Large-amplitude and anharmonic corrections to the internuclear distances were calculated using new theoretical approaches for ED analysis and quadratic and cubic force constants from MP2/6-31G(d) calculations. The large-amplitude approach was based on the adiabatic separation between large- and small-amplitude motions. In addition to the vibrational terms, the Hamiltonian explicitly included rotational effects as well as interactions between overall rotation and intramolecular motion. These corrections were estimated to amount *ca.* 0.01 Å for the C=C and C–C bond lengths and 0.02 Å for the C–H bond lengths.
