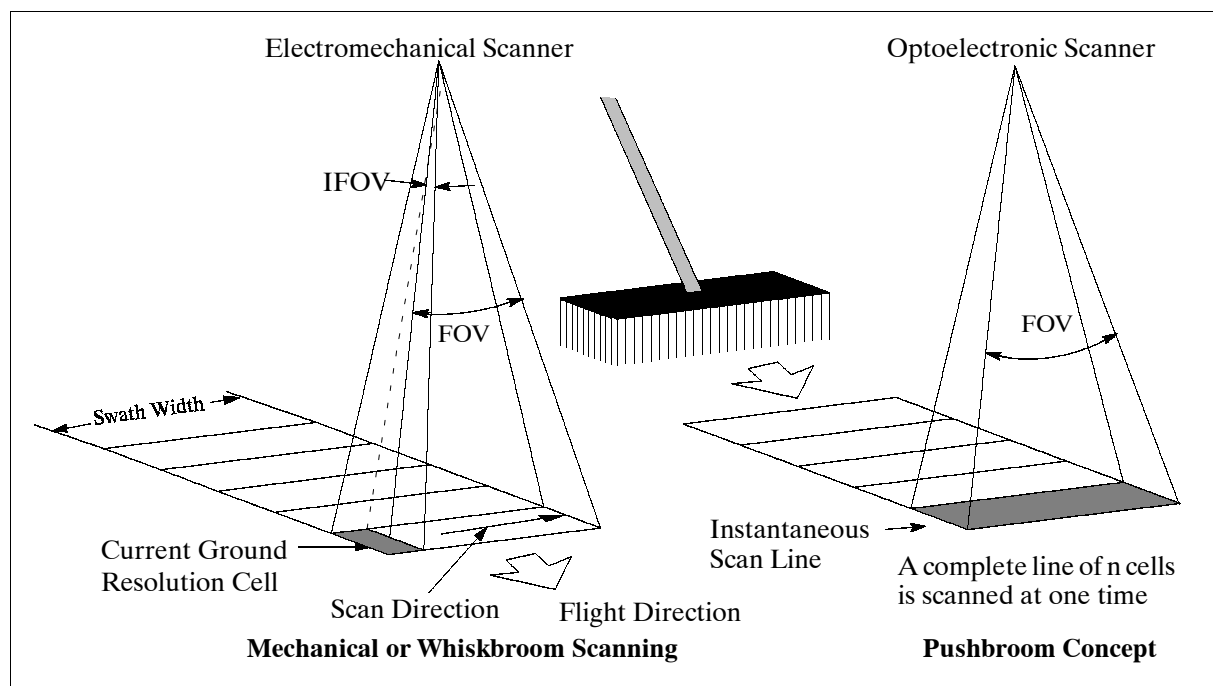

Figure 365: Schematic scanning/imaging geometries on a ground surface

The forward motion of the satellite or aircraft in the along-track direction provides the second image dimension. ¹⁹⁰⁹⁾

Basic scan patterns are oscillatory scan motion or rotating scans (continuous rotary scan motion). Key scan characteristics are: high precision, linearity, and high-speed.

By its very nature a scanner directs a moving beam of radiative energy. The direction of the beam is determined either by reflection with a mirror or by refraction with a prism. Movement of the beam is affected by either:

- An electromechanical or piezoelectric device that moves the mirror or prism in the line of path (cross-track direction)
- An electro-optical (optoelectronic) or acousto-optical device by applying electric waves or sound waves to change the refractive index of a photoelastic material.

A rotary scanner (polygon or disk scanner) is a high-inertia device in which the optical element is a refractive prism, a reflective polygon, or a disk of lenses or mirrors that rotates continuously in one direction. In such a system, a prism or a number of mirrors or lenses are arranged concentrically around an axis. The rotating device moves each facet, mirror, or lens through the energy path, creating a regular, repetitive scanning pattern.

Polygon scanners nearly always rotate continuously in one direction at a constant speed. Thus, high scan rates are easily attained, relatively large optical elements can be used. Typical design types are: inverted (inward-facing) polygons, pyramidal polygon scanners, and like mirror polygons (refractive or prism scanner). A typical scan pattern of a conical scanner is shown in Figure 381.

An oscillatory scanner is a low-inertia device in which the optical element is either an oscillating mirror (electromechanical - the scanner moves a mirror in a limited angular direction, rather than rotating it continuously), or an electro-optic (optoelectronic) device, or an acousto-optic deflector.

The effect of a scanning motion may also be provided by a spinning spacecraft. The world's first weather satellite, TIROS-1 (launch April 1, 1960) and the follow-up TIROS and ESSA series (up to ESSA-9, launch Feb. 26, 1969) were spin-stabilized. The first generation of Meteosat spacecraft employed also the spinning concept to collect imagery. From a historical point of view the electromechanical (or optomechanical) line scanner (whiskbroom) is one of the first solid-state designs in use of remote sensing. Since the early 1980s the conventional whiskbroom design has been succeeded by the introduction of optoelectronic (pushbroom) devices.

The viewing geometries remain constant for circular orbiting satellites which feature a nadir-viewing imaging instrument. This is in general not the case for nadir-viewing imagers on aircraft where the scanning geometries vary. An important relationship of an aircraft imager design is for instance the velocity-to-height ratio (v/H) because it determines the scan rates, the number of detectors scanned in parallel, and the electrical signal bandwidth. The v/H ratio describes the angular rate of image motion in the focal plane (rad/s). The maximum value of v/H is used to start the design trade-off process.

O.3.2 Electromechanical Line Scanner

The scanner records within its IFOV (instantaneous field of view) a very small area (ground cell), and builds up a line of recorded signals of these small areas referred to as pixels (picture elements). In this serial arrangement, each pixel requires a certain dwell or integration time for the radiation to be detected; thus, the time is additive. The next scan line depends

¹⁹⁰⁹⁾ The interested reader is referred to chapter 3 of the book: "The Infrared & Electro-Optical Systems Handbook," W. D. Rogatto, editor, Vol. 3, Electro-Optical Components, copublished by ERIM and SPIE, 1993

on the forward motion of the satellite. The electromechanical line scanning concept is also referred to as **whiskbroom**, creating an observation swath on the ground surface in obvious analogy to the successive sweep motion of a whiskbroom (in the cross-track direction) to clear a path (Figure 365). Note: The early whiskbroom designs with a single scan line improved considerably with the introduction of parallel scan lines in the along-track direction; thus, providing a wider along-track coverage in a single cross-track scan sweep.

A disadvantage of the electromechanical scanner design is the large sampling frequency per line needed for an unbroken coverage of a sufficiently wide swath. A typical Earth observation platform moves at about 6.5 km/s, hence, a 100 m resolution requires 65 lines/s. This in turn implies a sampling rate of 65,000/s for a swath of a 1000 pixels.

A whiskbroom scanner may provide panchromatic or multispectral imagery in the optical region of the spectrum with medium to high spatial resolutions and medium spectral resolutions. There are single-line scanners in use as well as multi-line scanner arrangements in the along-track direction. **A very important advantage of the single-camera whiskbroom concept: the whiskbroom scan arrangement permits large FOVs.** It means that rather wide swaths can be obtained without severe optical distortions at the swath edges. Disadvantage: the available time to dwell on each detector element (or ground cell) is very brief resulting in less spatial/spectral resolution and/or radiometric resolution. Scanning methods: scanners may use on-axis optics or telescopes with a flat scan mirror located in front of the collecting aperture (the scanning mechanism may be implemented with an oscillating mirror, rotating mirror, fiber scanner, etc.). Examples of line scanners with whiskbroom electromechanical technology are: TM and MSS on Landsat (also the ETM+ instrument on Landsat-7), MSU-SK on Resurs and Meteor series, AVHRR on NOAA series, OCTS on ADEOS, SeaWiFS on Orbview-2 (SeaStar), and CZCS on Nimbus-7. Airborne whiskbroom instruments are AVIRIS and MERIS.

Flying Spot. The flying spot scanner is a subset of whiskbroom scanners, in which the focal plane consists of only a single detector. It scans with the same geometry as a line-array whiskbroom (e.g., unidirectional barrel roll or bidirectional sinusoidal scan), but it must scan relatively quickly in order to cover the swath in the along-track direction in a contiguous manner with only a single detector. One advantage to the flying spot is the lack of a potential for image striping due to detector-to-detector sensitivity variations that are not perfectly accounted for by radiometric calibration corrections. An example implementation of the flying spot concept is realized on OLS (Operational Linescan System) flown on the DMSP satellite series since 1976.¹⁹¹⁰⁾

O.3.3 Optoelectronic Scanners

Electro-optic (or optoelectronic) devices are parallel line-scanning systems with no moving parts (electronic steering of beam motion). The beam deflectors are either analog or digital. In analog deflectors, an applied voltage varies the phase delay across the incident beam; the phase front is tilted when the beam emerges, and the beam direction is changed by the same angle. In digital deflectors the beam direction is controlled by modulation of the polarization direction of the incident radiation.

The radiation of the total field of view (TFOV of n cells in a swath) in the cross-track direction is being imaged simultaneously by a corresponding detector line array (with n cells) positioned in the focal plane of a sensor. This parallel sensing arrangement allows naturally for more integration time of each individual pixel [in the serial whiskbroom concept the integration time for a long line of pixels (hundreds or even thousands) had to be very short]. Successive lines are imaged and sampled by the multiplexer as the platform moves along the orbital path. The time that elapses between the imaging of two successive lines can be as

¹⁹¹⁰⁾Flying Spot information provided by David L. Glackin of The Aerospace Corporation, El Segundo, CA

long as the platform takes to move the distance in the scene. The general sweep motion in this scanning concept is now in the along-track direction and is referred to as **pushbroom** (see Figure 365). Commonly, the system is designed so that the instantaneous field of view (IFOV) moves through its own width during the frame period, the distance moved in the detector integration period is called GSD (Ground Sampling Distance).¹⁹¹¹⁾ Examples of optoelectronic scanners are: HRV on Spot series, MSU-E on Almaz-1B, on Priroda, and on Resurs, MOS on IRS-P3 and Priroda, MOMS on Shuttle, LISS-III on IRS-1C/D, etc.

Advantages: Longer dwell times lead to low noise in the received signals. There are no moving parts on a pushbroom sensor; hence, scan speeds of less than 1 μ s access time are possible. The design remains attractive for high-resolution imaging systems with a FOV <15°. **Disadvantages:** a very large number of detectors are needed for high resolution images (in the meantime the microelectronics industry is quite capable of producing large detector arrays); in addition, the pushbroom scheme requires a wide field-of-view optics system to obtain the same same swath as for a corresponding whiskbroom scanner.

The detector arrays associated with such a line-scanning pushbroom system are usually of the type CCD (Charge-Coupled Device), but they may of course also be of type CID (Charge-Injection Device), CMOS/APS, etc. However, the long association of ‘pushbroom’ and ‘CCD’ has resulted in treating the two terms practically interchangeably as synonyms. In any case, a CCD detector is never associated with a whiskbroom (serial) sensing concept.

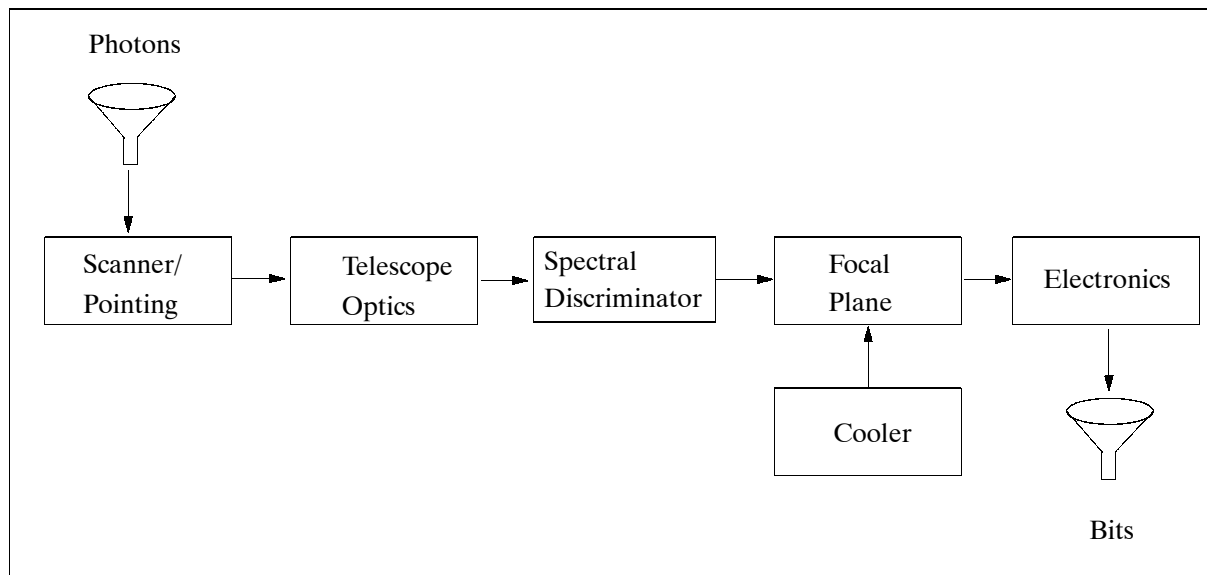

Figure 366: Illustration of the generic optoelectronic sensor

O.3.4 Observation Schemes

The most common detector formats and architectures in imaging sensor technology are: single elements in circular, rectangular, cruciform, and other geometries for rectile systems, the **line detector array** and the **area detector array** as illustrated in Figure 367.¹⁹¹²⁾

Line detector arrays are in principle one-dimensional whiskbroom and pushbroom systems oriented in the cross-track direction. In both systems an image is formed on a line-by-line basis in the scan direction (identical to the along-track direction).

¹⁹¹¹⁾ Note: In a pushbroom line array, the “frame” is represented by a single line of CCD detectors covering the swath width. In a multispectral or hyperspectral design, the “frame” is represented by an area array, where each line of the CCD detectors covers the swath width of a particular spectral band.

¹⁹¹²⁾ “The Future of Remote Sensing from Space: Civilian Satellite Systems and Applications,” Office of Technology Assessment, US Congress, OTA-ISC-558, ISBN 0-16-041884-4, July 1993, pp. 142-143, original source: SBRC

Area arrays may be operated in either **scanning** or **staring** mode.

- **Scanning mode operation:** The 2-D array (say 2048 x 16 - is usually much longer in the cross-track direction than in the along-track direction) is scanned sequentially, on a line-by-line basis if it is a parallel pushbroom system (one-dimensional scan in the along-track direction). Usually, the detector line arrays (in this case 16) are utilized for different tasks, by dividing them up between panchromatic and multispectral bands, or using them for TDI imaging of a single band, or a combination thereof. Naturally, a large square size area array can also be operated in scanning mode. In fact, most 2-D arrays are operated in scanning mode.
- **Staring mode operation:** No scanning is needed for the 2-D array, although periodic shuttering may be used. The entire array (frame) is clocked and sampled periodically (see O.3.5).

	Detector Format		
Imaging System	Single Element	Linear Array	Area Array (2-D)
Scanning 2 axes	x	TDI	
Scanning 1 axis		x	TDI
Staring			x

Table 535: Correlation of imaging system and detector formats

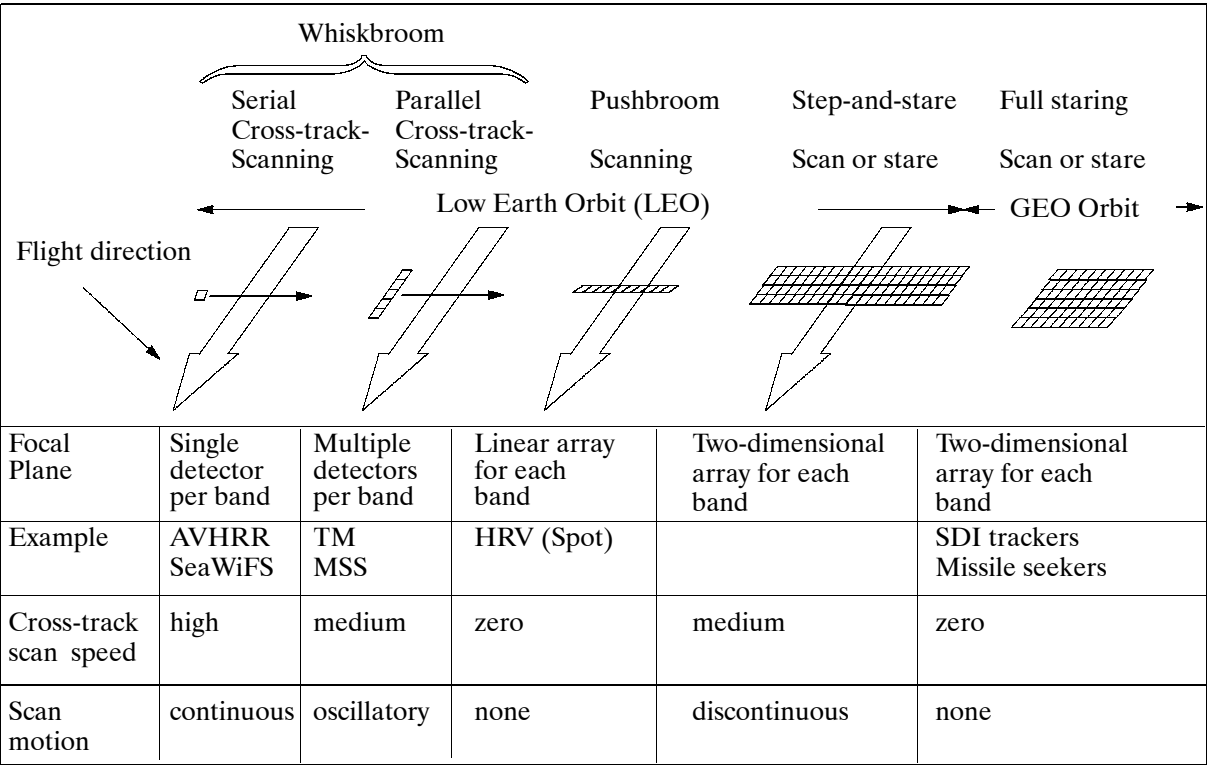

Figure 367: Some optical remote sensing observation schemes

O.3.4.1 Line (or linear) Detector Array

The conventional CCD line array consists of a single row of small, photosensitive cells (or pixels, usually square in size) onto which the incident radiation is focused. The line array observes a target with its length side positioned in the cross-track direction (normal to the forward motion of the satellite). An image is formed on a line-by-line basis in the along-track direction. Such a 'line' has in reality area - with the corresponding field of view (FOV), the array length translates to the swath width, the narrow stripe is one pixel wide. An image

is made up of a number of contiguous stripes. In analogy to the older serial whiskbroom scan (where each imaging sweep is in the cross-track direction), this alternate parallel scan arrangement is referred to as **pushbroom** (Figure 365), with the sweep in the along-track direction. All systems with a pushbroom configuration are classified as electronic (or opto-electronic) scanning systems, while a whiskbroom system refers to the older mechanical scan technology (serial cross-track scan).

The parallel pixel observation scheme of the line array provides for relatively long dwell times which in turn leads to low noise in the received signals. There are no moving parts on a pushbroom sensor. Modern CCD line arrays with panchromatic and multispectral capabilities feature a separate detector line for each spectral band.

The current market (1997) offers line arrays of up to 12,000 pixels per line. This configuration provides a fairly good swath width and multispectral measurements with high radiometric resolution in parallel. Line arrays are used in camera systems, including stereoscopic applications.

Parameter	CCD Line Array	CCD Area Array
Number of pixels (max)	14,000	7,000 x 9,000
Pixel size FW (Full Well) QE (Quantum Efficiency)	6.5 μm x 6.5 μm 100,000 e 0.3 at 600 nm	12 μm x 12 μm 500,000 e 0.7 at 600 nm
TDI (Time Delay Integration) sensor		possible but operated in pushbroom mode
Geometric accuracy	high	very high
Stereo capability	two or three-line implementation	overlapping stereo
Spectral performance	sequential only (e.g. filter wheel)	one filter per line
Shutter	not required	required
Operation mode	pushbroom	pushbroom or staring

Table 536: Some configuration/performance capabilities of CCD line and area arrays

O.3.4.2 Area Arrays

The microelectronics integration technology lead eventually to the development of area arrays (CCD, CID, etc.) with the ability to observe in two dimensions simultaneously (an image per integration time). The resulting speed-up of the imaging process requires an alternate observation scheme such as step-and-stare. In this scheme, observations are made intermittently, i.e., after a certain step in the along-track direction occurs due to platform motion. An overlapping step-and-stare method is normally used for sensors in LEO orbit.

The step-and-stare imaging scheme in LEO requires motion compensation to allow the array to stare for a certain period at the same ground target as the platform is moving forward. The array is then stepped to a new location and held again until the cross-track imaging process is completed. The advantages of this scheme are an increased dwell time, only moderate field-of-view optics are needed. Area arrays are particularly suitable for TDI (Time Delay Integration) operations to increase the dwell times. In this case the integration times can be electronically adjusted to the conditions of illumination simply by commanding the number of TDI steps. The disadvantage is that a larger and more complex focal plane array (FPA) than the linear pushbroom scheme is needed.

O.3.5 Staring Array Systems

The staring concept was first formulated in the early 1970s with the advent of large mosaic focal plane arrays. The earliest staring systems were placed into geostationary orbit. The same area of the Earth's surface (footprint) is continuously in view, providing a fixed-position relation between the satellite and its target area. However, this concept has its limita-

tions, since small motions induced by drift or jitter of the satellite cause clutter-induced noise. The field of space surveillance (the detection and tracking of remote point-source objects or targets located within a background scene) is a typical application of a staring system. The prime objective is to extract very weak target signals from a relatively bright and heavily cluttered background.

Staring FPAs (Focal Plane Arrays) are available in the UV, VNIR, SWIR, MWIR and TIR regions. The photon detection scheme is identical to that of non-staring systems (charge-carrier pattern). This pattern is usually integrated in parallel on a storage surface. Before integration, the photocurrent can first be amplified in an intensifier to provide extremely low-light-level detection. Readout of almost all staring sensors is done serially.

The photon flux levels from natural backgrounds are generally much lower at lower wavelengths. The use of staring sensors is desirable because photons imaged by the optics are collected with essentially 100% efficiency due to complete population of the image plane with detector elements.

The step-and-stare concept was later introduced for LEO satellites. In this concept, a sensor with a small FOV can be stepped periodically to new (overlapping or non-overlapping) staring positions as the satellite progresses in its flight path.

O.3.6 Time Delay Integration (TDI)

The TDI technique refers to a cumulative exposure concept of each ground image line by a CCD detector array (or any equivalent array). The main objective is to improve the SNR (signal-to-noise ratio) value which is one of the most important issues for high resolution imaging. The simplest TDI case is the superpositioning and co-addition of two independently acquired images, assuming precise co-registration. TDI is a focal plane technology which sums signals collected by a selectable long column of individual detector elements in the along-track direction, permitting controllable increased sensitivity of the imaging system appropriate to ground scene and illumination conditions. Multiple imaging of a scene with defined sub-pixel shifts will lead to improved spatial resolution, if the displacement between successive optical images can be kept fixed in the sub-pixel range. ^{1913) 1914) 1915)}

For a 2-D CCD array (say 14,000 x 32) moving with the satellite in the along-track direction, multiple one-dimensional images can be taken of each cross-track stripe as illustrated in Figure 368. Motion compensation is not needed if the detector row shifts are synchronized with the forward motion of the satellite. - In general, the TDI function may be performed off focal plane (normally after digitization) or in the readout circuitry. On-chip TDI requires temporary frame storage for each TDI stage and a multiplexer to transport the signal for the summing process. TDI may be done with a large array of storage capacitors; however, it is most commonly implemented on a CCD line array.

The phrase "time-delay" is used because the scanning process which naturally projects one long single line of detectors (of a total of 32 single lines, in our case) upon a given very narrow ground area (FOV line), projects the next single line upon the same area only after the time interval of one "integration time" has passed. Therefore the sensor electronics is set up to "delay" the input of data produced from photons encountering each single line until the next single line's data is ready, and so on. This permits summation (integration) of the signals produced for the same area element (ground pixel) by the total contributions of the detectors receiving that area element's photons, even though each individual signal was originally received by a detector on a separate single line.

1914) R Nagura, "SN Improvement Ratio by Time Delay and Integration for High-Resolution Earth Observation System," Electronics and Communications in Japan, Part 1, Vol. 78, No. 3, 1995

1915) Information provided by S. Kilston of Space Imaging Eosat of Thornton, CO

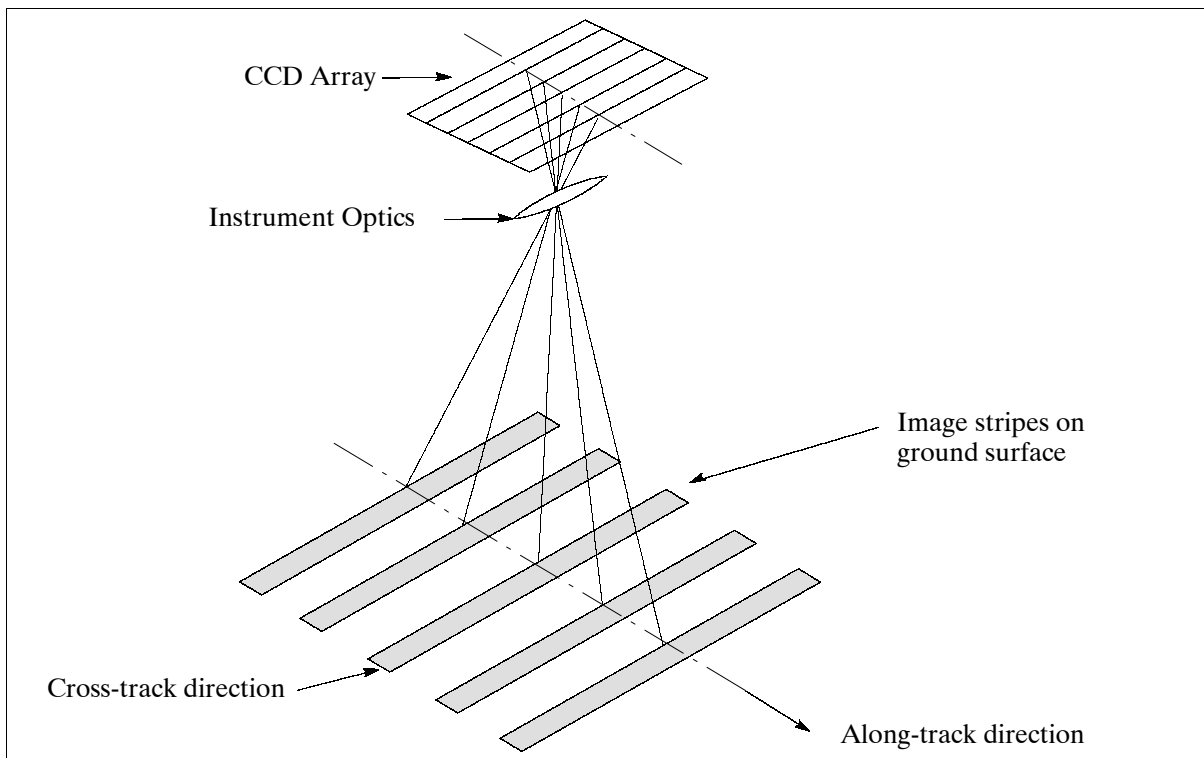

Figure 368: Illustration of the TDI concept

The “total integration time” is then the sum of individual integration times, for a longer effective exposure, and therefore a larger effective signal. The signal builds up in direct proportion to the number of TDI stages, whereas the random noise builds up only in proportion to the square root of that number, so the signal-to-noise ratio is greatly enhanced by this process. The technique is far superior to the use of one single line (say, 14,000 x 1 in size) of detectors exposed 32 times longer, because such detectors would offer far less spatial resolution in the along-track direction.

The TDI method is of course applicable for the entire optical spectrum. It can accommodate different scene and lighting conditions (image integration requires a large dynamic range of 10 to 11 bits). TDI is particularly suitable for weak infrared detection due to its signal enhancement capability.

The TDI concept was developed along with the early CCD technology at several places in the US industry and at NRL (DoD) in the later 1970s as well as at RSRE (Royal Signal and Radar Establishment, Malvern, UK) and first introduced into an infrared detector system by the name of SPRITE (Signal Processing In The Element). The first SPRITE detector had the following specification: eight intrinsic photoconductive detector elements each with a nominal sensitive area of $62.5 \mu\text{m} \times 62.5 \mu\text{m}$, HgCdTe detector material in the range 8-14 μm , cooling to 77 K, $\text{FOV} = f 2.5$.^{1916) 1917)} - The SeaWiFS instrument of SeaStar (Orbview-2, launched Aug. 1, 1997) and the OSA instrument of the Ikonos-1 (CRSS) satellite are examples of more recent (1998) TDI implementations in 2-D CCD line-array technology in the visible range of the spectrum.

O.4 Sensor Detector Systems

The quality of all radiation sensing depends directly on the quality/capability of the observing instrument, in particular its detector technology. This realization has generated a lot of research and development in the field of detector technology.

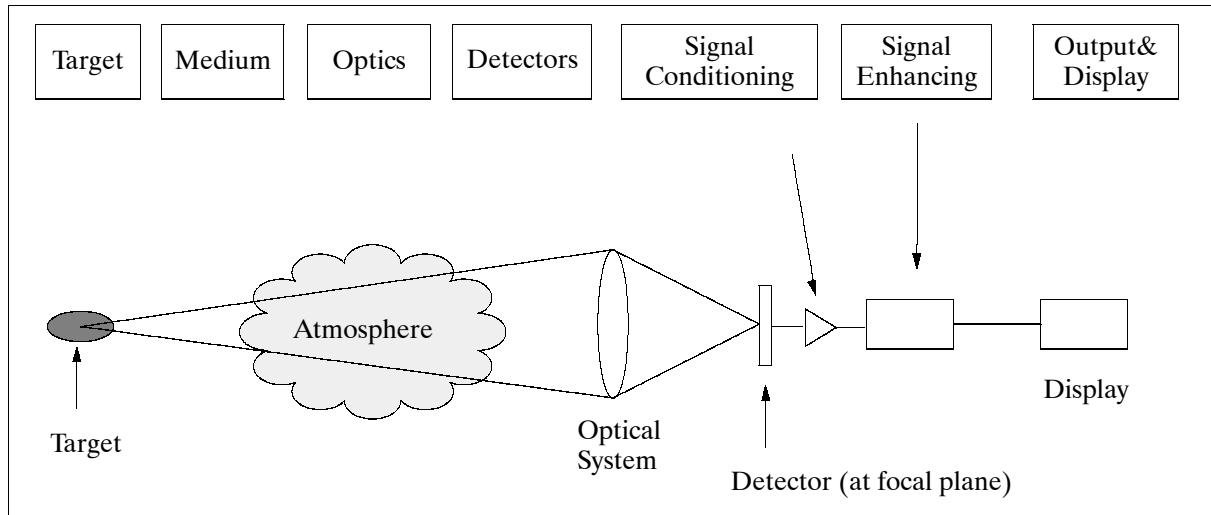

Figure 369: Schematic illustration of an optical system

The principal detection methods used in optical spectroscopy are photographic (e.g., film), photoemissive (photomultipliers), and photoconductive (semiconductor). Prior to about 1940, most spectra were recorded with photographic plates or film, in which the film is placed at the image point of a grating or prism spectrometer. An advantage of this technique is that the entire spectrum of interest can be obtained simultaneously, and low-intensity spectra can be easily taken with sensitive film.

O.4.1 Definitions

Detector. A detector is a device that detects and linearly transduces radiative power into an electrical signal. It refers to the unit cell comprising the smallest resolution element and the first stage of signal processing electronics with that pixel.

A detector typically takes an average value of the signal over a length of time (from about 1 ns to about 1 ms), namely the integration time. Thus, it is not possible to measure any signal variations at the rate of either the optical or the infrared frequency spectrum below the integration time limit. The electrical signal is usually proportional to the average power or photon rate or the integral over the integration time.

Photon detector. Refers to the class of detectors (also called photodetector or quantum detector), where the responsive element is sensitive to changes in the number of free electron carriers, namely electron-hole pairs, that are brought about by the absorption of incident photons. Incident radiation excites electrical charge carriers, causing them to move from one energy level to another energy level within the crystal lattice of the detector. Charge carriers which are at lower energy levels are said to exist in the valence band of the crystalline detector. If a charge carrier is excited into an energy level such that it can move freely throughout the crystalline structure of the detector, it is said to exist in the conduction band.

Photon detectors are usually semiconductor devices on silicon basis or compound materials, where the incident photon flux interacts directly with electrons in bound states, exciting them to a free (conducting) state. In item a) of the energy-level diagram (Figure 370), there is a band of many filled levels (valence band), separated by a gap of a band of many vacant

levels (conduction band). In item b) there is only a very small bandgap between the two bands.

Figure 370: Energy level diagram

If a material is to conduct electricity, it must contain electrons that can have their energy increased by a small amount, thus producing a current. Materials with an energy level as in item b) are conductors. There are vacant levels available near the filled band - the electrons are thus able to accept a small amount of energy. Materials with energy levels as in item a) are insulators. It takes a certain amount of energy to cross the bandgap. Thus, a small increment in energy will not cause a current to flow.

The division of ‘internal’ and ‘external’ photon detectors in table 537 is according to whether the interactions are confined to the unit cell (pixel) or are in part external to the detector cell.

Intrinsic detector. Refers to narrow bandgap energy transfer (a current may flow due to a small energy change; however, the electron flow is very small). Detector materials of InSb and HgCdTe are in this class. Intrinsic arrays are those in which the detection and readout are accomplished using an intrinsic semiconductor substrate material.

Photon Detectors		Thermal Detectors	Electromagnetic Detectors
External	Internal	Bolometers	Heterodyne detection
<u>Photocathode:</u> Conventional Neg. electron affinity <u>Gain multipliers:</u> Photomultiplier tube Microchannel plate Gas avalanche	<u>Photoconductive:</u> Intrinsic Extrinsic <u>Photovoltaic:</u> P-N junction Avalanche diode P-I-N diode Schottky diode Heterojunction Graded junction	Thermistors Metal Superconductor Superinductor Cryogenic semiconductor	Metal-metal oxide-metal photodiode

	Photon drag	Golay cell	
	Hot electron bolometer		

Table 537: Classification of detectors

Extrinsic detector. Refers to wide bandgap energy transfer. Detectors of the type silicon (Si), silicon compounds (SiGa, SiAs, SiPt, SiIn, etc.), doped silicon, photodiodes, and Schottky diodes are in this class. The extrinsic silicon detector type relies on photoexcitation of impurity levels within the bandgap of silicon. The spectral response depends on the energy level of the particular impurity and density (the long-wavelength spectral cutoff is a function of the doping density) state as a function of energy in the band to which the bound charge carrier is excited. Extrinsic silicon detectors operate either as high-impedance photoconductors or as IBC devices. An example of an extrinsic silicon IBC detector is SiAs.

	I Narrow (intrinsic) bandgap	II Wide (extrinsic) bandgap
Photoconductor	PbS HgCdTe	SiIn SiGa SiAs
Photodiode	InSb HgCdTe	SiX (impurity band) SiPt (Schottky diode)

Table 538: Detector types and representative examples

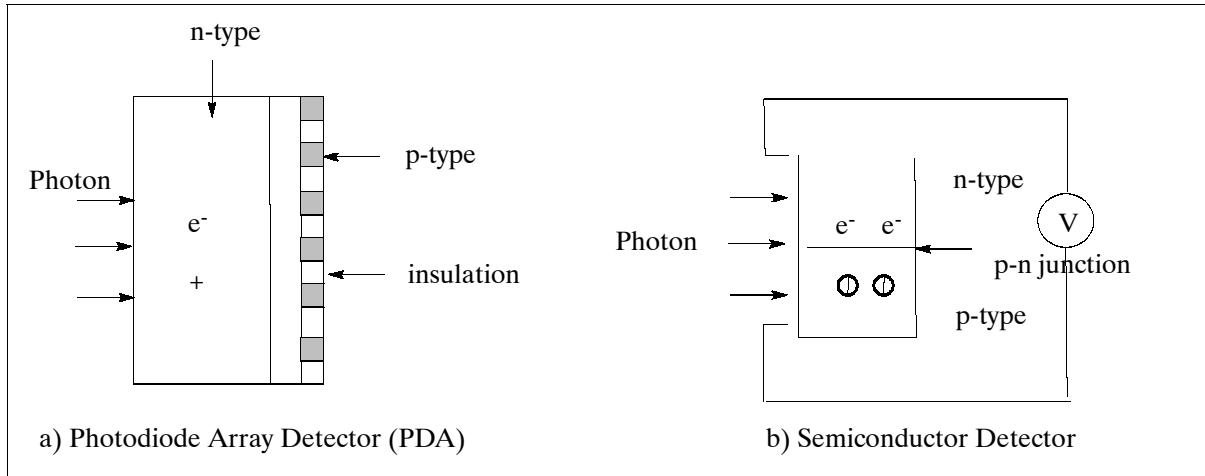

Figure 371: Schematic illustration of a PDA and a semiconductor detector

Quantum efficiency (QE). A measure of the efficiency with which incident photons are detected (such as a photodiode). Some incident photons may not be absorbed due to reflection or may be absorbed where the electrons cannot be collected. The QE is the ratio of the number of detected electrons divided by the product of the number of incident photons times the number of electrons each photon can be expected to generate. Visible wavelength photons generate one electron-hole pair. More energetic photons generate one electron-hole pair per each 3.65 eV of energy.

Thermal detector. Refers to the class of detectors, where the responsive element is sensitive to changes in temperature, brought about by changes in incident radiation. Thermal detectors include: thermocouples, bolometers, Golay cells, and pyroelectric devices. ¹⁹¹⁸⁾

- **Thermocouple.** Refers to a junction of dissimilar metals. A change of temperature causes a current to flow across the junction. When a scene is optically focused onto a thermocouple, its temperature changes as the incident radiation flux changes. The change in flux can be detected by monitoring the voltage generated by the thermocouple. - A thermopile is a series of thermocouples connected together to provide increased responsivity. Thermopiles are used in applications where DC or staring performance is required (typical of Earth sensors that “ride” the horizon and respond to changes in the FOV due to changes in the “dip” angle).
- **Bolometer.** A bolometer is a thermal detector that makes use of the change in electrical resistance of certain materials when their temperature is changed. The change in resistance can be detected as a voltage signal by passing a small current through the bolometer (they operate as thermal equilibrium devices, whereas quantum detectors operate as nonequilibrium devices). Bolometer materials are selected for their small thermal capacity. Usually bolometers are cooled with liquid helium (to 4 K) to provide the needed efficiency. Bolometers are suitable detectors for the infrared and microwave regions. A thermistor is an example of a bolometer. Thermistor bolometers have been used for many years as the primary sensor in horizon crossing indicators, scanning Earth sensors, and payload instruments such as ERBE, CERES, HALOE, etc.

¹⁹¹⁸⁾ M. Schlessinger, “Infrared Technology Fundamentals,” 2nd edition, 1995, Marcel Dekker Inc., New York, Basel, Hong Kong

- Golay cell. A gas thermometer with an infrared window and membrane acting as an indicator. Absorption of radiation results in an increase of temperature and pressure, causing the membrane to move.
- Pyroelectric device. Pyroelectric sensors respond to the rate change of temperature. As such they are first derivative sensors and usually require that the scene be “chopped” or scanned. Incident infrared radiation increases the temperature of the crystalline responsive element. This temperature change alters the dipole moment producing an observable, external, electric field. Pyroelectric detectors consist of polarized material which, when subjected to temperature changes, change polarization. These detectors operate in a chopped system. The fluctuation in the exposure to the scene generates a corresponding fluctuation in polarization and thus an alternating current that can be measured.

At the start of the 21 century, the MEMS (Micro Electronic Machined Structures) technology makes it possible to be introduced into high-performance thermal detectors. MEMS has the advantage to allow a high-volume production of closely-packed thermal isolation structures required of high-performance thermal detectors. Prior to the use of MEMS technology, array of thermal detectors were difficult and expensive to produce and required larger geometry, pixel spacing and fill factors. MEMS produces higher performance devices, reduced crosstalk between pixels and better thermal management (Table 539).¹⁹¹⁹⁾

Thermistor Bolometers		
Parameter	Conventional Packaging	MEMS Packaging
Min. element size and spacing	0.1 mm x 0.1 mm	0.025 mm x 0.25 mm

Table 539: Comparison of conventional/MEMS manufacturing techniques of IR sensors

Photoconductive (PC) effect (discovered by W. Smith in 1873). The electrical conductivity of a material depends on the number of free charge carriers (i.e. free electron-hole pairs) per unit volume and on the rate at which carriers move under the influence of an electric field. The photoconductive effect occurs when a bias voltage is applied across a uniform piece of detector material. The photocurrent is then proportional to the density of electrons excited into the conduction band by the incoming photons.

Photoemissive effect. Incident photons with sufficient energy striking a detector surface may cause an ejection of electrons from the surface thereby causing an electric current flow. Energetic radiation in the spectral ranges from gamma-ray to VNIR (up to wavelengths of about 1.5 μm) is responsible for the photoemissive effect. - Electrons are also emitted from a detector surface when it is bombarded with high-velocity electrons. This process of secondary emission with high internal amplification is utilized in photomultipliers (PMT).

¹⁹¹⁹⁾A. Doctor, “MEMS Technology Based Sensors for Payload Instruments and Attitude Control for Small Satellites,” Proceedings of the 14th AIAA/USU Conference on Small Satellites, Logan, UT, Aug. 21-24, 2000, SSC00-III-4

Photoemissive detectors (photodiode, photomultipliers, image tubes, microchannel plate).

- A photoemissive diode (photodiode, see Figure 371) consists of a surface (cathode) permitting the ejection of electrons and a separate electrode (anode) on which the electrons are collected (both are often sealed within an evacuated glass envelope).
- A photomultiplier tube (PMT) is a sensitive radiation detector for low intensity applications (spectral range from EUV to NIR or from 0.1 to 1.1 μm). A PMT consists of a photoemissive cathode, a series of electrodes (dynodes), and an anode sealed within a common evacuated envelope. Photons that strike the cathode emit electrons due to the photoelectric effect. Voltages applied to the cathodes, dynodes, and anode cause electrons that are ejected from the photoemissive cathode to make collisions with the dynodes in succession, knocking out more electrons at each collision. In this arrangement the dynodes provide signal amplification up to factors of 10^6 . The amplified signal is taken off the anode.

Figure 372: Schematic illustration of a PMT

- Microchannel plate (MCP). A detector system, covering the spectral range from UV to x-ray and to gamma-rays and particles, employing large-area electron multipliers that provide spatial resolution as well as amplification. Depending on requirements MCPs may be coupled with a scintillator, a film, or a CCD array to provide imaging in the spectral range. MCPs consist of a matrix of hollow glass tubes. The hole diameter and spacing is typically 5-50 μm . The surface of a plate is usually coated with a photocathode material, while the interior of the holes is coated with a material of a high secondary emission coefficient. MCPs are used for plasma particle, ion, photon, and/or electron counting applications (measurement of ionospheric fluxes in the solar wind, etc.). They exhibit a high count-rate capability; a stack of two or more MCPs allow ray-tracing for angular measurements (position-sensitive). Among photomultiplier detectors of single photons, MCPs have the best intrinsic detector resolution, in the order of 20 ps. The detection efficiency of a microchannel plate for photons is a function of the angle of incidence and photon energy.

Photovoltaic (PV) and Photoconductive (PC) detectors. These are often referred to as photon detectors since the effect is to convert the incident photon energy directly into the excitation of electrons in the conduction band. The two types differ in the method of sensing the photo-generated electrons electrically.

- The photovoltaic (PV) effect is achieved when a photon-produced electron hole pair is separated by a space charge field [examples: a p-n junction, Schottky barrier devices, IBC (Impurity Band Conduction) devices], thus producing a photocurrent. [Photons with sufficient energy create electron-hole pairs, they are separated by the internal field existing at the p-n junction. The valence-to-conductance bandgap in InSb is 0.23 eV at liquid nitrogen temperature. This accounts for the detector's sensitivity cutoff at a wavelength of 5.5 μm]. PV devices operate in the diode's reverse bias region; this minimizes the current flow through the device which in turn minimizes power dissipation. In addition, PV detectors are low noise because the reverse bias diode junction is depleted of minority carriers.
- The photoconductive (PC) effect occurs when a bias voltage is applied across a detector. The photocurrent is then proportional to the density of electrons excited into the conduction band by the incident photons. [The presence of electrons in the conduction band lowers the resistance. Intrinsic electron-hole pairs are created by raising an electron from a valence band to the conduction band. Extrinsic excitation refers to electrons raised to levels within the forbidden band of the semiconductor]. PC detectors require readout amplifiers which bias the detectors with a constant current; this causes higher on-chip power dissipation. PC detectors can respond to fluctuation in radiation at operating temperatures greater than PV detectors with equivalent semiconductor bandgaps.

A variety of semiconductors can be used to exploit either or both effects. Intrinsic semiconductors of the type HgCdTe use both effects. InSb and InAs are commonly used as photovoltaic detectors. Typically, an InSb detector, operated at 77 K (liquid nitrogen), has a spectral response from 1 - 5.5 μm , peaking in responsivity at 5.3 μm .

IBC (Impurity Band Conduction) devices use a thin, heavily doped detection layer grown epitaxially on a lightly doped silicon substrate. Photons enter through the substrate and are absorbed in the heavily doped region. A bias applied to the surface detector contact depletes the detection layer of ionized donors. The impurity band holes are swept from the region that becomes the active region of the detector. Photodetection occurs when a photon ionizes a neutral donor site in the detection region, thus producing a free electron that is collected by the surface detector contact.

Schottky barrier detector (named after Walter H. Schottky). A photon detector, which utilizes internal photoemission of 'hot' carriers (holes) from metal or metal silicide electrodes into silicon for the detection of radiation. A back-illuminated Schottky barrier detector operates by photoemission of holes over the so-called Schottky barrier from a silicide into the valence band of silicon. Photons with energies between the bandgap and the barrier height are transmitted through the silicon substrate and absorbed by the metal electrode of the junction.

A Schottky diode has a metal-semiconductor contact (e.g., an Al layer in intimate contact with an n-type silicon substrate). It is electrically similar to a p-n junction, though the current flow in the diode is due primarily to carriers having an inherently fast response. It is used for high-frequency, low-noise mixer and switching circuits. Schottky implementations are limited to the SWIR range, they require low operating temperatures and display low quantum efficiencies. Their ease of fabrication and excellent uniformity may offset the disadvantages.

From a historic point of view, the first Schottky sensors were vidicons with a spectral range between 1-2 μm . These devices used P₂Si electrodes on n-type silicon. The first solid-state Schottky sensors had Pd₂Si electrodes on p-type silicon together with integral CCD multiplexers (spectral range: 1-3.5 μm). Since 1980 Schottky sensors use PtSi electrodes providing a spectral response from 3-5 μm at 80 K cooling and a range of 8-12 μm with 45 K cooling.

QWIP (Quantum Well Infrared Photodetector). Infrared photons excite ground state electrons out of a stack of quantum wells in a QWIP, producing a current in an applied electric

field. QWIPs are extrinsic devices (for the 6-14 μm range, TIR) in which dopant concentrations are limited by the epitaxial growth processes. The technology of GaAs and AlGaAs multiple quantum well detectors is currently (later 1990s) the most mature among the different types of QWIPs. The potential advantages of QWIPs (GaAs and AlGaAs) include the use of standard manufacturing methods based on GaAs growth and processing techniques [monolithic integration of these detectors with GaAs field effect transistors (FET), CCDs and high-speed signal processing electronic is possible], highly uniform and well-controlled molecular beam epitaxy (MBE) growth on large GaAs wafers, high yield and thus low cost, thermal stability, and extrinsic radiation hardness. The QWIP limitations are: low quantum efficiency and high dark current. ^{1920) 1921)}

SLS (Strained Layer Superlattice). SLS (InAs, InGaSb) photodetectors employ transitions across a fundamental gap. Thus carrier lifetime is limited by radiative and Auger recombination processes rather than the much faster hot-electron processes in QWIPs. SLS technology is based on the type II interface where the conduction band of one material (e.g. InAs) is lower than the valence band of the second material (e.g. InGaSb). Because of this unusual band lineup, the superlattice can have a bandgap smaller than of either constituent material. Absorption of infrared radiation occurs between the valence band of the first material and the conduction band of the second one. The resultant effective bandgap is dependent upon the composition, well width, and strain within the superlattice layer. SLSs detectors are intrinsic devices (absorption occurs via interband transitions) that are utilized in the TIR spectral range.

Photographic detectors (plates and films). A photographic system is a framing system, it means that all of the data of an image are acquired simultaneously. The film serves as the radiation detector (photochemical surface). Photographic films have the disadvantage of a very limited spectral range (VNIR spectrum only), however, they feature very good spatial resolutions.

Josephson junction detectors. Make use of the nonlinear interaction between the incident photon's electromagnetic field and the high-frequency oscillating currents and voltages in a biased Josephson junction to perform millimeter-wave mixing and direct detection. The detectors are particularly useful for millimeter- and submillimeter-wave detection.

Figure 373: Optical heterodyning principle - measurement of difference frequencies

Heterodyning (optical heterodyning). A process in which the incoming frequency f_1 (to be analyzed) in an optical receiver system is superimposed over a second stable reference frequency f_2 prior to measurement of the total intensity with a photodetector. The measured intensity contains a term which is modulated by the frequency difference ($f_1 - f_2$) of the two light waves. The heterodyning technology is particularly suitable for the detection of very weak infrared and microwave radiation sources; heterodyning instruments (such as microwave limb sounders) play a crucial role for the monitoring performance of the Earth's atmosphere (chemical composition of the atmosphere, monitoring/deduction of the fine structure of the spectra) as well as in the study of astronomical objects. The heterodyning tech-

nique is applicable in the spectral range from about UV (0.3 μm) to the microwave region of about 10 mm wavelength.

- **Coherent detection** (optical). In coherent detection, a complete frequency band at the observed wavelength is converted with a local oscillator (LO) frequency to a much lower center frequency, where it can be amplified and spectroscopically analyzed without further degradation in SNR, and where the spectral resolution is being limited only by the spectral purity of the LO. The coherent technique combines the weak (observed) optical signal at nominal frequency f_1 with a strong optical reference beam, the frequency-stable LO at frequency f_2 , on a wideband square-law detector, thereby producing radio frequency beats at the frequency difference $f_1 - f_2$. The sources must be narrowband, hence single-mode (both longitudinal and transverse) lasers are preferred. The power in the beat signal is proportional to both the signal power and the LO power.¹⁹²²) Quantum-limited detection performance can be obtained, even on thermally noisy detectors, if the LO “shot” noise can be made to dominate the thermal noise. Frequency resolutions of better than 10^{10} can be obtained, enabling full spectral analysis of the optical signal. The first three spectral moments of signals backscattered from either solid or distributed targets in the lidar’s scattering/receiving volume measure reflectivity, velocity and velocity spread, respectively.
- **Homodyne detection.** A form of coherent detection where the LO is derived from the transmitting laser; hence, nominally $f_1 = f_2$. This form of detection is often used on CW (Continuous Wave) systems where f_1 is Doppler-shifted slightly from f_2 , and radio frequency beats occur at both $+(f_1 - f_2)$ and $-(f_1 - f_2)$.
- **Heterodyne detection.** A form of coherent detection where the LO is derived from an independent source that is locked to the transmitting source at some offset frequency; hence, $f_1 \neq f_2$. Beat frequencies occur in a band around $(f_1 - f_2)$, known as the intermediate frequency (IF). The frequency offset permits one to discriminate approaching from receding velocities, and is often used in conjunction with pulsed transmitters.
- **Incoherent detection.** Refers to direct detection of an optical signal on an optical detector, with no LO present. In the direct detection method, the optical signal field is analyzed and dispersed in an interferometric filter (or in diffraction grating) prior to detection. The measurement accuracy of a direct-detection interferometric system depends only on the total scattered signal, it is not dependent on the energy of individual pulses, but on the total laser energy. Incoherent detection is normally the method of choice at shorter wavelengths, where the thermal background emission gets rapidly less important due to the rapid drop of the radiation intensity on the Wien side of the blackbody curve, and at low to moderate spectral resolution.

In this context: **Superheterodyning** is primarily used to detect signals entirely in the radio-frequency domain, beating the beat signal again with a third stable source, the second LO, at another frequency, f_3 .

The principal configuration of a heterodyne receiver consist of the following elements: quasi optics [a low power signal is combined with a closely spaced strong fixed frequency LO (Local Oscillator) signal], mixer [non-linear detector element; due to the non-linearity of the mixer the frequency difference of the signal and LO radiation which is called IF (Intermediate Frequency), can be obtained at the mixer output port], low-noise amplifier, band-pass filter, spectrometer, data acquisition and instrument control.¹⁹²³⁾

Photoelectromagnetic (PEM) effect. Refers to incident radiation (photons) being absorbed at or near the surface of a semiconductor, thereby producing free electron-hole pairs. These pairs diffuse from the surface into the crystal. The presence of a magnetic field B directed

along the y-axis causes the electrons to separate from the holes as they diffuse away from the surface. The separation of charges produces a voltage across the terminals. If the external circuit is shorted, a current flows as long as incident photons arrive at the surface. If the exterior circuit is left open, a voltage appears across the open terminals and remains as long as the surface is irradiated.

Figure 374: Illustration of the PEM effect

Array or detector type	Useful spectral range
Scintillation counters	0.03 - 0.100 Å
MCP (Microchannel Plate)	γ-rays to UV (..nm - 0.3μm)
Silicon photodiodes and photoemissive devices such as photomultiplier tube (PMT)	0.3-1.3 μm
InSb (indium antimonide)	1.3 - 5.5 μm
InGaAs (Indium Gallium Arsenide)	
HgCdTe (mercury cadmium telluride, also referred to as MCT) or photo-conductors	1.3 - 35 μm
Semiconductor bolometer	>30 μm
Avalanche photodiode	
CdZnTe (Cadmium Zinc Telluride also referred to as CZT)	
PbS (Lead Sulfide)	
PbSi (Lead Silicon)	
PtSi (Platinum Silicon)	
QWIP (Quantum-Well Infrared Photodetector)	(6 - 25 μm)
Sb (antimonide)	
Si:As (Arsenic-doped silicon - Impurity Band Conduction (IBC) detector	infrared
AlGaAs/GaAS (Aluminum Gallium Arsenide)	
InSb/InAsSb long-wavelength strained-layer superlattice devices	
HIP (Heterojunction Internal Photoemission)	IR detector arrays
SiGe/SiHIP detectors	
Si:As IBC arrays	4-28 μm
Infrared tunneling sensor array	
Electron-tunneling Golay cell detector	
Superconducting micro bolometers	100 - 1000 μm
Resonant Infrared Photoconductor	

Table 540: Typical detector types utilized for spectral ranges

O.4.2 Charge-Transfer Devices

The collection/readout of photon-generated charge and the conversion of this charge into proper imagery is the purpose of charge-transfer devices in remote sensing systems. The

three dominant charge-transfer devices are CCD (Charge-Coupled Device), CID (Charge Injection Device), and CMOS/APS (Complementary Metal-Oxide Semiconductor/Active Pixel Sensor). Charge-transfer devices provide storage and manipulation capabilities for signal sequences. All three device types depend on silicon detector material.

For Earth observation applications, CCD is by far the most widely utilized and most mature technology. High-speed CCDs are available with extremely high pixel counts, ultra-low noise, almost perfect linearity, and with quantum efficiencies of 90% or more. - CIDs with x-y addressability and row/column readout amplifiers offer advantages in applications, where radiation hardness is required (outward-looking sensors), but they are not widely used due to their high readout noise. - CMOS/APS with readout amplifiers resident in each photosite are an emerging technology with the availability of sub-micron semiconductor technology. The transistor sizes are now small enough to cover about 75% of the pixel area, allowing for the incoming radiation to get through a portion of the pixel. The drawbacks of CMOS/APS devices are: inherently higher readout noise, non-uniformity, and low quantum efficiency.

Parameter	CMOS/APS		CID	CCD
Manufacturer	Photobit	JPL	CID Technologies	Pixel Vision Inc.
Product	Pb256G			Kino
Format	256 x 256	1024 x 1024	1024 x 1024	2049 x 1024
Pixel size	11.9 μm x 11.9 μm		27 μm x 27 μm	12 μm x 12 μm
Pixel type	Photogate APS	Photodiode APS	Photogate CID	Back-illuminated CCD
Output	Analog	Analog	Analog	Analog
Number of outputs	1	1	1	8
Peak QE	20%	45%	30%	90%
Fill factor	40%	25%	25%	100%
Read noise	17 e^- rms	5 e^-	350 e^-	2 e^- rms
Saturation	88,400 e^-	300,000	1,000,000	240,000
Dynamic range	5,200:1	60,000:1		120,000:1
Operating voltage	3.3 V	3.3 V	± 15 V	± 15 V
On-chip quantization	No	No	No	No
Power	2 mW/Mp/s	30 mW/Mp/s		500 mW/Mp/s
Max pixel rate	1 Mp/s	1 Mp/s	21 Mp/s	160 Mp/s
